Introduction: In animal models of liver fibrosis transplant of hADSCs (adipose-derived stromal cells) improved hepatic function and reduced fibrotic tissue. Besides, systemic administration of Ad-huPA diminished liver fibrosis and increased tissue regeneration.
Aims & Methods: The aim of this study was to evaluate if the simultaneous administration of both therapies shows an enhanced antifibrogenic effect in cirrhotic rats. ADSCs were isolated from human fat tissue, expanded and characterized by expression of cellular markers ($CD105^+$, $CD73^+$, $HLA\text{-}ABC^+$, CD45, $CD34^-$,$HLA\text{-}DRII^-$) and cell differentiation to osteogenic, adipogenic and hepatogenic linage. Ad5-huPA vector was generated under CMV promoter control. CCl_4-cirrhotic rats via ileac vein were administered with $2X \times 10^6$ cells/rat hADSCs or $3x10^{11}$ vp/rat Ad-huPA or both therapies. One day before treatment, all animals begin immunosuppression with 10mg/kg/day of Cyclosporine A until sacrifice 10 days later. Fibrotic tissue, Collagen fibers and α-SMA immunoreactivity as well as expression of TGF-β1, collagen α1, CTGF, PAI-I and α-SMA were evaluated. Also, serum levels of ALT, AST and albumin, biodistribution of hADSCs and liver levels of huPA protein were examined.
Results: Administration of hADSCs, Ad-huPA and Ad-huPA/hADSCs reduces ($p < 0.01$) liver fibrosis in 78.9%, 65.2% and 72% respectively, compared to cirrhotic controls and diminishes Collagen α1, CTGF and α-SMA mRNA liver levels ($p < 0.05$). Furthermore, TGF-β1 and PAI-I liver mRNA levels ($p < 0.05$) decreases in animals treated with Ad-huPA and hADSCs. ALT and AST serum levels showed a significant decrease in hADSCs group ($p < 0.05$). Serum levels of albumin increased in the Ad-huPA, hADSCs and Ad-huPA/hADSCs groups ($p < 0.05$) compared with control group. hADSCs, Ad-huPA and hADSC/Ad-huPA administration reduced 4.3, 2.4 and 2.7 fold respectively ($p \leq 0.001$) collagen staining, compared to cirrhotic controls. hADSCs were mainly detected in liver and few of them in lung and spleen. huPA protein was expressed in similar levels in liver homogenates of Ad-huPA and Ad-huPA/hADSCs groups.
Conclusion: The combination of Ad-huPA and hADSCs reduced liver fibrosis and expression of pro-fibrogenic molecules in CCl_4-cirrhotic animals; however, it does not improve antifibrogenic effects of individual treatments.

Introduction: Development of models and indexes incorporating non-invasive markers of liver fibrosis in chronic cholestatic liver diseases, namely primary biliary cirrhosis (PBC) and primary sclerosing cholangitis (PSC), is essential to facilitate the assessment of liver fibrosis progression and the effectiveness of new therapies.
Aims & Methods: The aim of this study was to evaluate the ability of indirect serum markers for discriminating between mild and significant fibrosis in patients with PBC and PSC. Data from 82 patients with PBC and 22 patients with PSC were analyzed retrospectively (admitted between 2008 and 2014). Forns index, Fibrosis 4 score (FIB4), aspartate aminotransferase (AST)/alanine aminotransferase (ALT) (AST/ALT) ratio index, AST to the platelet ratio index (APRI) and platelet count/spleen diameter ratio index were calculated based on results of blood analyses and abdominal ultrasound. Results of the histological study of the liver with the histology activity index (according the Knodell score) and stage of fibrosis assessment (according the METAVIR score) were used as a reference method and were available for all included patients. Receiver operating characteristic curve (ROC) analysis was conducted to determine diagnostic performance of these indexes for identification of significant liver fibrosis in patients with PBC and PSC.
Results: Among all the patients with PBC (n = 82; median age [25th – 75th interquartile range] 54.5 years [48.75-60.25]; 95.12% were female) 52.4% (n = 43) had significant fibrosis (F ≥ 2) and 23.17% (n = 19) had cirrhosis. In PSC group (n = 22; median age 38 years [26.5-48.5]; 27.2% were female) 50% (n = 11) and 31.8% (n = 7) of patients had significant fibrosis (F ≥ 2) and cirrhosis, consequently. Platelet count/spleen diameter ratio index (AUROC = 0.761) was superior to APRI, AST/ALT ratio index, FIB4, and Forns index at distinguishing between mild and significant fibrosis in patients with PBC. With a cut-off of > 19.8, the presence of significant fibrosis could be excluded with a 74.4% negative predictive value (NPV) and 78% specificity. In patients with PSC FIB4 index (AUROC = 0.843), platelet count/spleen diameter ratio index (AUROC = 0.752), and APRI (AUROC = 0.744) were superior to Forns index and AST/ALT ratio index at distinguishing between mild and significant fibrosis. With a FIB4 index cut-off value of < 0.76, the presence of significant fibrosis could be excluded with a 85.7% NPV and 90.9% specificity.
Conclusion: Application of platelet count/spleen diameter ratio index in patients with PBC enabled correct classification of 74% of patients included in this study. Overall 73% of patients with PSC could be correctly classified by using FIB4 index. Thus, application of tests, incorporating indirect serum markers of live fibrosis, could help to decrease the need for liver biopsy in these patients.

P0003 EXPRESSION ANALYSIS OF PLASMA APOLIPOPROTEINS IN HEPATOCELLULAR CARCINOMA: A PROTEIN-BASED HCC-ASSOCIATED STUDY

D. Bharali[1], P. C. Ray[1], P. Kar[1]
[1]*Medicine, Maulana Azad Medical College, New Delhi, India*

Contact E-mail Address: dipubhli@gmail.com
Introduction: Hepatocellular carcinoma (HCC) is the 6th cancer in incidence worldwide and the 3rd leading cause of cancer death. We aimed to identify new markers of HCC using a protein-based analysis.
Aims & Methods: To find out differential expression of apolipoproteins- ApoA1 and ApoAIV in HCC and controls without HCC. 30 Patients with HCC and 30 liver cirrhosis were included in the study. Target apolipoproteins were separated by SDS PAGE from blood plasma and the expression changes of ApoA1 and ApoA4 were confirmed by Western blotting followed by densitometric protein semiquantitaion estimation along with ELISA-based protein quantification.
Results: Western blotting densitometry image analysis of the plasma samples following CDC protocol and the comparison between patients with and without HCC revealed differential expression of ApoA1 and ApoA4. Levels of Apo-A4 were significantly higher in patients of liver cirrhosis and chronic hepatitis without HCC than in patients with HCC (0.208 ± 0.07 & $0.119 \pm .016$ vs 0.119 ± 0.005; $P < 0.01$). Levels of Apo-A1 were significantly higher in patients with HCC than in controls without HCC (0.279 ± 0.003 vs 0.171 ± 0.034 & $0.199 \pm .014$; $P < 0.01$).
Apo-A1 and ApoA4 were further tested whether quantitative measurement could be utilized as a diagnostic tool to distinguish patients with HCC from the controls without HCC by ELISA. Once calibration curves were proven to be analytically optimal, Apo-A1, ApoA4 and AFP were measured in blood plasma samples by ELISA according to the manufacturer's protocol. The result showed significant increased Apo-A1 expression in HCC group ($P < 0.01$).
Mean ApoA1 concentration in human blood plasma: HCC- 81726.61 ng/ml; LC-16388.09 ng/ml; chronic hepatitis – 22172.30 ng/ml; Mean ApoA4 concentration in human blood plasma: HCC-307.79 ng/ml; LC- 614.86 ng/ml; chronic hepatitis – 495.13 ng/ml. ELISA Assays revealed that there was a deregulation in expression of both ApoA1 and ApoA4 proteins deflected from the normal levels in healthy controls. It showed that the plasma levels of ApoA1 were higher in HCC than both the healthy and disease controls. On the other hand plasma levels of ApoA4 were lower in HCC than controls with liver cirrhosis and chronic hepatitis but without HCC. Plasma levels of ApoA4 were significantly higher in liver cirrhosis than that of HCC as well as healthy control. Plasma levels of AFP were higher in HCC than that of healthy control and liver cirrhosis along with chronic hepatitis.
Conclusion: Apolipoprotein A1 is highly expressed in HCC in comparison to cirrhosis and may be used as future diagnostic tool in addition and associated with other conventional biomarkers for HCC after further analysis of a higher number of population.

Introduction: Non alcoholic fatty liver disease is the most common liver disease in the world. In addition it is commonly associated with the methabolic syndrome. There is possibility that the disease may be associated with the increase fructose consumption
Aims & Methods: In this study, we investigated the preventive effect of rifaximin in steatohepatitis induced by fructose in rats. In this study, 42 male Sprague-Dawley rats were divided in 6 groups with an equal number. Normal diet was given to Group 1. Fructose was given to Group 2, fructose + rifaximin once a week was given to Group 3, fructose + rifaximin three days a week was given to Group 4, normal diet + rifaximin once a week was given to Group 5 and normal diet + rifaximin three days a week was given to Group 6. Rifaximin was administered at a dose of 15 mg/kg by orogastric catheter. 50% fructose was added to drinking water. The rats were decapitated at the end of 8 weeks. At the end of 8 weeks, hepatic tissue samples were obtained from the rats for histopathological examination and MDA, TNF-α, NF-kB, Nrf-2 and HO-1 levels. Biochemical examination was performed and plasma glutathione peroxidase, TNF-α, 4-hydroxynonenal levels were measured.
Results: The body and liver weights were increased in all rats fed with fructose compared to the control group. On histopathological examination, balloning degeneration, inflammation and grade 1 steatosis developed in the rats who were given 50% fructose. Steatosis Grade 2 and above and fibrosis was not found in any rat. Ballooning degeneration and inflammation were found with a significantly lower rate in rates who received rifaximin. No significant difference was found between different doses of rifaximin. Plasma and tissue TNF-α levels and NF-κB were found to be significantly lower in the groups who received rifaximin compared to the group who received fructose. In addition, GSH-Px, Nrf-2, HO-1 levels were found to be high in the group who received rifaximin. No significant difference was found between different doses of rifaximin.
Conclusion: Rifaximin protects aganist steatosis, ballooning degeneration and inflammation induced by high fructose diet in rats. It was thought that rifaximin may be prevent the steatohepatitis inhibiting NF-kB, TNF-α, with decreasing intestinal translocation of endotoxin. New studies on this subject are needed.

Introduction: Liver cirrhosis is an inevitable outcome triggered by chronic inflammation. However, the mechanism of inflammatory infiltration in the liver is largely unknown. It is accepted that intestinal epithelial barrier dysfunction might contribute to liver cirrhosis by facilitation of inflammatory infiltration along the gut-liver axis. In the present study, we characterize the effects of celecoxib on inflammatory infiltration and intestinal epithelial barrier of cirrhotic rats.
Aims & Methods: Liver cirrhosis was induced by peritoneal injection (i.p.) of thiacetamide (TAA, 200 mg/kg every 3 days for 16 weeks). 36 male Sprague-Dawley rats were randomized into control, TAA and TAA + celecoxib groups with 12 animals in each group. TAA + celecoxib group received TAA plus celecoxib (20mg/kg/day) from the initiation of TAA administration. TAA group received TAA plus placebo and control group received normal saline (i.p.). The parameters for fibrosis (Collagen III and a-SMA), inflammatory infiltration (TNF-α, IL-6, and CD3/CD4/CD8 lymphocytes), barrier function (ZO-1, claudin-4 and E-cadherin) and integrated signal pathways (cyclooxygenase-2 (COX-2), p-Akt, p-ERK and NF-kB) were determined. Moreover, the content of TNF-α, IL-6 and lipopolysaccharide (LPS) was quantified. *In vitro*, human colorectal adenocarcinoma cells Caco-2 was treatment with vehicle, celecoxib, PGE2, PGE2 antagonist, EP-2 antagonist, ERK inhibitor and Akt inhibitor, respectively. Afterwards, ZO-1, claudin-4 and E-cadherin, Akt/p-Akt and ERK/p-ERK were evaluated by immunocytofluorescence and Western blot.
Results: *In vivo*, compared with TAA group, fibrotic areas and Ishak's scoring in TAA + celecoxib group were remarkably decreased by 40.4% and 36.1%. The mRNA levels of a-SMA and collagen III in TAA + celecoxib group were also reduced. Moreover, hepatic and intestinal inflammatory infiltration, which express as increased mRNA and protein level of TNF-α, IL-6, LPS and decreased portal venous CD3+, CD3+/CD4+, CD3+/CD8+ and CD3+/CD4+/CD8+ T cell, were observed in TAA group when compared with those in control group. Interestingly, the hepatic and intestinal inflammatory infiltration was attenuated after treatment with celecoxib. Disruption of intestinal barriers that induced by TAA, which was verified by ultrastructure and decreased mRNA and protein of junction molecular (ZO-1, Cluadin-4 and E-cadherin), was partly restored after treatment with celecoxib. Moreover, activation of p-Akt, p-ERK and NF-kB in TAA group was significantly inhibited by celecoxib treatment. *In vitro*, compared with vehicle treated Caco-2 cells, the protein levels of ZO-1, Cluadin-4, E-cadherin were obviously increased by celecoxib, PGE2 antagonist, EP-2 antagonist and ERK inhibitor treatment but not by Akt inhibitor.
Conclusion: Long-term treatment with celecoxib attenuates liver cirrhosis via blockage of inflammatory infiltration along the gut-liver axis and restoration of intestinal epithelial barrier. This effect afforded by celecoxib may attribute to its modulation on COX-2 – PGE2 – p-ERK integrated signal pathways. Our results suggest that celecoxib might be considered as a potential therapeutic agent in the preventive strategy for the patients suffering from liver cirrhosis.

Introduction: Bile acids and activation of the bile acid receptor FXR inhibit autophagy, a cellular self-digestion process necessary for cell homeostasis and regeneration. The effects of chronic bile acid accumulation in chronic cholestatic liver disease on autophagy have not been studied in detail. However, indirect evidence (e.g. accumulation of Mallory-Denk bodies in primary biliary cirrhosis) indicate that autophagy may be impaired in human cholestasis.
Aims & Methods: We aim to determine whether ursodeoxycholic-acid (UDCA) and Rifampicin (Rifa), two drugs for the treatment of human cholestatic liver disease, may activate autophagy as a potential mode of drug action.
Markers of autophagy (LC3, p62, ATG5, 7, 12) and the upstream mTOR signaling pathway (Raptor, ULK1, pS6K) have been studied by Western blot and immunofluorescence in liver biopsy from patients treated with UDCA and Rifampicin. Mechanistic details of UDCA and Rifa action have further been studied in human HepG2 cells and primary hepatocytes.
Results: Both UDCA and Rifampicin induce LC3 as the main autophagy readout in human biopsies. UDCA activates autophagy via mTOR-ULK1 signaling whereas Rifampicin induces autophagy on transcriptional levels (LC3C, LAMP1, ATG10) without impacting on mTOR signaling. Knockdown of the Rifampicin activated transcription factor PXR significantly represses autophagy already under basal conditions on mRNA and protein levels. In addition, PXR knockdown prevents Rifampicin induced autophagy induction.
Conclusion: UDCA and Rifampicin induce autophagy in the liver via different mechanisms. UDCA induces autophagy via mTOR signaling pathways and Rifampicin induces autophagy mTOR independently via the transcription factor PXR. Part of the beneficial effects of UDCA and Rifampicin in the treatment of cholestatic liver disease may be attributed to an induction of autophagy. Both compounds, UDCA and Rifampicin may have additional beneficial effect by inducing autophagy on other hepatological as well as non-hepatological diseases.

Introduction: Cirrhosis is a distortion of normal tissue architecture which develops when the liver is chronically damaged. Activated hepatic stellate cells (HSC) participate actively in liver fibrosis development where endocanabinoids receptors CB1 and CB2 regulate this process. Quercetin, a flavonoid with antioxidant properties has shown prevent liver fibrosis.
Aims & Methods
Aim: To elucidate the effect of quercetin on CB1 and CB2 expression and on HSC activation in an experimental model of cirrhosis.
Methods: Wistar rats were intoxicated with CCl_4 for eight weeks and concomitantly treated with quercetin (150mg/Kg/day). Animals were sacrificed, livers were taken for histology (Masson, Sirious red, immunohistochemistry (IHC) for a-sma and TUNEL for apoptosis), for gene expression (Col-1 TGF-b, CTGF, CB1 and CB2) and for western blot (CB1 and CB2).
Results: Expression of Col-1, TGF-b1 and CTGF significantly increased in CCl_4 cirrhotic rats compared to healthy rats. Tretament with quercetin significantly decreased expression of all these genes. Liver fibrotic rats presented a fibrosis index of 22.5% while rats with quercetin treatment had a fibrosis index of 10.76%. Activated HSC determined by IHC for a-sma and quantity of apoptotic cells were 40% less and 17 times more respectively in quercetin group respect to control. CB1 expression was 20% decreased where CB2 was 47% increased with quercetin treatment respect to group without quercetin treatment.
Conclusion: Quercetin administration prevents liver injury in an animal model of cirrhosis increasing CB2 expression and reducing CB1 expression. In the

same way, quercetin promotes HSC apoptosis decreasing activated hepatic stellate cells number.

Contact E-mail Address: oshapoval@rambler.ru

Introduction: As chronic liver disease progresses, an imbalance between synthesis and breakdown of extracellular matrix (ECM) occurs. Matrix metalloproteinases (MMPs) are involved in ECM degrading while tissue inhibitors of metalloproteinases (TIMPs) prevent their fibrolytic action. Circulating levels of tissue inhibitor of metalloproteinase (TIMP)-1 was investigated as parameters for the diagnosis of fibrosis in chronic liver disease. Removal of excess collagen after cessation of liver injury is regulated by TIMP-1 and TGF-β1 (transforming growth factor-β1). Among growth factors, TGF-β1 appears to be a key mediator in human fibrogenesis.
Aims & Methods: The aim of research was to assess the level of TGF-β1 and TIMP-1 in patients with liver cirrhosis (LC).
Materials and methods: 80 patients with LC of nonviral etiology were examined. Classification of the International Working Group and the World Congress of Gastroenterology (Los Angeles, 1994) was used for the diagnosis of LC. Diagnosis was based on anamnestic, clinical and laboratory data, ultrasound evidence of liver damage, detection and absence of serological markers of viral hepatitis and alcoholic origin of the disease. Parameters of free-radical oxidation and antioxidant system (malonaldehyde, diene conjugates, the activity of ceruloplasmin, transferrin saturation with iron) and medium molecular weight peptides as manifestation of endogenous intoxication were determined in the patients' the blood. For all patients ^{13}C-metacetin breath test was performed to assess the functional capacity of hepatocytes. TIMP-1, TGF-β1 and bacterial endotoxin were determined with the ELISA method. The investigated group included the patients with LC at stage A and B according to Child-Pugh.
Results: Examined patients included 71 men (88.7%) and 9 women (11.3%). Age of patients ranged from 34 to 64 years on average (47.7 ± 0.82) years. Disease duration in patients ranged from 2 to 9 years.
The level of TIMP-1 in patients with LC was (523.5 ± 6.5) pg/ml and significantly different from healthy persons - (164.6 ± 8.50) pg/ml ($p < 0.05$). TGF-β1 levels in patients with LC was 437.7 ± 5.9 pg/ml and 166.98 ± 6.73 pg/ml ($p < 0.05$) in healthy persons. The level of bacterial endotoxin in patients with LC was 79.32 ± 2.1 pg/ml and significantly different from healthy persons – 23.6 ± 0.91 pg/ml ($p < 0.05$). Endotoxin was positively correlated with TGF-β1 ($r = 0.338$, $P < 0.05$), and positively correlated with medium molecular weight peptides ($r = 0.413$, $P < 0.05$).
Conclusion: Cytokines are released under the influence of bacterial endotoxin from Kupffer cells causing the production of fibrogenic factors (such as TGF-β1), and leading to stimulation of fibrogenesis and progression of disease.

P0009 ADMINISTRATION OF ANTISENSE OLIGODEOXYNUCLEOTIDES TO NERVE GROWTH FACTOR ATTENUATES INFLAMMATION AND LIVER DAMAGE IN ACUTE LIVER DAMAGE MODELS

R. Bruck[1], E. Hubel[1], I. Zvibel[1]
[1]*Gastroenterology, Tel Aviv Medical Center, Tel Aviv, Israel*

Contact E-mail Address: rafib@tlvmc.gov.il

Introduction: Nerve growth factor (NGF) has pro-inflammatory effects in lung and skin inflammatory diseases. During liver regeneration, NGF secreted by hepatocytes induces hepatic stellate cell apoptosis. However, NGF involvement in models of liver damage and inflammation has not yet been assessed.
Aims & Methods
Aim: We investigated the possible inflammatory effects of NGF on isolated hepatic stellate cells (HSC), as well as the *in vivo* effect of silencing NGF on acute liver damage and inflammation.
Methods: Primary HSC from rats and mice were isolated and cultured for 7d and 14d to obtain activated and fully activated HSC, respectively. HSC were treated with 100ng/ml NGF and proNGF and inflammatory cytokine expression was assessed by qRT-PCR and ELISA. Acute liver damage was induced by two i.p. injections of CCl_4 (1ml/g body weight) or by bile duct ligation (BDL) and mice received daily treatment with antisense oligodeoxynucleotide to NGF (ODN)(25mg/kg body weight).
Results: Both NGF and proNGF induced expression of pro-inflammatory cytokines TNFa and IL-6 in activated and fully activated primary rat and murine HSC. Administration of antisense ODN to NGF in the acute CCl_4 and BDL models reduced liver damage, as demonstrated by significantly reduced serum liver enzymes. In addition, antisense ODN to NGF resulted in dramatically reduced (6- fold) hepatic mRNA expression of pro-inflammatory cytokines IL-6, TNFa and MCP1 in the acute CCl_4 acute model. In the BDL-induced acute liver injury, administration of ODN resulted in a two-fold reduction in TNFa, MCP-1 and CXCL1expression.
Conclusion: Silencing NGF may have a beneficial, anti-inflammatory and protective effect in acute hepatotoxicity models.

Introduction: Ingredients of soy and fermented products have been widely utilized as food supplement for health-enhancing properties, such as reducing the risk of osteoporosis, protection from cardiovascular diseases, and prevention of prostate and breast cancer. This study was carried out to examine the effects of fermented soymilk (FSM) on the free fatty acid-induced lipogenesis in an in vitro model of hepatocellular steatosis model.
Aims & Methods: HepG2 cells were incubated with 0.2 mM of palmitic acid (PA) for 24 h to induce lipogenesis and to accumulate the intracellular lipid accumulation, which was observed by oil red O and Nile red staining. The PA-treated cells were co-incubated with 0.04~1.0% of lyophilized FSM, 0.05 mM of genistein, and 50 nM of estrogen, respectively. Western blot analysis of sterol regulatory element-binding protein-1 (SREBP-1) and nuclear factor erythroid 2-related factor-2 (NRF-2) were performed to examine the lipogenesis related extracellular signal-regulated kinase (ERK) pathway. Cellular reactive oxygen species (ROS) was measured by the DCFDA assay kit.
Results: Lipid accumulations in the PA and FSM co-incubated cells were significantly decreased by 0.5% and 1.0% of FSM without cytotoxicity. Treatments of PA and combining with genistein and estrogen significantly increased the expressions of SREBP-1. However, FSM co-incubation significantly attenuated the expression of SREBP-1 in the PA treated cells. In addition, expression of NRF-2 and phosphorylation of ERK were significantly increased in the PA and FSM co-incubated cells. PA-induced ROS production was significantly reduced by 1.0% of FSM. Meanwhile, genistein or estrogen alone did not lead to significant differences in ROS production.
Conclusion: Our results show that bioactive components, except genistein and phytoestrogen, in fermented soymilk protect hepatocytes against lipid accumulation and ROS production induced by free fatty acid. These effects may be mediated by inhibition of SREBP-1 and activation of NFR-2 via ERK pathway in hepatocytes.

Introduction: Classically linked with increased risk of Crohn's disease, the polymorphisms of the *NOD2*, a gene involved in the immune response regulation, have been associated, more recently, with a higher risk of some infections and neoplasms. In liver cirrhosis, carriers of *NOD2* variants have been related with an increase in the risk of spontaneous bacterial peritonitis (SBP) because of impaired intestinal mucosa barrier function.
Aims & Methods: The aim of this study was to assess whether *NOD2* mutations are risk factors for alcoholic liver cirrhosis (ALC) and whether there are genotype-phenotype correlations in these patients.
Methods: Case-control study involving the research of the 3 main *NOD2* mutations (3020insC, R702W e G908R) in 202 patients with ALC and in 202 healthy controls.
Results: *NOD2* mutations were found in 43 patients (21.3%) and in 27 controls (13.4%) ($p = 0.064$). The mean age of patients was 59.3 ± 12.6 years old and 79.8% were males. The average age at diagnosis of ALC was significantly lower in patients with mutation (48.3 ± 11.8 *vs.* 58.2 ± 12.4 years old; $p = 0.008$). The incidence of *NOD2* mutations, especially of the R702W variant, was significantly higher in patients with SBP (38.0% vs 13.7%; $p = 0.022$). No significant associations were detected between *NOD2* mutations and hepatocellular carcinoma (22.2% vs 19.7%, $p = 0.603$), hepatorenal syndrome (28.5% vs 19.7%, $p = 0.454$), hepatic encephalopathy (22.5% vs 20.0%, $p = 0.727$), gastroesophageal variceal bleeding (17.6% vs 23.1%, $p = 0.775$), acute alcoholic hepatitis (31.2% vs 20.4%, $p = 0.403$) or other infectious intercurrences (18.7% vs 22.9%, $p = 0.674$).

Conclusion: In this study, the *NOD2* mutations are associated with a trend for increased risk of ALC, earlier onset of the disease and showed to be a risk factor for PBE.

P0012 HEPATIC EXPRESSION OF SOMATOSTATIN RECEPTOR 2 MAY BE REGULATED BY CYCLOOXYGENASE-2 IN RAT MODEL OF LIVER CIRRHOSIS

Y. Lu[1], J. Gao[1], S. Wen[1], C. Tang[1]
[1]*West China Hospital, Sichuan University, Chengdu, China*

Contact E-mail Address: luyaoyao512@163.com
Introduction: Somatostatin has been used in liver cirrhosis for several decades. Its effects are mediated through binding to its 5 receptors, somatostatin receptor 1-5 (SSTR1-5), among which SSTR2 takes part in an interesting physiopathological process. Hepatic expression of Somatostatin receptor 2 (SSTR2) is upregulated in liver cirrhosis. However, its regulatory mechanism during liver cirrhosis remains obscure.
Aims & Methods: The present study aimed to examine the mechanisms of SSTR2 regulation in liver tissue during the development of liver cirrhosis. Eighteen rats were randomly assigned into control group, cirrhosis group and cirrhosis + celecoxib group, with 6 in each group. Liver cirrhosis was induced in rats by injection of thioacetamide (TAA) intraperitoneally. Expressions of SSTR2, Cyclooxygenase -2 (COX-2) were assessed by western blot and real-time PCR. DNA methylation level of SSTR2 was investigated by bisulfite sequencing. To explore possible regulation effect of COX-2 on the expression of SSTR2, COX-2 was induced in L02 cell lines by transfection of COX-2 and addition of TAA with final concentration from 20mg/L to 80mg/L.
Results: Hepatic expression of SSTR2 and COX-2 were upregulated in liver cirrhosis group compared with control group, both of which were inhibited by the addition of celecoxib. Celecoxib (20uM and 40uM) inhibited the upregulation of SSTR2 in L02 cell line transfected with COX-2 gene or treated with TAA, in which COX-2 was induced, compared with control group. DNA methylation level in promoter region of hepatic SSTR2 is similar between liver cirrhosis group and control group (3.7% VS 3.9%, $p > 0.05$).
Conclusion: Hepatic expression of SSTR2 is upregulated in liver cirrhosis which may be regulated by COX-2 but not DNA methylation.

Introduction: Gut microbiota (GM) contributes to host metabolism and energy balance, and significant modifications have been reported in malnourished populations. Liver cirrhosis is often associated with malnutrition and sarcopenia but GM changes in this setting have not been investigated yet.
Aims & Methods: The aim of this study was to assess whether GM composition may change in relation to nutritional status in cirrhotic patients. Fecal samples of cirrhotic patients without exposure to antibiotics, pre-/pro-biotics and bowel colonoscopy preparation for at least one month were collected. Nutritional status was assessed by two questionnaires including clinical and anthropometric parameters (Subjective Global Assessment, SGA, and Mini Nutritional Assessment, MNA). GM composition was assessed by a metagenomic gene-targeted approach (16S rRNA) using the Roche 454 GS Junior, following DNA isolation from stool samples stored at –80°C. Data were analyzed in Qiime. Biostatistic analysis was performed using R-statistics packages.
Results: Eighteen cirrhotic patients provided fecal samples. Median age was 60 years, Child-Pugh A/B/C 9/3/6, 3(66%) were well-nourished, 12(17%) at risk of malnutrition and 3(17%) severely malnourished according to MNA; 13(72%) were well-nourished, 2(11%) presented mild to moderate malnutrition and 3(17%) severe malnutrition according to SGA. PCoA of weighted-Unifrac distance evidenced samples clustering according to MNA and SGA rather than to Child-Pugh score ($p = 0.004$, $p = 0.002$ and $p = 0.284$ respectively; PERMANOVA). Malnutrition was associated to the reduction of several taxa, mainly related to the genus Bacteroides, Parabacteroides, Prevotella, Streptococcus, Faecalibacterium, Veillonella (adj. p-value < 0.05). These changes were not related to Child-Pugh score.
Conclusion: Changes in GM composition are strictly associated with nutritional status in cirrhotic patients. Metabolomic analyses should be performed to reveal the significance of these alterations and to evaluate potential therapeutic approaches.

Contact E-mail Address: nabila.hassan25@yahoo.com
Introduction: Hepatitis C virus (HCV) infection is a major public health problem worldwide. The prevalence of infection is nearly 3% worldwide. Egypt has one of the highest prevalence rates of HCV infection in the world, about 16-18%. Blood donations screening, achieved mainly by serological identification of HCV-Antibody (Ab), has largely reduced HCV transmission. However, Ab detection is not a reliable marker in the pre-seroconversion phase of infection, infection stage assessing or/for monitoring individuals on anti-viral therapy. HCV Core Antigen (CAg) tests have been introduced to supplement anti-HCV tests and HCV PCR analyses. It may be a useful test for identifying window phase blood donations from Ab negative donors infected with HCV and for the monitoring of antiviral therapy.
Aims & Methods: In this study we aimed to analyze the clinical performance of a commercially available enzyme linked immunosorbent assay (Cell Biolab, Diagnostic. Inc. USA) for HCV CAg and compare the performance of it with reverse transcription polymerase chain reaction (RT-PCR).
This study was done on 88 persons who were divided into two groups. Group 1 included 44 persons diagnosed as anti HCV antibody positive and group 2 included 44 persons diagnosed as anti HCV antibody negative. Sera from all patients were analyazed for both HCV (CAg) and PCR tests. The positive cases to HCV infection in both groups and could be treated by anti HCV therapy reanalyzed by both HCV (CAg) and PCR tests after 12 week.
Results: Out of 88 patients; 26 patients were positive by both CAg and PCR; 5 patients were positive by CAg and negative by PCR while 2 patients were positive only by PCR test. The diagnostic sensitivity, specificity, and positive and negative predictive values of the HCV (CAg) test compared to the HCV RNA test were 92.9%, 91.7%, 83.9%, and 96.5%, respectively. There was statistically positive correlation ($n = 26$, $r = 0.4$) between of the patients HCV (CAg) titer and HCV RNA levels by RT-PCR in ($P < 0.01$). 12 cases (from 26 patients positive to HCV infection from both groups) that could be treated by antiviral therapy using interferon (IFN) and ribavirin (RBV) were reanalyzed by (CAg) and PCR tests after 12 week of therapy and there was a positive correlation ($r = 0.7$) between of the patients HCV (CAg) titer and HCV RNA levels by RT-PCR in ($P < 0.02$).
Conclusion: HCV core antigen testing can be a reliable test used to identify current HCV infection and follow up of treatment especially in areas with poor facilities.

P0015 PATHOGENETIC ROLE OF SMALL INTESTINAL BACTERIAL OVERGROWTH IN NONALCOHOLIC STEATOHEPATITIS

S. Tkach[1], T. Cheverda[1]
[1]*Internal Medicine #1, National Medical University, Kyiv, Ukraine*

Contact E-mail Address: tkachsergio@yahoo.com
Introduction: Among the various potential contributions of the microbiota to liver disease, small intestinal bacterial overgrowth (SIBO) has historically been shown to be common in chronic liver disease, to correlate with its severity, to be linked to minimal and overt encephalopathy and increased risk of spontaneous bacterial peritonitis. Most recently, more credence has been given to a suggestion that the gut microbiota might play a role in the pathogenesis or progression of certain liver diseases, including alcoholic liver disease, non-alcoholic fatty liver disease (NAFLD) and non-alcoholic steatohepatitis (NASH) through the direct effects of bacteria or their products, via nflammatory mediators such as tumor necrosis factor-α.
Aims & Methods: Our aim was to evaluate the frequency of SIBO in patients with NAFLD/NASH and the influence of eradication of SIBO on clinical course of NASH. We investigated 104 obese patients (66 male, mean age – 54 years, mean BMI – 30.5 ± 3 ,9) who were categorized into two groups: 54 patients with liver steatosis and 50 patients with NASH. Diagnosis of NALFD was confirm by use of ultrasonography or/and computed tomography. Diagnosis of NASH was based on increasing level of ALT (1.26 ± 0.18 mmol/l) and/or positive results of NASHTest (Poynard *et al.*, 2006). In patients with NASH the evaluation of liver function with ^{13}C-methacetine breath test (^{13}C-MBT) also was performed (IRIS by WAGNER, Germany). The presence of SIBO was diagnosed by using a hydrogen glucose breath test (EC60

Gastrolyzer 2, Bedfont Scientific Ltd, Rochester, UK). All patients with positive results of hydrogen glucose breath test (H_2-GBT) were treated with rifaximine (1200 mg/day during 10 days). The efficacy of treatment was controlled with repeated biochemistry, H_2-GBT and ^{13}C-MBT (after 1 month).
Results: Overall, positive results of H_2-GBT and presence of SIBO were found in 12 pts (22.2%) with liver steatosis and 28 (56%) with NASH ($P < 0.005$). Abnormal results of ^{13}C-MBT were occurred in 2 pts with liver steatosis and SIBO (16.6%) versus 12 pts with NASH and SIBO (42.9%, $P < 0.005$). Eradication of SIBO was achieved in 34 of 40 pts (85%) after use of rifaximine (1200 mg/day during 10 days). Obvious improvement of the level of ALT (0.48 ± 0.06, $P < 0.005$) and liver function with repeated biochemistry and ^{13}C-MBT (after 1 month) was occurred in 22 pts (64.7%) and 18 pts (52.9%), accordingly.
Conclusion: We concluded that the changes of intestinal microbiota, including SIBO, plays an important pathogenetic role in initiation and progression of NASH. The modulation of intestinal microbiota and eradication of SIBO with antibiotics (rifaximine) decreased the level of liver inflammation, improved biochemical and liver functional indicators and can be considered as an effective and prospective method of treatment of NASH.

Introduction: In cases of insufficient efficacy of conventional therapy of chronic hepatitis and cirrhosis, the search for cellular sources of liver regeneration is becoming more and more urgent. One of the cell types claiming the role of liver regional stem cells (RSC) is hepatic stellate cell (HSC). The aim of our study was to investigate the influence of HSC transplantation on liver regeneration in rats after partial hepatectomy (PH) and administration of 2-acetylaminofluorene (AAF).
Aims & Methods: HSC were isolated from the intact rat livers by the collagenase-pronase perfusion method and then transfected with the green fluorescent protein gene (GFP). Isolated cells were injected immediately after performing PH into the portal vein of operated rats, which were administered with intraperitoneal injection of AAP for 5 days before PH and after PH till sacrifice date at a dose of 12 mg/kg per day. Animals were euthanized after HSC transplantation. Liver paraffin sections were stained immunohistochemically with antibodies against GFP, α-fetoprotein (a-FP) – marker of hepatoblasts, cytokeratin 19 (CK19) – marker of hepatoblasts and cholangiocytes.
Results: After the 1st day of HSC transplantation GFP-positive cells were not detected. After 2 days there were single GFP-positive hepatocytes. Their number reached maximum at 2–3 days after surgery and then rapidly decreased. At the early experimental stages CK19 was present only in the cells of intrahepatic bile ducts and in individual small cells in the periportal areas, the number of which had increased gradually till the 5th day, and up to this moment in the liver developed the evident ductular reaction: the number of bile ducts was increasing, their branching signs and holangioblasts' migration were noted. Further, the evidence of the ductular reaction decreased, but there was also noted decrease of interportal distances indicating the formation of new liver lobules by dividing of existing ones. After the 1st day of PH and injection of native HSC, morphological analysis revealed multiple α-FP + hepatocytes. Besides, many hepatocytes had two cell nuclei. At the same time at all experimental dates we identified GFP + sinusoidal cells and small round α-FP + cells located in periportal sinusoids, which obviously were hepatoblasts. After the 2nd postoperative day the number of α-FP + hepatocytes sharply decreased, α-FP + binuclear hepatocytes and sinusoidal cells were still visible in parenchyma and periportal areas. After 2 weeks only single α-FP + sinusoidal cells were observed in the liver of HSC recipients.
Conclusion: We concluded that at the early stages of our experiment transplanted HSC stimulate activation of RSC in recipients' liver presumably by releasing a variety of growth factors. This leads to expression of hepatoblasts markers cytokeratin-19 and α-FP by RSC localized in liver sinusoids. Later transplanted HSC begin to differentiate into the hepatocyte linage direction which is less pronounced. This probably occurs both due to the direct differentiation of transplanted cells and their fusion with host liver hepatocytes which is indirectly evidenced by the large number of GFP-positive binucleated hepatocytes.

P0017 ROLE OF HUMAN UMBILICAL CORD-DERIVED MESENCHYMAL STEM CELLS IN MANAGEMENT OF CARBON TETRACHLORIDE-INDUCED HEPATIC FIBROSIS IN SPRAGUE DAWELY RATS

D. Bakr[1], M. Maher[1], A. Lotfy[1], on behalf of medical experimental research center, S. El Desouky[1], on behalf of medical experimental research center, F. El Husseiny[1], on behalf of medical experimental research center, H. El Askalany[1], M. Hamed[1]
[1]*Faculty of Medicine Mansoura University Egypt, Mansoura, Egypt*

Contact E-mail Address: bakrdoaa@gmail.com
Introduction: Hepatic fibrosis is a reversible wound-healing response to either acute or chronic cellular injury that reflects a balance between liver repair and scar formation. During acute injury, the changes in liver architecture are transient and reversible. With chronic injury, there is progressive substitution of the liver parenchyma by scar tissue. Advanced liver fibrosis results in cirrhosis, liver failure, and portal hypertension and often requires liver transplantation.
Chronic HCV is a major health problem in Egypt with a 10% prevalence of chronic HCV infection among persons aged 15-59 years, which, if left untreated, can result in cirrhosis and liver cancer.
Aims & Methods
Aim of work: To study the antifibrotic effect of umbilical cord mesenchymal stem cells (UCMSCs) and their ability for differentiation into functioning hepatocytes in early and late carbon tetrachloride(CCL4) induced hepatic fibrosis.
Methods: The study was conducted on 40 rats with average weight 180-200 gm, rats were housed under $25^{\circ}C \pm 2^{\circ}C$ and a 12-h light/dark cycle in clean cages with access to food and water ad libitum.
Rats were divided into 2 main groups (control group and UCMSCs-treated group) and each one of them was subdivided into 2 subgroups:
Control group : consists of 20 rats and subdivided into 2 subgroups A) Negative control group (control vehicle (CV) group) : injected by olive oil intraperitonealy equivalent to their body weight and they were scarificed at 2and 6 weeks , blood samples and liver were taken for histopathological examination. B) Positive control group: Rats were injected by carbon tetrachrolide (CCl4) by dose 0.5 mg/kg in olive oil in ratio of 1:1 intraperitonially twice per week for 2 weeks (early fibrosis) and 6 weeks (late fibrosis).
UCMSCs-treated group: they were treated by UCMSCS after 2 weeks and 6 weeks of CCL4 injection in a dose of one million cells/cm3 medium by single injection into the inferior pole of the spleen under general anasthesia using mixture of valium (5mg/kg) and ketamine (5 mg/kg). Then, we closed the wound layer by layer using interrupted sutures by vicryl 3/0. Injection of subcutaneous saline into the rat to avoid its dehydration. Rats were sacrificed 2 weeks after treatment.
Results: As regard laboratory parameters, there was significant reduction in AST & ALT levels in UCMSCs-treated group when compared with the control group with minimal statistical difference in both albumin and INR with significant reduction in area of fibrosis and effective tracing of human albumin gene in the rat's liver by RT-PCR technique in early and late fibrosis.
Conclusion: UCMSCs have both antifibrotic and regenerative powers in treatment of CCL4-induced liver fibrosis in rats at early and late stages.

Introduction: Nonalcoholic fatty liver disease (NAFLD) is one of the most common liver diseases in western countries, affecting 20-30% of adult population. This condition can progress to more severe liver diseases - nonalcoholic steatohepatitis, cirrhosis or hepatocellular carcinoma (1). Incretin hormone glucagon-like peptide-1 (GLP-1) exerts beneficial effects on liver functions and liver metabolism, especially in NAFLD condition. In our previous experiment we described a diminishing effect of GLP-1 analogue Liraglutide (LIRA) on an early phase of liver regeneration after partial hepatectomy in rats. In our present work we evaluated an effect of LIRA on cell viability and oxidative stress parameters in primary cultures of rat hepatocytes isolated from lean and steatotic livers.
Aims & Methods: Primary cultures of hepatocytes were obtained from male Wistar rats fed a standard laboratory diet (ST1-group, 10% of energy from fat) or a high-fat diet (HF-group, 71% of energy from fat) for 6 weeks. Hepatocytes were isolated by a two-step collagenase perfusion of rat liver, cell viability was >90%. After the establishment of monolayers, hepatocytes were incubated in supplemented Williams' E medium containing LIRA at concentrations of 0.1-1000 nmol/l for 24 hours. After this period the medium was collected for biochemical assays. We assessed cell viability (leakage of lactate dehydrogenase (LDH) and activity of cellular dehydrogenases - WST-1 assay), synthetic capacity of the hepatocytes (production of albumin determined by ELISA) and markers of oxidative stress (malondialdehyde concentration (MDA), and DCFDA assay).
Results: HF-groups vs. ST1-groups showed lower cell viability (lower cellular dehydrogenases activity, higher LDH leakage, $p < 0.001$) and increased MDA production ($p < 0.001$). LIRA increased activity of cellular dehydrogenases in

ST1-groups ($p < 0.01$), decreased oxidative stress in steatotic hepatocytes (DCFDA assay, $p < 0.05$) and showed no negative effects on other parameters.
Conclusion: In conclusion, GLP-1 analogue Liraglutide does not exhibit negative effects on cell viability and oxidative stress in primary cultures of rat hepatocytes isolated from lean and steatotic livers.
This work was supported by grants GAUK 1488213 and PRVOUK P37/02.

P0019 THE ROLE OF ALBUMIN AND HEPATIC ELASTOGRAPHY LEVELS ON VITAMIN D DEFICIENCY

M. Silva[1], A. Peixoto[1], H. Cardoso[1], G. Macedo[1]
[1]*Gastrenterology, Centro Hospitalar São João, Porto, Portugal*

Contact E-mail Address: marcocostasilva87@gmail.com
Introduction: Liver is the major organ involved in vitamin D metabolism. Recent studies described a high prevalence of vitamin D deficiency in patients with different liver diseases and portal hypertension.
Aims & Methods
Aims: The authors propose to assess vitamin D deficiency in patients with liver disease and its association with clinical and analytical parameters related to hepatic and phospho-calcium metabolism.
Methods: Retrospective analysis of clinical records of patients followed on Hepatology Clinic in a single center. A vitamin D level <20ng/mL was considered as deficiency, according to guidelines. FibroScan transient elastography was used to estimate liver stiffness.
Results: In this study were included 250 patients: 156 men with a median age of 54 years, of which 38% patients had liver cirrhosis. The most common etiologies were VHB infection (31%), alcohol (18%) and VHC infection (16%). Median vitamin D levels were 16 (IQR: 15) ng/mL. Vitamin D deficiency was detected in 60% of total sample, 71% in those with cirrhosis and 53% in those without cirrhosis. Patients with vitamin D deficiency had lower calcium serum levels ($p = 0.004$) and increased hepatic elastography ($p = 0.013$). In multivariate analysis, using logistic regression, vitamin D deficiency was independently associated with liver cirrhosis (OR = 2.2, $p = 0.005$) and the albumin levels were a protective factor (OR = 0.86, $p = 0.002$).
Conclusion: Vitamin D deficiency is very common in liver disease, even without cirrhosis. This deficiency can lead to hypocalcemia, and should be prevented. Our results suggest that this deficiency may be primarily related with the severity of hepatic disease as reflected by the protective role of albumin levels and the association with cirrhosis and increased hepatic elastography.

Introduction: Thromboxane A2 (TxA2) contributes to liver repair after acute liver injury as well as to tumor-associated angiogenesis.
Aims & Methods: The present study was to examine whether TxA2 receptor (TP) signaling in platelets facilitates sinusoidal restoration to repair the injured liver from chemical hepatotoxicity.
Treatment with carbon tetrachloride (CCl4) (1.0 mg/kg, ip) was used to induce acute liver injury in male TP knock out mice (TP-/-) and their wild counterparts (WT). At 0, 12, 24, 48, 72, and 96 h after CCl4 administration, plasma activity of ALT, necrotic area, proliferating cellular nuclear antigen (PCNA) index, and hepatic mRNA levels of growth factor relevant to angiogenesis were determined. Liver microcirculation was assessed by intravital microscopy.
Results: Both of WT and TP-/- experienced the maximal liver injury as evidenced by ALT levels at 24 h, and ALT levels were gradually decreased to basal levels at 96 h. Hepatic necrotic area in WT peaked at 48 h, and reduced thereafter, while that at 48 h in TP-/- was greater and remained high thereafter. The PCNA expression in WT peaked at 48 h, while that in TP-/- mice delayed and peaked at 72 h. Liver microcirculation was impaired and reached at nadir at 48 h, and delayed restoration in TP-/- compared with WT. Liver sinusoidal endothelial cell functional recovery was impaired in TP-/-. Platelets adhesion to the sinusoids was enhanced in WT at 48 and 72 h compared with TP-/-. This was associated with reduced mRNA levels of HGF, VEGFR2, basic FGF, and CD31 in liver from TP-/-. HGF levels in platelets from TP-/- treated with CCL4 for 48 h were lower than WT.
Conclusion: TP signaling promotes liver repair and sinusoidal restoration through enhancement of hepatic pro-angiogenic factors including HGF derived from platelets.

P0021 BACTERIAL INFECTION IN PATIENTS WITH LIVER CIRRHOSIS USING ACID SUPPRESSIVE MEDICATION: AN EXPERIENCE OF A SINGLE TERTIARY HOSPITAL IN QATAR

A.-N. Elzouki[1], N. Nefati[1], F. Rasoul[1], O. Othman[1], A. Saad[1], A. Badi[1]
[1]*Medicine, Hamad Medical Corporation, Qatar, Doha, Qatar*

Contact E-mail Address: nelzouki_1999@yahoo.com
Introduction: The association between bacterial infections and acid suppressive medications (i.e., proton pump inhibitors, PPIs) has been recently studied with debatable results.
Aims & Methods: The aim of this study was to investigate the relationship between PPIs and the development of bacterial infections in cirrhotic patients. Consecutive cirrhotic patients above 18 years old hospitalized from 2007 through 2012 to Hamad General Hospital-Qatar were enrolled. We specifically inquired for PPIs consumption in the last 90 days prior to hospitalization and classify as PPIs-users and non-users. Cirrhosis diagnosis was established either with a liver biopsy or the combination of physical, laboratory and ultrasonography findings. Cirrhotic patients with active gastrointestinal bleeding, using immunosuppressive therapy or using antibiotics in the previous two weeks prior to hospitalization were excluded.
Results: A total of 333 patients were included, 171 (51.4%) with and 162 (48.6%) without PPIs. The PPIs-users were significantly older in age ($p = 0.001$). There was no statistical difference between the two groups in sex distribution and etiology of cirrhosis ($p > 0.05$ for both parameters). The PPIs-users had a significantly higher incidence of overall bacterial infection rate (25.7%) than non-PPIs-users (13.5%), $p = 0.005$. On the multivariate analysis, older age >60 years, ($p = 0.02$), and PPIs-use ($p = 0.01$) were independent predicting factors for overall bacterial infection. The indication for PPIs use was undocumented in 43% of patients.
Conclusion: The present study shows that PPIs use, as well as older age >60 years, were independent predicting factors for the development of bacterial infection in hospitalized cirrhotic patients. Unless it is indicated, PPI therapy should be avoided in this group of patients, in particular those older than 60 years of age.

Contact E-mail Address: alvess.anarita@gmail.com
Introduction: Malnutrition is a risk factor for increased morbidity and mortality in liver cirrhosis. Nutritional assessment has been recognized as an important step to identify cirrhotic patients at greater risk of complications in clinical practice.
Aims & Methods
Aim: To evaluate nutritional status of hospitalized patients with decompensated liver cirrhosis.
We performed a prospective six-month study in a gastroenterology unit. All consecutive patients hospitalized due to decompensated liver cirrhosis were submitted to nutritional assessment by the following methods: anthropometric parameters (body mass index-BMI, skinfolds and circumferences), biochemical parameters, dynamometry and questionnaires. Demographic and relevant clinical data were also collected.
Results: A total of 50 patients were included, with a mean age of 60.9 ± 12.1 years, predominantly male gender (80.0%) and alcoholic cirrhosis (90.0%). Main admission causes: ascites and edema 24.0%, hepatic encephalopathy 20.0%, digestive hemorrhage 18.0% and spontaneous bacterial peritonitis 10.0%. All patients except two were classified as Child-Pugh B or C (B-36.0%; C-58.9%) and presented high MELD scores (mean 19.2 ± 7.3). The prevalence of malnutrition, according to the different methods used, was: BMI 22.0%, triceps skin thickness 86.0%, midarm circumference 78.0%, midarm muscle circumference 78.0%, Mini Nutritional Assessment 32.0% (with 62.0% of patients at risk), Subjective Global Assessment 86.0% and the Royal Free Hospital Global Assessment 86.0%. Malnutrition in Child-Pugh C patients was significantly higher comparing with Child-Pugh B, with all the methods used ($p < 0.05$), except for BMI ($p > 0.05$). MELD score was significantly higher in malnourished patients, compared with non malnourished patients (27 versus 13), independently of the method ($p < 0.05$).
Conclusion: Prevalence of malnutrition in advanced cirrhosis was superior to 70% with all the evaluation methods, except for BMI. Greater severity of disease was associated with higher prevalence of malnutrition.

Introduction: Cirrhotic cardiomyopathy (CCM) is a clinically silent complication of liver cirrhosis that becomes overt after stressful events such as infections, placement of transjugular intrahepatic portosystemic shunts or liver transplant. Diagnostic criteria as well as clinical relevance of this entity in patients suffering from cirrhosis are currently under debate.
Aims & Methods: We aimed to determine the impact on survival and disease-related adverse events in a cohort of consecutive patients with liver cirrhosis.
Seventy cirrhotic patients examined in our tertiary referral centre were enrolled in a prospective observational study. Prior history of cardiovascular disease, diabetes, acute renal failure, severe anaemia, obesity or cachexia, active malignancy, infections were considered exclusion criteria.
Full physical examination, routine blood work, N-terminal pro-brain natriuretic peptide (NT-proBNP) levels, 12-lead electrocardiograms and transthoracic echocardiography examination with tissue Doppler imaging were performed in all patients. CCM was diagnosed according to the consensus criteria [1] in the presence of left ventricular ejection fraction $<55\%$ and/or diastolic dysfunction (E/A <1, E wave deceleration time >200ms, isovolumetric relaxation time >80ms). Patients were contacted by telephone every 3 months and invited for a study visit one year after enrollment. Disease-related adverse events (gastrointestinal bleeding, encephalopathy, new-onset or worsening of ascites, severe infections, hepatocarcinoma) and death were the main outcomes reported. Patients were stratified according to the presence of CCM and hypothesis testing was two-tailed with $p < 0.05$ considered significant. Survival analysis was performed by Kaplan-Meier curves.
Results: According to consensus criteria cirrhotic cardiomyopathy was diagnosed in 31 patients (44%). 3 patients were lost to follow-up. There was no difference in etiology or severity of cirrhosis amongst the groups. NT-proBNP levels and length of rate adjusted QT interval did not differ significantly according to the presence or absence of CCM (189 vs 238 pg/mL and, respectively, 414 vs 420 ms). During follow-up (range:3-15 months) there were 10 deaths and 31 patients experienced at least one disease-related adverse event. The median time to appearance of decompensation was 9 months. There were no significant differences between patients with and without CCM in rate of death (4 vs 6 patients, $p=0.9$), risk of adverse-event (14 vs 17 patients, $p=0.1$). There was a statistically insignificant trend towards earlier decompensation in the CCM group (8.8 vs 10.2 months, $p=0.2$). Higher MELD score was the only risk factor for earlier decompensation.
Conclusion: Cirrhotic cardiomyopathy has a high prevalence in the general population of patients with cirrhosis when consensus criteria are used for diagnosis. The presence of cirrhotic cardiomyopathy did not influence survival or time to first decompensation during up to 15 months follow-up in this cohort.

Contact E-mail Address: sergiogiao@hotmail.com
Introduction: One of the most important complication of cirrhosis is ascitic fluid infection (AFI) and occurs in up to 25% of patients. Current literature suggests that ascitic fluid analysis by paracentesis should be done for all patients with ascites that are admitted to the hospital to exclude AFI. Beside membrane inflammation, AFI is also associated with increased systemic inflammation. The mean platelet volume (MPV) as an indicator of larger, active platelets, is being widely studied as a marker for systemic inflammation in areas like Cardiology and Rheumatology, because of its low cost and availability in routine analysis (platelet count).
Aims & Methods: To evaluate the value of MPV as (1) an inflammation marker in decompensated chronic liver disease (2) its ability to exclude AFI.
Retrospective analysis of all patients admitted to our center with the diagnosis of decompensated chronic liver disease, between the period of 2010 and 2014. We excluded admissions for gastrointestinal bleeding and those where paracentesis was not done. At admission, patients were divided in 3 groups: with active infection, infected without AFI and with AFI. A receiver operating characteristics (ROC) curve was obtained, and sensitivity and negative predictive value were calculated for MPV as a predictive marker for AFI exclusion.
Results: We identified 434 patients, 232 with active infection and 99 with criteria for AFI.
The MPV was statistically higher in the group of patients with active infection compared to not infected (10.84 vs 10.43 fL; $p = 0.000$). Within the group of patients with active infection, those with criteria for AFI presented higher values of MPV (11.28 vs 10.49 fL; $p = 0.000$) compared to the other infections.
When compared, the MPV of patients with criteria for AFI versus the rest of the patients, the variables MPV (10.45 fL vs. 11.28; $p = 0.000$), leukocyte count (11.3 vs $8.7x10^9$ /L, $p = 0.003$) and CRP (65.30 vs 34.15 mg/L; $p = 0.00$) were significantly higher; no statistically significant differences were found for the variables number of platelets and platelet distribution width (PDW).
The ROC curve analysis suggested that the optimum MPV level cut-off point for cirrhotic patients with AFI, was 9.75 fL with a sensitivity of 92% and a negative predictive value of 91% (area under the curve: 0.701).
Conclusion: Our results show that MPV is significantly increased in patients with active infection, and represents a good marker for inflammation. We propose the MPV as a noninvasive useful marker for AFI exclusion, with an average discriminating power.

P0025 THE ROLE OF BIOMARKERS AND SYSTEMIC INFLAMMATORY RESPONSE SYNDROME IN THE EXCLUSION OF BACTERIAL INFECTION IN PATIENTS WITH DECOMPENSATED CHRONIC LIVER DISEASE

A. G. Antunes[1], M. Eusébio[1], A. Vaz[1], P. Queirós[2], T. Gago[1], P. Caldeira[1], B. Peixe[1], H. Guerreiro[1]
[1]*Gastroenterology Department, Centro Hospitalar Do Algarve, Faro,*

Introduction: It is estimated that up to 35% of patients hospitalized for decompensated chronic liver disease have a bacterial infection [(1-2)]. The usual biomarkers (C reactive protein- CRP, leukocyte count and mean platelet volume - MPV), together with criteria for systemic inflammatory response syndrome (SIRS), do not behave like in healthy population.
Aims & Methods: We sought to evaluate the diagnostic role of SIRS, CRP, leukocyte count and MPV as predictors of infection at admission in patients with decompensated chronic liver disease.
Retrospective study conducted from 2010 to 2014, which evaluated patients admitted to our center for decompensated chronic liver disease. We excluded gastrointestinal bleeding and those that had not had paracentesis. The patients were divided according to the presence or absence of active infection. We recorded demographic, clinical and laboratory data and assessed the effectiveness of SIRS, CRP, leukocyte count and MPV in predicting infection by using areas under the curve (AUCs).
Results: We identified 434 patients with a mean age of 60 years (80% male). Alcohol was identified as a causative agent for liver disease in 90% of patients and in 24% there was chronic viral infection. About 52% of patients were classified as Child-Pugh C and 13% had criteria for SIRS.
The variables CRP (57 versus 27 mg/L; $p = 0.000$), MVP (10.85 versus 10.42 fL; $p = 0.000$) and leukocyte count (10.54 versus $7.33x10^9$/L; $p = 0.000$) were significantly higher in the group of patients with active infection compared to uninfected. In univariate analysis, the presence of SIRS was associated with infection (X^2: 55.6; $p = 0.000$, OR = 68). Regardless of the Child-Pugh score, when compared, the variables CRP (AUC: 0.754), leukocyte count (AUC: 0.633), SIRS (AUC: 0.621) and MPV (AUC: 0.600), CRP presented the highest discriminating power, and was statistically superior when compared to other variables (respectively, $p = 0.0006$; $p < 0.0001$; $p < 0.0001$). This superiority is still maintained whether is analyzed only Child-Pugh B patients or in Child-Pugh C patients.
Conclusion: The set of our results, only identified CRP as a good marker for exclusion of infection in patients with decompensated chronic liver disease. SIRS and the biomarkers MPV and leukocyte count showed an average discriminatory power (AUC <0.75).

P0026 PREVALENCE AND PREDICTORS OF MORTALITY IN PATIENTS WITH ACUTE-ON-CHRONIC LIVER FAILURE

H. Singh[1], **C. G. Pai**[1], S. Shetty[1], G. Balaraju[1]
[1]*Kasturba Medical College, Manipal Univeristy, Manipal, India*

Contact E-mail Address: cgpai@yahoo.co.in

Introduction: Acute-on-chronic liver failure (ACLF) is characterized by acute hepatic insult manifesting as jaundice and coagulopathy, complicated within 4 weeks by clinical ascites and/or encephalopathy in a patient with previously diagnosed or undiagnosed chronic liver disease/cirrhosis, and is associated with high 28-day mortality.

Aims & Methods: To determine the prevalence of ACLF in patients with chronic liver disease and variables which predict mortality in the former condition. Consecutive patients with known or unknown chronic liver disease (CLD), admitted to Kasturba Hospital, Manipal, between May 2014 and February 2015 were included. ACLF was diagnosed at baseline in patients based on Asia Pacific Association for the Study of Liver (APASL) definition and all were given standard intensive care. All patients were followed up for 28 days or till mortality whichever was earlier. Univariate analysis and subsequently multivariate analysis was done to determine the factors which predict mortality in ACLF.

Results: 115 (male = 109) patients with CLD were included prospectively of whom 37 (32.2%) had ACLF. Alcohol was the most common cause of underlying chronic liver disease (80%) followed by cryptogenic (13.9%). Alcohol (62.16%), Hepatitis E infection (27.03%) and Reactivation of Hepatitis B virus (5.41%) were the most common acute insults. The 28-day mortality was 56.7% among those with ACLF and 23.1% in those without. On multivariate analysis, high serum creatinine ($p = 0.043$) and high C-reactive protein (CRP) ($p = 0.044$) were found to be independent predictors of mortality. Among the severity scores studied, Model for end-stage liver disease (MELD) score was individually able to differentiate between survivors and non-survivors ($p = 0.004$) and fared better than Child-Turcotte-Pugh score ($p = 0.312$).

Conclusion: Patients with ACLF have a higher mortality than those with CLD. High serum creatinine, high CRP and higher MELD scores predict poor outcome in patients with ACLF.

P0027 ROLE OF ACOUSTIC RADIATION FORCE IMPULSE ELASTOGRAPHY AND 13C-METHACETIN BREATH TEST IN PREDICTING THE SEVERITY OF CHRONIC LIVER DISEASE

C. Fierbinteanu-Braticevici[1], A. Moldoveanu[1], L. Tribus[1], A. Petrisor[1]
[1]*Gastroenterology, University of Medicine Carol Davila, University Hospital Bucharest, Bucharest, Romania*

Contact E-mail Address: cfierbinteanu@yahoo.com

Introduction: Noninvasive investigations, such as various imaging techniques and breath tests offer considerable promise in their ability to stage liver disease and avoid an invasive liver biopsy.

Aims & Methods

Aim: To evaluate the role of Acoustic Radiation Force Impulse (ARFI) elastography and ^{13}C-methacetin breath test (MBT) in predicting the severity of chronic liver disease.

Methods: We performed ARFI elastography and ^{13}C-methacetin breath test (MBT) in 179 patients with chronic liver disease of different etiologies (alcoholic, chronic hepatitis C, chronic hepatitis B and nonalcoholic fatty liver disease – NAFLD) who underwent liver biopsy for diagnosis and treatment. The METAVIR scoring system (chronic hepatitis C and chronic hepatitis B) and the Brunt scoring system (alcoholic hepatopathy and NAFLD) served as references for the histological staging of liver fibrosis. The accuracy of non-invasive tests to predict the severity of liver disease (Fibrosis ≥ 2 and cirrhosis) was assessed using the area under receiver operating characteristic curve (AUROC) with 95% CI.

Results: The Spearman's correlation coefficient between ARFI (0.795) and MBT (0.678) and the histological diagnosis of NASH was highly significant ($p < 0.001$). The AUROC of ARFI elastography and MBT was 0.861 (95% CI = 0.808 - 0.914) and respectively 0.804 (95% CI = 0.740 - 0.867) for the diagnosis of significant fibrosis ($F \geq 2$). The diagnostic accuracy of ARFI elastography in predicting cirrhosis ($F = 4$) had a validity of 95.4% (95% CI AUROC = 0.928 - 0.981) while MBT had a validity of 82.7% (95% CI AUROC = 0.765 - 0.890, $p < 0.001$). MBT also enables the evaluation of the microsomal liver function involved in severe chronic liver disease.

Conclusion: ARFI Elastography and MBT are very good methods for assessing the severity of liver disease. Due to the complementary role in evaluating microsomal liver function, ^{13}C-methacetin breath test could be a reliable diagnostic and follow-up test for patients with chronic liver disease.

P0028 THE IMPACT OF CARVEDILOL VERSUS NON-SPECIFIC BETABLOCKERS ON THE MORTALITY IN CIRRHOSIS

C. Sfarti[1], C. Cojocariu[1], A.-M. Singeap[1], C. Petrovici[2], O. Chiriac[2], A. Trifan[1], C. Stanciu[2]
[1]*Institute of Gastroenterology and Hepatology, University of Medicine and Pharmacy IASI,* [2]*Institute of Gastroenterology and Hepatology, Institute of Gastroenterology and Hepatology, Iasi, Romania*

Contact E-mail Address: cvsfarti@gmail.com

Introduction: Carvedilol is a good alternative to propranolol for the prophylaxis of variceal bleeding, some researchers suggesting even a greater impact on portal and systemic hypertension. There is still an open debate about the effect of carvedilol and non-specific betablockers (NSBB) on mortality in patients with cirrhosis.

Aims & Methods: We compared retrospectively the impact on mortality of carvedilol versus NSBB in patients with cirrhosis hospitalized in a tertiary referral center in Romania. We included patients with alcoholic and viral cirrhosis admitted in our center from 01 January 2010 to 31 December 2014. We defined risk time for the bleeding as the time between the first administration of betablockers until death or end of follow-up. We adjusted for age, gender, heart disease, variceal bleeding, Child-Pough score to assess the HR.

Results: We identified 2625 cases: 684 patients receiving carvedilol and 1941 patients who were treated with NSBB, respectively. There were 1147 (43.7%) cases with viral cirrhosis and 1478 (56.3%) cases with non-viral cirrhosis. Regarding the Child-Pough score in each group, we identified in the first group 431 (63%) Child A patients, 205 (30%) Child B patients and 48 (7%) Child C patients, while in the NSBB group we had 1296 (66.7%) Child A patients, 452 (23.3%) Child B patients and 193 (10%) Child C patients. The prevalence of variceal bleeding was 23.7% in the first group vs. 26.2% in the second group without significant difference, while the heart disease was significantly more frequent in the carvedilol group (57% vs. 24%). We recorded significantly fewer deaths in the carvedilol group during follow-up compared with the NSBB group (10.7% vs. 21.3%, Chi-square ($p < 0.05$). We found the un-adjusted HR for carvedilol vs. NSBB to be 0.56 (95% CI 0.3-0.7) and the HR adjusted for covariates was 0.58 (95% CI 0.3-0.7).

Conclusion: The use of carvedilol in patients with cirrhosis was associated with a significant lower mortality compared with the use of NSBB even though the variceal bleeding rate was similar between the two groups.

Introduction: Sponteneous bacterial peritonitis (SBP) in patients with hepatic cirrhosis is mostly related to gram negative enterobacteriaceae. Recent studies have reported a change in the epidemiology of microbes that are being isolated in SBP and an increased prevalence of gram positive and multiresistant bacteria.

Aims & Methods: Record the bacteria that have been isolated in the ascitic fluid of patients with hepatic cirrhosis and their resistance in commonly used antibiotics. Positive ascitic fluid cultures of cirrhotic patients that have been admitted in our hospital and the respective antibiograms have been retrospectively recorded.

Results: 62 patients (49 male) with hepatic cirrhosis with a median age of 66 years (32-68) had positive ascıtic fluid culture. In 36/62 cultures Gram + positive bacteria have been isolated. In detail the isolated bacteria were: enterococcus spp. (19), Escherichia coli (13), streptococcus spp (12), Klebsiella (6), staphylococcus (5), Proteasspp (2), Enterobacter (2) Acinetobacter (1), Cronobacter (1), Pseudomonas aurigonosa (1).
Resistance to 3rd generation cephalosporines has been found in 20 out 47 strains, in ciprofloxacine in 20 out of 40 and in ampicilline in 29 out of 46.

Conclusion: Gram + bacteria have been isolatedin the majority of positive ascitic fluid cultures. Resistance to 3rdgeneration cephalosporines and ciprofloxacine is common. Therapy should be individualized according to culture results and patients' characteristics.

P0030 EARLY IN-PATIENT MANAGEMENT OF ALCOHOL-RELATED LIVER DISEASE: RESULTS OF A LIVER CARE BUNDLE TO IMPROVE QUALITY OF CARE

C. Mason[1], I. Huang-Doran[1], M. McPhail[1], S. Peake[1], K. Monahan[1], C. Collins[1]
[1]*Department of Gastroenterology, West Middlesex University Hospital, London, United Kingdom*

Introduction: The incidence of Alcohol Related Liver Disease (ARLD) is rising in the UK, as is its associated mortality. A recent National Confidential Enquiry into Patient Outcome and Death (NCEPOD) report highlighted recurring deficiencies in the management of ARLD in UK hospitals and the British Society of Gastroenterology provided guidance in the treatment of these patients during acute hospital admissions.
Aims & Methods: Between 1 August 2013 and 31 October 2013, consecutive admissions of patients with ARLD to a district general hospital were identified from discharge and mortality data. A liver care bundle (LCB) using NCEPOD recommendations was generated. Case notes were analysed prior to institution of this LCB and re-audited following its inception from 1 April 2014 to 31 July 2014. Electronic referrals to specialist gastroenterology and dieticians formed part of the LCB, as well as a checklist of actions for the admitting physician.
Results: 20 patients (median age 51 (28-67) years) were identified initially with ARLD, of which 13 (65%) were male. Median Model for End-stage Liver Disease (MELD) score was 14 (range 6-35). Post LCB institution a further cohort of 25 patients studied was matched for age (59 (32-79) years), sex (13/25 (52%) male) and MELD score (13 (6-40)). Inpatient mortality was 7/20 (35%) prior to and 2/23 (9%) post LCB ($p = 0.065$). All patients were screened for ongoing alcohol use and in 65% a withdrawal regime was prescribed. Only 1/20 (5%) had dietician input in the first 48 hours rising to 11/25 (44%) post LCB institution ($p < 0.001$). In all patients with ascites in the presence of acute kidney injury, diuretics were discontinued in both cohorts. In 92% of cases of ascites, diagnostic parascentesis was performed, however blood cultures were performed on admission in only 6/20 (30%) initially rising to 40% post LCB. 13/20 of patients (65%) had consultant review within 12 hours pre LCB with 18/25 (72%) post LCB. The proportion of patients receiving specialist review by a gastroenterologist within 72 hours rose from 45% to 54% following LCB use.
Conclusion: Instituting a liver care bundle for the management of alcohol-related liver disease at our centre improved both the quality of care and outcome from patients admitted during acute decompensation, particularly related to early specialist review. Initiation of bundles of care in liver disease requires close collaboration between specialist medical services and allied health professionals such as dieticians to optimise patient care.

P0031 SPONTANEOUS BACTERIAL PERITONITIS IN PATIENTS WITH CIRRHOSIS AND ASCITES – ITS PREVALENCE, CLINICAL AND PARACLINICAL FEATURES

D. Matei[1,2], A. David[1], N. Al Hajjar[1,2], I. Groza[2], R. Prundus[2], V. Andreica[1,2], M. Tantau[1,2]
[1]*University of Medicine and Pharmacy Iuliu Hatieganu,* [2]*Regional Institute of Gastroenterology and Hepatology , Cluj Napoca, Romania*

Introduction: Spontaneous bacterial peritonitis (SBP) is a severe complication occurring in patients with liver cirrhosis and ascites and it is associated with a high mortality rate.
Aims & Methods: The aim of this study is to evaluate the prevalence of the SBP in hospitalised patients with cirrhosis and ascites and also their clinical and paraclinical characteristics.
Materials and methods. This cross-sectional study enrolled all patients diagnosed with liver cirrhosis and ascites , who were hospitalised in a tertiary medical center over a period of 18 months (January 2012- June 2013).
The diagnosis for SBP consists of polymorphonuclear (PMN) counts ≥ 250 cells/mm^3 and/or a positive ascitic fluid culture, without any evidence of external or intra-abdominal infectious source.
To evaluate our patients, who were divided in two groups (SBP and non-SBP), we compared the following data: age, gender, etiology of cirrhosis, volume of ascitic fluid, hypotension, tachycardia, hepatic encephalopathy, upper gastrointestinal bleeding, hepatorenal syndrome, hepatocellular carcinoma, hepatic hydrothorax, leukocytosis and MELD Score (Model of End-stage Liver Disease).
Results: 763 patients with cirrhosis and ascites were included in our study. The mean age was 60.41 years (min 17 years, max 91 years) and there was a male predominance (63.3%). 11.1% of the patients had SBP.
By comparing the SBP and the non-SBP patients, the following significant differences were discovered: male gender 75.3% vs 61.8% ($p = 0.02$); voluminous ascites 83.5% vs 31.6% ($p < 0.001$); hepatic encephalopathy 82.4% vs 54% ($p < 0.001$); hepatorenal syndrome 15.3% vs 2.5% ($p < 0.001$); hepatic hydrothorax 24.7% vs 11.7% ($p = 0.001$); leukocytosis 32.9% vs 18% ($p = 0.002$) and the MELD Score ≥ 17 points 68.2% vs 39.7% ($p < 0.001$).
Using multivariate analysis, four out of these factors were identified as being independent factors significantly associated with SBP: voluminous ascites (OR = 8.33, 95%CI:4.50-15.42, $p < 0.001$), hepatic encephalopathy (OR = 2.25, 95%CI:1.21-4.20, $p = 0.010$), hepatorenal syndrome (HR = 4.21, 95%CI:1.71-10.38, $p = 0.002$) and the MELD Score ≥ 17 points (HR = 1.77, 95%CI:1.03-3.02, $p = 0.037$).
Conclusion: Spontaneous bacterial peritonitis was found in 11.1% patients with liver cirrhosis and ascites and was significantly associated with voluminous ascites, hepatic encephalopathy, hepatorenal syndrome and a MELD Score ≥ 17 points.

P0032 PANTOPRAZOLE VERSUS RABEPRAZOLE EFFECTS ON CYTOCHROME P450 ACTIVITY ASSESSED BY 13C-AMINOPYRINE BREATH TEST IN PATIENTS WITH LIVER CIRRHOSIS

A. Rocco[1], **D. Angrisani**[1], C. Rubicondo[1], M. Sanduzzi Zamparelli[1], D. Compare[1], P. Coccoli[1], L. Staiano[2], D. Amoruso[2], C. Coppola[2], G. Nardone[1]
[1]*Department of Clinical Medicine and Surgery, Gastroenterology Unit, Federico II University, Naples,* [2]*Hepatology and Interventional Ultrasound Unit, Gragnano Hospital, Gragnano, Italy*

Contact E-mail Address: deborangrisani@hotmail.it
Introduction: Proton pump inhibitors (PPIs) are one of the most widely used drugs worldwide. Almost all PPIs, undergo extensive hepatic metabolism via cytochrome (CYP)-P450 system and their clearance significantly depend on CYP-2C19 activity. Otherwise, the primary pathway of rabeprazole metabolism is non-enzymatic. In patients with advanced liver disease, the activity of CYP-P450 system is impaired, thus leading to a drug clearance reduction and an increased risk of drug-drug interaction. 13C-aminopyrine breath test (13C-ABT) is a non-invasive, liver function test that explores CYP enzyme activity.
Aims & Methods: Aim of the study was to evaluate the effects of different PPIs on the activity of CYPs by 13C-ABT in patients with Hepatitis C virus (HCV)-related liver cirrhosis. We compared two PPIs with different metabolic pathway: pantoprazole, which employs the CYP-P450 pathway, and rabeprazole, which undergoes non-enzymatic metabolism.
Thirty consecutive patients with HCV-related liver cirrhosis, Child-Pugh A, needing PPI therapy, were randomly assigned to pantoprazole (40mg/day) or rabeprazole (20mg/day) treatment. Exclusion criteria were: other causes of liver cirrhosis, severe cardiovascular or respiratory disorders, use of PPI in the 30 days before the study. 13C-ABT was performed before and 15 days after starting therapy according to the following protocol: breath samples were collected baseline and at 30-minute intervals for 2 hours after oral administration of 13C-aminopyrine (2mg/Kg body weight). 13C-enrichment of CO2 was determined by purification-isotope ratio mass spectrometer. Results were expressed as maximum percentage of 13CO2-recovery per hour (max 13C% dose/h) at any time (“excretion peak”) and percentage of 13CO2-cumulative dose recovered in 2 h (%13C cum dose at 120 min).
Results: Overall, we enrolled 13 males and 17 females with a mean age of 60.9 ± 7.5 yrs. Age, gender distribution, BMI and laboratory findings did not significantly differ among pantoprazole and rabeprazole group. Baseline, 13C-ABT results were altered in 13/30 (43%) patients (6 in pantoprazole and 7 in rabeprazole group). Fifteen day after starting therapy, the pantoprazole group had a mean 13C-ABT %dose/h at 30 min of 6.20 ± 4 versus 6.35 ± 4.5 at baseline and a mean %dose/cumulative at 120 min of 11.52 ± 6.9 versus 11.27 ± 7 at baseline. Similarly, during rabeprazole treatment, the mean %dose/h at 30 min was 5.81 ± 3.9 versus 6.13 ± 4.3 at baseline and the mean %dose/cumulative at 120 min was 10.9 ± 6.5 versus 10.7 ± 7.5 at baseline.
Conclusion: No differences is detectable between pantoprazole and rabeprazole use in patients with HCV-related liver cirrhosis. Pantoprazole do not significantly impair the CYP-450 pathway activity in these patients. Both PPIs are safe for treatment of patients with advanced liver disease.

Introduction: Gastric variceal bleeding accounts for 10% of upper gastrointestinal bleeding related to portal hypertension. Level of evidence in managing gastric varices is low.

Aims & Methods: We aimed to determine the modalities of management of non-GOV1 gastric varices in France. Hepato-gastroenterologists (HGE) working in general hospitals (GH) or in university hospitals (UH) received a self-administered questionnaire.

Results: One hundred and fifty four HGE from 109 centers (37UH, 72GH) among the 336 (32.4%) contacted responded. Regarding primary prophylaxis, beta-blockers were used by 96% of HGE. Only 17.2% of HGE used glue obliteration (UH: 27.7% vs GH: 9.3%; $p=0.004$), 8% used TIPS and 5.3% proposed no treatment. Most HGE (77.6%) estimated that they had local access to glue obliteration but 64.2% declared that TIPS placement required transfer to another center. Obliteration was performed under general anesthesia by 86% of HGE. N-butyl-2-cyanoacrylate plus methacryloxysulfolane (Glubran®) and N-butyl-2-cyano-acrylate (Histoacryl®) were used respectively in 48.2% and 55.9% of cases (3.5% of HGE used both). Dilution with lipiodol was performed in 78% of cases. The technique of obliteration was variable between centers and within the same center: maximal dilution was 1/10; injected volume varied from 0.5 to 20mL per varix and from 1 to 30mL per procedure. To control active bleeding, 77.6% of HGE used obliteration (UH: 85.7% vs GH: 70.9%, $p=0.04$) and 34% used band ligation (UH: 28.6% vs GH: 38.8%; $p=0.02$). Early-TIPS was proposed by 56.3% of HGE (UH: 71.7% vs GH: 39.2%, $p<0.001$). Regarding secondary prophylaxis, 74.4% used betablockers, 66% used obliteration (UH: 76.6% vs GH: 56.6%; $p=0.014$) and 14% used TIPS. Endoscopic control was performed by 62.6% of HGE, 70% evaluated the varix stiffness with a closed biopsy forceps. Side effects of obliteration were reported by 59.5% of HGE (UH: 70.4% vs GH: 41.2%; $p=0.08$) and concerned mainly glue migration (UH: 66.7% vs GH: 33.3%; $p<0.001$), an event systematically searched by 22.9%.

Conclusion: The management of gastric varices in France is very heterogeneous between centers and even within the same center. University hospitals have a better access to obliteration and especially to TIPS. Obliteration as a primary prophylaxis procedure was rarely performed. Glue migration was frequently observed although probably underreported. Specific guidelines on the management of gastric varices should be established by expert groups to standardize clinical practices.

Introduction: The prognostic performance of the Chronic Liver Failure-Sequential Organ Failure Assessment (CLIF-SOFA) score in cirrhotic patients admitted to Intensive Care Units deserves large external validations.

Aims & Methods: The aim of this meta-analysis was to assess the ability of the CLIF-SOFA to predict in-ICU, in-hospital, and 6-month mortality in ICU survivors.

The CLIF-SOFA was computed retrospectively in 6 studies including 1221 cirrhotic patients admitted between 1995 and 2012. Studies have been selected by the participation of the corresponding authors who responded to a standardized questionnaire. The prognostic performance of different cutoffs of the CLIF-SOFA to predict mortality at different timepoints was assessed by the weight-adjusted odds ratios and positive predictive values and compared to that of the SOFA, the modified SOFA (mSOFA) and the MELD.

Results: On admission, 72.1% of patients ($n=880$) had a CLIF SOFA ≤ 14 and only 1.1% ($n=13$) had a CLIF-SOFA > 22. Among all the available prognostic scores, the best predictor of in-ICU mortality was a CLIF-SOFA ≥ 22 (OR = 5.94; CI95%: 1.71-20.64; $p=0.005$; PPV = 1.00), followed by a SOFA > 19 (OR = 10.37; 95%CI: 5.65-19.01; $p<0.001$; PPV = 0.94). Predictive value of in-ICU mortality was better for a CLIF-SOFA ≥ 15 (OR = 7.44; CI95%: 3.43-16.12; $p<0.01$; PPV = 0.81) than for an increased SOFA on day 3 (OR = 4.75; 95%CI: 2.33-8.97; $p<0.001$; PPV = 0.71) or a MELD score ≥ 26 (OR = 5.37; 95%CI: 4.01-7.21; $p<0.001$; PPV = 0.66). Prognostic value of in-hospital mortality was good for a CLIF-SOFA ≥ 15 (OR = 3.93; 95CI%: 2.13-7.26; $p<0.001$; PPV = 0.88), for a mSOFA > 13 (OR = 11.92; 95%CI: 4.59-30.94; $p<0.001$; PPV = 0.94) and a SOFA > 19 (OR = 11.56; 95%CI: 3.23-41.32; $p<0.001$; PPV = 0.94). Among ICU survivors, 6-month mortality was still predicted by a CLIF-SOFA ≥ 22 (OR = 7.43; 95%CI: 1.18-46.62; $p=0.032$; PPV = 1.00), and a MELD ≥ 26 (OR = 3.97; 95%CI: 1.92-8.22; $p<0.001$; PPV = 0.75), whereas high values of SOFA and mSOFA did not provide any significant prediction.

Conclusion: In critically ill cirrhotic patients, the CLIF-SOFA is able to predict both in-ICU mortality and 6-month mortality in ICU survivors, conversely to the SOFA and mSOFA. High values of CLIF-SOFA better predict in-ICU mortality than high values of SOFA or increase in SOFA on day three, and better predict 6-month mortality in ICU survivors than the MELD score. The CLIF-SOFA thus appears as the prognostic score of choice for the critically ill cirrhotic patients.

Introduction: The medium-term survival of cirrhotic patients who survived intensive care and its determinants have never been evaluated, due to the small number of ICU survivors in the published studies.

Aims & Methods: This meta-analysis evaluated the predictors of 6-month mortality in ICU survivors.

13 studies (2695 cirrhotics) were analyzed after selection of original articles and response to a standardized questionnaire by the corresponding authors. The endpoint was 6-month mortality of 412 ICU survivors (reported in 5 studies). 95 pooled analyses concerned patient characteristics, reason for admission, organ replacement therapy, and composite scores.

Results: Only 48 patients (3.4%) were transplanted during follow-up. Six-month mortality was lower in high volume centers (OR = 0.45; 95%CI: 0.30-0.67; $p<0.001$), in general ICUs (OR = 0.31; 95%CI: 0.21-0.47; $p<0.001$) in centers with TIPS (OR = 0.42; 95%CI: 0.25-0.46; $p=0.002$), but not with liver transplantation available (OR = 2.21; 95%CI: 1.21-4.04; $p=0.008$). Age, sex and alcohol-related cirrhosis had no significant impact on 6-month mortality. Unlike for in-ICU mortality, high values of SOFA did not predict 6-month mortality in ICU survivors. Eight parameters of liver and renal function were associated with 6-month mortality, including Child-Pugh C stage (OR = 2.43; 95%CI: 1.44-4.10; $p<0.001$), MELD ≥ 26 on ICU admission (OR = 3.97; 95%CI: 1.92-8.22; $p<0.0001$; PPV = 0.75), hepatorenal syndrome (OR = 4.67; 95%CI: 1.24-17.64; $p=0.022$; PPV = 0.88) and admission for acute renal failure (OR = 3.29; 95%CI: 1.70-6.40; $p<0.001$; PPV = 0.73). Septic shock (OR = 3.95; 95%CI: 1.38-11.30; $p=0.010$; PPV = 0.62) and nosocomial infection on admission (OR = 2.72; 95%CI: 1.09-6.76; $p=0.031$; PPV = 0.76) were also associated with higher 6-month mortality. Among medical interventions, only the use of norepinephrine (OR = 2.07; 95%CI: 1.07-4.00; $p=0.029$; PPV = 0.61), given for hepatorenal syndrome, was predictive of 6-month mortality.

Conclusion: Only a minority of ICU survivors undergo liver transplantation. Liver and renal failures in ICU have a sustained impact on long-term mortality. The prognostic performance of general ICU scores decreases over time, unlike Child-Pugh and MELD scores, even measured in the context of organ failure. Eligible patients could thus be listed for transplantation in ICUs or shortly after ICU discharge.

Contact E-mail Address: vdimartino@chu-besancon.fr
Introduction: The impact of inflammation and infection on the outcome of cirrhotic patients admitted to Intensive Care Units (ICU) has been little studied.
Aims & Methods: This meta-analysis aimed to assess the ability of events related to inflammation or infection present on admission, to predict in-ICU mortality and to investigate whether inflammation or infection present on ICU admission was associated with 6-month mortality in ICU survivors. 13 studies (2695 cirrhotics) were analyzed after selection of original articles and response to a standardized questionnaire by the corresponding authors. The endpoint was the prognostic performance of 25 variables (including SIRS and its compounds, biochemical makers of inflammation, overt bacterial infection, germ involved, infection site) to predict short- and medium-term mortality.
Results: On admission, 57.5% of patients had ≥ 2 criteria for SIRS. Lung was the most common infected site (14.2%), followed by spontaneous bacterial peritonitis (11.4%). 12.8% of patients had positive blood culture(s). The most common bacteria were GN bacillus (GNB) (13.7%), followed by GP cocci (10.1%). Fungal infection was diagnosed in 3.9% of patients. Higher in-ICU mortality was predicted by 14 variables related to inflammation/infection, including fungal infection (OR = 3.98; 95%CI: 1.28-12.36; $p < 0.001$; PPV = 0.86), pneumonia-induced acute respiratory failure (OR = 4.48; 95%CI: 4.60-18.15; $p < 0.001$; PPV = 0.81), sepsis-related refractory oliguria (OR = 9.14; 95%CI: 4.60-18.15; $p < 0.001$; PPV = 0.79), sepsis-induced hypotension (OR = 5.74; 95% CI: 3.41-9.71; $p < 0.001$; PPV = 0.77), GNB infection (OR = 2.24; 95%CI: 1.49-3.37; $p < 0.00$; PPV = 0.70), community acquired infection (OR = 2.37; 95%CI: 1.29-4.34; $p < 0.001$;PPV = 0.68), the presence of ≥ 2 criteria for SIRS (OR = 2.44; 95%CI: 1.64-3.65; $p < 0.001$; PPV = 0.57), CRP > 29mg/dL (OR = 1.82; 95%CI: 126-2.62; $p < 0.001$; PPV = 0.57) and leucocytes < 4000/mm3 (OR = 10.29; 95%CI: 6.63-16.00; $p < 0.001$; PPV = 0.45). Most of these parameters better predicted in-ICU mortality than a MELD score ≥ 13 (OR = 4.95; 95%CI: 2.47-9.89; $p < 0.001$; PPV = 0.51), a Child Pugh stage C(OR = 3.87; 95%CI: 2.47-6.07; $p < 0.001$; PPV = 0.52), or a SOFA ≥ 7 (OR = 7.70; 95%CI: 3.01-15.17; $p < 0.001$; PPV = 0.53). Among ICU survivors, only nosocomial infection on admission (OR = 2.72; 95%CI: 1.09-6.76; $p = 0.03$; PPV = 0.76) and admission for septic shock (OR = 3.95; 95%CI: 1.38-11.29; $p = 0.01$; PPV = 0.62) were associated with higher 6-month mortality.
Conclusion: In critically ill cirrhotics, some parameters related to SIRS and infection are able to better predict short-term mortality than prognostic scores. A history of septic shock is a strong predictor of 6 month mortality, even after the control of organ failures allowing ICU discharge, and may become an indication for secondary antibioprophylaxis and/or liver transplantation. Nosocomial infection also have sustained impact on mortality.

P0037 ESOPHAGEAL VARICES BAND LIGATION IN THE PROPHYLAXIS OF VARICEAL HEMORRHAGE – EFFICACY AND SAFETY CONCERNS

D. Branquinho[1], R. Cardoso[1], S. Lopes[1], J. Pina Cabral[1], C. Sofia[1]
[1]*Gastroenterology, Coimbra University Hospital (CHUC), Coimbra, Portugal*

Contact E-mail Address: diogofbranquinho@yahoo.com
Introduction: Variceal hemorrhage is a severe complication of chronic liver disease with a well-known tendency to recur. Following the first episode, recurrence risk is over 60% in the following years. As such, safe and effective primary and secondary prophylactic strategies must be adopted.
Aims & Methods: All patients that underwent elective esophageal varices band ligation in 2012 and 2013 were followed for a year. Immediate, 24-hour and long term complications of these procedures were recorded. The success of this strategy was evaluated through its capacity to prevent new episodes of variceal bleeding.
Results: A total of 82 patients were submitted to 104 procedures with a 2-4 or 6-8 week interval until eradication of varices was achieved (male patients – 78%, average age – 63.8 ± 10.6 years-old; Primary prophylaxis – 73.2%, Secondary prophylaxis – 26.8%). Concomitant treatment with beta-blockers was prescribed to 43.9% of patients. Most patients were sedated by the Gastroenterologist (70.7%), while anesthetic support was adopted in 17% of the procedures. Immediate complications occurred in 10 patients (9.6%): self-limited bleeding in 6, while sclerotherapy was performed in 3 of them. In one patient, a Sengstaken-Blackmore balloon was placed to stop the hemorrhage. In the 24 hours after the procedure, no further complications occurred. In the following year, 14 patients had episodes of variceal hemorrhage (13.7%), on average about 7 months after the elective procedure. Six of them eventually died (5.8%). Variceal bleeding recurrence was less common in patients that underwent less frequent procedures (6-8 weeks).
Conclusion: Esophageal varices band ligation is an effective method to prevent both inaugural and recurrent episodes of bleeding. A larger time span between procedures is probably a safer option to prevent bleeding from scars. Its safety profile is good and the 24-hour admission for surveillance is not necessary as no further complications usually occur in that period.

P0038 CIRRHOTIC PATIENTS IN ICU WITH GASTRO-INTESTINAL BLEEDING MANAGED ACCORDING TO RECENT GUIDELINES DISPLAY ALTERED BRAIN HEMOGLOBIN OXYGEN'S SATURATION ASSESSED BY NEAR INFRARED SPECTROSCOPY

D. Thabut[1], M. Mallet[1], S. Tripon[1], M. Rudler[1], N. Weiss[2], on behalf of Brain Liver Pitie-Salpetriere Study Group (BLIPS)
[1]*Hepatological ICU,* [2]*Neuro-ICU, La Pitie-Salpetriere Hospital, Assistance Publique - Hopitaux de Paris, PARIS, France*

Contact E-mail Address: dthabut@gmail.com
Introduction: Near Infrared Spectroscopy (NIRS) is a non-invasive optical technique allowing a continuous measurement of brain's hemoglobin saturation in oxygen (rSO2). It is considered as a surrogate marker of cerebral insult, and recognized as a useful tool in in cardiovascular surgery and neuromonitoring. A rSO2 < 50% is associated with increased neurological impairment and post-operative mortality. In cirrhotic patients with gastrointestinal bleeding (GIB), hemoglobin (Hb) threshold for transfusion has been recently lowered to 7g/dL. Some patients develop hepatic encephalopathy (HE) after GIB. In subarachnoid hemorrhage, a threshold of 7g/dL of Hb could worsen neurological outcome.
Aims & Methods: The aim of this study was to assess brain oxygenation using NIRS in cirrhotic patients with acute GIB admitted to ICU and managed according to recent guidelines, and to determine if brain injury was associated with Hb levels.
Cirrhotic patients admitted in ICU for acute GIB were prospectively included. Bilateral continuous recording of rSO2 was started upon admission using a NIRS monitor (INVOS 5100c Cerebral Oxymeter (Covidien©) with two sensors placed on the patient's forehead. Minimal rSO2 (mini rSO2), average rSO2 (avr rSO2) and AUC of rSO2 50% (AUC50% rSO2), an integrated parameter depending on the depth/duration of desaturation under 50%, were extracted.
Results: 26 patients were included (median age: 60 years; 69%men). Etiology of cirrhosis was alcoholic 54%/ viral 19%/ NASH 23%/other 4%; Child Pugh A 15%/ B 20%/ C 65% and median MELD score 18. Median initial Hb was 7.9g/dL and nadir within 24 first hours was 7.8g/dL. 14 patients (54%) had a nadir of Hb below 8 g/dL within the 24 first hours, and 15 (58%) patients were transfused. Median mini rSO2 was 37% right/37% left, avr rSO2 46% right/48% left and AUC50% rSO2 1138 right/698 left. 22 patients (85%) had mini rSO2 < 50%. Mini rSO2 was significantly lower in patients having a nadir of Hb below 8g/dL. Mini rSO2, avr rSO2 and AUC50% rSO2 were independently correlated to initial Hb ($p < 0.01$ for all), nadir of Hb within the 24 first hours ($p < 0.005$ for all), and MELD score ($p < 0.05$ for all).
Conclusion: 85% of cirrhotic patients admitted to ICU for acute GIB and managed according to recent guidelines displayed mini rSO2 below 50% within 24 hours after admission. Low Hb levels within the 24 first hours were associated with brain desaturation. Further studies are mandatory to assess the influence of Hb thresholds on the development of HE.

P0039 CHANGES OF SERUM LEVELS OF CYTOKERATIN-18 FRAGMENTS IN PATIENTS WITH CHRONIC HEPATITIS C UNDER ANTIVIRAL THERAPY

A. Kandemir[1], I. Polat[2], M. Arabul[3], E. Alper[4], F. Aslan[3], B. Unal[3]
[1]*Gastroenterology,* [2]*Internal Medicine, Afyonkarahisar State Hospital, Afyonkarahisar,* [3]*Gastroenterology, Izmir Katip Celebi University, Izmir,* [4]*Gastroenterology, Izmir Katip Celebi University, Afyonkarahisar, Turkey*

Contact E-mail Address: altaykandemri@yahoo.com
Introduction: Studies performed in the recent years have indicated that the cleavage level of serum CK-18 is correlated with hepatic fibrosis and disease severity in chronic hepatitis C and non-alcoholic steatohepatitis. Significant correlation between apoptosis level and responses to chronic viral hepatitis B and C treatments have shown a correlation between decreased CK18 levels during the treatment, and sustained viral response is also defined.
Aims & Methods: Our aim was to reveal the correlation between CK 18 level and treatment response in patients with chronic viral hepatitis C. 60 patients with diagnosis of chronic viral hepatitis C were enrolled to the study. Eligible patients for treatment criteria received PEG-interferon-ribavirin administration for 48 weeks. In Weeks 12-24, HCV RNA amount was measured at the end of treatment. Additionally, CK 18 levels were measured in Weeks 0-24 and at Week 72.
Results: Mean age of 60 patients was 52 ± 10.9 years. Of patients, 31 (51.6%) were in sustained viral response (SVR) group with the CK 18 level with CK 18 level of 116 ± 12.4 at the Week 24 of, whereas 29 (48.4%) were in non-SVR group with CK 18 level of 134 ± 23.5 (U/L). When the change in CK 18 levels between Week 0 (baseline value) and Weeks 24 and 72 in SVR-obtained patients and the level in the Week 24 in patients without SVR were compared, CK 18 levels in SVR-obtained patients were 243 ± 214 (U/L) in the Week 0, and 115 ± 12 (U/L) in the Week 24, thus the change was defined as 127 ± 209 (U/L), and the change was statistically significant ($P = 0.014$). While CK 18 level in the Week 0 was

270 ± 143 (U/L) in patients without SVR, it was 133 ± 19 (U/L) in the Week 24; the change was defined as 136 ± 156 (U/L). This change was statistically insignificant ($P > 0.5$).

Conclusion: There are many studies proving clinically that disease progression and fibrosis, which are related to significant decreases in cytokeratin 18 levels in the circulation in hepatocellular apoptosis, are decreased in patients who had successful HCV clearance. Similarly, significant decrease was detected in CK 18 levels in SVR-obtained patients our study. However, no significant correlation was defined in recurrent and nonresponsive patients. In conclusion, it has been shown that hepatocellular apoptosis is significantly decreased in chronic viral hepatitis C patients by successful antiviral therapy; and CK 18 is a reliable marker to indicate apoptosis of hepatocyte. When the obtained data are evaluated, CK-18 can be used in the follow up of treatment efficacy and improvement in apoptosis level as well as it can be used as a non-invasive marker instead of liver biopsy.

P0040 NEWS TOOLS OF SCREENING VIRAL HEPATITIS IN REAL LIFE: NEW FRENCH MODEL OF CARE

A. J. Remy[1], H. Bouchkira[1], H. Wenger[1], S. Montabone[1]
[1]*Mobile Hepatitis Team Hepatology Unit, Perpignan Hospital, Perpignan, France*

Contact E-mail Address: andrejean.remy@orange.fr

Introduction: Hepatitis B and C screening was usually done by serology in laboratories or medical centers. If serology was positive, viral load and genotype was determined and after that patient saw hepatologist if viral load was also positive. Liver fibrosis was usually measured after first medical consultation. All steps took 3 to 6 months. Drug injection was main contamination route of hepatitis C virus (HCV) in France and western Europe since 1990. Although highest European screening rate in France, 44% of patients didn't take care of hepatitis C. French guidelines were to treat all inmates and drug users, even fibrosis level.

Aims & Methods: Hepatitis Mobile team was created in July 2013. We proposed 10 services to patients and to our partners: 1/ Point of Care Testing POCT (HIV HBV HCV) 2/ Mobile liver stiffness Fibroscan* (indirect measurement of liver fibrosis) in site 3/Social screening and diagnosis 4/ Advanced on-site specialist consultation 5/ Easy access to pre-treatment commissions (''RCP'') with hepatologists, nurse, pharmacist, social worker, GP, psychiatric and/or addictologist 6/ Individual psycho-educative intervention sessions 7/ Collective educative workshops 8/ Staff training 9/ Drug users information and prevention 10/ Green thread: outside POCT and FIBROSCAN* with specific converted truck. So our French mobile mobile team proposed a new model of triple screening high risk patients for hepatitis C or B. All team members (nurses and social worker) came together in outreach centers, jailhouses, drug services centers and all structures which care for drugs users, homeless or other vulnerable patients. They offer triple screening at the same time: social screening with specific score of 11 questions called EPICES, POCT for HCV HBV (and also HIV if necessary) and liver fibrosis screening by FIBROSCAN*. With the results of triple screening, patient could do his/her biology quickly and see a hepatologist in 2 or 3 weeks only.

Results: 711 POCT were done in first 12 months; 19 were positive for new patients and 69 were positive for already known patients who returned to medical care by this pathway. One POCT was positive for HIV and 7 for HBV (but only done for 6 months); 393 FIBROSCAN* were done with medium rate of 7.8 KPa (fibrosis level F2): 68% for HCV, 3% for HBV and 29% for alcoholic liver disease. Social screening showed that 91% of our patients were vulnerable. 134 patients were addressed by on site hepatologist consultations and 112 came almost at one time. 45% of patients were treated and only 3% were lost to sight. All these patients had access to new direct antiviral agents. Follow up of treated patients showed only one relapser for 41 finished treatments.

Conclusion: In our model of care, triple screening by mobile services and follow up was necessary and successful to increase number of patients diagnosed, treated and cured.

P0041 MEASURING QUALITY OF LIFE IN HCV-INFECTED PATIENTS TODAY: THE BURDEN OF A "LIMITED" ACCESS TO THE NEW ANTI-VIRAL DRUGS

A. Rocco[1], **D. Angrisani**[1], M. Carbone[1], D. Compare[1], G. Nardone[1]
[1]*Department of Clinical Medicine and Surgery, Gastroenterology, Federico II University, Naples, Italy*

Contact E-mail Address: deborangrisani@hotmail.it

Introduction: The Health Related Quality of Life (HRQoL) in patients with chronic HCV infection is significantly impaired in respect to uninfected people and directly correlates with severity of hepatic dysfunction. The achievement of a sustained virological response (SVR) is associated with a significant and long-lasting improvement in the HRQoL. The recent introduction of new potent direct antiviral agents seems to promise the definitive cure for HCV infection in almost the totality of infected individuals. However, the economic burden of the therapeutic schedules significantly limits the access to therapy particularly for patients with early stage liver disease.

Aims & Methods: To evaluate the impact of the awareness of new therapy availability on HRQoL, anxiety, depression and stress in patients with early-stage of HCV-related liver disease.

A set of questionnaires was administered to consecutive patients with chronic active HCV-related diseases to evaluate the HRQoL (Short Form Health Survey, SF-36), the depression, anxiety and stress levels (Depression Anxiety Stress Scale, DASS-42) and the perception of discrimination for such a difficult therapy access (Visual Analog Scale, VAS).

Exclusion criteria were: clinical, laboratory or histological signs of liver cirrhosis, concomitant liver diseases (HBV infection, autoimmunity or alcohol abuse) or hepatocellular carcinoma, HIV coinfection, < 3 years of education, diagnosis of major depression or other psychiatric disorders, current use of antidepressant medications or other pharmaceuticals known to affect cognitive function, cerebrovascular disease.

Results: Sixty patients with active chronic HCV infection (HCV-RNA +) and 36 patients with SVR to prior treatment were enrolled. There were… male, mean age was 60.6 years (range 32-74 years).

Patients with chronic active HCV infection showed significantly lower scores than the SVR group, in the following SF-36 domains: ''Physical Functioning'' (70 ± 26.2 vs 81.6 ± 22.2; p = 0.001), ''General Health'' (45.9 ± 22 vs 63.3 ± 17.7; p < 0.0001), ''Vitality'' (55.8 ± 23.6 vs 65.8 ± 24.6; p = 0.001) and ''Role-Physical'' (69.8 ± 25.1 vs 87.4 ± 18.7; p < 0.0001).

In addition, patents with showed higher scores, compared to the SVR group, in all the three DASS-42's scales: ''Depression'' (10.5 ± 8.4 vs 6.9 ± 6.5; p = 0.03), ''Anxiety'' (10.6 ± 7.2 vs 7.2 ± 6.1; p = 0.02) and ''Stress'' (13.4 ± 7.5 vs 9.3 ± 7.5; p = 0.012).

Finally, the mean VAS score for the perception of discrimination was 7.27 ± 2.62.

Conclusion: The awareness of new effective antiviral drugs and, at the same time, the limited access to therapies significantly reduce the HRQoL and increase depression, anxiety and stress in patients with chronic active HCV infection.

P0042 HIGH RISK OF INFECTION DURING TRIPLE THERAPY WITH FIRST-GENERATION PROTEASE INHIBITORS: A NATIONWIDE RETROSPECTIVE COHORT STUDY

F. A. Berden[1], I. van Zwietering[1], R. Maan[2], R. J. de Knegt[2], W. Kievit[3], J. P. Drenth[1]

Introduction: Peginterferon (PegIFN) remains the backbone of therapy for chronic hepatitis C (CHC) in many economically constrained regions, as all oral regimens are not globally available. However, PegIFN has a high rate of (serious) adverse events, frequently reported is neutropenia due to bone marrow suppression. Addition of a first-generation protease inhibitor (telaprevir or boceprevir) to PegIFN and ribavirin (RBV) can lead to a higher risk of neutropenia. Guidelines recommend dose reduction or treatment discontinuation in case of moderate or severe neutropenia out of concern for infections.

Aims & Methods: The aim of this study is to assess the risk of infections during first-generation protease inhibitor-based therapy in clinical practice and its relation to treatment-induced neutropenia. This nationwide multicenter retrospective cohort study included CHC patients treated with PegIFN, RBV and telaprevir or boceprevir in 37 centers in the Netherlands. Absolute neutrophil counts (ANC) were divided in 3 categories: severe (< 500/μL), moderate (500-750/μL) and mild (750-1500/μL). Likewise, infections were classified as severe (i.v. treatment with antibiotics or hospitalization), moderate (oral or topical antibiotics or antimycotics) or mild (no treatment). We assessed associations between risk factors and infectious events adjusting for multiple measurements with multivariable logistic regression analysis.

Results: We included 409 CHC patients: 233 telaprevir and 176 boceprevir treated patients. In our cohort 277 (68%) patients were male, mean age was 50.4 (range 19-77) years and 236 (58%) patients were treatment naive. Based on liver biopsy, fibroscan, ultrasound or FIB-4 index, 127 (31%) patients were classified as cirrhosis.

A total of 238 infections occurred in 156 patients (38%) and 35 (15%) were severe occurring in 29 (7.1%) patients. Mean baseline ANC was 3.421/μL and 4.4% of patients had a baseline ANC < 1500/μL. During treatment 274 patients developed neutropenia (severe, n = 28). In 40 patients ANC was

P0043
Table: SVR and SAE in WQ vs. WNQ patients.

	Phase 3 trial	n	n WQ (%) / n WNQ (%)	SVR % WQ / WNQ	p	SAE % WQ / WNQ	p
Boceprevir	SPRINT2/RESPOND2[a]	134	68(51)/66(49)	76.5/60.6	**0.048**	7.4/18.2	0.06

missing. Multivariable analysis showed that female sex (OR 1.81, 95 CI 1.30-2.51, $p < 0.001$), diabetes mellitus (OR 1.50, 95 CI 1.04-2.16, $p = 0.030$), COPD (OR 2.77, 95 CI 1.72-4.46, $p < 0.001$) and history of decompensated liver cirrhosis (OR 1.69, 95 CI 1.04-2.75, $p = 0.033$) were associated with the infection incidence. Neutropenia at the previous visit was not associated with infection (univariable analysis: OR 0.83, 95 CI 0.59-1.15, $p = 0.263$).
Conclusion: This nationwide multicenter retrospective cohort study showed that triple therapy with first generation protease inhibitors was complicated by an infection in 38% of patients. The majority of infections were mild or moderate. Female gender, diabetes mellitus, COPD and a history of decompensated liver cirrhosis were associated with an increased risk of infections during treatment, suggesting that these patients should be monitored carefully.

Contact E-mail Address: Floor.Berden@Radboudumc.nl
Introduction: Registration of drugs in chronic hepatitis C (CHC) is supported by phase 3 trials. These randomized controlled trials preserve internal validity using strict eligibility criteria which may limit the generalizability of findings.
Aims & Methods: This study aims to compare effectiveness and safety of boceprevir and telaprevir based treatment in CHC clinical practice patients who would qualify (WQ) and would not qualify (WNQ) for phase 3 trials. We performed a nationwide multicenter retrospective cohort study of CHC genotype 1 patients treated with boceprevir or telaprevir in 37 centers in the Netherlands. We compared sustained virological response (SVR) and serious adverse events (SAE) in WQ vs. WNQ patients. Phase 3 clinical trials were identified through systematic review [1-5], eligibility criteria of original protocols were applied to clinical practice population to determine WQ and WNQ. Given comparable SVR in treatment naive (TN) and relapse patients, we combined these groups in the analysis.
Results: This study includes 409 CHC patients, 236 TN and 173 treatment experienced: 71 relapse and 102 prior nonresponders (NR), viral breakthrough or early discontinuation patients (NR-group). In total, 35% to 49% of TN and relapse patients would not qualify for one of the phase 3 trials (Table). WNQ patients treated with boceprevir have lower SVR rates ($p = 0.048$) and a trend for higher SAE rates ($p = 0.06$) than WQ patients. WNQ patients on telaprevir had similar SVR rates, but higher SAE rates than WQ patients ($p = 0.037$ and $p = 0.011$). Between 48% and 52% of NR-group patients would not qualify for trials, but there SVR and SAE rates were comparable between WQ and WNQ.
Conclusion: Patients in clinical practice are likely to not qualify for phase 3 trials and these patients are at higher risk for developing serious adverse events. Phase 3 trials should extend eligibility criteria to increase generalizability to clinical practice. Physicians should be aware that first generation protease inhibitors have worse safety profile and decreased effectiveness (boceprevir) in patients that would not qualify vs. patients that would qualify for clinical trials.

P0044 DOES NORMAL ALT MEAN HEALTHY LIVER IN HCV INFECTION ?

G. Par[1], H. Hajdu[1], A. Vincze[1], A. Miseta[2], A. Par[1]
[1]*First Department of Medicine,* [2]*Department of Laboratory medicine, University of Pecs, Pecs, Hungary*

Contact E-mail Address: pargabriella@gmail.com
Introduction: HCV carriers with persistently normal ALT (PNALT) have usually mild and stable liver disease with favourable prognosis than patients with elevated ALT. However, several studies reported worsening of liver injury in 20-30% of subjects with PNALT and development of cirrhosis and even HCC. Aim of our study was to compare liver fibrosis stage and fibrosis progression in chronic hepatitis C (CHC) patients with ALT levels within normal limits and CHC patients with elevated ALT.
Aims & Methods: Aim of our study was to compare liver fibrosis stage and fibrosis progression in chronic hepatitis C (CHC) patients with ALT levels within normal limits and CHC patients with elevated ALT. Patients: Eighty-eight CHC patients were followed up in a five-year period. Fifty-three patients (60%) had ALT levels above our laboratory normal limit (ULN: > 50 Iu/ml), 35 patients (40%) had normal ALT. Liver fibrosis (F0-F4 stages) were assessed by measuring liver stiffness (LS) using transient elastography (Fibroscan).
Results: Female CHC patients had normal ALT more often than males (44% vs. 34%). Out of 35 CHC patients with normal ALT fifteen (49%) had no or only mild liver fibrosis (LS < 6 kPa). In the group of patients with elevated ALT, 17% had F0 or F1 liver fibrosis stage. Advanced liver fibrosis (LS > 12 kPa) was more frequent in patients with elevated ALT compared to normal ALT group (56% vs 23%). Although moderate or more severe liver fibrosis occured more frequently in patients with elevated ALT compared to normal ALT group (83% vs 51%), high proprotion of patients with normal ALT had LS suggesting moderate (> F1) fibrosis stage. In a five-year follow-up period most of the CHC patients with normal ALT had stable liver disease with no fibrosis progression.
Conclusion: Our results prove that normal ALT in CHC does not always mean "healthy liver" since a great proportion of these patients had minimal or moderate liver fibrosis and the possibility of progression to more severe condition. We do suggest that patients with normal ALT should not be excluded a priori from antiviral treatment. Decision on antiviral treatment should depend on multiple factors (e.g. histology, LS, symptoms, co-morbidities) as well as the motivation and the age of the patient, rather than on ALT level alone.

P0045 IS OLDER AGE A RISK FACTOR FOR HEPATOCELLULAR CARCINOMA DEVELOPMENT IN PATIENTS WITH CHRONIC HEPATITIS C EVEN IF SUSTAINED VIRUS ERADICATION IS REACHED?

G. Sirin[1], O. Sentürk[2], A. Celebi[2], M. Sezikli[1], H. Yılmaz[2], S. Hulagu[2]
[1]*Gastroenterology, Derince Education and Research Hospital,* [2]*Gastroenterology, Kocaeli University, Kocaeli, Turkey*

Contact E-mail Address: gsirin@live.com
Introduction: Hepatitis C virus (HCV) is one of the major leading causes of hepatocellular carcinoma (HCC) in Turkey. We aimed to clarify the clinical features of patients with chronic hepatitis C who develop HCC after gaining sustained viral response (SVR) to interferon (IFN)-based treatment.
Aims & Methods: Clinical parameters of 212 patients (mean age: 54 years old, E/K: 132/80) who achieved a SVR from 2002 to 2014 in two reference center hospital were evaluated.
Results: Eighteen patients (8.49%) developed HCC within a median follow-up period of 74 months (range 18–132 months). Cox regression analysis showed that the strongest predictive factor of HCC occurrence was lower platelet ($< 10x10^4$ cells/microL) count (hazard ratio [HR] 5.42, $P = 0.032$) followed by prolonged (< 80%) prothrombin time (HR 3.68, $P = 0.041$) and higher AST (> 50 IU/L) level, (HR 3.18, $P = 0.048$), before IFN therapy. At the time of SVR24, the predictive factors of HCC occurrence were higher AFP (> 10 ng/ml) level (HR 4.33, $P = 0.028$) and older (> 65 years) age (HR 4.40, $P = 0.032$). In multivariate analysis showed that higher AFP (> 10 ng/ml) level and older (> 65 years) age at SVR24 were independent variables of the development of HCC, too.

Conclusion: Patients of older (>65 years old) age at SVR24 should be considered very carefully to detect early HCC development after IFN therapy, especially who have higher AFP level, even if SVR is reached. In patients with chronic HCV, viral eradication of HCV infection should be achieved at a young age as possible to prevent HCC development after IFN based therapy.

Introduction: Liver stiffness measurement (LSM) by transient elastography (TE) accurately predicts severity of chronic liver disease (CLD). (1-2) Point quantification shear-wave elastography (pSWE-ElastPQ) is a newly developed technique incorporated into a conventional US system which allows evaluation of LSM.
Aims & Methods: Aim of this study was to assess the feasibility and reproducibility of PSWE-ElastPQ in a consecutive series of patients with CLD who concomitantly underwent TE and liver biopsy. Over a sixteen-months period, 164 patients (103 males, 61 females) (mean age 54 yrs) were consecutively enrolled. CLD was related to HCV (n = 113) and miscellaneous causes (n = 51). pSWE- ElatPQ was blindly performed by two raters whereas TE was performed by one single operator. pSWE-ElastPQ examinations were considered reliable if >10 validated measurements were obtained from each patient with SD <30% of the mean value. TE examinations were considered reliable if >10 validated measurements were obtained from each patient with a success rate >60% and if the interquatile range (IQR) was <30% of the median value. Interobserver agreement for pSWE-ElastPQ was analyzed using the intraclass correlation coefficient (ICC), that was interpreted according to Fleiss classification: agreement was considered poor (ICC = 0.00-0.40), fair to good (ICC = 0.40-0.75) or excellent (ICC < 0.75). Stage of liver fibrosis was classified according to METAVIR score classification.
Results: Reliable LSM (n = 328)determinations were obtained in 100% of the cases by pSWE-ElastPQ and in 97% by TE (n = 5 with SR <60%, IQR > 30%). pSWE-ElastPQ and TE values correlated significantly (r = 0.68, p = 0.0001). LSM values (mean ± SD, median) measured by pSWE-ElastPQ resulted 7.9 ± 4.4, 6.6 kPa for the first rater and 7.7 ± 4.0, 6.6 kPa for the second one. ICC concordance was not influenced by age, BMI, ALT, alkaline phosfatase and GGT levels. ICC in the first 5-months study period was significantly lower (0.69, 95% CI 0.50-0.81) as compared to the second period (0.78, 95% CI 0.64-0.87) and the third one (0.89, 95% CI 0.80-0.95).
Conclusion: pSWE-ElastPQ is a reliable and reproducible technique, whose interobserver agreement significantly improves by experience. Moreover it is not affected by BMI or presence of liver necroinflammation.

Sacco,'' Università degli Studi di Milano,* [3]*Gastroenterology and Hepatology Unit, Fondazione IRCCS Ospedale Maggiore Policlinico, Università degli Studi di Milano, Milan, Italy*

Contact E-mail Address: benedetta.conti1@gmail.com
Introduction: Spleen stiffness measurement (SSM) using transient elastography (TE) has widely been demonstrated to predict liver disease severity and progression of chronic liver disease (CLD) [1 - 3]. Its reliability and accurately predicts portal hypertension, oesophageal varices and such clinically relevant outcomes as decompensation [4]. Point quantification shear-wave elastography (pSWE-ElastPQ) is a newly developed technique to measure SSM incorporated into a conventional US system.
Aims & Methods: To assess feasibility and reproducibility of SSM by pSWE-ElastPQ in a consecutive series of patients with CLD who concomitantly underwent spleen TE and liver biopsy.
Over a 16-month period 160 patients were consecutively enrolled. Three were excluded due to previously splenectomy, thus 157 patients (99 males and 58 females; median age 55 years) were analysed.
CLD was HCV related in 109 and miscellaneous in 51. pSWE-ElastPQ was blindly performed by two different raters whereas TE was performed by a single operator. Both pSWE-ElastPQ and TE examinations were considered reliable if >10 validated measurements were obtained from each patient. SD of all measurement was < 30% of the mean value for pSWE-ElastPQ, whereas a success rate >60% and an interquartile range (IQR) of all validated measurements <30% of the median value were considered for TE.
Interobserver agreement for pSWE-ElastPQ was analyzed using the intraclass correlation coefficient (ICC), according to Fleiss classification: was considered poor (ICC = 0.00-0.40), fair to good (ICC = 0.40-0.75) or excellent (ICC > 0.75).
Results: Reliable SSM determinations were more frequently obtained by pSWE-ElastPQ (155 cases; 96%) than by TE (141, 87%) (p = 0.007) . pSWE-ElastPQ and TE SSM values correlated significantly (r = 0.54 , p = 0.0001). SSM values (mean ± SD, median) measured by pSWE-ElastPQ resulted 17.8 ± 8.6, 15.7 kPa for the first rater and 17.6 ± 8.3, 15.6 kPa for the second one. Overall, interobserver ICC for pSWE-ElastPQ was 0.72, 95% (CI 0.64-0.79). Concordance was not influenced by patient's age, sex and BMI. The ICC in the first 10-months study period was significantly lower (0.69, 95% CI 0.58-0.79) as compared to the second 6 months (0.86, 95%CI 0.75-0.93)
Conclusion: pSWE-ElastPQ is a reliable and reproducible technique to assess spleen stiffness in CLD, whose interobserver agreement significantly improves by experience. Noteworthy, pSWE-ElastPQ is feasible in more patients than TE.

P0048 ULTRASOUND DIAGNOSTICS SIMULATORS FOR GASTROENTEROLOGISTS: IMPLEMENTATION EXPERIENCE

D. Venidiktova[1], A. Borsukov[1]
[1]*Smolensk State Medical University, Problem scientific-researh laboratory ''Diagnostic researches and miniinvasive technologies'', Smolensk, Russian Federation*

Contact E-mail Address: darya.venidiktova@gmail.com
Introduction: Nowadays various types of hospitals and clinics require professional specialists in ultrasound diagnostic not only among radiologists, but also among clinicians to ensure fast and correct diagnosis for adequate treatment prescribing. Unfortunately there is no opportunity for all specialists to have education by the standard scheme ''mentor-specialist in training-patient'' because of limited time, so there is a necessarity to put inexpensive and available for clinicians ultrasound simulators into training-practice.
Aims & Methods: The aim was to create the experimental model of Doppler ultrasound simulation system which will be able to imitate arterial and venous blood flow and focal lesions of parenchymal organs with various type of vascularization for the gastroenterologists ultrasound education.
Material and methods: Vascular phantom was created in our Problem scientific research Laboratory ''Diagnostic researches and miniinvasive technologies'' in 2014. It represents tube system and consists of two parts. The 1st part is vascular - with imitative characteristics of arterial and venous blood flow (with the opportunity of laminar and turbulent flow recreation, using semi-automatic dispenser). The 2nd part is ''pathological foci'', it represents hemodynamics of capillary and cavernous hemangioma, focal nodular hyperplasia and hyper-vascular liver metastases. There were 2 groups of 6-year medical students of Smolensk State Medical University with 20 in each group for the Phantom's efficiency testing. Educational process in the 1st group was by the standard scheme ''mentor-student-patient'' (3 times). Educational process in the 2nd group consisted of 2 stages: at the 1st stage all of the students had practice with the ultrasound simulator and at the 2nd stage there was standard scheme ''mentor-student-patient'' (3 times).
Results: After 3-weeks of training all of the students were tested in real work with patients with arterial blood flow pathology (aneurysm, n = 4), venous blood flow pathology (cavernous portal vein transformation at cirrhosis n = 8, capillary and cavernous hemangioma, n = 13, focal nodular liver hyperplasia n = 2, colorectal liver metastases, n = 4). In the 1st group true-positive results amounted 58.1%, false-positive results - 24.4%, false-negative results - 17.5%. In the 2nd group true-positive results amounted 79.3%, false-positive results - 13.9%, false-negative results - 6.8%.
Conclusion: Phantom's use at the 1st stage of gastroenterologists education in ultrasound technique qualitatively improved the efficiency of medical specialists' work, so it requires overall introduction of simulator-training in courses of postgraduate professional education.

P0049 GASTROINTESTINAL NEUROENDOCRINE TUMORS OF UNKNOWN PRIMARY SITE: REPORT FROM A SERIES AT A SINGLE INSTITUTE

S. Massironi[1], I. Fanetti[1,2], **F. Cavalcoli**[1,2], A. Zilli[1,2], D. Conte[1,2]
[1]*Gastroenterology and Endoscopic Unit, Fondazione IRCCS Ca' Granda - Ospedale Maggiore Policlinico* , [2]*Department of Pathophysiology and Transplantation, Università degli Studi di Milano, Milano, Italy*

Contact E-mail Address: cavalcoli.federica@gmail.com
Introduction: Neuroendocrine neoplasms (NENs), a heterogeneous group of neoplasms, differ in biologic behavior, histologic appearance and response to treatment. NENs with unknown primary site (NENs-UP) account for 10 to 13 percent of all NENs.
Aims & Methods: We here describe clinical findings, histologic and anatomic characteristics and the diagnostic work-up of patients with histologically proven metastatic NENs of unknown primary.
Between January 2005 to January 2015, of the 93 patients with metastatic gastrointestinal NENs seen at our Institution, 17 (18%) (M:F = 11:6; median age at the diagnosis 64 years, range 33-74) presented with immunohistochemically proven neuroendocrine metastases without evidence of primary site despite an exhaustive work-up based on computed tomography (CT), magnetic resonance (MRI) and somatostatin receptor scintigraphy (SRS).
Results: Of the 17 patients with NENs-UP, 14 (82%) showed hepatic metastases, whereas an abdominal nodal involvement was detected in the other three patients. Sixteen of the 17 tumors (88%) were well differentiated (G1 in five cases and G2 in 11), with a poorly differentiated carcinoma in the last patient. Carcinoid, Zollinger-Ellison and Verner-Morrison syndromes were diagnosed in eight, two and one case, respectively, accounting for a total number of 11 functioning tumors (65%). In 14 of the 17 cases (82%), liver or nodal metastases were firstly diagnosed by abdominal ultrasound, performed during surveillance of chronic diseases in six patients and for gastrointestinal symptoms in the other eight. In the course of a strict work-up, the primary tumor was eventually diagnosed after a median of 8.5 months (range 3-120) in 12 cases (71%), eight of whom (67%) had a functioning form. In detail, the primary site was identified as pancreas by a repeated abdominal CT (#3); terminal ileum (#2) and colon (#1) by colonoscopy; central ileum by double balloon enteroscopy (#1) and pancreas by endoscopic ultrasound (EUS) (#1). Again, laparoscopy identified a jejunal, ileal, Meckel's diverticulum and pancreatic primary tumor in further four patients, whereas the remaining five were still classified as NENs-UP.
Conclusion: NENs-UP represent a clinical challenge, involving multidisciplinary expertise. Despite the continuous advances in diagnostic techniques, including radiologic, endoscopic and immunohistochemical methods, metastatic NENs remain of unknown primary origin in a notable proportion of cases (5/93, 5.3% in present series), even after an in-depth work-up. Noteworthy, however, the presence of hormone-related symptoms may help to better localize the primary site.

P0050 COMPARATIVE STUDY BETWEEN FOUR ULTRASOUND SHEAR WAVE ELASTOGRAPHIC METHODS FOR LIVER STIFFNESS ASSESSMENT

I. Sporea[1]
[1]*Gastroenterology and Hepatology, University of Medicine and Pharmacy Victor Babes Timisoara, Timisoara, Romania*

Contact E-mail Address: isporea@umft.ro
Introduction: Many different types of ultrasound based elastographic methods have been developed for the non-invasive liver stiffness assessment.
Aims & Methods: The aim of this study was to compare the performances of the latest elastographic methods used for liver fibrosis evaluation (Point Shear Wave Elastography-PSWE using ARFI technique-VTIQ and ElastPQ, respectively; and SuperSonic Shear Imaging-2D-SWE) considering Transient Elastography (TE) the reference method, since TE is a validated method for liver fibrosis evaluation.
The study included 151 consecutive subjects with or without chronic hepatopathies (excluding patients with ascites), in which liver stiffness (LS) was evaluated in the same session by means of 4 elastographic methods: TE (FibroScan, Echosens), VTIQ (Siemens Acuson S2000™), ElastPq (Philips, Affinity) and 2D-SWE (Aixplorer™SuperSonic Imagine S.A). Reliable LS measurements were defined as follows: for TE and VTIQ–the median value of 10 LS measurements with a success rate $\geq$ 60% and an interquartile range $<$ 30%, for 2D-SWE–the median value of 3 LS measurements acquired in an homogenous area and for ElastPQ-the median value of 10 LS measurements.
LS was expressed in kPa for TE, 2D-SWE, ElastPQ and m/s for VTIQ . For differentiating between stages of liver fibrosis we used the following cut-off values: for TE-significant fibrosis (F $\geq$ 2)–7.2 kPa and for liver cirrhosis (F4)-14.5kPa (Tsochatzis, 2011); for VTIQ: F $\geq$ 2–1.35m/s, F4 = 1.84m/s (Nierhoff, 2013); for 2D-SWE F $\geq$ 2–7.1 kPa, and F4 = 13.5 kPa (HCV,NAFLD) and 11.5 kPa in HBV (Herrmann, 2015); and for ElastPQ F $\geq$ 2-5.9 kPa, F4 = 12kPa (Ferraioli, 2013).
Results: Considering TE as the reference method, the diagnostic accuracy of VTIQ, 2D-SWE and ElastPQ for the diagnose of absence or mild fibrosis (F $<$ 2) was similar: VTIQ vs. 2D-SWE (86.2% vs. 82.5% p = 0.57); VTIQ vs. ElastPQ (86.2% vs. 84.4% p = 0.85), 2D-SWE vs. ElastPQ (82.5% vs. 84.4% p = 0.84).
For significant fibrosis (F $\geq$ 2) the values obtained were: VTIQ vs. 2D-SWE (84% vs. 76.1% p = 0.19); VTIQ vs. ElastPq (84% vs. 80.7% p = 0.64), 2D-SWE vs. ElastPq (76.1% vs. 80.7% p = 0.50).
For diagnosing cirrhosis we obtained similar diagnostic accuracies: VTIQ vs. 2D-SWE (96.3% vs. 93.6% p = 0.54); VTIQ vs. ElastPQ (96.3% vs. 94.5% p = 0.75), 2D-SWE vs. ElastPQ (93.6% vs. 94.5% p = 0.99).
Conclusion: Considering TE as the reference method for liver fibrosis evaluation, VTIQ, ElastPQ and 2D-SWE had similar accuracies for diagnosing at least significant fibrosis (F $\geq$ 2) and liver cirrhosis.

P0051 FEASIBILITY OF FOUR ULTRASOUND SHEAR WAVE ELASTOGRAPHIC METHODS FOR LIVER STIFFNESS ASSESSMENT

I. Sporea[1], R. Mare[1], O. Gradinaru Tascau[1], A. Popescu[1], R. irli[1]
[1]*Gastroenterology and Hepatology, University of Medicine and Pharmacy Victor Babes Timisoara, Timisoara, Romania*

Contact E-mail Address: isporea@umft.ro
Introduction: In the last decade , different types of ultrasound-based elastographic methods that non-invasively quantify liver fibrosis, have been developed. Even though Transient Elastography is a validated method for liver fibrosis assessment in chronic B and C hepatitis, being included in EASL Guidelines, reliable elasticity measurements are difficult to obtain in obese (BMI $>$ 30kg/m^2) patients.
Aims & Methods: The aim of this study was to compare the feasibility of four elastographic methods used for liver fibrosis evaluation (Transient Elastography-TE, Point Shear Wave Elastography (PSWE) using ARFI technique -VTIQ and ElastPQ and SuperSonic Shear Imaging-2D-SWE).
The study included 151 consecutive subjects with or without chronic hepatopathies (excluding patients with ascites), in which liver stiffness (LS) was evaluated in the same session by means of 4 elastographic methods: TE (Fibroscan, Echosens), VTIQ (Siemens Acuson S2000™), ElastPQ (Philips, Affinity) and 2D-SWE (Aixplorer, SuperSonic Imagine S.A). Reliable LS measurements were defined as follows: for TE and VTIQ[1] – the median value of 10 LS measurements with a success rate $\geq$ 60% and an interquartile range $<$ 30%, for 2D-SWE[2] – the median value of 3 LS measurements acquired in an homogenous area and for ElastPQ- the median value of 10 LS measurements. For TE M and XL probes are used. LS was expressed in kPa for TE, 2D-SWE, ElastPQ and m/s for VTIQ. All elastographic measurements were performed by experienced operators.
Results: Reliable LS measurements were obtained in a significantly higher proportion of patients by means of ElastPQ as compared with TE, 2D-SWE and VTIQ: 99.3% vs. 87.4% (p $<$ 0.0001), 99.3% vs. 87.4% (p $<$ 0.0001) and 99.3% vs. 92.7% (p = 0.08). TE and 2D-SWE had similar rates of reliable LS measurements 87.4% vs. 87.4% (p = 0.86).
Reliable LS measurements by all four shear waves ultrasound elastographic methods were obtained in 72.2% (109/151 subjects).
Comment: No study concerning the usefulness of technical quality criteria for ElastPQ was published.
Conclusion: ElastPq elastography was the most feasible shear-waves elastographic method for liver fibrosis assessment, followed by VTIQ, while TE and SSI had similar rates of reliable LS measurements.

P0052 INTERSTITIAL CAJAL-LIKE CELLS/TELOCYTES AND GALLBLADDER AUTONOMIC NERVOUS SYSTEM INTERPLAY IN THE PATHOGENESIS OF CHOLELITHIASIS

A. Pasternak[1], M. Szura[2], A. Matyja[2], M. Kurnik[3], J. Walocha[1], K. Gil[3]

Introduction: The major mechanisms of gallstone formation include biliary cholesterol hypersecretion, supersaturation and crystallization, mucus hypersecretion, gel formation and bile stasis. Gallbladder hypomotility seems to be a key event that triggers the precipitation of cholesterol microcrystals from supersaturated lithogenic bile. Recently, we reported a significant decrease in interstitial Cajal-like cell (ICLC) density in gallbladders of patients with cholelithiasis. Such cells in the gallbladder were strongly influenced by lithogenic bile. ICLCs, as well as the autonomic neurons located within gallbladder muscularis propria are considered as predominant regulatory cells of gallbladder motility.

Aims & Methods: The purpose of the current study was to determine the influence of lithogenic bile on the gallbladder autonomic neurons, in relationship to ICLCs. Gallbladder specimens were collected from 20 patients (8 males and 12 females) who underwent elective laparoscopic cholecystectomy for symptomatic gallstone disease. The control gallstone-free group consisted of 20 consecutive patients (9 males and 11 females) who received elective treatment for pancreatic head tumors. ICLCs were visualized in paraffin sections of gallbladders with double immunofluorescence using primary antibodies against c-Kit (anti-CD117) and anti-mast cell tryptase. The telocytes were stained with anti-CD34 antibody and assessed simultaneously. Autonomic neurons within the gallbladder wall were visualized by immunohistochemistry using anti-PGP9.5, anti-ChAT and anti-NOS antibodies and assessed semi-quantitatively. Cholesterol, phospholipid and bile acid concentrations were measured in bile samples obtained by needle aspiration from the gallbladder during surgery.

Results: The number of ICLCs in the gallbladder wall was significantly lower in the study group than in the control group (3.2 ± 1.5 vs. 6.6 ± 1.8 cell/area of view in the muscularis propria, $P < 0.001$) and correlated with a significant increase in the cholesterol saturation index, so did the telocytes count. The glycocholic and taurocholic acid levels were significantly elevated in the control subjects compared with the study group. Numerous PGP9.5-positive neural fibers were present, including some neuron bodies. Only sparse cholinergic (ChAT-positive) as well as nitrergic (NOS-positive) neurons were found. The cumulative neurons count was slightly decreased in patients with gallstones.

Conclusion: These results suggest that bile composition plays an important role in the reduction of ICLC and autonomic neurons density in the gallbladder, and this might lead to the gallbladder dysmotility in patients with cholelithiasis.

P0053 SCORING SYSTEM IN ALGORITHM FOR DIAGNOSIS AND TREATMENT OF PATIENTS WITH A SPHINCTER OF ODDI DYSFUNCTION

M. V. Repin[1], A. V. Popov[1], V. Y. Mikryukov[2], T. E. Vagner[2]
[1]*Perm State Medical University named after E.A. Vagner,* [2]*Perm regional clinical hospital, Perm, Russian Federation*

Contact E-mail Address: max_repin@inbox.ru

Introduction: It is difficult to exclude organic pathology, to choose a proper sequence for examination and treatment of patients with a suspected sphincter of Oddi dysfunction (SOD).

Aims & Methods: To develop diagnostic and medical algorithm for patients with a suspected SOD on the basis of integral estimation of clinical, laboratory and instrumental studies. Multifactor analysis performed in 164 patients after cholecystectomy permitted to single out and express in scores the most significant estimation signs. Typical hepatic colic scored 3; arrested colic – 2 scores, uncertain pains in the right hypochondrium – 1 score; jaundice – 2 scores, jaundice in anamnesis – 1 score; moderate rise in transferases – 1 score; 2-4 fold rise – 2 scores, more than four-fold rise – 3 scores; increase in total bilirubin: up to 40 mcmol/l – 1 score, 40-100 mcmol/l – 2 scores, more than 100 mcmol/l – 3 scores; elevation in serum α-amilase by 1.5-2 times – 1 score; increase in alkaline phosphatase – 1 score; increase in total blood leukocyte number: 9-12 thousand – 1 score, more than 12 thousand – 2 scores; the common bile duct dilatation by TUS data: from 7-12 mm – 1 score, from 13-22 mm – 2 scores, more than 22 mm – 3 scores. Peculiarities of bile outflow were estimated by the results of hepatobiliary scintigraphy (HBSG). In case of doubtful diagnosis, computed tomography, magnetic resonance cholangiopancreatography and/or retrograde cholangiopancreatography were used.

Results: By the developed scoring system, patients were divided into 4 groups. Accordance of this gradation to III Roman classification for patients with SOD was established. In group 1, 60 patients had 4 and more scores (5.1 ± 1.8). HBSG was performed only in 5 (8.3%) patients and bile outflow was delayed in all cases. Later on, choledocholithiasis (CL) was detected in 32 patients, Oddi's sphincter stenosis – 28. All patients underwent surgery. In group 2, in 31 patients the sum of scores varied from 3 to 4 (3.1 ± 0.3) and was lower than in group 1 ($p < 0.05$). 21 patients experienced HBSG, in most cases bile outflow was normal and only in 2 patients bile flow was delayed. Further, CL was diagnosed in 3 patients, Oddi's sphincter stenosis – 2. They underwent papillotomy (PT) with lithoextraction (LE). Group 3 enclosed 63 patients with the sum of scores varying from 1 to 2 (1.5 ± 0.5). In all the cases with HBSG accelerated bile outflow, considered by us as Oddi's sphincter insufficiency, was stated. However, 2 patients were diagnosed CL that became an indication for PT and LE. Group 4 included 10 patients with increase in serum α-amilase. The sum of scores varied from 1 to 3 (2.5 ± 0.5). In all cases with HBSG accelerated bile outflow, as in group 3, was noted. No operative interventions were required in this group.

Conclusion: The developed algorithm for patients with suspected SOD facilitates determination of the sequence of studies and the choice of management. A four-score excess by the estimation sign scale can serve as a reason for invasive studies and surgery. Use of HBSG permits to assess noninvasively the status of bile outflow that is not impaired in most cases but even accelerated. Oddi's sphincter insufficiency can be an independent type of functional disorders which should be taken into consideration when choosing management tactic.

P0054 RIP3 KINASE CONTRIBUTES TO NECROINFLAMMATION IN THE CHOLESTATIC LIVER

M. B. Afonso[1], P. M. Rodrigues[1], A. L. Simão[1], H. Cortez-Pinto[2,3], D. Ofengeim[4], J. D. Amaral[1], **R. E. Castro**[1], J. Yuan[4], C. M. P. Rodrigues[1]
[1]*Instituto de Investigação do Medicamento (iMed.ULisboa), Faculdade de Farmácia, Universidade de Lisboa,* [2]*Gastrenterology, Hospital Santa Maria,* [3]*Faculty of Medicine, Universidade de Lisboa, Lisbon, Portugal,* [4]*Department of Cell Biology, Harvard Medical School, Boston, MA, United States*

Contact E-mail Address: mbafonso@ff.ulisboa.pt

Introduction: Cholestasis is associated with liver inflammation and hepatocyte damage, through incompletely understood pathophysiological processes. The kinase activity of receptor interacting protein 3 (RIP3) plays an important role in necroptosis, a novel immunogenic cell death type that may contribute to inflammation-driven liver diseases.

Aims & Methods: Here we aimed to evaluate the role of necroptosis after common bile duct ligation (BDL) in mice, a classic experimental model for acute cholestasis and secondary biliary fibrosis, and in patients with primary biliary cirrhosis (PBC), a cholestatic chronic liver disease.

BDL or sham surgery was performed in C57BL/6 wild-type (WT) or RIP3 knockout (KO) mice. Serum and livers were collected 3 and 14 days after BDL. Histology, serum liver enzymes and bilirubin were evaluated. Liver RIP3, proinflammatory cytokines and fibrosis markers were determined by qRT-PCR. Total and soluble/insoluble liver proteins were analysed by Western blot. RIP3 kinase activity was determined *in vitro*. The functional crosstalk between RIP3 and antioxidant responses was investigated. Finally, RIP3 and phosphorylated mixed lineage kinase domain-like protein (p-MLKL) were evaluated by immunohistochemistry in liver specimens of patients with PBC and healthy controls.

Results: In WT mouse livers, BDL resulted in bile duct hyperplasia, multifocal necrosis, fibrosis and inflammatory cell infiltration. Concomitantly, necroptosis was activated as assessed by: 1) sequestration of RIP3 and its target MLKL in the insoluble protein fraction of the liver; 2) increased RIP3 kinase activity; and 3) increased RIP3 mRNA and protein expression (at least, $p < 0.05$). Remarkably, histological analysis revealed that RIP3 deficiency significantly decreased liver necrosis and inflammation induced by BDL at both 3 and 14 days ($p < 0.05$). At day 3, but not at day 14, BDL RIP3 KO mice showed lower circulating levels of hepatic enzymes, decreased inflammatory and fibrogenic liver gene expression, and enhanced antioxidant responses (at least, $p < 0.05$). Finally, RIP3 and p-MLKL expression was induced in PBC patients ($p < 0.05$).

Conclusion: In conclusion, RIP3-dependent signaling is triggered in human PBC and mediates hepatic necroinflammation in BDL-induced acute cholestasis. As such, targeting RIP3-dependent pathways may provide an unprecedented opportunity to develop novel therapeutic strategies to ameliorate cholestatic liver injury, although complementary approaches may be required to control progression to fibrosis.

Supported by PTDC/SAU-ORG/119842/2010, HMSP-ICT/0018/2011 and SFRH/BD/91119/2012, from FCT, Portugal.

Contact E-mail Address: a.h.vandijk@amc.nl

Introduction: Complicated cholecystolithiasis occurs in about a third of all patients with gallstones and is frequently associated with a difficult cholecystectomy with unclear anatomy. Several techniques to safely remove the gallbladder in these patients exist, including a subtotal cholecystectomy (SC).

SC is reported to be safe and feasible, but an increase in bile leaks and retained gallstones have also been described.

The objective of this study was to assess the short- and long-term outcomes following SC.

Aims & Methods: A retrospective review of all patients who received cholecystectomy in 3 hospitals (from January 2003 to October 2013) in the Netherlands was performed. Patients who underwent SC were identified based on operative reports. Patient characteristics, operative details and the short and long term outcomes were recorded from patients files.

Short-term outcome was defined as the occurrence of bile duct injuries, intra-abdominal abcesses, biloma's, woundinfections and the rate of readmittance and reinterventions. The completion of the cholecystectomy and the occurrence of bile duct strictures were considered long-term outcomes.

Results: A total of 5155 operative records were screened, of which 190 were SC (3.7%). A third of patients (n = 56, 30%) had SC for symptomatic uncomplicated cholelithiasis. The remaining patients were diagnosed with complicated cholelithiasis, of whom 72 patients (38%) had acute cholecystitis. Short-term total morbidity was 34.2% (n = 65). A total of 25 patients (13.2%) were diagnosed with a bile duct injury, of which 24 patients solely had a leakage of the cystic duct. In only one patient an injury to the common bile duct (0.5%) was seen. An ERC was necessary in 41 patients, mostly due to persistent bile leakage (9.5%) or common bile duct stones (11.1%). In the long-term a bile structure was seen in only 1 patient (0.5%) and 20 patients (10.5%) underwent a completion of the cholecystectomy with an associated morbidity of 30%.
Conclusion: Subtotal cholecystectomy is an effective strategy to circumvent severe bile duct injury and bile strictures, but the risk is transferred to cystic duct leakage in 1 out of 10 patient and associated postoperative morbidity.

Contact E-mail Address: gimy54861439@gmail.com
Introduction: In Asia, as well as in some European countries , South America, and the Middle East , conscious sedation is not used routinely for therapeutic endoscopic retrograde cholangiopancreatography (ERCP). However, conscious sedation may easily progress to anesthesia once verbal contact has been lost. Therefore, general anesthesia sedation is conducted for ERCP in our institution, but not moderate conscious sedation anesthesia.
Aims & Methods: We carried out a retrospective evaluation to analyze common bile duct stone extraction in ERCPs under non-sedation and general anesthesia, to determine the safety, successful rate, and complications in these two groups. In retrospectively reviewed study, all ERCPs with stone extraction under general anesthesia or non sedation from Jan, 2010 to Sep. 2013. The participants were aged 18 years and above. Criteria for exclusion: procedure failed due to anatomy change after operation, pyloric ring stenosis, and tumor related obstruction. Non sedation (NS) group: pethidine 40-50mg for pain control 10 minutes before papilloplastic balloon dilatation. General anesthesia (GET) group: general endotracheal anesthesia before ERCP. The definition of primary outcomes: success of stone removal (complete bile duct stone clearance), major complications (post ERCP pancreatitis (PEP) (amylase > 3times of upper limit level), perforation, bleeding, pneumonia in 30 days and mortality in 30 days). The operation time in ERCP was defined as cannulation starting time to complete stone removal.
Results: There are consecutive 166 patients enrolled. Eleven cases are excluded, 2 cases post whipple procedure, 2 case post Billroth II subtotal gastrectomy, 4 cases with stenting to stone obstruction, no attempt to remove. 2 cases with pyloric ring stenosis, one case failed to find papilla. There are 77 patients with NS method and 78 with GET for attempt to bile duct stone removal. Age, sex, personal habitats (alcohol, smoking), American Society of Anesthesiologists (ASA) score, previous ERCP experience, and comorbidities were similar in these two groups. Nine patients (11.5%) in NS group could not complete the procedure due to intolerance. Successful rate of complete stone extraction was higher in the GET (93.6%) versus in the NS (77.9%) group; p = 0.005. The rate of post-ERCP pancreatitis (PEP) was higher in NS group versus the GET group (20.8% versus 10.3%; p = 0.004). The operation time was shorter in NS group versus GET group(23.1 ± 10.1 versus 28.3 ± 13.7, p = 0.023). The complication rate was similar between NS and GET groups (no bleeding case; perforation: 1.3% versus 0%, p = 0.313; pneumonia: 2.6% versus 3.8%, p = 0.660; mortality: 1.3% versus 1.3%, p = 0.993). In multivariate analysis for the clinical factors influencing PEP, sedation group is a negative facotr for PEP (*coefficient of variation:* -1.23 ± 0.55, 95% C.I. 0.29(0.10~0.86), p = 0.026), and operation time (≥*30mins*) (*coefficient of variation:* 1.43 ± 0.57, 95% C.I. 4.20(1.36~12.97), p = 0.013)is a positive predisposing factor.
Conclusion: We conclude that ERCP under GET is safe and effective for common bile stone removal, with lower PEP rate than non-sedation patients.

P0057 RECURRENCE OF CHOLEDOCHOLITHIASIS FOLLOWING ENDOSCOPIC BILE DUCT CLEARANCE: LONG-TERM RESULTS AND FACTORS ASSOCIATED WITH RECURRENT BILE DUCT STONES

C. Konstantakis[1], K. Thomopoulos[1], V. Theopistos[1], G. Theoxaris[1], C. Triantos[1], G. Diamantopoulou[1]
[1]*Department of Gastroenterology, University Hospital of Patras, Patras, Greece*

Contact E-mail Address: asraiah@yahoo.com
Introduction: Recurrence of bile duct stones is a possibility following endoscopic extraction.
Aims & Methods: The aim of our study was to evaluate the rate of recurrence of symptomatic choledocholithiasis and to identify factors associated with the recurrence of bile duct stones in patients who underwent endoscopic retrograde cholangiopancreatography (ERCP) and endoscopic sphincterotomy (ES) for bile duct stone disease.
Patients who underwent ERCP and ES for bile duct stone disease and had their bile duct cleared from 1/1/2005 until 31/12/2008 were enrolled. All symptomatic recurrences during the study period (until 31/12/2014) were recorded. Clinical and laboratory data potentially associated with common bile duct (CBD) stone recurrence were retrospectively retrieved from patients' files.
Results: A total of 495 patients were included. Sixty seven (67) out of 495 patients (13.5%) presented with recurrent symptomatic choledocholithiasis after 39.2 ± 25.6 months (13-168 months) while twenty one (21) of these patients (31%) experienced a second recurrence after 9 – 78 months.
Factors associated with recurrence were the size (diameter) of the largest CBD stone found at first presentation (10.2± 6.9 mm vs 7.2± 4.1 mm p = 0.024) and the diameter of the CBD at the first examination (15.5 ± 6.3 mm vs 12.0 ± 4.6 mm p = 0.005). Number of stones at first presentation (3.9 ±4.3 vs 3.5 ±2.3), age or sex of the patient did not influence recurrence. Moreover oblique CBD angulation (calculated by measuring the angle enclosed between the horizontal portion of the CBD and the horizontal plane) was significantly associated with stone recurrence (43.4 ± 10 vs 50.5 ± 15 p = 0.016).
Conclusion: Bile duct stone recurrence is a likely late complication following endoscopic stone extraction and CBD clearance. It appears to be associated with anatomical parameters (CBD diameter, angulation) and stone characteristics (stone size) at first presentation.

P0058 LIMITED PRECUT SPHINCTEROTOMY COMBINE ENDOSCOPIC PAPILLARY BALLOON DILATION TO TREAT DIFFICULT BILIARY CANNULATION WITH COMMON BILE DUCT STONES

C.-M. Kuo[1], C.-M. Liang[1], W.-C. Tai[1]
[1]*Division of Hepato-gastroenterology, Department of Internal Medicine, Kaohsiung Chang Gung Memorial Hospital and Chang Gung University, Kaohsiung, Taiwan, Province of China*

Contact E-mail Address: kuo51116@gmail.com
Introduction: Difficult biliary cannulation in endoscopic retrograde cholangiopancreatography (ERCP) causes the failure of common bile duct stones removal. Difficult biliary cannulation can also cause more post-ERCP complications (acute pancreatitis, biliary tract infection (BTI) and bleeding).
Aims & Methods: To evaluate the outcome and complications of limited precut sphincterotomy combined with endoscopic papillary balloon dilation (EPBD) to treat difficult biliary cannulation with common bile duct stones retrospectively. From Oct 2009 to Sep 2014 in CGMH, total 3305 patients received ERCP examination and treatment. Of all, 258 (7.8%) patients belonged to difficult biliary cannulation and 145 patients were difficult biliary cannulation with common bile duct stones. We performed limited precut sphincterotomy combined EPBD in 58 patients (M:28, F:30; age 64.02 ± 16.37 yr (26-96). The definition of difficult biliary cannulation in our study was: (1)10 min time limits for cannulation or (2) 5 passage or injection into pancreatic duct or (3) 10 attempts on the papilla without time limit. Limited sphincterotomy means the extent of needle knife cutting < 1/2 length of the papillary mound, then combined CRE balloon dilation (8-20 mm) with dilation time 2 minutes.
Results: Overall successful common bile duct (CBD) stones removal was 94.8% (55/58) and 1st session success was 87.9% (51/58). Mean procedure time was 41 ± 11.48 (20-72) min. Mean CBD size was 1.47 ± 0.44 (0.7-2.6) cm and mean stone size was 1.11 ± 0.40 (0.4-2.0) cm. CBD stone number with 1:2: ≥3 was 28:14:16. Need of mechanical lithotripsy (ML) was 10.3% (6/58). Post-treated complications were bleeding 3.4% (2/58), pancreatitis 8.6% (5/58) and BTI 2.7% (1/58). We analyzed and investigated the relationship of risk factors in published studies in post-treated bleeding and pancreatitis. Coronary artery disease (CAD), stroke, end-stage renal disease (ESRD), liver cirrhosis (LC), age > 70 yrs, distal CBD narrowing, and BTI were not statistically significant factors for post-treated bleeding. Sex, age < 60 yrs, jaundice, previous pancreatitis, lithotripsy, > 3 CBD stones, and CBD < 0.8 cm were not statistically significant factors for post-treated pancreatitis.
Conclusion: There was no significant post-treated duodenal bleeding (3.4%) compared to published studies in patients with post-endoscopic sphincterotomy (EST) (1-3%) or post-precut spincterotomy (2-2.7%) or post-EST + endoscopic papillary large balloon dilation (EPLBD) (5.2-10.3%). There was no significant

post-treated pancreatitis (8.6%) compared to published studies in patients with difficult biliary cannulation (4.3-11.3%) or post-EPBD (5-15%) or post-EST + EPLBD (0-6%). Overall successful stone removal (94.8%) and reduced need for ML (10.3%) is similar to patients with EST + EPLBD (80-100% and 1-11%). Limited precut sphincterotomy combined with EPBD to treat difficult biliary cannulation with common bile duct stones is safe and effective.

P0059 ENDOSCOPIC ULTRASOUND VS MAGNETIC RESONANCE CHOLANGIOPANCREATOGRAPHY FOR COMMON BILE DUCT STONES. A SYSTEMATIC REVIEW

D. Ledro Cano[1], D. López Peñas[1]
[1]*Gastroenterology, Hospital de Llerena, Llerena, Spain*

Contact E-mail Address: diego.ledro@ses.juntaextremadura.net
Introduction: Endoscopic ultrasound (EUS) and magnetic resonance cholangiopancreatography (MRCP) are tests used in the diagnosis of common bile duct stones in patients suspected of having common bile duct stones prior to undergoing invasive treatment.
Aims & Methods
Aims: To determine and compare the accuracy of EUS and MRCP for the diagnosis of common bile duct stones.
Methods: We searched MEDLINE, EMBASE, Science Citation Index Expanded, BIOSIS, and Clinicaltrials.gov until September 2012. We did not restrict studies based on language or publication status, or whether data were collected prospectively or retrospectively.
We included studies that provided the number of true positives, false positives, false negatives, and true negatives for EUS or MRCP. We only accepted studies that confirmed the presence of common bile duct stones by extraction of the stones (irrespective of whether this was done by surgical or endoscopic methods) for a positive test, and absence of common bile duct stones by surgical or endoscopic negative exploration of the common bile duct or symptom-free follow-up for at least six months for a negative test, as the reference standard in people suspected of having common bile duct stones. At least two authors independently screened abstracts and selected studies for inclusion.
Two authors independently collected the data from each study. We used the bivariate model to obtain pooled estimates of sensitivity and specificity.
Results: We included a total of 18 studies involving 2366 participants (976 participants with common bile duct stones and 1390 participants without common bile duct stones). Eleven studies evaluated EUS alone, and five studies evaluated MRCP alone. Two studies evaluated both tests. For EUS, the sensitivities ranged between 0.75 and 1.00 and the specificities ranged between 0.85 and 1.00. The summary sensitivity (95% confidence interval (CI)) and specificity (95% CI) of the 13 studies that evaluated EUS (1537 participants; 686 cases and 851 participants without common bile duct stones) were 0.95 (95% CI 0.91 to 0.97) and 0.97 (95% CI 0.94 to 0.99). For MRCP, the sensitivities ranged between 0.77 and 1.00 and the specificities ranged between 0.73 and 0.99. The summary sensitivity and specificity of the seven studies that evaluated MRCP (996 participants; 361 cases and 635 participants without common bile duct stones) were 0.93 (95% CI 0.87 to 0.96) and 0.96 (95% CI 0.90 to 0.98). There was no evidence of a difference in sensitivity or specificity between EUS and MRCP (P value = 0.5). From the included studies, at the median pre-test probability of common bile duct stones of 41% the post-test probabilities (with 95% CI) associated with positive and negative EUS test results were 0.96 (95% CI 0.92 to 0.98) and 0.03 (95% CI 0.02 to 0.06). At the same pre-test probability, the post-test probabilities associated with positive and negative MRCP test results were 0.94 (95% CI 0.87 to 0.97) and 0.05 (95% CI 0.03 to 0.09).
Conclusion: Both EUS and MRCP have high diagnostic accuracy for detection of common bile duct stones. The two tests are similar in terms of diagnostic accuracy and the choice of which test to use will be informed by availability and contra-indications to each test.Further studies that are of high methodological quality are necessary to determine the diagnostic accuracy of EUS and MRCP for the diagnosis of common bile duct stones.

P0060 CLINICAL APPLICABILITY OF TOKYO GUIDELINES 2013 IN DIAGNOSIS APPROACH AND SEVERITY EVALUATION OF ACUTE CHOLANGITIS

E. Gravito-Soares[1], M. Gravito-Soares[1], D. Gomes[1], N. Almeida[1], S. Mendes[1], E. Camacho[1], R. Mesquita[1], C. Lérias[1], C. Sofia[1]
[1]*Gastroenterology, Centro Hospitalar e Universitário Coimbra, Coimbra, Portugal*

Contact E-mail Address: es18497@gmail.com
Introduction: Acute cholangitis may be associated with high morbidity and mortality. The Tokyo guidelines (TG) allowed diagnosis improvement and severity assessment of acute cholangitis and cholecystitis. However the accuracy/applicability of the updated TG 2013 remains unclear.
Objective: Diagnostic accuracy of TG13, predictors of poor prognosis in acute cholangitis and relationship with TG.
Aims & Methods: Retrospective case-control study of all episodes of obstructive jaundice, admitted to the gastroenterology service in a year, divided into two groups: those with acute cholangitis (G1: 183cases) and without acute cholangitis (G2), randomly selected in a ratio of 1:1. Variables evaluated were the clinic, analytical parameters, presence of Charcot's triad, TG07 and TG13. The prognosis was defined in terms of mortality, need of hospitalization in the intensive care unit or early ERCP (<48hours).
Results: Patients with acute cholangitis were predominantly women (58.5% vs 41.5%), with mean age 76.1 ± 11.3 years. Charcot's triad was present in 35.5%. The sensitivity/specificity for the diagnosis of acute cholangitis based on Charcot's triad, TG07 and TG13 were respectively 35.5%/100.0%, 96.2%/77.6% and 100.0%/84.7%; giving a diagnostic accuracy ($p < 0.001$) of 67.8%, 86.9% and 92.3%, respectively.
In relation to severity based on the TG, 30.6% of cases were severe. A worse prognosis was found in 26.8% of patients. After multivariate analysis, systolic blood pressure <90mmHg (OR 11.010[1.473;9.899]; p = 0.006), serum albumin <3g/dL (OR 1.355[1.098;1.613]; p = 0.006), active oncologic disease (OR 3.818[1.473;9.899]; p = 0.006) and malignant etiology of obstructive jaundice (OR 3.224[1.197;8.685]; p = 0.021) represented independent predictors of poor prognosis. The discriminative ability of the model with these 4 variables was high (AUROC 0.799; $p < 0.001$). The severity defined by the TG showed sensitivity/specificity of 65.3%/82.1%, with an accuracy of 77.6%, being explained by the 4 factors model in 80.0% ($p < 0.001$).
Conclusion: The TG13 showed high diagnostic accuracy in acute cholangitis, being higher than the Charcot's triad and TG07. Comparing to the TG, the simplified model allows select the patients that will benefit of admission in the intensive care unit and early ERCP.

P0061 CLINICAL IMPACT OF PERIAMPULLARY DIVERTICULUM AS RISK FACTOR OF THE POST-ERCP PANCREATITIS

E. J. Kim[1], **J. H. Yoon**[1], H. S. Kim[1], C. S. Bang[1]
[1]*Gastroenterology, Hallym University Medical Center, Chuncheon-si, Republic of Korea*

Contact E-mail Address: pure0826@hanmail.net
Introduction: Endoscopic retrograde cholangiopancreatography (ERCP) is now the therapeutic modality for biliary as well as pancreatic diseases. The correlation between Post-ERCP pancreatitis (PEP) and periampullary diverticulum (PAD) was evaluated in several studies. However, the risk of Post-ERCP pancreatitis, according to the types of PAD was not elucidated. The aim of this study was to investigate risk factors for post-ERCP pancreatitis, including three types of PAD.
Aims & Methods: We evaluated risk factors for post-ERCP pancreatitis, according to types of periampullary diverticulum. This is a retrospective case-control study, which included a total of 306 ERCPs, performed by four endoscopists in a single center. 142 (50.2%) patients with PEP, and 141 (49.8%) patients without PEP were enrolled. The correlation between PEP and risk factors, including PD, angle of common bile duct (CBD), endoscopic sphincterotomy (EST), canulation time, procedure time, and three types of PAD were investigated by univariate and multivariate analyses. PAD were classified into three types by the location of ampulla of Vater: type 1 (n = 6), inside the diverticulum; type 2 (n = 79), on the margin of diverticulum; type 3 (n = 44), outside the diverticulum.
Results: In univariate analysis, all types of PAD, type 1 PAD, type 2 PAD, type 3 PAD had variable results for PEP (Odd ratio = 1.654, 0.709, 2.815, 0.359; p = 0.036, 0.732, 0.005, 0.007, respectively). Cannulation time and total procedure time were significantly related with PEP (p = 0.004, and 0.009, respectively). However, the angle of CBD, and EST were not meaning risk factors in this study (p = 0.373, and 0.405, respectively). Age-sex adjusted multivariate analysis showed only cannulation time as independent risk factors for (OR = 1.043, p = 0.01)
Conclusion: PAD, especially Type 2 PAD, cannulation time and procedure time were risk factor for PEP in univariate analysis. However, only cannulation time was significant related to PEP in multivariate analysis. Although, this study had limitations of retrospective case-control study, prospective randomized control study in multi-center was required.

P0062 RECURRENCE OF BILE DUCT STONES AFTER ENDOSCOPIC PAPILLARY LARGE BALLOON DILATION COMBINED WITH SPHINCTEROTOMY: LONG-TERM FOLLOW-UP. A PROSPECTIVE STUDY

G. Paspatis[1], E. Vardas[1], E. Voudoukis[1], A. Theodoropoulou[1], A. Tavernaraki[1], M. Fragaki[1], G. Chlouverakis[2], K. D. Paraskeva[3]
[1]*Gastroenterology, Benizelion General Hospital,* [2]*Social Medicine, University of Crete, Heraklion,* [3]*Gastroenterology, Konstantinoopoulion Hospital, Athens, Greece*

Contact E-mail Address: gpaspatis@gmail.com
Introduction: Endoscopic papillary large balloon dilation (EPLBD) with endoscopic sphicterotomy (ES) is safe and effective in patients with large bile duct stones. Data regarding the recurrence rate of common bile duct (CBD) stones after EPLBD with ES are limited and the existing studies are retrospective.
Aims & Methods: The aim of this study was to prospectively estimate the recurrence rate and the risk factors for CBD stones after EPLBD + ES. To the best of our knowledge this is the first prospective study on this issue. In total, 106 patients who underwent EPLBD + ES from 2009 to 2011 and had successful clearance of the CBD were prospectively monitored for a minimum of three years for recurrence of CBD stones. These patients belong to a group enrolled in a randomized controlled trial and their data regarding the EPLBD + ES procedure have previously been published [1]. The follow-up was performed with regular appointments in the outpatient clinics. In those patients who became symptomatic during the follow-up period and the presence of a CBD stone was radiologically confirmed, an ERCP was performed.
Results: Of the 106 patients, the duration of follow-up was 30.5 ± 5.5 months. The recurrence rate of CBD stones was 7.5% (8/106). The mean diameter of CBD was higher for the patients with stone recurrence than for those without (2.0 ± 4.9 vs 1.65 ± 0.9, $p = 0.008$). A multivariate stepwise logistic regression analysis revealed that the size of CBD diameter was significantly associated with the recurrence of CBD stones (odds ratio:1.2, $p = 0.01$). Among the others evaluated parameters (sex, stone diameter, CBD tapering, cholocystectomy) no significant differences were detected as far as the stone recurrence is concerned.
Conclusion: These data show that the recurrence rate of CBD stones after EPLBD + ES is low, and a dilated CBD appears to increase the risk of bile duct stone recurrence.

P0063 SAFETY OF LONG-TERM BILIARY STENTING FOR COMMON BILE DUCT STONES

H. Tsugeno[1], D. Kawai[1], K. Takemoto[1], R. Takenaka[1], A. Taira[1], S. Fujiki[1]
[1]*Digestive Endoscopy Center, Tsuyama Chuo Hospital, Tsuyama, Japan*

Contact E-mail Address: attractively21@yahoo.co.jp
Introduction: Though long-term biliary stenting is a useful alternative to endoscopic extraction for common bile duct stone (CBDS) in the elderly and/or frail patients with poor tolerance for prolonged endoscopic and/or surgical procedures, the safety of long-term stenting has remained uncertain. Few reports with sufficient observation period and sample size are available on this method so far.
Aims & Methods: The immediate and long-term outcome of endoscopic biliary stenting as sole treatment of CBDS was therefore compared with the result of biliary sphincterotomy (EST) and endoscopic extraction, along with a survey on complications by cholangitis. In the past 12 years, 1195 patients with CBDS in our hospital were referred to endoscopic treatment. Among these, 401 with high risk were subjected to permanent biliary stent insertion for common duct stones and stent exchange only on complications. In 105 of 401 patients, EST had been used prior to stenting. The remaining 794 patients were subjected to endoscopic stone removal after EST. Kaplan-Meier estimates of survival and time to recurrence of cholangitis were conducted on clinical variables using the Cox model for multivariate analysis.
Results: Successful biliary drainage was achieved in all patients regardless of stone removal. The mean treatment time was significantly shorter in stent patients (21.2 min) than EST patients (41.0 min) ($p < 0.01$). Early complications occurred in 2.7% of stent patients and 6.1% of EST patients. Most of them were trivial except for a few with serious pancreatitis and duodenal perforation requiring surgery in EST patients. The mean hospital stay after treatment was significantly shorter in stent patients (5.3 days) than EST patients (9.3 days) ($p < 0.01$), and than EST patients with stone removal at once (7.9 days) ($p < 0.01$). Late complication of cholangitis occurred more frequently in stent patients (59.7%) than in EST patients (18.8%) within five-year observation ($p < 0.01$, log-rank test). The mean duration to clinical presentation of cholangitis after treatment was 3.4 years (Median: 2.7 years) in stent patients and 8.1 years in EST patients. All patient in need tolerated re-treatment adequately, without biliary tract-related mortality. In stent patients, only the size of stones was significantly correlated with occurrence of cholangitis ($p < 0.05$), but addition of EST was ineffective to prevent recurrence.
Conclusion: This study confirmed the usefulness and safety of long-term biliary stenting as an alternative to endoscopic common duct stone removal and in shortening the hospital stay in CBDS patients. Although recurrence of cholangitis is frequent, this method can be repeated safely, providing a feasible option for selected patients, such as the elderly and or debilitated patients with short life expectancy. Additional EST to biliary stenting failed to prevent late occurrence of cholangitis.

P0064 COULD IT BE POSSIBLE TO PREDICT THE RISK OF RECURRENT RESIDUAL SYMPTOMATIC CHOLEDOCHOLITHIASIS AFTER CHOLECYSTECTOMY?

M. Gravito-Soares[1], E. Gravito-Soares[1], D. Gomes[1], N. Almeida[1], S. Mendes[1], E. Camacho[1], R. Mesquita[1], S. Lopes[1], C. Sofia[1]
[1]*Gastroenterology, Centro Hospitalar e Universitário Coimbra, Coimbra, Portugal*

Contact E-mail Address: ms18498@gmail.com
Introduction: Usually, lithiasis of common biliary duct (CBD) results of the migration of sludge/gallstones from the gallbladder. Cholecystectomy would be useful in relapse prevention. However, the recurrence after cholecystectomy is observed in a considerable number of patients.
Objective: Prevalence and risk factors of recurrent residual symptomatic choledocholithiasis after cholecystectomy (RRSCC).
Aims & Methods: Of total of 1084 inpatient episodes for biliary pathology between 2011-2014, we selected 160 patients with choledocholithiasis after cholecystectomy, after exclusion of episodes with earlier recurrence, before 6 months after cholecistectomy. They were divided into 2 groups: >1 RRSCC episode (cases) versus patients with only one RRSCC (controls). All the cases had done biliary endoscopic drainage. We evaluated clinical variables, comorbidities, biochemical analysis, ultrasound and endoscopic retrograde cholangiopancreatography (ERCP) abnormalities and surgical specimens. The presence of duodenal diverticulum was based on Boix et al. classification.
Results: RRSCC occurred in 26.9% of patients (n = 43). The efficacy of ERCP was 76.3% with a mean number of 1.4 ± 0.7(vs 1.2 ± 0.5; $p = 0.109$) exams. It was technically impossible in 4.4% of cases and the complications peri/post- procedure, mainly pancreatitis, was 13.1%, without any case of mortality. Of cases, the mean time of cholecistectomy-recurrence was 8.5 ± 11.2 years, the mean number of relapses was 3.6 ± 2.2 with mean inter-relapses of 11.5 ± 14.1 months, mean number of choledocholithiasis episodes before cholecistectomy of 1.6 ± 1.2(vs 1.3 ± 0.7; $p = 0.017$) and necessity of surgical treatment in 7.0%. The duodenal diverticulum was presented in 32.6% (vs 9.4%; $p = 0.001$), periampullary(<2cm of papilla) in 27.9%(vs 12.0%; $p = 0.005$) and intradiverticular papilla in 16.3%(vs 4.3%; $p = 0.017$). After multivariate analysis, independent risk factors for relapse of RRSCC were American Society of Gastrointestinal Endoscopy (ASGE) criteria at admission ≥2 (2.8 ± 0.5 vs 2.4 ± 0.6; OR1.554 ,$p = 0.030$; AUROC0.624, $p = 0.017$), CBD ultrasound dilatation ≥12mm at admission (16.5 ± 5.2 vs 13.1 ± 4.5; OR1.145, $p = 0.002$; AUROC0.702, $p < 0.001$) and the presence of periampullary diverticulum (27.9% vs 12.0%; OR3.115, $p = 0.003$).
Conclusion: After a first episode of RRSCC, approximately ¼ of patients will relapse after about 9 years. Patients with ASGE criteria ≥2 at admission, biliary ultrasound dilatation ≥12mm at admission or periampullary diverticulum, will require a careful follow-up and eventually surgical treatment.

P0065 THE ECTOPIC OPENING OF COMMON BILE DUCT INTO THE DUODENAL BULB AND GASTRIC ANTRUM AND ITS CLINICAL IMPORTANCE

M. Kaya[1], N. Ekin[1], **R. Bestas**[2], F. Ucmak[1]
[1]*Gastroenterology, Dicle University School of Medicine,* [2]*Gastroenterology, Diyarbakır Gazi Yasargil Education and Training Hospital, Diyarbakır, Turkey*

Contact E-mail Address: bestasr@gmail.com
Introduction: Ectopic of the common bile duct (CBD) into the duodenal bulb and gastric antrum is an extremely rare congenital anomaly, but its clinical significance has not been adequately determined.
Aims & Methods: The aim of this study was to comprehensively describe the features of this rare anomaly. Clinical, laboratory, endoscopic and cholangiographic findings, therapeutic interventions, and clinical course of consecutive patients that underwent endoscopic retrograde cholangiopancreatography (ERCP) and were diagnosed as ectopic opening of CBD into the duodena bulb and gastric antrum.
Results: Ectopic opening of the CBD was observed in 10 (1.5%) (7 males and 3 females; median age: 56.3 years) of 637 patients that underwent ERCP. All but 1 of the patients with ectopic opening of the CBD had a history of recurrent episodes of cholangitis, and 1 had compensated cirrhosis. The ectopic opening was into the antrum in 2 patients and into the duodenal bulb in 8 patients. In all, 6 of the patients had an ulcer (duodenal: n = 4; gastric: n = 2) and 7 had duodenal deformity associated with apical stenosis. Cholangiography showed dilatation of both the extrahepatic and intrahepatic bile ducts, and tapered narrowing and a hook-shaped configuration of the distal end of the CBD in all 10 patients, bile stones in 7 patients, and bile sludge in 3 patients. Complete clearance of the bile ducts was achieved in all patients with bile sludge and in 1 of the 7 patients with bile stones following balloon dilation of the orifice.
Conclusion: Ectopic opening of the CBD into the duodenal bulb and gastric antrum is usually associated with gastroduodenal and biliary disease. ERCPists should be aware of this anomaly. Abnormal configuration of the biliary tree prevents complete extraction of bile stones in most patients.

P0066 PREVALENCE AND RISK FACTORS OF GALLBLADDER STONE IN KOREAN HEALTH EXAMINEE

T. N. Kim[1], S. B. Kim[1], S. H. Sohn[1], Y. H. Jeong[1], K. H. Kim[1], K. O. Kim[1], S. H. Lee[1], B. I. Jang[1]
[1]*Gastroenterology and Hepatology, Yeungnam University Hospital, Daegu, Republic of Korea*

Contact E-mail Address: tnkim@yu.ac.kr

Introduction: Female gender, age, diabetes mellitus, rapid weight loss, use of oral contraceptives, pregnancy, menopause, chronic hepatitis C, chronic kidney disease and metabolic syndrome have been known as the risk factors of gallbladder (GB) stones. In western countries, females showed higher prevalence of gallbladder (GB) stone than males. However, prevalence of GB stone was higher in males than females in some studies.

Aims & Methods: The aims of this study were to evaluate the prevalence and risk factors of GB stone. Patients who underwent examination through health promotion center in Yeungnam university hospital from Jan 2010 to Dec 2013 were analyzed retrospectively. All subjects checked height, weight, abdominal circumference, and blood pressure and underwent laboratory tests and abdominal ultrasonography. Diagnosis of GB stone was made by abdominal ultrasonography. Subjects with history of cholecystectomy or without visible GB were excluded from this study.

Results: Of the total 23,899 subjects (mean age, 50.0 ± 11.4 years, male to female ratio, 1.3:1), GB stone was diagnosed in 1,259 subjects with overall prevalence of 5.2%. Mean age of the patients with GB stone was 55.4 ± 11.3 years and male to female ratio was 1.6:1. Prevalence of GB stone was significantly higher in male than female (5.7% vs 4.4%, p < 0.001). Males had higher prevalence of GB stone than females in all age groups. Metabolic syndrome (MS) was more frequent in male subjects than females (18.6% vs 13.9%, p < 0.01). Subjects with MS had higher incidence of GB stone compared to subjects without MS (23.3% vs 16.2%, p < 0.001). Males had higher prevalence of MS than females in the age below 60 (22.4% vs 15.5%, p = 0.016). However, the prevalence of MS was higher in females than in males in age above 60 (41.6% vs 23.0%, p = <0.001). On multivariate analysis, older age (95% CI, 1.035-1.046; p < 0.001), male gender (95% CI, 1.171-1.496; p < 0.001), high blood pressure (95% CI, 1.491-1.876; p < 0.001), low HDL cholesterol level (95% CI, 1.106-1.436; p = 0.001), abdominal obesity (95% CI, 1.082-1.408, p = 0.003) and chronic hepatitis B (95% CI, 1.008-1.684; p = 0.036) were found as risk factors of GB stone.

Conclusion: The prevalence of GB stone was 5.7% in males and 4.4% in females with overall prevalence of 5.2%. Age, male gender, high blood pressure, low HDL cholesterol, abdominal obesity and chronic hepatitis B were found as risk factors of GB stone.

P0067 THE MANAGEMENT OF BILE DUCT STONES IN VERY ELDERLY PEOPLE

T. Suzuki[1], O. Togawa[1], T. Watanabe[1], H. Kogure[1], Y. Osawa[1], H. Oyama[1], E. Goto[1], Y. Isomura[1], M. Seto[1], Y. Koike[1]
[1]*Gastroenterology, Kanto Central Hospital, Setagaya-Ku, Japan*

Contact E-mail Address: suzutatsu86@gmail.com

Introduction: Life expectancy has been prolonged all over the world, particularly in Japan. The increasing population of very elderly people raises the prevalence of bile duct stones. Very elderly patients often have concomitant heart or cerebrovascular diseases. We evaluated the safety of the endoscopic treatment for bile duct stones.

Aims & Methods: From April 2010 to March 2015, 289 consecutive patients (58.5% men; mean age, 75 years) with bile duct stones who underwent endoscopic retrograde cholangiopancreatography (ERCP) were included in the present study. Patients were divided into two age groups: group A (≧85 years old) (n = 76) and group B (<85 years old) (n = 213). We performed endoscopic papillary balloon dilation (n = 242), endoscopic papillary large balloon dilation (n = 25), endoscopic sphincterotomy (n = 22) to remove bile duct stones.

Results: Patients in group A had larger (8.3mm vs 6.8mm, p = 0.031) and more (3.4 vs 2.3, p = 0.004) stones than in group B with significant differences. Overall, bile duct clearance rates were similar in the two groups (96.1% vs 98.6%, p = 0.188), and the mean number of sessions required for complete stone removal was similar in the two groups (1.3 vs 1.2, p = 0.395). The incidence of post-ERCP pancreatitis was lower in group A than in group B (3.9% vs 11.3%, p = 0.067) but was not statistically different. The incidence of pneumonia was higher in group A than in group B (2.6% vs 0%, p = 0.069) but was not statistically different. Duration of hospitalization was significantly longer in group A than in group B (20.0 vs 12.9, p < 0.001).

Conclusion: Although very elderly patients had larger and more stones, bile duct clearance rate was similar. ERCP is safe technique for the treatment of bile duct stones in very elderly patients as well, without increased occurrence of pancreatitis.

P0068 THE EFFICACY OF RECOMBINANT HUMAN SOLUBLE THROMBOMODULIN IN PATIENTS WITH BILIARY TRACT INFECTION-INDUCED DISSEMINATED INTRAVASCULAR COAGULATION

T. Ito[1], A. Nagahara[1], J. Kato[1], H. Ueyama[1], H. Saito[1], R. Kanazawa[1], R. Shimizu[1], K. Tomishima[1], S. Ishii[1], J. Sai[1], S. Shiina[1], S. Watanabe[1]
[1]*gastroenterology, Juntendo University, Tokyo, Japan*

Contact E-mail Address: tmitou@juntendo.ac.jp

Introduction: The biliary tract infectious disease is sometimes serious, sometimes resulting in disseminated intravascular coagulation (DIC). Recently, recombinant human soluble thrombomodulin (rTM) was approved and has been used in clinical practice for DIC treatment in Japan. However, there are few studies to evaluate the efficacy of rTM for DIC with the biliary tract infection. The purpose of this study is to make a comparison between rTM-treated patients and patients treated other agents, and to evaluate the efficacy of rTM.

Aims & Methods: Thirty-nine inpatients at our department with biliary tract infection-induced DIC between January 2009 and March 2015 were retrospectively analyzed. The patients were classified into the rTM treatment group (n = 20), and conventional treatment group (rTM was not used) as the control group (n = 19). Diagnosis of DIC was made according to the criteria of acute DIC of the Japan Association of Acute Medicine (JAAM). Platelet count, prothrombin time-international normalized ratio (PT-INR), levels of fibrin/fibrinogen degradation products (FDP), C-reactive protein (CRP), DIC scores based on JAAM criteria were measured on days 0.3, and 7 to evaluate therapeutic results. Furthermore, DIC resolution rate were assessed 3 and 7 days after the start of DIC treatment.

Results: There were no significant differences between two groups regarding patient characteristics. All patients underwent biliary drainage. The duration of rTM administration was 3.6 ± 1.7 days (range 1 to 8 days). As shown in the table, significant intra-group improvement was observed in all parameters except for FDP in both groups. However, there were no significant inter-group differences in comparison of all parameters except DIC scores. Significant improvements were seen in the DIC scores in the rTM-treated group (p < 0.05). DIC resolution rate on day3 were higher in the rTM group than in the control group (65% vs 32% on day3, p < 0.05).

Conclusion: These results suggest that rTM would be the useful medicine for early improvement of biliary tract infection-induced DIC.

P0069 LASER LITHOTRIPSY FOR GIANT STONES OF BILE DUCT UNDER PERORAL DIRECT CHOLANGIOSCOPY THROUGH TRACTION OF THE BENDING PART OF ULTRASLIM GASTROSCOPE

Y.-H. Huang[1], H. Chang[1], Y. Wang[1], W. Yao[1], Y.-P. Zhang[1]
[1]*Peking University Third Hospital, Beijing, China*

Contact E-mail Address: pksunking@live.cn

Introduction: To evaluate the feasibility and usefulness of a new peroral direct cholangioscopy(PDSC) technique through traction of the bending part of ultraslim gastroscope for the laser lithotripsy of giant stones of bile duct.

Aims & Methods: This study involved 9 patients with giant stones of bile duct whose endoscopic treatment failed by a conventional method involving mechanical lithotripsy. Firstly, endoscopic retrograde cholangiography (ERC)

and small sphincterotomy was performed using a conventional duodenoscope. Endoscopic papillary balloon dilation was performed up to 12-15mm before the introduction of an ultraslim upper endoscope(Fijinon 530NW). Before inserting the ultraslim gastroscope, a snare was tightened around the end of the bending section of the scope(about 6cm from the tip). Then the ultraslim gastroscope was advanced into the duodenum with the snare. A J turn was made in the second portion of the duodenum, and the tip of the endoscope was positioned facing the papilla. Then the snare was pulled slightly as a fulcrum to prevent the endoscope be pushed too far downward in the duodenum and to make insertion of the endoscope easier. Using this method, the ultraslim gastroscope was advanced into the CBD, and laser lithotripsy (U100plus, Germany) was performed. The stone fragments were extracted by basket and balloon through PDSC or ERC finally.

Results: The procedures of PDSC and laser lithotripsy were succeeded in all 9 patients (5 men and 4 women; mean age 79.7 years, range 52-93 years). The mean diameter of giant CBD stones was 23.2mm (range, 14-40mm). The overall success rate of bile duct clearance by laser lithotripsy and extraction was 100%. The mean intubation time was 8.8 minutes (range, 4-16 minutes). No procedure-related complications were observed.

patient	sex	age	Stone size (mm)	Intubation time (min)	No. of times entering CBD
1	M	70	14	10	1
2	F	93	20	8	1
3	M	52	25	14	4
4	M	77	40	4	6
5	M	93	20	4	2
6	F	85	20	7	2
7	F	86	22	9	2
8	F	86	30	8	3
9	M	75	18	16	1

Conclusion: Snare-assisted PDSC through traction of the bending part of ultra-slim gastroscope and laser lithotripsy were safe, simple and practical techniques for the treatment of giant stones of bile duct. The new PDSC method sometimes facilitated the entrance into bile duct repeatedly for further procedures including direct removal of stone fragments.

Introduction: Endoscopic sphincterotomy (EST) combined with mechanical lithotripsy (ML) is an established method for the removal of difficult biliary stones. Some bile duct stones were difficult to remove because of their large size, the rectangular shape of the CBD, or anatomical difficulties interfering with endoscopic procedures. Ersoz et al. first reported on the usefulness of large balloon (10–20 mm in diameter) dilation after EST (EPLBD) for the removal of large bile duct stones in 2003[1]. However, difficult cases have been encountered with large stones and without dilatation of the lower part of the CBD (WDLBD). The usage of the combination of EST and ML in such cases often requires multiple treatment procedures, whereas EPLBD has been avoided so far because of the high risk of procedure-associated complications.

Aims & Methods

Aims: To evaluate the technical feasibility and safety of EPLBD for the removal of large bile duct stones in WDLBD patients.

Methods: Between October 2009 and July 2014, 212 patients underwent EPLBD for the removal of bile duct stones at Yokohama City University Hospital, NTT Tokyo Medical Center, and Tokyo Metropolitan Hiroo Hospital. We retrospectively reviewed them. There were 60 patients (28.3%) in the WDLBD group and 152 patients (71.7%) in the non-WDLBD group. The state WDLBD was defined as a state with the diameter of the lower part of the extra-hepatic bile duct <10 mm and its length >10 mm as measured by cholangiography.

Results: There were no significant differences between the two groups in the total success rates (100% vs. 98.7%), frequencies of the use of mechanical lithotripter (31.7% vs. 23.0%, $P = 0.193$), and recurrence rates (3.3% vs. 4.6%). The success rate in the first session was significantly lower (63.3% vs. 75.7%, $P = 0.040$) and the procedure time was significantly higher (58.1 ± 31.5 vs. 48.1 ± 22.9, $P = 0.032$) in the non-WDLBD group. There were no significant differences in the rates of post-ERCP pancreatitis, perforation, and bleeding (6.7% vs. 3.3%, $P = 0.471$, 0% vs. 1.3%, $P = 0.917$, and 1.7% vs. 0.7%, $P = 0.917$, respectively).

Conclusion: EPLBD appears to be a safe and effective method for the common bile duct stone removal in WDLBD patients.

P0071 COST-EFFECTIVENESS TRIAL OF SELF-EXPANDABLE METAL STENTS AND PLASTIC BILIARY STENTS IN MALIGNANT BILIARY OBSTRUCTION

A. Fábián[1], R. Bor[1], T. Daróczi[1], K. Farkas[1], A. Bálint[1], F. Nagy[1], Á. Milassin[1], M. Rutka[1], M. Szűcs[2], T. Molnar[1], Z. Szepes[1]
[1]*University of Szeged, First Department of Medicine,* [2]*Department of Medical Physics and Informatics, University of Szeged, Szeged, Hungary*

Contact E-mail Address: szepes.zoltan@med.u-szeged.hu

Introduction: Self-expandable metal (SEMS) and plastic stents can be applied in the palliative endoscopic treatment for patients with unresectable malignant biliary obstruction. SEMS is substantially expensive, but the stent patency is significantly longer. Current guidelines recommend the use of SEMS if the patient's life expectancy is more than four months.

Aims & Methods: The aims of this study were to compare the therapeutic efficacy and cost-effectiveness of SEMS and plastic stents in the treatment of malignant biliary obstruction. 74 patients with unresectable malignant biliary obstruction were retrospectively enrolled who received a SEMS (34 patients) or a plastic stent (34 patients). We evaluated the technical and functional success, the complication rate, the stent patency and the cumulative cost of treatment.

Results: The complication rate of SEMS was lower compared with plastic stents (40.54% vs. 56.76). The stent occlusion was the most frequent complication. The mean time of stent patency were significantly higher in the SEMS group (19.11 vs. 8.29 weeks; $p = 0.0041$). In these cases the length (10.89 vs. 13.7 days; $p = 0.19$) and frequency (1.18 vs. 2.32; $p = 0.05$) of hospitalization of patients in context with stent complications were substantially lower, but the necessity of reintervention for stent dysfunction was higher (17 vs. 27; $p = 0.033$). In the plastic stent group the multiple stent implantation increased the stent patency: the second stent raised it from 7.68 to 10.75 weeks. In the three quarter of cases the stent complications were manageable endoscopically in both groups: re-ERCP, re-stent implantation or stent replacement were performed. There was no difference in the total cost of treatment of malignant biliary obstruction between the two groups ($p = 0.848$). If the patients' survival time was more than two months, the cost-effectiveness of SEMS was better than plastic stents.

Conclusion: Considering the cost of treatment, the burden of patients and health care system we recommend the SEMS implantation if the life expectancy of patients is more than two months. In short survival cases or if the SEMS not available the multiple plastic stent implantation is recommended.

P0072 GALLBLADDER CARCINOMA: THE 6 YEARS EXPERIENCE OF A TERTIARY REFERRAL CENTER

A. Peixoto[1], M. Silva[1], P. Pereira[1], G. Macedo[1]
[1]*Gastroenterology, Centro Hospitalar de São João, Porto, Portugal*

Contact E-mail Address: armandoafp5@gmail.com

Introduction: The gallbladder carcinoma is an uncommon neoplasm but often fatal, with a high geographical variability in relation to its incidence.

Aims & Methods: The authors propose to evaluate the clinical and pathological aspects of this neoplasm and its relation with cholelithiasis, as well as its prognosis. Retrospective analysis of patients with diagnosis of gallbladder cancer between 2008-2013, in a referral tertiary center.

Results: We included 44 patients (68% women), with a median age of 70 years. The median time of follow-up was 6 months, with a mortality rate of 71% ($n = 31$). The majority of patients (61%) had history of cholelithiasis and 46% were diagnosed after cholecystectomy (35% of these in the context of acute cholecystitis). The most common symptoms reported at admission were abdominal pain (59%), jaundice (41%), and nausea/vomiting (34%). The majority of the patients had slight cholestasis in laboratorial analysis. The neoplasms involved the gallbladder body or were panvesicular in 77% of cases. A non-specific adenocarcinoma was the most common diagnosis (86%), with a median size of 33mm. At diagnosis, 84% were in an advanced stage (III/IV). A surgery of curative intent was performed in 59% of patients. The palliative approaches more frequently used were percutaneous drainage (39%) and chemorradiotherapy (27%). An endoscopic drainage was performed only in 6 patients (14%). The mortality rate at 3, 6, 12 and 24 months was 23%, 39%, 55% and 66%, respectively. The presence of cholestasis ($p = 0.036$) and renal dysfunction ($p = 0.012$) at diagnosis correlated independently with early mortality.

Conclusion: The gallbladder carcinoma was more prevalent in women with advanced age, in many cases with prior cholelithiasis and in an advanced stage at diagnosis. Adenocarcinoma was the most common histological type. Despite the high rate of surgical approaches for curative intent, 66% did not survive beyond 2 years after the diagnosis.

P0073 DIRECT RETROGRADE CHOLANGIOSCOPY-DIRECTED BIOPSY IS SUPERIOR TO FLUOROSCOPY-GUIDED BIOPSY TO DIFFERENTIATE INDETERMINATE BILIARY STRICTURE IN THE DISTAL COMMON BILE DUCT, BUT NOT IN THE PORTA HEPATIS

D. Walter[1], M. Friedrich-Rust[1], S. Zeuzem[1], J. Albert[1]
[1]*Medical Department 1, University hospital Frankfurt, Frankfurt, Germany*

Contact E-mail Address: dirk.walter@kgu.de

Introduction: Differentiation of indeterminate biliary stricture (IBS) by imaging modalities is limited. Definite diagnosis is based on histopathology, but high rates of false negative biopsies constrain the clinical management.

Aims & Methods

Aims: To investigate reason of high false negative results of intraductal biopsies obtained under fluoroscopic guidance in comparison to direct retrograde cholangioscopy (DRC).

Methods: All patients were retrospectively included who presented for diagnostic workup of IBS at our University hospital and who underwent an intraductal biopsy between 2009 and 2015. Histopathological results of fluoroscopic vs DRC-directed intraductal biopsies were compared with the golden standard of either postoperative histology or follow-up of at least one year and underlying disease of false negative biopsies in proximal and distal biopsies was compared.

Results: 106 patients were included in this study. IBS was evaluated by fluoroscopy-guided biopsy in 68 patients and by DRC-directed biopsy in 38 patients. A malignant stenosis was diagnosed in 47/106 cases (44.3%). Sensitivity and specificity for fluoroscopy guided and DRC directed biopsies were 46% and 100% vs. 58% and 100%, respectively. Underlying disease in the 24 false negative histological diagnoses was cholangiocarcinoma (CCA, 14/24, 58%), adenocarcinoma of the pancreatic head (PC, 7/24, 29%) and others (3/24, 13%). Majority of false negative samples was in distal biopsies (19/24, 79%), where etiology was mainly CCA (9/20, 45%) and PC (7/20, 37%). Etiology in false negative biopsies in the hilar region was only CCA (n = 5, 100%). DRC directed biopsy correctly detected all PC (2/2, 100%) compared to 2/9 PC (22%) found by fluoroscopy guided biopsy and 4/8 CCA (50%) compared to 6/16 CCA (37.5%), respectively.

Conclusion: DRC is superior to fluoroscopy in distinguishing ductal infiltration from external common bile duct compression, e.g. in PC, and might be preferred to direct intraductal biopsies.

Introduction: ERCP is unsuccessful in 10% of the cases of biliary obstruction. Previously, percutaneous transhepatic drainage was the only alternative. Recently, endosonography (EUS) –guided drainage was suggested as an alternative. However, the technique is still in evolution

Aims & Methods

Aim: To assess the efficacy and safety of different techniques in EUS-guided biliary drainage.

Patients and Methods: We collected the data of 59 patients treated over 46 months. The data included baseline characteristics, indications, techniques, success rates and complications. Patients were classified according to the different types of approaches shown in Table. In the first 41 months, we used tapered ERCP catheter, and in case it fails, needle-knife sphincterotomy for inital tract dilation and plastic or metal stents eventually. For the last five months, we revised our technique so that we used exclusively 6F cystotome. We preferred CDS over HGS in distal obstructions in long-scope position.

Results: The overall results and the results after it was broken down to previous 41 months (group B) vs. the last 5 months (group A) are shown in Table 1. Work volume was 0.97 patient per month in group B vs. 3.8 in group A ($p < 0.05$). There was no significant difference between the groups for any indication (NS). Technical success rate in group A was significantly higher in group A (p: 0.046) and complication rate was lower ($p = 0.045$).

Conclusion: Experience, volume of the centre and the initial tract dilation technique and use of metallic stent are the most important determinants of success and complications in EUS-guided biliary drainage.

Introduction: Statins are cholesterol-lowering medications and are associated with a number of signaling pathways involved in carcinogenesis. Recent observational studies raised the possibility that the use of statins may reduce the overall mortality in various types of cancer. We investigated whether statins used after pancreatic cancer diagnosis reduce the pancreatic cancer mortality in patients with pancreatic cancer.

Aims & Methods: We analyzed data on 2981 patients newly diagnosed with pancreatic cancer between January 1, 2006 and December 31, 2014. We used the Cox proportional hazards regression model to estimate mortality among pancreatic cancer patients according to statin use.

Results: Among the 2981 patients, 428 pancreatic cancer patients had used statins. During the study period, 1616 patients (54.2%) died. After adjustment for age, sex, tumor characteristics, DM, dyslipidemia, BMI, and tumor marker, statin use was associated with lower risk of pancreatic cancer death (HR, 0.821; 95% Confidence interval, 0.716 – 0.941), especially among simvastatin users (HR, 0.620; 95% Confidence interval, 0.448 – 0.858). Subgroup analysis showed that patients who used simvastatin in non-resectable pancreatic cancer had more favorable outcomes than patients with resectable pancreatic cancer.

Conclusion: We found that the use of statins after cancer diagnosis is associated with longer survival in patients with pancreatic cancer. This effect was stronger in patients who used simvastatin in advanced pancreatic cancer.

Introduction: Gallbladder cancer (GBCa) is one of the most difficult to treat cancers in the field of gastroenterology. To achieve good treatment effect in future, so called "custom-made" therapy based on the character of the each tumor is mandatory. However, GBCa tissue cannot be obtained easily. In this study, we try to elucidate the possibility of "liquid biopsy" with bile juice on the concept of non- invasive diagnostic method as circulating tumor DNA in blood.
Aims & Methods: Eleven patients with GBCa enrolled in this study. Surgically removed tumors and their surrounding normal tissue were analyzed for mutations of 48 oncogenes (Cancer panel; Haloplex, Agilent Technology) by next generation sequencing (NGS; Illumina, San Diego, CA, USA) in all patients. Bile juice obtained from 6 of 11 patients prior to the treatment was examined simultaneously. As negative controls, additional 2 healthy gallbladder tissue samples were analyzed.
Results: We set cut-off value at 3% for rare mutation rate. TP53 mutation was detected in 2/11 (18.2%) of the tumor tissue. Mutations of CTNNB1, MET, AR were detected in 1/11 (9%), 1/11 (9%), 1/11 (9%) samples, respectively. In these mutation-positive samples, more than 10% of the DNA was mutated in 23.8% of TP53 (E153K), 15.9% of TP53 (R148K) and 29.7% of CTNNB1 (T41I). None of the corresponding normal tissues and controls had any mutations. Interestingly, we could detect the same TP53 mutation even in bile juice as liquid biopsy in patients who had TP53 mutation in tumor tissue (2/2; 100%).
Conclusion: Tumor DNA in bile juice could be detected by NGS. It may allow us to make a new genetic diagnosis of GBCa.

Introduction: Several single-arm studies demonstrated the feasibility of metallic stent (MS) in the management of the malignant hilar biliary strictures (HBS). However, the efficacy of the bilateral MS deployment to the malignant HBS has not been compared and discussed with those of unilateral MS deployment yet.
Aims & Methods: We conducted the multi-center prospective randomized study to investigate the clinical significance of the bilateral MS deployment to the patients with malignant HBS caused by unresectable biliary tract carcinoma (BTC) (UMIN000005182). To exclude the possibility to include the patients who absolutely needed bilateral stenting, the patients with HBS due to pathologically confirmed unresectable BTC were subjected to the unilateral biliary decompression before MS deployment. The patients whose unilateral portal blood flow was lost due to tumor invasion were also excluded. The biliary branch to be drained first was that which drained the most part of the liver under the CT or MR imaging. After confirming the improvement of the liver function, the patients gave informed consent and were randomly allocated to the endoscopic unilateral or bilateral MS deployment. The MS which was employed in this study is Zeostent (Zeon Medical, Tokyo, Japan). The patients who were allocated to the bilateral stenting (BS) had two MS deployed in the initially inserted branch and the branch of the contralateral lobe using the endoscopic partial stent-in-stent procedure. The patients who were allocated to the unilateral stenting (US) had one MS deployed in the initially selected branch. The primary endpoint is the stent-functioning (SF) time, the definition of which is the time from the MS deployment to the stent dysfunction which necessitates the biliary interventions. The data was analyzed based on the intention-to-treat.
Results: Between April 2011 and March 2014, 86 patients with BTC were enrolled in this study. After excluding 7 patients due to patients' refusal, death before stenting, breach of protocol or misdiagnosis, 40 patients were randomly allocated to the BS group and 39 patients to the US group. The procedure success rate was 93% (37/40) in BS group and 100% (39/39) in US group (ns). The early pancreatobiliary complication rate was 25% (10/40) in BS group and 23% (9/39) in US group (ns). The mean survival time was 237 days in BS group and 236 days in US group (ns). The mean SF time was 295 days in BS group and 187 days in US group (ns, $p = 0.075$). The biliary re-intervention was successfully performed on both groups. Other late complications were noted in US group only.
Conclusion: Judging from these data, it is suggested that the bilateral MS deployment is the procedure to try first for the patients with HBS due to unresectable BTC.

Introduction: Endoscopic transpapillary brush cytology and forceps biopsy are used widely for the pathological diagnosis of malignant biliary strictures (MBS). However, the diagnostic yield remains unclear because of the wide variation in reported values, and predictive factors for a positive diagnosis using these methods have not been established.
Aims & Methods: We aimed to clarify the diagnostic yields of the two methods and predictive factors for a positive diagnosis.
We reviewed 241 patients with biliary strictures who underwent transpapillary brush cytology ($n = 202$) and/or forceps biopsy ($n = 208$) between 2004 and 2014 at a single academic center.
Results: The sensitivity of forceps biopsy for MBS was significantly higher than that of brush cytology (60.6% [97/160] vs. 36.1% [57/158]; $P < 0.001$). The sensitivity of forceps biopsy was significantly higher in bile duct cancer than pancreatic cancer (82.0% [50/61] vs. 42.4% [28/66]; $P < 0.001$). Multivariate analysis revealed that a serum total bilirubin level (T-Bil) ≥ 4 mg/dL (OR: 2.51, 95% CI: 1.14-5.50; $p = 0.022$) was a significant independent predictive factor for a positive diagnosis by brush cytology, and bile duct cancer (OR: 4.93, 95% CI: 2.18-11.11; $p < 0.001$), length of stricture ≥ 30 mm (OR: 2.94, 95% CI: 1.12-7.75; $p = 0.029$), and T-Bil ≥ 4 mg/dL (OR: 2.25, 95% CI: 1.05-4.83; $p = 0.037$) were significant indicators of a positive diagnosis by forceps biopsy.
Conclusion: Endoscopic transpapillary forceps biopsy showed higher sensitivity than that of brush cytology for MBS. Bile duct cancer, length of stricture ≥ 30 mm and T-Bil ≥ 4 mg/dL are good indicators of a forceps biopsy.

P0079 COPPER DEFICIENCY RESULTS IN PANCREATIC STELLATE CELLS ACTIVATION WITHOUT THEIR TRANSDIFFERENTIATION INTO MYOFIBROBLASTS

A. Galyavieva[1,2], A. Abdulkhakova[1], A. Trondin[1], G. Pevnev[2], M. Mavlikeev[2], S. Abdulkhakov[1,2], A. Gumerova[2], A. Kiassov[2]
[1]*Kazan State Medical University,* [2]*Kazan (Volga region) Federal University, Kazan, Russian Federation*

Introduction: Pancreatic stellate cells (PSCs) are supposed to play an important role in pancreatic fibrogenesis. However as they are quite common with hepatic stellate cells their role in pancreatic regeneration couldn't be excluded.
Aims & Methods: The aim of our work was to study the role of PSCs in pancreatic tissue regeneration in rat copper-deficient diet model.
24 white Wistar male rats (80-100 g weight) were maintained on copper-deficient diet (MP Biomedicals, USA) containing a relatively non-toxic copper-chelating agent, triethylenetetramine tetrahydrochloride (Tokyo Chemical Industry Co., Ltd, Japan) in final concentration of 0.6% w/w for 8 weeks, and then returned to normal rat chow for another 8 weeks (recovery phase). Animals of control group were maintained on normal rat chow for the whole duration of experiment.
Groups of 3 animals each were killed after 2, 4, 6, and 8 weeks of copper-deficient diet and 2, 4, 6, and 8 weeks of recovery phase. Paraffin sections of pancreas were stained immunohistochemically using antibodies to desmin, a marker of PSCs, and alpha smooth muscular actin (a-SMA), a marker of myofibroblasts, which are supposed to be involved in pancreatic fibrogenesis.
Results: Signs of pancreatic acinar tissue injury were observed in rats after 4 weeks of copper-deficient diet. After 6 and 8 weeks of copper deficiency tissue was almost totally destroyed, however, few ducts and islets were still present; the similar pattern was observed 2 and 4 weeks after animals were returned to normal rat chow. Partial restoration of acinar tissue was observed by the 6 and 8 weeks of recovery phase.
Staining with antibodies to desmin revealed single desmin-positive cells located mainly around the blood vessels in control group animals. Similar results were found after 2 and 4 weeks of copper-deficient diet.
After 6 weeks of a diet intensive colouring of desmin-positive cells on periphery of islets was noted, the number of desmin-positive cells in acinar tissue increased. After 8 weeks of copper-deficient diet some desmin-positive cells located around blood vessels and ducts were observed along with the more intensive colouring of islet cells.

After rats were transferred to normal rat chow the number of desmin-positive cells slightly decreased. Along with the pale colouring of islets few desmin-positive stellate-shaped cells were found in islets and on the border of the existing islets and newly formed acinar tissue.
Staining with antibodies to a-SMA revealed only smooth muscle cells of blood vessels for the whole duration of the experiment.
Conclusion: The increased number of PSCs in areas of the newly formed acinar tissue probably reflects their participation in pancreas regeneration. However PSCs activation doesn't result in their transdifferentiation into myofibroblasts thus not increasing the risk of pancreatic fibrosis.
Disclosure of Interest: None declared

P0080 PANCREATIC ISLET CELLS COULD BE THE SOURCE OF PANCREAS RESTORATION IN COPPER-DEFICIENT MODEL OF PANCREAS INJURY

A. Abdulkhakova[1], **A. Galyavieva**[1,2], A. Trondin[1], G. Pevnev[2], M. Mavlikeev[2], S. Abdulkhakov[1,2], A. Gumerova[2], A. Kiassov[2]
[1]*Kazan State Medical University,* [2]*Kazan (Volga region) Federal University, Kazan, Russian Federation*

Introduction: Few possible sources of pancreas regeneration including islet cells are discussed in literature.
Aims & Methods: The aim of our work was to study the phenotype of rat pancreatic islets cell in copper-deficient model of pancreas injury.
24 white Wistar male rats (80-100 g weight) were maintained on copper-deficient diet containing a copper-chelating agent, triethylene tetraminetetrahydrochloride, in final concentration of 0.6% w/w for 8 weeks, and then returned to normal rat chow for another 8 weeks. Control group animals were maintained on normal rat chow for the whole duration of experiment.
Groups of 3 animals each were killed after 2, 4, 6, and 8 weeks of copper-deficient diet and 2, 4, 6, and 8 weeks after return to normal rat chow. Paraffin sections of pancreas were stained immunohistochemically with antibodies to cytokeratin 19 (CK19), marker of pancreatic ducts cells, and alpha-fetoprotein (AFP), which is considered to be the marker of hepatoblasts as well as hepatocellular carcinoma cells.
Results: Both large ducts and small ductules between the acini stained with antibodies to CK19 were observed in pancreas sections in control group rats. No positive staining was found in pancreatic islets. Similar results were observed after 2 weeks of copper-deficient diet.
After 4 weeks of diet CK19-positve ducts as well as positive staining in central part of pancreatic islets was noted. After 6 and 8 weeks the number of CK19-positive cells and duct-like structures increased substantially, central part of islets was still CK19-positive.
After rats were transferred to normal rat chow the number of CK19-positive cells and ducts decreased, however, the central part of islets was positive until the end of the experiment.
The presence of CK19-positive cells in pancreatic islets was found recently in pancreas embryogenesis. So we suppose CK19-positive cells could be one of the steps of pancreatic stem cells differentiation in case of tissue recovery after injury.
Staining with antibodies to AFP was negative in normal pancreas as well as after 2 weeks of copper-deficient diet. After 4 weeks of diet solitary AFP-positive cells in acinar tissue were noted. After 6 and 8 weeks both single positive cells and duct-like structures as well as staining of central parts of pancreatic islets were observed.
After rats were transferred to normal rat chow the number of AFP-positive ducts decreased and disappeared by 8th week, the cells of central part of islets remained positive until the end of the experiment.
Our results allow us to suppose that in the case of copper deficiency progenitor cells which could be common for liver and pancreas timely change their phenotype to hepatoblast-like cells, as described by Rao et al. (1989). However there is no possibility of oncogenic transformation as the number of AFP-positive cells decreased by the end of the experiment.
Conclusion: The abovementioned changes of CK19- and AFP-positive cells number allows us to suppose that pancreatic islet cells could be the source of pancreas regeneration. These progenitor cells are probably common for pancreas and liver and under certain conditions can express markers of hepatoblasts.

Contact E-mail Address: vinciane.rebours@bjn.aphp.fr
Introduction: Recently, obesity and metabolic syndrome have been identified as independent risk factors for chronic pancreatitis and pancreatic cancer. Visceral adipose tissue (VAT) of obese patients induces pro-inflammatory cytokines synthesis (TNF-α, IL- 6, adiponectin, leptin) known to be involved in pancreatic fibrogenesis by the activation of pancreatic stellate cells (PSC).
Aims & Methods
Aim: To study interactions between VAT from obese patients and ex-vivo pancreatic parenchyma by developing a co-culture model
Methods: We developed a 3D co-culture model. A slice of normal pancreas (300 µm) was cultured with 0.4g of VAT from obese patients embedded in a collagen gel layer. Culture was realized under normoxemic conditions (21% O2) and incubation time ranged from 24h to 48h. Morphological analysis of pancreas and VAT were performed at baseline, 24h and 48h. Cell differentiation (CK7, insulin), apoptosis (caspase 3), proliferation (Ki-67) and PSC activation (smooth muscle actin (SMA)) were assessed using immunostaining. Adiponectin and leptin were measured by ELISA method in the culture media. Control experiments were pancreas slice culture and VAT culture alone.
Results: 11 co-cultures were performed: 3 for 24h, 8 for 48h. Pancreatic necrosis at 24h and 48H were 30% [0- 70] and 37% [5-100] for pancreas culture versus 44% [0-80] and 62% [10- 100] for co-cultures, respectively. Necrosis was higher at 48h in co-cultures ($p = 0.024$). In co-cultures, we observed an increase of 1/ SMA expression in PSC, 2/ number of duct cells in apoptosis or proliferation, 3/ insulin expression in the Langerhans islets. Leptin and adiponectin concentrations were high in VAT culture and very low in pancreas culture. After 24h of co-culture, adiponectin concentration decreased in co-cultures compared to VAT culture ($p = 0.016$). At 24h and 48h of co-culture, leptin concentration compared to VAT culture decreased ($p < 0.05$).
Conclusion: This model is the first co-culture model between VAT and human pancreas tissue. It validated the lipotoxic role of VAT from obese patients on pancreatic tissue by altering pancreatic cells population (duct cells, Langerhans islet, PSC). It obtained reproducible results and was able to underline the interactions between these two tissues through the cytokines secretions. This new method could permit to clarify the physiopathology of obesity and metabolic syndrome in pancreatic diseases.

P0082 PANCREATIC EXOCRINE FUNCTION IN PATIENTS WITH TYPE 2 DIABETES MELLITUS

D. Illés[1], G. Zsóri[1], V. Terzin[1], G. Holzinger[2], K. Kosár[2], L. Czakó[1]
[1]*First Department of Internal Medicine,* [2]*University of Szeged, Szeged, Hungary*

Contact E-mail Address: olionx@gmail.com
Introduction: An exocrine pancreatic insufficiency has been demonstrated to be present in about 50% of type 1 and 30- 50% of type 2 diabetes mellitus (T2DM) cases. However, the significance of an exocrine pancreatic dysfunction in DM has recently been questioned.
Aims & Methods: The aim of our study was to assess the prevalence of exocrine pancreatic dysfunction in T2DM.
Methods: Consecutive patients with type 2 DM treated in our clinic were prospectively recruited into the study. Exocrine pancreatic insufficiency was diagnosed by fecal elastase-1 (FE1) determination. All patients underwent abdominal ultrasound and pancreatic diabetes cases were excluded.
Results: One hundred eighty four patients (91 male, 93 female, mean age 61.74 ± 17 years) were recruited in the study. FE1 was abnormal in 37 patients, 12 patients had non-insulin treated T2DM and 25 patients insulin-treated T2DM. The severity of exocrine insufficiency was mild in 29 and severe in 8 patients. The FE1 level was not correlated with HbA1c ($p = 0.487$), the duration of DM ($p = 0.88$), age ($p = 0.907$), BMI ($p = 0.157$), pancreatic steatosis ($p = 0.528$) or the presence of microvascular complications of DM ($p = 0.465$).
Conclusion: Exocrine pancreatic insufficiency is less frequent in type 2 DM, than in previous study, probably because pancreatic diabetes cases were excluded. Exocrine pancreatic insufficiency was not associated with the duration of DM, BMI, HbA1c level, pancreatic steatosis or the presence of microvascular complications of DM.

P0083 BETAINE ATTENUATES ALCOHOLIC PANCREATIC STEATOSIS THROUGH DOWN-REGULATION OF STEROL REGULATORY ELEMENT BINDING PROTEIN-1C

W.-J. Yang[1], J. Li[1], **J.-H. Gao**[1], Z.-Y. Huang[1], C.-W. Tang[1]
[1]*Department of Gastroenterology, West China Hospital, Sichuan University, Chengdu, China*

Contact E-mail Address: yangwenjuan19860@163.com
Introduction: Growing studies have shown that chronic alcohol consumption caused pancreatic steatosis. However, medical interventions for alcoholic pancreatic steatosis have not been extensively investigated. Betaine was found to alleviate alcoholic fatty liver disease in multiple studies. In the present study, we investigated the effect of betaine on alcoholic pancreatic steatosis and its mechanism.
Aims & Methods: 45 male Wistar rats were randomized into control, alcohol and alcohol + betaine group with 15 animals in each group. Rats in the three groups were given free access to distilled water, ethanol (25%, v/v) and ethanol (25%, v/v) plus betaine (1%, w/v), respectively, for six months. Morphological changes of the pancreatic acinar cells were identified by hematoxylin-eosin staining, oil red O staining and transmission electron microscope. Pancreatic triglyceride (TG) and total cholesterol (TC) contents were measured by enzymatic colorimetric assay. Serum adiponectin levels were determined by enzyme-linked immunosorbent assay. The protein and mRNA expression of pancreatic adiponectin receptor-1 (AdipoR1), AdipoR2, sterol regulatory element binding proteins-1c (SREBP-1c), and SREBP-2 were determined by immunohistochemistry (IHC), Western blot (WB) and quantitative real-time PCR (qRT-PCR). The effect of betaine (168 mmol/L) and/or adiponectin (0.5 µg/mL) on SREBP-

1c expression in ethanol-treated (100 mmol/L) SW1990 pancreatic adenocarcinoma cells was also assessed by WB and qRT-PCR.
Results: Alcohol-induced morphological changes of the pancreatic acinar cells, including lipid droplets, swelling mitochondria and reduced zymogen granules, were attenuated after betaine treatment. Compared with control group, pancreatic TG level in ethanol group was markedly increased by 90.5% ($P<0.01$). Interestingly, betaine treatment dramatically reduced pancreatic TG level of alcoholic rats by 39.3% ($P<0.05$). However, pancreatic TC content was similar among the three groups ($P>0.05$). Serum adiponectin level in alcohol-fed rats was significantly decreased by 66.5% ($P<0.01$) when compared to that in control group and was greatly increased by 148.6% after treatment with betaine ($P<0.01$). Immunohistochemical staining showed that pancreatic AdipoR1 expression was dramatically down-regulated after ethanol exposure and was up-regulated to control level after betaine treatment. Moreover, pancreatic SREBP-1c expression was elevated in alcohol group but remained at control level after treatment with betaine. Nevertheless, no significant difference was shown in pancreatic AdipoR2 and SREBP-2 expression by IHC among the three groups. The immunohistochemical staining results were further confirmed by qRT-PCR and WB. *In vitro*, betaine or/and adiponectin significantly suppressed up-expression of SREBP-1c induced by ethanol with the maximum inhibitory effect achieved when they were given in combination.
Conclusion: Betaine attenuated alcohol-induced pancreatic steatosis probably by suppressing SREBP-1c activation and this effect of betaine was partly attributed to the restoration of pancreatic adiponectin signaling as well as the direct action of betaine on pancreatic SREBP-1c.

Introduction: Our previous results showed that high concentration of chenodeoxycholate (CDC) strongly inhibits ion transporters via destruction of mitochondrial function in guinea pig pancreatic ductal epithelial cells (PDECs). Ursodeoxycholic acid (UDC) has been reported to protect mitochondria against hydrophobic bile acids and have antiapoptotic effect.
Aims & Methods: The aim of this study was to investigate the effect of UDC on CDC-induced cell damage.
Intra-interlobular ducts were isolated from the pancreas of guinea pig. Ducts were then pretreated with UDC (0.1 mM and 0.5mM) for 5 h and 24 h and changes in intracellular Ca^{2+}concentration $[Ca^{2+}]_i$, ATP level $[ATP]_i$, pH $[pH]_i$ and mitochondrial permeability transition pore (MPTP) opening were measured by microfluorometry. Mitochondrial transmembrane potential (MTP) was studied by confocal microscopy. Expressions of bile acid transporters were analysed by reverse transcriptase PCR (RT-PCR). Morphological changes of mitochondria were investigated by transmission electron microscopy. We also developed a CDC induced pancreatitis model in rats. Rats were fed with 250 mg/kg UDCA for 2 weeks then pancreatitis was induced by intraductal administration of 0.1% CDC.
Results: 5 h pretreatment with 0.1 or 0.5 mM UDC and 24 h pretreatment with 0.1 mM UDC did not significantly influence the effect of 1 mM CDC on duct cells. However, 24 h pretreatment with 0.5 mM UDC significantly reduced the rate of ATP depletion, mitochondrial injury, MPTP opening and the decrease of MTP induced by 1 mM CDC. In addition, 0.5 mM UDC prevented the inhibitory effect of CDC on the acid-base transporters, however, had no effect on the CDC-induced calcium signaling. mRNA expression of Slc10A1 and A2 was detected in the ducts by RT-PCR. Animal experiments showed, that UDCA fed group had less severe pancreatitis in CDC induced pancreatitis model.
Conclusion: Our results indicate that UDC administration protects the bile-induced mitochondrial injury which may represent a novel therapeutic option in pancreatitis.

Contact E-mail Address: drocesar@gmail.com
Introduction: Human pancreatic cancer/PCa and chronic pancreatitis/CP are characterized by neural hypertrophy, neural sprouting, and reduced sympathetic innervation. However, our knowledge on the innervation of current murine models of PCa and CP and even of normal mouse pancreas is very scarce.
Aims & Methods: In this study, we aimed to systematically analyze the structure, distribution and quality of nerves in the mouse pancreas. Whole pancreata derived from 6-8-week-old C57BL/6J mice (n = 10) were paraffin-embedded and entirely sectioned into 3µm consecutive sections from the anterior to the posterior/retroperitoneal plane. All sections were immunostained with the pan-neural-marker PGP 9.5, with the sensory fibre markers substance-P/SP and calcitonin-gene-related-peptide/CGRP and were subject to systematic morphometric analysis.
Results: Nerves enter the mouse pancreas around pericapsular lymphoid structures and penetrate into the tissue along vessels and interlobular septae. The size and the density of nerves in the pancreatic head and corpus were significantly greater than in the pancreatic tail. The majority of nerves were localized in the anterior and posterior surface of the head and the anterior surface of the corpus. The proportion of sensory fibres was ca. 8% of all nerve fibres in the mouse pancreas and did not vary between the head, corpus and tail. 74% of sensory fibres were localized in the pancreatic head, 19% in the corpus and 7% in the tail.
Conclusion: Murine pancreatic head has the highest density of pancreatic nerves. Overall, due to its intraperitoneal and perilymphoid localization, the mouse pancreas bears a substantially different structural innervation pattern when compared to the human pancreas.

Introduction: Smoking represents an independent risk factor for the development of chronic pancreatitis (CP). It is well documented that secretion of pancreatic ductal alkaline fluid (which is regulated mostly by the anion exchanger and CFTR) is diminished in CP. In this study we would like to understand whether smoking has any effects on pancreatic ductal fluid and HCO_3^- secretion.
Aims & Methods: Intra/interlobular pancreatic ducts were isolated from guinea pig pancreas. Cigarette smoke extract (CSE) was prepared by smoking of 30 cigarettes into 20ml distilled water by a smoking machine. Three different doses (20, 40 and 80µg/ml) were diluted using the stock solution. Basal and forskolin-stimulated fluid secretion was measured by video microscopy. Intracellular pH and Ca^{2+} concentration were evaluated by microfluorometry. Luminal anion exchange activity was determined by the chloride withdrawal technique using microperfusion. CFTR currents were detected by whole-cell configuration of patch clamp technique.
Results: CSE dose dependently decreased forskolin-stimulated fluid secretion in guinea pig pancreatic ducts, bicarbonate secretion (20µg/ml by 17.3%, 40µg/ml by 40.5%) and forskolin-stimulated Cl^- current of CFTR Cl^- channel (20µg/ml by 44.5%, 40µg/ml by 69.3% and 80µg/ml by 81.3%). Moreover, CSE induced dose-dependent intracellular calcium elevation suggesting that some of the inhibitory effects may be regulated by calcium signalling.
Conclusion: CSE inhibits pancreatic ductal fluid and HCO_3^- secretion and the activity of the CFTR which may play role in the smoke-induced pancreatic damage. This study was supported by OTKA, MTA and NFÜ/TÁMOP.

Introduction: Serotonin (5-hydroxytryptamine, 5-HT) is a potent bioactive molecule, which regulates zymogen secretion in pancreatic acinar cells and inhibits pancreatic ductal epithelial secretion. Recently it was demonstrated that tryptophan hydoxylase-1 (TPH-1) knock-out mice, which lack peripheral 5-HT, develop less severe acute pancreatitis (AP) compared to wild type (WT) controls. Decreased pancreatic fluid and bicarbonate secretion can lead to more severe AP, however the pancreatic ductal secretion of TPH-1 knock-out mice has not been evaluated, which might contribute to the protection against AP.
Aims & Methods: Our aim was to evaluate the pancreatic ductal secretion in TPH-1 knock-out and WT mice.
Intra/interlobular pancreatic ducts were isolated from the pancreas of TPH-1 knockout and WT mice. *In vitro* pancreatic ductal fluid secretion has been evaluated using videomicroscopy. Bicarbonate secretion of pancreatic ductal epithelial cells was measured by microfluorimetry.
Results: *In vitro* pancreatic ductal fluid secretion was significantly elevated in TPH-1 knock-out mice compared to WT controls. Basolateral administration of 20mM NH_4Cl revealed that the activities of the apical Cl^-/HCO_3^- exchanger (CBE) and the basolateral Na^+/HCO_3^- cotransporter and Na^+/H^+ exchanger were significantly elevated in TPH-1 knock-out mice. The acidification caused by basolateral administration of dihydro-4,4'-diisothiocyanostilbene-2,2'-disulfonic acid (H_2DIDS) and amiloride was markedly increased in TPH-1 knock-out mice confirming the increased activity of the apical HCO_3^- secretion. The administration of serotonin significantly decreased the activity of the acid/base transporters in TPH-1 knock-out and WT ductal epithelial cells. As a further step we provided evidence that the Cl-/HCO3- exchanger is crucially important in the elevated ductal secretory process important in the elevated ductal secretory processesion, since. T the rate of pHi recovery was significantly elevated in TPH1-/- mice from the intracellular alkalization-caused byafter Cl-withdrawal from the lumeinal space of the microperfused pancreatic ducts
since the rate of pHi recovery significantly elevated in TPH1-/- mice from the intracellular alkalization-caused by Cl- withdrawal from the luminal space of the microperfused pancreatic ducts.
Conclusion: These findings indicate that the fluid and bicarbonate secretion is significantly increased in the absence of serotonin, which might contribute to the decreased severity of AP in TPH-1 knock-out mice.

Introduction: The IAP/APA evidence-based (EBM) guidelines for the management of acute pancreatitis(AP) have been published in 2013. Unfortunately in many countries, especially in Eastern and Central Europe, it has not been translated to national languages and no EBM guidelines are available so far. The Hungarian Pancreatic Study Group (HPSG) has established a national registry in 2011 for prospective data collection of patients suffering from different pancreatic disorders,including AP.
Aims & Methods: Our aim was to summarize the Hungarian cohort and importantly, assess and validate the usefulness of the IAP/APA guidelines. 580 patients with AP have been enrolled from 23 centers.
Results: The diagnosis of AP was made according to the 2/3 rule. 322 males and 258 females with mean age of 58.4 ± 16.5 were enrolled.The most common cause of AP was biliary disease (44%)followed by regular alcohol consumption or dietary mistake (26%). 61.9% of the patients had mild, 29.6% moderate, whereas 8.5% severe pancreatitis. Concerning the intravenous fluid therapy, only 41% of the patients received 2500-4000 ml of fluids during the first 24 hours.The mortality was only 0.51% in this group, however, it was increased by 4 times among those patients who received either more or less fluid. In terms of the enteral feeding, 31% of patients with severe pancreatitis did not receive it. The mortality rate in this group was unacceptably high(42.9%) compared to those patients who received the right treatment(19.3%).
Conclusion: Proper utilization of the IAP/APA EBM guidelines could save thousands of lives. It is vitally important to make the guidelines available in all languages of the countries.

Introduction: Acute pancreatitis (AP) is characterized by a wide range of clinical courses, varying from interstitial edema to pancreatic necrosis. This determines the relevance of simple and fast criteria for early detection of the disease severity.
Aims & Methods: The aim is to determine the effectiveness of rating scales for early stratification of AP. The severity of patient's condition was estimated in 24 hours with the help of such rating scales as BISAP, HAPS, SOFA, SIRS, US scale [1]. The severity of AP was detected in accordance with the classification of Atlanta 2012 in 48-72 hours. Balthazar-Ranson scale was used at the same time period. ROC-analysis of the scales was performed with the calculation of the area under the operating characteristic curve (AUC).
Results: There were 61 patients with AP (mean age 44.0 ± 1.7, 57.3% male), of which 24.7% were classified as mild, 34.4% as moderate & 40.9% as severe. Determination of mild AP according to the BISAP ≤ 1 и US scale ≤ 3 was characterized by high accuracy (AUC (95% confidence interval) 0.77 (0.66–0.87) & 0.90 (0.82–0.98) respectively), sensitivity (71.1 & 81.0% respectively) and negative predictive value (48.0 & 66.6% respectively). The scales HAPS ≤ 1, SOFA ≤ 3 and SIRS ≤ 1 had smaller AUC ($p < 0.05$) (0.62; 0.62 & 0.66 respectively), lower quality of determining of mild AP (60.0; 68.8 & 51.1% sensitivity respectively). They also had smaller negative predictive value (35.7; 36.6 & 35.2% respectively).
Conclusion: The BISAP scale and US scale are reliable methods for early detection of mild AP (in 24 hours). Their high positive prognostic values (81.6 & 88.8%) allow to identify on early stage the patients that are not needed intensive care. This could save significant costs for the hospital.

Introduction: Acute pancreatitis (AP) varies from mild, to moderately-severe and severe forms, the last with complications and high mortality rate. Knowledge of its natural course and recurrence is limited.
Aims & Methods: The aim of this study was to evaluate the severity pattern of recurrent AP and compare the clinical outcomes to those with a single episode. We performed a retrospective study on 1079 patients (58.7% male, 41.3% female) with mean age of 55 ± 16 years old admitted in our unit from 2006 to 2014 with acute pancreatitis. We compared patients with recurrent AP to those who had a single episode. We looked to the mortality, the severity of AP, the trend of the recurrences and made an overview analysis.
Results: In the 9-year analysis, 995 patients (92.2%) were admitted with a single episode of AP and 84 (7.8%) patients had a recurrent form. The readmissions varied from 2 episodes in most cases (78.5%) to 3(13.1%), 4 (4.8%), 5(1.2%) and 6 episodes (2.4%). The severity pattern for the majority of AP readmission was mostly unchanged, 70% of them presented at recurrences a similar form with the initial episode, 14% had a worse outcome and 16% had a milder form. The mortality rate in patients experiencing a single episode of AP was 3.7%, as compared to 0% in patients with recurrent AP ($p = 0.0096$). Recurrent episodes of AP seem to be protective against multiple organ failure (odds ratio 0.056, 95% CI 0.0034-0.928, $p = 0.0442$). Regarding the etiology, in patients that had only 2 recurrences the most common cause was biliary (50.7%) followed by alcohol (33.8%) and other etiologies (15.5%) whereas in patients with 3 or more recurrences, the predominant cause was alcohol (66%) as compare to non-alcoholic etiologies (33%).
Conclusion: Patients that have recurrent form of AP seem to have lower risk of clinically severe course. The severity pattern remains stable in most cases of recurrent AP. Furthermore, the mortality of these patients seems to be lower as compared to that of patients with a single episode of AP.

P0091 IMIPENEM PROPHYLAXIS FOR PREDICTED SEVERE ACUTE PANCREATITIS - PRELIMINARY RESULTS OF A RANDOMIZED CLINICAL TRIAL

G. Poropat[1], V. Giljaca[1], V. Licul[1], G. Hauser[1], S. Milic[1], D. Stimac[1]
[1]*Department of Gastroenterology, University Hospital Rijeka, Rijeka, Croatia*

Introduction: Infected necrosis is a serious complication of acute pancreatitis leading to a mortality rate of about 40%[1]. Although prophylactic antibiotics are not recommended, meta-analytic data show that imipenem significantly reduces the rate of infected necrosis[1].
Aims & Methods: The aim of our study is to evaluate the prophylactic use of imipenem in patients with predicted severe acute pancreatitis. We conducted a prospective randomized trial in a tertiary care setting in Rijeka. Patients with AP and an APACHE II ≥ 8 were randomized to receive either imipenem 500 mg i.v. three times daily for the first ten days or an identical placebo. Exclusion criteria included age < 18 years, any infection present at admission, chronic pancreatitis, active malignancy, immunodeficiency, post-surgical patients, pregnant and breastfeeding women and patients unwilling to participate in the study. All patients received early enteral nutrition administered via a nasojejunal tube. Concomitant treatment was similar in both groups. All patients had an abdominal CT scan performed between days 3 to 7, and in cases of clinically suspected infected pancreatic necrosis.
Results: Forty-seven consecutive patients were randomized. Twenty-three received imipenem and 24 received placebo. Three patients died in the imipenem group, while two patients died in the placebo group ($p = 0.667$). There were no differences in the occurrence of infected necrosis, with 2 vs. 3 cases, respectively. Other local complications were present in 7 and 13 patients ($p = 0.142$), while persistent organ failure was present in 4 and 5 patients ($p = 1.00$) in the imipenem and placebo group, respectively. Other infection were detected in 2 patients receiving imipenem and 5 patients on placebo ($p = 0.416$).
Conclusion: Preliminary data showed no significant beneficial effects of prophylactic imipenem use in patients with predicted severe acute pancreatitis.

P0092 A SYSTEMATIC REVIEW OF ENTERAL NUTRITION FORMULATIONS FOR ACUTE PANCREATITIS

G. Poropat[1], V. Giljaca[1], G. Hauser[1], D. Stimac[1]
[1]*Department of Gastroenterology, University Hospital Rijeka, Rijeka, Croatia*

Introduction: Acute pancreatitis (AP) is a common disease with increasing incidence. Severe cases are characterized with high mortality and despite improvements in intensive care management, there is still no specific treatment that relevantly benefits clinical outcome.
Aims & Methods: To assess effects of different enteral nutrition (EN) formulations in patients with AP. We conducted searches of Medline, Embase, Central, and SCI-E for RCTs assessing use of a specific EN formula compared to control (other EN formula, TPN, placebo, or no intervention). We assessed the following outcomes: mortality, organ failure, and local septic complications (LSC).
Results: Twenty-five RCTs with a total of 1979 patients were included. Immunonutrition significantly decreased mortality ($P = 0.005$), but subgroup analysis comparing immunonutrition to another EN did not confirm this finding. Probiotics did not confirm any significant effect, however sensitivity analysis by exclusion of one trial with inconsistent results showed decrease in mortality ($P = 0.02$) and LSC ($P = 0.002$), but not organ failure. Semi-elemental EN reduced mortality ($P = 0.002$), organ failure ($P < 0.00001$), and LSC ($P < 0.00001$). Few trials evaluated polymeric and fibre-enriched formulas, showing no significant effect. Any EN compared to TPN confirmed reduced mortality ($P < 0.0001$), organ failure ($P < 0.00001$) and LSC ($P < 0.00001$), and any EN compared to no intervention was associated with lower mortality ($P = 0.01$).
Conclusion: Whether supplementation of EN with potential immunomodulatory agents leads to beneficial effects is still debatable. Studies assessing probiotics yielded inconsistent results, therefore we do not support the routine use of these formulations in clinical practice, but further research is required. EN is significantly more efficient than TPN and no nutritional support.

Introduction: Severe acute pancreatitis which constitutes 20-30% of all acute pancreatitis, may cause pancreatic necrosis, persistent organ failure and mortality. Beginning and progression of acute pancreatitis is accompanied with systemic inflammatory cascade activation and pancreatic microcirculation disturbance. Heparin inhibits inflammatory cascade, and improves pancreatic microcirculation. The purpose of this study is to determine the effect of low molecular weight heparin (LMWH) in the prevention of pancreatic necrosis in severe acute pancreatitis.
Aims & Methods: A total of sixty-eight moderately severe and severe acute pancreatitis patients were randomised to receive conventional therapy or conventional therapy plus LMWH therapy. LMWH was administrated 1 mg/kg by subcutaneous injection two times per day between 1th and 7th days. Revised Atlanta criteria are used in the diagnosis. Imrie Score, HAPS (Harmless Acute Pancreatitis Score), Balthazar computed tomography (CT) score are evaluated. Patients with coagulation disorders, severe comorbidities, using clopidogrel or warfarin, under hemodialysis, pregnant and lactating women are excluded.
Results: The mean age $\pm$ SD of the patients (31 male and 37 female) were 52.1 ± 19.7 years (range; 17-100 years). There were 34 (50%) patients in the LMWH group and 34 (50%) patients in the control group. The etiology of these patients included biliary diseases in 43 patients (63.2%), hyperlipidemia in 4 (5.9%), and other in 9 (13.3%). Etiology can not be defined in 12 (17.6%), On admission, all the clinical and laboratory parameters and Balthazar CT score in the two groups were similar. After one week of follow-up, pancreatic necrosis developed in 3 (8.8%) patients in the LMWH group and 9 (26.4%) in the control group (p:0.049). Complications were observed in 6 (17.6%) patients of LMWH group and 11 (32.4%) patients of controls group. No haemorrhagic complications occurred. Three patients died in the control group, while no death occured in LMWH group (p: 0.072).
Conclusion: LMWH treatment is safe and provides a tendency for better prognosis in severe acute pancreatitis.
Disclosure of Interest: None declared

P0094 HEMORRHAGE COMPLICATING THE COURSE OF SEVERE ACUTE PANCREATITIS

Introduction: Course of severe acute pancreatitis (SAP) can be complicated by hemorrhage, which is associated with poor outcome.
Aims & Methods: 183 patients (mean age 39.6 ± 13 years, M:F 2.6:1) of SAP were evaluated prospectively ($n = 86$) and retrospectively ($n = 97$) for hemorrhagic complications. Hemorrhagic complications were categorised based upon the site (luminal or intra-abdominal), timing (occurring prior to or after an intervention) and severity (minor or major, depending on the need for blood transfusion). Data was analysed using SPSS version 22 and outcome measures studied were predictors of bleed, mortality and final outcome.
Results: 24 (13.1%) patients had hemorrhagic complications; 12 intra-abdominal and 12 intraluminal. 13 had a major and 11 had minor bleed; 16 patients bled before and 8 after intervention (radiological 3, surgical 5). The mean duration of pancreatitis prior to bleed was 27.0 ± 27.2 days. Predictors of bleed on univariate analysis were male sex ($p = 0.014$), organ failure ($p = 0.008$), venous thrombosis ($p = 0.033$), infected necrosis (0.001) and systemic sepsis (0.037). On multivariate analysis, infected necrosis ($p = 0.015$, OR 5.55) was a significant risk factor. Radiological drainage was associated with decreased risk of bleeding (45.8% vs 54.4%; $p = 0.000$). Need for surgery (50% vs 12.6%, $p = 0.003$), intensive care stay (7.4 ± 7.9 vs 5.4 ± 5.2 days; $p = 0.001$) and mortality (41.7% vs 10.7%; $p = 0.000$) were significantly higher in bleeders. 7/13 of major bleeders had pseudoaneurysms. 4/12 with luminal bleed had hollow viscus erosion, all needed surgery. CT severity index and surgical intervention, were significantly associated with intra-abdominal bleed. 7/12 intra-abdominal bleeders required surgical intervention. Organ failure, presence of pseudoaneurysm and surgical intervention were associated with major bleed. No significant factor could be identified for post-intervention bleed.
Conclusion: Infected necrosis predisposes to hemorrhage. Luminal bleed may be indicative of erosion into the adjacent viscera. Pseudoaneurysms were associated with major bleeding.

Contact E-mail Address: irma.kuliaviene@gmail.com
Introduction: It is suggested that oxidative stress (OS) may play a role in the development of pancreatic injury and systemic complications during acute pancreatitis (AP). Iron is one of important payers in the redox state. The data about iron metabolism and its role during AP is limited to some experimental findings. To our knowledge this study is the first evaluating the disturbance of iron metabolism as well as its associations with oxidative stress in the early phase of AP.
Aims & Methods: The study was addressed to find out possible disturbances of iron metabolism and its interactions with oxidative stress during the early phase of acute pancreatitis. Blood samples were collected from patients with mild (n = 22) and severe (n = 17) AP, and a group of healthy individuals (n = 26). Serum oxidative stress markers measured in serum included Reactive Oxygen Metabolites (ROM) and Ferric Reducing Antioxidant Power (FRAP), Total Oxidative Capacity (TOC) and Total Antioxidative Capacity (TAC). Serum ferritin, iron (Fe) and transferrin were measured and the iron saturation of transferrin (TS) was calculated.
Results: A disturbed iron status in all pancreatitis groups was found. Iron, transferrin and the iron saturation of transferrin were significantly lower and ferritin was significantly higher in all AP groups. The serum oxidative stress parameters reflecting the lipid peroxidation process ROM and TOC showed significantly decreased levels in the AP group as well as mild and severe AP groups comparing to controls. TOC decreased more in mild AP patients than in severe AP patients, the difference was significant. One of the measurements of total antioxidant capacity (FRAP) was increased in all AP groups, compared with the control group. TAC showed no significant changes in the groups. There was a significant correlation between ROM with transferrin (Spearman's correlation coefficient 0.44, p = 0.00) and with ferritin (Spearman's correlation coefficient 0.32, p = 0.008), between FRAP and transferrin (Spearman's correlation coefficient 0.38, p = 0.001) and ferritin (Spearman's correlation coefficient 0.52, p = 0.000). There was a significant correlation between TOC and TS (Spearman's correlation coefficient 0.352, p = 0.006) as well as TOC and Fe (Spearman's correlation coefficient 0.346, p = 0.007).
Conclusion: The iron metabolism is disturbed and the oxidative stress markers are altered during the early phase of acute pancreatitis. The disorders of iron metabolism are associated with the changes of oxidative stress markers.
Disclosure of Interest: None declared

P0096 IMAGING OF PANCREATIC CYSTIC LESIONS WITH CONFOCAL LASER ENDOMICROSCOPY: AN EX VIVO PILOT STUDY

A. Kadayifci[1], M. Atar[1], M. Yang[2], C. Fernandez-del Castillo[3], M. Mino-Kenudson[2], W. R. Brugge[1]
[1]*Gastroenterology,* [2]*Pathology,* [3]*Surgery, Mass General Hospital, Harvard Medical School, Boston, United States*

Contact E-mail Address: kadayifci@hotmail.com
Introduction: The differential diagnosis of pancreatic cystic lesions (PCLs) is an increasingly common clinical challenge. A needle-based confocal laser endomicroscopy probe (nCLE, Cellvisio, Maura Ken Technologies, France) through a 19 G needle has been shown to be helpful for differential diagnosis of PCLs by imaging the cyst wall during endoscopic ultrasound-fine needle aspiration. However, clinical experience is still limited, and better image definition and characterization of the cyst wall from different lesions are needed.
Aims & Methods: The aim of this pilot study was to develop a reference standard in CLE characterization of various types of PCLs. Patients who underwent surgery of a PCL at Mass General Hospital were enrolled to study if they gave their consent. During surgery, intravenous fluorescein (2.5 ml of 10%) was injected just prior to the ligation of blood vessels supplying the pancreas. The injected fluorescein was expected to retain for at least an hour after the injection. The fresh specimens were transected along the long axis to fully expose the luminal surface. A Gastroflex-UHD CLE probe (pCLE) was used manually to acquire images directly from the surface of the cyst wall. The cyst walls were screened longitudinally in 2 millimeter ranges by the tip of the probe and sequences recorded for a total 15 minutes. The entire resected specimen subsequently underwent cross sectional histology. All recorded data were analyzed by two investigators for predefined and original image findings of PCLs.
Results: During the 4-month study period, 10 cases (4 male and 6 female) were recruited into the study. The median age of the patients was 77 (range, 33-88). All patients underwent surgery because of a mucinous cyst with worrisome features or a symptomatic PCL. The median duration between fluorescein injection and confocal imaging was 55 minutes (range, 40-90). Imaging was successful in all patients, and various papillary projections with a vascular core and mucinous epithelial borders were visualized in 8 of the patients. In 2 patients, typical vascular network were visiualized without papillary structures. The conventional pathological examination confirmed 6 cases with Intraductal Papillary Mucinous Neoplasm (IPMN), 2 cases with Mucinous Cystic Neoplasm (MCN) and 2 cases with serous cysts. Pancreatic ductal adenocarcinoma arising in high-grade dysplasia was found in one patient, and high-grade dysplasia in 2 patients. The sensitivity and specificity of ex-vivo confocal imaging to demonstrate papillary structures was 100%.
Conclusion: Pancreatic cyst epithelial wall can be visualized successfully by pCLE in *ex vivo* surgical specimens. Various papillary projections have been seen in all cases of IPMN and MCN in this examination. The variety of images which have been acquired in this model will be helpful for the definition of similar structures during *in vivo* examination of pancreatic cysts. To develop a reference standard for definition of IPMN subtypes and for grade of differentiation would be the ultimate aim of this model.

Introduction: Prediagnostic plasma adiponectin levels have been inversely associated with an elevated risk of pancreatic cancer (1). We recently demonstrated that in patients with pancreatic cancer (PC) adiponectin levels are inversely correlated with tumor size and tumor grading, identifying a potential link between adipokines and tumor proliferation (2). To date, however, no data on the possible prognostic significance of adipokines in patients with PC have been shown.
Aims & Methods: The aim of the study was to evaluate plasma concentrations of adiponectin and leptin in PC patients and to analyze their possible prognostic value in predicting relapse-free and overall survival. Baseline levels of adiponectin and leptin were determined in 37 consecutive patients with resectable pancreatic adenocarcinoma followed-up from time of surgery for 28 months or until relapse. 37 control subjects were individually matched to case patients by age, sex and BMI. Survival analysis used the Kaplan-Meier curve and the Cox proportional hazards model.
Results: Adiponectin concentrations were lower in PC patients versus control subjects (8.1 vs 10.8. mg/mL, $p<0.01$) and inversely correlated with tumor size (r = -0.715, $p<0.05$). The mean leptin levels were not significantly decreased in PC patients ($p=0.465$). However, the levels of leptin were significantly decreased in cachectic PC patients (N = 19) compared with healthy controls (53.9± 25.5 *vs* 87.0 ± 23.9 ng/ml $p < 0.001$). Multivariate analysis showed that, beside tumor size, low adiponectin levels were the only independent predictor of recurrence (beta = 0.563, $p<0.001$). High adiponectin levels were associated with an increased overall survival (Cox F test = 2.213, $p<0.05$) and a reduced recurrence rate (Cox F test = 2.913, $p = 0.01$) compared to patients with low adiponectin levels.
Conclusion: This study suggests, for the first time, that serum adiponectin levels might represent a prognostic indicator in patients with resectable PC. Our results support the hypothesis linking adipokines levels to malignant tumor growth (3) and suggest that adipokines might exert an adjunctive tool in risk prediction and management of pancreatic adenocarcinoma patients.

Introduction: Chemotherapy regimens for locally advanced or metastatic pancreatic ductal adenocarcinoma (PDAC) have changed since the introduction of polychemotherapies such as FOLFIRINOX (5-fluoruracil (5FU/LV), oxaliplatin, irinotecan and leucovorin) which confer a significant survival benefit compared to gemcitabine-based monotherapy. Increased toxicity, mainly sensory peripheral neuropathy, limits its use and the number of applied chemotherapy cycles. In analogy to chemotherapy strategies in colon cancer we used a scheme of induction, maintenance, treatment pause and re-induction therapy in locally advanced or metastatic PDAC to alleviate such toxicities and increase the number of applied cycles. In this retrospective study we report our experience with this scheme.
Aims & Methods: We retrospectively identified all patients who received FOLFIRINOX for metastatic or locally advanced PDAC in our center using the induction, maintenance, treatment pause and re-induction scheme until March 2015. Response to therapy and toxicity of the treatment were assessed.
Results: Eleven patients met the inclusion criteria. The median number of cycles of induction therapy including all three active substances or only 5FU/LV combined with oxaliplatin was 6 (range 5-13). All patients had stable disease or partial response and received maintenance therapy consisting of 5FU/LV with a median cycle number of 6 (2-21). Four patients had a treatment pause after maintenance therapy of median 24 weeks (8-42). Re-induction due to progressive disease during treatment pause or maintenance therapy was applied in eight patients using all three active substances or only 5FU/LV combined with oxaliplatin, with a median of 4.5 (2-7) cycles of re-induction therapy. The median time to first progression, death or loss to follow up was 10.8 months (4.1-20.7). The median time to second progression, death or loss to follow up in patients undergoing re-induction chemotherapy was 14.1 months (8.9-29). Peripheral neuropathy was clinically relevant in ten patients after induction therapy. In four of these neuropathy has subsided completely before re-induction therapy.
Conclusion: The maintenance strategy after induction chemotherapy with subsequent re-induction in patients undergoing FOLFIRINOX chemotherapy for advanced PDAC seems to be safe. It might help reduce sensory peripheral neuropathy and potentially leads to a prolonged progression-free survival.

Introduction: The clinical management of patients with pancreatic cysts is currently imperfect. The recent identification of a distinct mutational profile in each of the main cyst types (SCAs, SPNs, MCNs and IPMNs) may improve the diagnosis of pancreatic cysts.
Aims & Methods: The aim of this study was to evaluate whether a combination of molecular markers and clinical information could improve the classification and management of pancreatic cysts. A multi-center, retrospective study of patients with resected pancreatic cystic neoplasms was performed. Cyst fluid was analyzed: (i) to identify subtle mutations in genes known to be mutated in pancreatic cysts: BRAF, CDKN2A, CTNNB1, GNAS, KRAS, NRAS, PIK3CA, RNF43, SMAD4, TP53, and VHL; (ii) to identify loss of heterozygozity at the CDKN2A, RNF43, SMAD4, TP53, and VHL tumor suppressor loci; and (iii) to identify aneuploidy. These analyses were performed with highly accurate massively parallel sequencing-based technologies for data acquisition and interpretation. An algorithm was used to select composite molecular markers for classifying cyst type and grade. The accuracy of these composite molecular markers was compared to that of the composite clinical markers, and to a combination of molecular and clinical markers.
Results: We analyzed 12 serous cystadenomas, 10 solid-pseudopapillary neoplasms, 12 mucinous cystic neoplasms, and 96 intraductal papillary mucinous neoplasms. The composite clinical and molecular features classified cyst type with sensitivities of 90% to 100% and specificities of 92% to 98%. The molecular marker panel correctly identified 67 of 74 patients who did not require surgery, thus potentially decreasing the number of unnecessary operations by 91%.
Conclusion: A combination of molecular and clinical markers shows promise for the accurate classification of cystic neoplasms of the pancreas and for the identification of cysts that require surgery.

Introduction: High-intensity focused ultrasound (HIFU) is anticipated as a new advanced therapy for unresectable pancreatic cancer (PC). HIFU therapy with chemotherapy is being promoted as new method to control local advance by ablation of the tumor, and mainly to achieve relief of pain caused by PC.
Aims & Methods: We have evaluated the therapeutic effect of HIFU therapy in locally advanced and metastatic PC. We treated PC patients by HIFU as optional local therapy as well as systemic chemo / chemo-radiotherapy, with whom an agreement was obtained in adequate IC, from the end of 2008 in our hospital. This study was approved by the ethics society of our hospital. HIFU device used is FEP-BY02 (Yuande Bio-Medical Engineering Co.LTD., China). The subjects were 90 PC patients, i.e. 54 cases in stage III, 36 cases in stage IV.
Results: All tumors were visualized by HIFU monitor system. Treatment data in Stage III and IV were as follows: mean tumor size was 33.8 vs 35.7 mm, mean treatment sessions: 2.6 vs 2.4 times, mean total treatment time: 2.2 vs 1.8 hours, mean total number of irradiation: 2595 vs 1962 shots, respectively. There was no significant difference in treatment data between two groups. The effects of HIFU therapy in Stage III and IV were the following; the rate of complete tumor ablation was 87.0 vs 75.0%, the rate of symptom relief effect was 80.0 vs 68.2%, the effectiveness of primary lesion was CR:0, PR:7, SD:38, PD:9 vs CR:0, PR:4, SD:18, PD:14, primary disease control rate (DCR) more than SD was 83.3% vs 61.1%. Comparison of mean survival time (MST) after diagnosis in Stage III and IV was 32.6 vs 16.1 months, respectively ($p < 0.01$, $p = 0.002$). MST after diagnosis in HIFU with chemotherapy and chemotherapy alone (38 patients in our hospital) was 26.7 vs 12.2 months, respectively ($p < 0.001$). Combination therapy of HIFU with chemotherapy was better result than common chemotherapy alone in Stage III.
Conclusion: This study suggested that HIFU therapy has the potential of a new method of combination therapy for PC.

Introduction: Due to the aggressive nature of pancreatic cancer (PC), the diagnosis of an early stage is essential. In more than 80% of cases, PC is connected with paraneoplastic hyperglycemia called diabetes mellitus associated with PC (DMPC), although only 1% of recent onset diabetics (RODM) have PC.[1] The group of RODM in addition with progressive weight loss or unexplained dyspepsia is a potential screening group for sporadic PC.[1,2] Current diagnostic procedures fall short in distinguishing DMPC from the very frequent type 2 diabetes mellitus (DM2), which represents most of RODM.
Aims & Methods: To specify the differences between DMPC and DM2, we tested a new approach based on combination of spectroscopic methods. The main aim is to determine the sensitivity and specificity of these spectroscopic methods. Plasma samples collected from 23 DMPCs and 24 DM2 patients were analysed by chiroptical spectroscopy, specifically electronic circular dichroism (ECD) and Raman optical activity (ROA), which are inherently sensitive to the 3D structure of chiral molecules.[3] To obtain more structural information, the ROA and ECD measurements were supplemented by conventional infrared (IR) and Raman spectroscopies.
Results: The ECD spectra of the DMPCs generally showed not only a lower intensity profile than type 2 diabetics, but also slight changes in the spectral patterns. In the IR spectra, we also observed intensity and spectral pattern variations in the regions corresponding to protein secondary structure. The Raman and ROA spectra showed mainly α-helical peptide/protein conformation with a low content of β-structures. Other observed differences corresponded to aliphatic and saccharide/glycoprotein moieties. The spectra obtained from all four spectral methods were processed by linear discriminant analysis (LDA) showing a clear separation of DMPCs and DM2 patients. The quality of the established statistical model was confirmed by leave-one-out cross-validation where sensitivity and specificity reached 90%.
Conclusion: The results obtained in this pilot study show a high potential of the combination of chiroptical and vibrational spectroscopy as a promising tool in the identification of potential screening group for the diagnosis of early PC.

Introduction: It is generally accepted that cystic lesions in the pancreas (CLPs) 3 cm or less in size and without features suggesting malignancy can be managed conservatively with follow-up. However, the optimal duration and interval of follow-up for CLPs is not yet well established.
Aims & Methods: We have performed the current study to investigate the optimal duration and interval of follow-up for CLPs in clinical practice. Patients with CLPs 3 cm or less in size and without features suggesting malignancy received follow-up with computed tomography at 6, 12, 18, and 24 months and then per 12 months. A retrospective analysis with prospectively collected data was performed.
Results: A total of 205 patients with CLPs detected from 2004 to 2009 (initial mean size, 1.8 ± 0.7 cm) received follow-up during the median period of 56.6 months. Within the first 12 months of follow-up, no patients experienced the growth of cyst and three patients (1.5%) underwent surgery for the presence of symptoms related to CLPs. 11 patients (5.4%) experienced the growth of cyst after 5 years of follow-up. A total of 18 patients underwent surgery during follow-up and four malignant cysts were detected. Overall rate of malignant progression during follow-up was 2.0%. The malignant progression occurred after 48 months and 60 months of follow-up in one and three patients, respectively.
Conclusion: The results of this study provide the evidence of the optimal duration and interval of follow-up for CLPs in clinical practice. Long-term follow-up of more than 5 years should be performed because of the potential for malignant transformation of CLPs. The 12 months interval of follow-up for asymptomatic CLPs might be sufficient in clinical practice.

Introduction: Individuals with a genetic susceptibility for cancer often have a lower quality of life (QoL) than the general population. Little is known about the QoL of individuals with increased risk for familial pancreatic cancer (PC).
Aims & Methods
Aims: 1) To compare the QoL and the cancer worry of asymptomatic adult high-risk individuals (HRI) in a screening program with that of control patients and the general population; 2) To compare the QoL and cancer worry before and after surgical treatment for suspected pancreatic neoplasms detected during screening and surveillance.
Methods: Asymptomatic HRI with a family history of PC or PC genetic syndrome were screened with EUS and MRI within the Cancer of the Pancreas Screening (CAPS) studies from 2000-2011. Participants completed a baseline 36-Item Short-Form Health Survey (SF-36) for QoL analysis and the Cancer Worry Scale (CWS) prior to screening. Cross-sectional comparison of measures was performed with that of concurrently enrolled normal and disease (chronic pancreatitis, pancreatic cyst) controls. Baseline and post-operative scores were compared in surgical patients > 1 year from treatment.
Results: Scores from baseline pre-screening SF-36 and CWS questionnaires of 307 HRI (46% M, mean age 59 years) with 54 controls (42% M, mean age 63 years) were compared. 29 of 32 surgically-treated HRI had follow-up assessments; 13 of these completed both baseline and follow-up questionnaires. Prior to screening, 7 of the 8 QoL domain scores were significantly higher in HRI compared to controls: Physical Functioning (PF; 92 vs 81.9, $p = 0.005$), Role limitation-Physical (RP; 91.2 vs 71.5, $p < 0.001$), Bodily Pain (BP; 85.3 vs 71.8, $p < 0.001$), General Health (GH; 71.9 vs 64.5, $p < 0.001$), Vitality/fatigue (VT; 63.7 vs. 53.4, $p < 0.001$), Social Functioning (SF; 91 vs 77.2, $p < 0.001$), and Role limitation–Emotional (RE; 91.3 vs 82.4,$p = 0.005$). Mental health (MH) was comparable (78.7 vs 76.6, $p = 0.21$). HRI had significantly higher mean CWS scores than controls (6.4 vs 5.2, $p = 0.001$). Qol domain scores for the control group were comparable to published normative data for the average U.S. population. There were no statistically significant changes in the QoL parameters before and after surgery: PF (90.4 vs 91.2, $p = 0.87$), RP (80.8 vs 96.2, $p = 0.09$), BP (81.7 vs 87.9, $p = 0.24$), GH (63.5 vs 66.2, $p = 0.56$), VT (59.6 vs 64.2, $p = 0.54$), SF (89.6 vs 88.5, $p = 0.83$), RE (87.2 vs 84.6, $p = 0.86$), and MH (74 vs 76.3, $p = 0.64$). In patients who had pancreatic resection, QoL was high and PC worry was lower after surgery (11.1 pre-op vs 4.8 post-op, $p = 0.004$).
Conclusion: The baseline QoL of asymptomatic HRI is high, and is generally better than that of the controls, despite greater cancer worry. Pancreatic surgery does not negatively impact the QoL of HRI and results in a reduction in cancer worry

Introduction: Despite several advances in sensitivity and accuracy of diagnostic techniques in abdominal imaging, in the last decades, pancreatic cancer still remains a high-mortality disease with a poor prognosis after 5 years.
Pancreatic cysts are a heterogeneous group of lesions; serous cystadenoma and pseudocyst shows a benign behavior, intraductal papillary mucinous neoplasia (IPMN), mucinous cyst adenoma are considered to be premalignant lesions.
While the management and work up of cystic pancreatic lesions is quite homogeneous between experts, the accuracy of diagnostic techniques is very low. A needle-based confocal laser endomicroscopy probe (nCLE), introduced through an FNA needle, has been presented as able to visualize epithelial layer of a cyst's wall and recently a specific criteria for identification of serous cystadenoma has been identified with nCLE. However nCLE criteria for IPMN, the most common incidental findings in EUS has note been defined yet.

Aims & Methods: The aim of the study was to identify specific imaging criteria of IPMN. After nCLE procedure, all patients underwent aspiration of cystic fluid for CEA, amylase and cytology analysis.
After EUS and nCLE examinations, all findings were compared to cytology, cystic fluid analysis and EUS findings if a surgical specimen was not available and discussed with pathologist in order to recognize typical findings IPMN.
Results: Sixteen patients consequently underwent nCLE during FNA (11 IPMN, 3 Serous cystadenoma, 1 mucinous cystic neoplasm, 1 pseudocyst). nCLE was able to identify images featured finger-like projection suitable with papillary structures in all IPMN (Sens. 100%, Spec 100%, $p < 0.02$). This finding was not present in serous cystadenoma/pseudocyst/mucinous cystadenoma.
Conclusion: In this pilot study, nCLE was able to identify a criteria common in all IPMN. Multicentric studies on this topic are ongoing.

Introduction: Increasing numbers of pancreatic cancer patients have been treated with neoadjuvant chemoradiotherapy (NCRT) to improve clinical outcome and survival. Neoadjuvant regimen in our institution would require 5 weeks of chemoradiotherapy, followed by a recovery period of an additional 4 to 6 weeks before surgery. We conducted this study to compare the efficacy and complication rates of covered and uncovered self-expandable metal stents (c-SEMS, u-SEMS) in relieving biliary obstruction in patients undergoing neoadjuvant therapy for pancreatic cancer.
Aims & Methods: We retrospectively analyzed patients who received biliary stent placement between April 2006 and December 2014. Forty-seven patients (34 men/13 women) with locally advanced pancreatic cancer and biliary obstruction had stent placement (24 cases c-SEMS, 23 cases u-SEMS). Endoscopic sphincterotomy (ES) was performed before stent placement.
Results: Stent occlusion occurred in 3 patients (12.5%) in c-SEMS group, 6 patients (26%) in u-SEMS group. Two cases (8.3%) in c-SEMS group and three cases (13%) in u-SEMS group had interruption of NCRT. There was no significant difference between two groups in occlusion rate and interruption of NCRT. There were also no significant differences in stent patency time between two groups ($p = 0.16$). Although tumor ingrowth with recurrent obstruction was more common in the u-SEMS group (21.7%vs 0%), acute cholecystitis (20.8% vs 4.3%) and acute pancreatitis (20.8%vs 8.7%) were more common in the c-SEMS group.
Conclusion: Both c-SEMS and u-SEMS are effective and safe in achieving durable biliary drainage in patients with pancreatic cancer receiving neoadjuvant therapy, despite different patterns of late stent failure.

Introduction: Enteropancreatic neuroendocrine tumors (EP-NET) are rare and heterogeneous diseases. The aim of our study was to identify clinical, histopathological and therapeutic factors impacting the survival of patients with EP-NET.
Aims & Methods: All patients with histopathological diagnosis of EP-NET in our university hospital between October 1994 and October 2013 were included. Data were retrospectively collected. When proliferative index (Ki67 and mitotic index) were not available on our database, a prospective review of tumor tissue was performed. Prognostic factors were determined by univariate analysis, survival rates were assessed by Kaplan-Meier method.
Results: One hundred and seventy-eight patients (Male: 53.9%, median age: 57, range: 5-87) were enrolled. There were 112 (62.9%) pancreatic NET and 66 (37.1%) intestinal NET. Sixty-six (37.1%) patients had secretory syndrome. According to the ENETS classification, NET were grade 1, grade 2 and grade 3 in 67 (37.6%), 95 (53.4%) and 9 (5.1%) cases, respectively. Overall survival was significantly longer for pancreatic NET than intestinal NET (192.9 versus 105.2 months, respectively ($p = 0.0003$)). For EP-NET, the identified negative prognostic factors were: age over 75 at diagnosis (HR = 5.39; 95% CI: 2.01-14.4), WHO performance status > 1 (HR = 9.49; 95% CI: 3.74-24.1), sporadic NET (HR = 2.09; 95% CI: 1.06-4.11), presence of distant metastases (HR = 2.49; 95% CI: 1.5-4.14), ovarian localization of metastases (HR = 6.13; 95% CI: 1.38-27.2) and Ki67 index > 5% (HR = 2.21; 95% CI: 1.3-3.76). For pancreatic NET, insulinomas (HR = 0.35; 95% CI: 0.14-0.87), primary tumor size < 25mm (HR = 0.31; 95% CI: 0.14-0.72) and mitotic index of 0 per 10 fields (HR = 0.38; 95% CI: 0.16-0.91) were positive prognostic factors. For intestinal NET, peritoneal localization of metastases (HR = 2.65; 95% CI: 1.12-6.28) and emergency surgery for acute complication (HR = 2.39; 95% CI: 1.07-5.34) were negative prognostic factors. For patients under 75 years, median survival time was 160 months for grade 2/3 NET while it was superior to 230 months for grade 1 NET ($p < 0.05$).
Conclusion: Negative prognostic factors such as ovarian or peritoneal metastases should be taken into account for the management of EP-NET. In intestinal NET, surgery should be performed as soon as possible, to avoid the occurrence of severe symptoms leading to emergency surgery. As a cut-off of 5% for the Ki67 index seems to better correlate with survival than a cut off of 2%, the ENETS classification should be reviewed.

P0108 PLAC8 OVEREXPRESSION REGULATES CELL GROWTH IN PANCREATIC NEUROENDOCRINE TUMOURS (PNET)

M. Haijat[1], H. Schmidt[1], L. Fiedler[1], T. Gress[1], M. Buchholz[1]
[1]*Klinik für Innere Medizin, SP Gastroenterologie, Philipps-Universität Marburg, Marburg, Germany*

Contact E-mail Address: malte.buchholz@staff.uni-marburg.de
Introduction: Plac8 is a small protein with unknown molecular function which depending on the cellular context shows different subcellular localisation and may be involved in a wide variety of physiological and pathophysiological processes. In normal pancreata, Plac8 is expressed neither in the endocrine nor in the exocrine compartment. Here we demonstrate that the protein is strongly upregulated in human pancreatic neuroendocrine tumours (pNETs) and centrally regulates the growth of cultured cells derived from pNETs.
Aims & Methods: Immunohistochemistry, RNAi, cell proliferation and viability assays, Western blots, apoptosis assays
Results: Plac8 is strongly overexpressed in primary human pNET tissues both on the mRNA level, as determined by quantitative RealTime PCR, as well as on the protein level, as determined by Western blot and immunohistochemistry. Moreover, strong Plac8 expression is also retained in cultured cell lines from human and rat pNETs. siRNA-mediated knockdown of Plac8 expression in these cells uniformly resulted in strong inhibition of cell growth, as determined by BrdU incorporation and MTT assays, while apoptosis levels were not influenced. This growth inhibition was associated with upregulation of the cell cycle inhibito p21/CDKN1A as well as downregulation of cyclin D1.
Conclusion: Overexpression of Plac8 protein in pancreatic neuroendocrine tumours is centrally important for the maintenance of the proliferative phenotype of the tumour cells. Further analyses to identify the involved molecular mechanisms and signalling pathways are ongoing.

Introduction: The most appropriate clinical management for small (≤ 20 mm) non functioning pancreatic neuroendocrine tumors (pNETs) is still a matter of debate and whether all the small and asymptomatic lesions should be routinely resected still has to be defined.
Aims & Methods: Primary endpoints of this prospective study were to evaluate the overall survival (OS) and the progression free survival (PFS) of pNETs, according to their clinical management.
From September 2009 to September 2014, a total of 51 patients had a definite diagnosis of pNETs based on clinical data, imaging (CT, MRI, Ga68-PET), ultrasound endoscopy, histology, and were consecutively enrolled. Among them, 15 patients (M/F = 6/9, median age 65 yrs, range 27-84 yrs) with small pNETs (diameter ≤20 mm) underwent an intensive 3-month follow-up for the first year and biannual thereafter (FU)). TNM stage was I in all but one patient who was at stage IIA. Twenty-one patients (M/F = 7/14, median age 52 yrs, range 27-82 yrs) underwent surgical resection (SR): TNM stage was I, IIA, IIIB and IV in two, nine, one and nine cases, respectively The remaining 15 patients (M/F = 7/8, median age 72 yrs, range 27-87 yrs) received systemic therapy (ST) due to advanced disease or contraindications to surgery; of them five, two and eight were at stage IIA; IIB and IV, respectively.
Results: Median follow up of the entire cohort was 56 months (range 3-70). OS was similar in FU and SR groups, whereas it was significantly worst in ST subset (log-rank test $P = 0.014$, median not reach in each group). Five-year survival rate was 100% in the FU group, 90% in the SR one, and 61% in the ST group ($p < 0.0001$), although these results were largely affected by the different stage at presentation. PFS did not differ in the three groups as disease remained stable in all but one patient in the FU group, whereas six patients (28%) in the SR group showed a pNET recurrence or metastatic spread and finally five (31%) showed disease progression in the ST group.
Conclusion: The "wait and watch"approach appears to be safe in ≤ 20mm, early stage pNETs, although further studies are needed to confirm these results in larger cohorts of patients.

Introduction: Endoscopic ultrasound (EUS) is used to identify pancreatic neuroendocrine tumors (PNETs) in multiple endocrine neoplasia type 1 (MEN1) syndrome. The role of surveillance in small (<20 mm), asymptomatic PNETs is unclear, mostly because the natural course of these lesions is largely unknown. Therefore, current advice is to perform EUS at 6-12 months intervals.

Aims & Methods: We assessed the incidence of small, asymptomatic PNETs in MEN1 patients using EUS and calculated the growth rate of PNETs in general, but also of the largest PNET per patient and of incident PNETs identified during follow-up EUS. All linear array EUS procedures in patients with MEN1 syndrome between May 2002 and April 2015 at the UMC Utrecht were identified. Number, size and location of PNETs were recorded. Mean growth rate of PNETs <20 mm identified at initial EUS (prevalent PNETs) and incident PNETs at follow-up was calculated with mixed model linear regression analysis.

Results: Fifty-four patients were identified. After excluding patients that underwent only one EUS-procedure (N = 14) and patients without PNETs (N = 2), 38 patients were included (13 males [34%]) with a mean age at the first procedure of 41 years (SD 14). Follow-up was 129 patient years (mean 3.4 years [SD 2.3]) and 169 EUS procedures were performed. In total, 225 PNETs were identified with a median size of 5 mm (IQR 4-8). Of these, 124 PNETs (55%) were identified during the initial EUS procedure (prevalent PNETs: median size 6 mm, IQR 4-9) and 101 (45%) during surveillance EUS (incident PNETs: median size 4.3 mm, IQR 3.0-6.0 mm) after a median of 2.4 years (IQR 1.1-3.5). Median size of the largest prevalent PNET (N = 33) was 9 mm (IQR 8-13). Mean annual growth rate of all PNETs was 0.10 mm (95% CI 0.02-0.19, P = 0.02); PNETs <10 mm did not grow (P = 0.50) whilst PNETs ≥10 mm grew 0.75 mm/year (95% CI 0.41-1.09, P < 0.0001). Prevalent PNETs grew 0.21 mm/year (95% CI 0.10-0.32, P = 0.0003), while incident PNETs did not grow over time (P = 0.21). Annual growth rate of the largest prevalent PNET was 0.28 mm (95% CI 0.06-0.50, P = 0.01). Annual incidence of new PNETs was 0.78 PNETs/patient/year (95%CI 0.72-0.86). In three patients (8%), a PNET grew to ≥20 mm during surveillance EUS (number needed to test: 12.7) after 26-30 months. None of the 101 incident PNETs grew beyond 15 mm.

Conclusion: Annual growth rate of small PNETs, especially when <10 mm, is low and the interval between EUS procedures could probably be prolonged without compromising safety. Clinical relevance of new small PNETs found during surveillance appears to be limited because all PNETs ≥20 mm during surveillance EUS were already identified during the initial EUS.

Introduction: Accumulating evidence suggests that Doublecortin-like kinase 1 (DCLK1) is a putative marker for intestinal and pancreatic stem cells, including cancer stem cells (CSCs) of these organs[1,2,3]. Recently, we have reported that DCLK1 was highly and diffusely expressed in human rectal neuroendocrine tumors[4]. However the function of DCLK1 has not been investigated in detail.

Aims & Methods: The aims of the present study were to assess expression levels of DCLK1 in pancreatic neuroendocrine tumors (PNETs) and to identify critical functions of this molecule in PNET cells that are highly metastatic despite of their relatively slow growing ability. Fifteen patients (8 male, 7 female; mean age, 56) with PNETs were enrolled in this study. Informed consent was obtained from all of the patients. The tumors were surgically resected between 1997 and 2012 in the Kurume University Hospital. Mean diameter of the tumors was 30.2 mm (range, 12-93 mm). Immunohistochemistry (IHC) was employed to assess expression levels of DCLK1. QGP1, a human PNET cell line, was used in this study, and the cells were transfected with *dclk1* cDNA to establish the DCLK1-overexpressing (QGP1-DOE) cells. The QGP1-DOE cells were subjected to *dclk1* silencing of to confirm acquired cellular characteristics by DCLK1 overexpression. Protein and mRNA expression levels were analyzed by Western blot and real-time PCR (ABI PRISM 7700), respectively.

Results: In IHC, all of the 15 PNET clearly and diffusely expressed DCLK1 in the tumor areas. The protein was expressed in QGP1 cells in both protein and mRNA levels; however, the expressed protein was a short form which lacked doublecortin domains. QGP1-DOE cells robustly expressed full length of DCLK1, showing morphological alteration reminiscent of epithelial-mesenchymal transition (EMT). Indeed, extremely high expression of Slug was found in QGP1-DOE cells compared with control cells at both protein and mRNA levels. Similar upregulation was demonstrated in E2A, Twist, and N-cadherin. The QGP1-DOE cells exhibited increased cellular motility. DCLK1 knockdown restored both cellular morphological change and the expressions of the EMT-associated molecules.

Conclusion: We demonstrated high expression of DCLK1 in human PNET tissues and PNET cells. Enforced expression of DCLK1 induced EMT via upregulating Slug and other EMT regulators. Therefore, it is speculated that inhibition of DCLK1 expression is a novel therapeutic strategy for PNETs.

Introduction: Rebamipide is a safe and widely used medication for oral administration to patients with gastritis or gastric ulcers. A combination therapy of proton pump inhibitor (PPI) and rebamipide was reported to effectively promote ulcer healing after endoscopic submucosal dissection (ESD).

Aims & Methods: In this preclinical study we developed a novel 2% rebamipide solution as a submucosal injection agent for ESD, used it for ESD experimentally in porcine stomachs, and examined the quality and speed of ulcer healing after the intervention.

Three domestic female pigs of about 30 kg underwent ESD. ESDs of approximately 30 mm in diameter were performed at four sites (anterior and posterior walls of both the upper body and middle body) in the stomach of each of the three pigs. An endoscopist blinded to the test agents performed the ESD with matrix alone at two sites (control group) and with the 2% rebamipide solution at the other two sites (rebamipide group). One pig was sacrificed 1 week later (pig 1) and two pigs were sacrificed 4 weeks later (pigs 2 and 3). In Examination 1 we evaluated the healing speed once a week using endoscopic ulcer staging. In Examination 2 we evaluated the quality of the ulcer scar histopathologically.

Results: Examination 1. We found no significant differences between the groups in the healing stage after resection of the gastric lesions at 1 week. Later, however, the S stage ratios in the rebamipide group and control group were significantly different: 75.0% (3/4) and 50.0% (2/4) respectively at 3 weeks and 100.0% (4/4) and 50.0% (2/4) respectively at 4 weeks. Furthermore, the folds into the centers of the ulcer scars were smoother and more uniform in the rebamipide group than in the control group at 4 weeks after the ESD. Examination 2. The ulcers at 1 week were not observably different between the two groups. At 4 weeks, mucosal healing was conspicuously better in the rebamipide group than in the control group, with a thicker and more uniform mucosal layer.

Conclusion: The use of 2% rebamipide solution as a novel submucosal injection material for ESD promoted the speed and quality of ulcer healing after ESD.

P0113 PREOPERATIVE PULMONARY FUNCTION TESTS ARE USEFUL TO PREDICT ASPIRATION PNEUMONIA AFTER ESD FOR GASTRIC TUMORS

A. Matsumi[1], R. Takenaka[1], Y. Sato[1], K. Takei[1], S. Okanoue[1], E. Yasutomi[1], T. Sunami[1], S. Oka[1], Y. Baba[1], D. Kawai[1], K. Takemoto[1], H. Tsugeno[1], S. Fujiki[1]

Contact E-mail Address: rodyrodyroddick.0616@gmail.com
Introduction: An experienced and skilled ESD operator enables us to perform ESD even for elderly patients with some comorbidities. Such patients whose pulmonary function is often poor may be at risk for postoperative aspiration pneumonia. However, few reports have discussed on the relationship between the pulmonary function and aspiration pneumonia after ESD for gastric tumors.
Aims & Methods: A total of 978 patients with gastric tumors who previously had received pulmonary function tests were treated by ESD between June 2006 and May 2014. ESD was performed under intravenous anesthesia using propofol. Chest radiography and blood chemistry were done on the next day after ESD. Computed tomography was added if aspiration pneumonia was suspected. Aspiration pneumonia was defined when the patients presented with lung consolidation by chest radiography or CT, in addition to respiratory infectious symptoms such as fever and oxygen desaturation. Pulmonary function tests were assessed using a spirometer. The patients were categorized into four groups according to the predicted vital capacity (%VC) and forced expiratory volume in 1 second as a percentage of forced vital capacity (FEV1.0%): normal; restrictive pulmonary dysfunction (%VC < 80%); obstructive (FEV1.0% < 70%); and combined (%VC < 80% and FEV1.0% < 70%). The factors associated with aspiration pneumonia were retrospectively analyzed using the preoperative parameters.
Results: The study subjects comprised 694 men (71%) and 284 females (29%) with a mean age of 73.6 years. Among the 268 cases (27%) with abnormal pulmonary function, 10 cases (3.7%) developed aspiration pneumonia. On the other hand, 7 cases (1.0%) with normal pulmonary function developed pneumonia. There was a significant correlation between pulmonary function and aspiration pneumonia ($p = 0.003$). The pulmonary function cases were stratified into subgroups, 2.5% of cases with restrictive pulmonary dysfunstion developed pneumonia, 5.5% with obstructive, and 7.9% with combined. Among the other preoperative parameters, serum albumin, pretreatment with glucagon, presence of antiplatelet agent, presence of cerebral vascular disease were significant factors by a univariate analysis. By multivariate analysis, pulmonary function and presence of cerebral vascular disease were identified as significant independent risk factors associated with aspiration pneumonia. The odds ratio for pulmonary function and cerebral vascular disease were 3.2 and 5.1, respectively.
Conclusion: Preoperative pulmonary function tests may be useful markers to evaluate the risk for aspiration pneumonia after ESD for gastric tumors.

Contact E-mail Address: t.rakira@gmail.com
Introduction: In recent years, image-enhanced endoscopy such as NBI is widely performed for detection and diagnosis of superficial ESCC. Especially, NBI has established the usefulness in detection and diagnosis of superficial ESCC. Blue LASER Imaging (BLI) is a novel image-enhanced endoscopy with two different lasers that enable us to allow narrow-band light observation. BLI-bright is a brighter BLI mode, and useful for endoscopic observation in a distant view.
Aims & Methods: The aim of this study is to evaluate the endoscopic recognition of ESCC using by four different methods (OLYMPUS white light: OWL, FUJIFILM white light: FWL, NBI, and BLI-bright). We retrospectively analyzed 25 superficial ESCCs that were examined using among OWL, FWL, NBI, and BLI-bright at Kyoto Prefectural University of Medicine (KPUM) from March 2012 to December 2014. A typical ESCC was observed as a reddish area (RA) by using OWL and FWL, or as a brownish area (BA) by using NBI and BLI-bright in a distant view. Subjective evaluation was investigated as a ranking score (RS) by three endoscopists who ranked the each image on the basis of the ease of detection of cancer area (very clear: 3 scores/ clear: 2 scores/ unclear: 1 score). As objective evaluation, we calculated the Color Difference Scores (CDS) of pixel values based on L*a*b* color spaces between each cancer and noncancerous area.
Results: There are no difference between the mean RS of OWL and FWL. The mean RS of NBI was significantly higher than OWL ($p < 0.01$) and that of BLI-bright was significantly higher than FWL ($p < 0.01$). Moreover, the mean RS of BLI-Bright was significantly the higher than NBI ($p < 0.01$). Furthermore, in the objective evaluation, the mean CDS of BLI-bright was significantly the highest than that of OWL ($p < 0.05$), FWL ($p < 0.01$) and NBI ($p < 0.01$). Therefore, BLI-bright images was significantly higher than that obtained from the other methods both RS and CDS.
Conclusion: The recognition of cancer areas using BLI-bright was the most clear than using the other methods (OWL, FWL, and NBI) both subjectively and objectively. BLI bright may be a valuable tool for identifying superficial ESCCs during screening endoscopy.

Introduction: Metal stent placement has been proposed as potential treatment for refractory benign esophageal strictures. Biodegradable stents (BDS) have been used to overcome the traditional shortcomings of metal stents for benign indications. However BDS were evaluated only in small cohort studies with a short follow-up.
Aims & Methods: Aim of this study is to report long-term outcome and safety of a large group of patients treated with BDS over 6 years. Prospectively maintained database has been used to collect data on consecutive patients with refractory benign esophageal strictures (according to Kochman criteria) treated at a single tertiary level centers using a BDS since 2008. BDS have been placed under fluoroscopy; endoscopic and radiologic follow-up was planned at 3 and 6 months followed by a phone interview or outpatient appointment. Technical success was defined as uneventful placement of the BDS at the level of the stricture. Clinical success was defined as the absence of dysphagia for at least 12 months after BDS placement. Recurrent dysphagia due to stricture formation was defined as any recurrent stricture that could not easily be passed by a standard endoscope (9.8mm) together with symptoms of dysphagia for solid food (grade ≥ 2).
Results: 42 patients (28M, mean age 53.2 y) received a BDS. In 26 patients a small size (18-23 mm) BDS was used while a larger BDS (23-25 mm) was placed in the reaming. Stricture etiology was post-surgery in 12 (28.5%), post-caustic ingestion in 20 (47%), post-radiotherapy in 8 (19%) and idiopathic in 2 (4.7%). Mean number of dilation before BDS was 12.6 (range 8-17) and 17 patients were previously treated with fully covered metal stent. BDS was successfully placed in all patients. Early complications occurred in 11 patients (26%) and were mainly related to thoracic pain requiring prolonged medical therapy in 10 and stent migration in 1 patient just two weeks placement. Late complications were observed in 3 patients (2 perforation occurred respectively 4 and 6 weeks after placement and 1 bleeding requiring hospitalization 8 weeks after placement). The overall complication rate was 33%. One patient died after surgery, required because of perforation. The second perforation was managed uneventfully placing a fully covered stent. Mean follow-up was 38.3 months (range 17-68). Long-term relief of dysphagia was obtained in 11 out of 42 treated patients (26%). The median dysphagia-free period was 293 days (range 35-1688). Long-term relief of dysphagia was significantly associated to post-surgery stricture ($p = 0.001$). There was no difference in terms of BDS diameter between patients with or without complications.
Conclusion: BDS in patients with esophageal refractory strictures was associated with 26% success rate and 33% complication rate, leading to surgical intervention in 2 cases and death in 1 case. Caution is recommended when BDS is considered for treatment of benign refractory strictures related to post-caustic ingestion or post-radiotherapy.

P0116 UPPER GASTROINTESTINAL CANCER MISSES: COULD WE DO BETTER?

A. H. Gahanbani Ardakani[1], **S. Mann**[1]
[1]*Gastroenterology, Barnet General Hospital, London, United Kingdom*

Contact E-mail Address: amir.ardakani@nhs.net
Introduction: Endoscopy is the gold standard investigation for the diagnosis of gastro-oesophageal cancer. As occurs with lower GI malignancy, cancers can be missed at endoscopy, but this may not be appreciated by the endoscopist, nor is audit of gastroscopy as well established as that for colonoscopy. Studies have suggested that endoscopy technique may account for the majority of misses. In general, a cancer detected within 3 years following an endoscopy is considered to be a 'potential miss' and if detected within 1 year after an endoscopy, that is likely to be a 'definite miss'. This is based on the premise that early oesophageal cancers have a long natural history (1,2).
Aims & Methods: The aim of this study was to establish the proportion of missed upper GI cancers at our institution. We conducted a retrospective, case study of patients diagnosed with oesophageal and gastric cancers between January 2011 and January 2015 from our hospital cancer registry. Information regarding any gastroscopies done within 3-36 months of cancer diagnosis was obtained for each patient using our electronic endoscopy reporting tool.
Results: There were 305 new cases (Male = 207; 68%; mean age 73.8 yrs; range 26-100 yrs) of upper GI cancer, of whom 23 (7.5%) had undergone a gastroscopy within 3–36 months of the diagnosis. Only 2 patients had undergone an endoscopy procedure in the 3–12 months prior to diagnosis. Alarm symptoms were present in 11 patients (48%; information available in 20 patients) at the time of the index 'miss' endoscopy.
Conclusion: Oesophago-gastric cancers appear to have been missed at endoscopy in 7.5% of patients in our unit. This value parallels outcomes reported elsewhere

(1,2). Given the poor prognosis associated with upper GI malignancy, this study reminds us to be vigilant when examining the mucosa, particularly at the cardia, which is most vulnerable with regards to missing a cancer. The endoscopist should also have a low threshold for suspicion in patients presenting with alarm symptoms. Although there are many established performance indicators for colonoscopy, endoscopists are less familiar with gastroscopy measures of quality. We believe that addressing gastroscopy technique will have an impact on early detection of upper GI cancers and improve outcomes for these patients.

P0117 PREDICTORS OF OUTCOMES AND LEARNING CURVE FOLLOWING PER ORAL ENDOSCOPIC MYOTOMY FOR ACHALASIA CARDIA

A. Maydeo[1], N. Joshi[1], S. Bhandari[1], V. Dhir[1]
[1]*Baldota Institute of Digestive Sciences, Mumbai, India*

Contact E-mail Address: amitmaydeo@gmail.com

Introduction: Per Oral Endoscopic Myotomy (POEM) is an effective treatment for achalasia cardia. There are no studies evaluating predictors of POEM outcome and the impact of learning curve. This single-center, retrospective study aimed at evaluation of predictors of POEM outcomes and assess the impact of learning curve.

Aims & Methods: 268 patients with achalasia cardia were subjected to POEM. POEM was done by posterior approach in first 208 patients, and anterior approach in the next 60 patients. Hybrid knife was used in 200 and triangular tip knife in 68 patients. Primary outcome measure was treatment success defined by Eckardt's score ≤ 3. Secondary measures were adverse events. Multivariate analysis was done for factors affecting outcome and learning curve determination was done.

Results: Technical success was achieved in all patients. There were 9(3.35%) treatment failures. Six failures occurred in the first 40 patients, while 3 occurred in the next 228 patients (15% vs. 1.3%, $p = 0.0005$). There were 12 adverse events (AE) in the first 40 patients (30%), and 26 (11.4%) in the next 228 patients ($p = 0.005$). On multivariate analysis, the factors adversely affecting treatment success were male gender ($p = 0.017$) and prolonged operative time ($p = 0.030$). Prolonged operative time ($p = 0.006$) and type of achalasia ($p = 0.034$) were found to be independent predictors of AE.

Conclusion: Male gender, type of achalasia and prolonged operative time are important predictors of adverse POEM outcome. The treatment success improves, and the rate of adverse events declines significantly after first 40 procedures

P0118 "DO WE ALWAYS HAVE WHAT WE FEEL?" - PREDICTIVE FACTORS FOR ESOPHAGEAL FOREIGN BODIES PRESENCE IN URGENT ESOPHAGOSCOPY

A. R. Alves[1], S. Giestas[1], P. Figueiredo[1], C. Sofia[1]
[1]*Gastroenterology Department, Coimbra Hospital and University Centre, Coimbra, Portugal*

Contact E-mail Address: alvess.anarita@gmail.com

Introduction: Urgent upper digestive endoscopy is frequently required in cases of suspected esophageal foreign bodies (EFD). Persistent esophageal symptoms following foreign bodies ingestion should be evaluated by endoscopy; however, absence of EFB requiring endoscopic removal when esophagoscopy is performed is frequently observed.

Aims & Methods

Aims: Identify predictive factors for EFB presence in urgent esophagoscopy.

Patients and Methods: Retrospective case-control study. All consecutive esophagoscopies performed due to persistent esophageal symptoms after involuntary foreign bodies ingestion were analyzed, during an 18 months period. Demographic and relevant clinical data from patients with presence or absence of EFB when esophagoscopy was performed were compared. Statistical analysis included *Fisher*, Qui^2 and t tests for univariate analysis and logistic regression for multivariate analysis.

Results: One-hundred and sixty-one patients were submitted to urgent esophagoscopy due to clinical suspicion of EFB impaction (mean age 60.5 ± 18.2 years, 61.2% female). Impaction of EFB was confirmed in 41.6% of patients. Most frequent foreign bodies were: meat bones 39.8%, fish bones 39.8%, pits 3.7%, dental prosthesis 3.1%, blister pills 2.4% and sharp metal objects 1.2%. Patients with EFB were significantly older than the patients without EFB (60.5 ± 18.2 *vs.* 49.7 ± 18.7 years; $p < 0.001$) and recurred earlier to the urgency (10.7 ± 15.1 *vs.* 21.0 ± 26.5 hours; $p = 0.003$). Relevant underlying diseases, namely neurological, psychiatric or otorhinolaryngological (ORL), were more prevalent in patients with EFB (17.9% *vs.* 2.1%; $p < 0.001$). Regarding specific pathology type, a higher prevalence of psychiatric (9.0% *vs.* 2.1%; $p = 0.049$) and ORL conditions (6.0% *vs.* 0.0%; $p = 0.016$) was found in patients with EFB. No differences were found between patients with or without EFB concerning gender, day of the week of ingestion, type of foreign body type ingested or underlying neurological problems. Multivariate analyses identified the following predictive factors for EFB presence in esophagoscopy: older age, earlier recurrence to urgency and underlying psychiatric or ORL diseases (OR = 7.0; IC95%:1.4-35.0).

Conclusion: In cases of persistent esophageal symptoms after involuntary foreign bodies ingestion, less than half of patients had an effective EFB. Older age, earlier recurrence to urgency and psychiatric or ORL problems were associated with EFB presence when esophagoscopy was performed.

P0119 ROUTINE PREOPERATIVE UPPER ENDOSCOPY IN PATIENTS UNDERGOING BARIATRIC SURGERY

A. Vaz[1], M. Eusebio[1], A. Antunes[1], T. Gago[1], P. Queirós[2], M. Sanchez[3], T. Sanai[3], J. Teixeira[3], R. Ornelas[1], H. Guerreiro[1]

Contact E-mail Address: anam_vaz@hotmail.com

Introduction: The difficulty of endoscopic evaluation of the remaining stomach after bariatric surgery is a fact that concerns a great number of doctors. However, the performance of a routine preoperative upper endoscopy (EGD) in every patient is not consensual, because these are mostly young and healthy patients with a low risk of malignancy.

Aims & Methods: Our aim was to evaluate the findings and relevance of preoperative EGD. We performed a retrospective study including patients who had undergone EGD before bariatric surgery between January 2012 and December 2014

Results: A total of 200 patients were studied; 90% were females, with a mean age of 44.2 ± 11.2 years. The mean weight and body mass index were 109.6 ± 18.2Kg and 42.2 ± 4.9 Kg/m^2, respectively. Sixty-nine patients (34.5%) reported symptoms (heartburn/regurgitation or epigastric pain) before the EGD. There were endoscopic findings in 47% of the patients, the most common being hiatal hernia (19.5%), gastritis (19.5%), esophagitis (10%), gastric polips (3.5%) and duodenitis (3%). Gastric biopsies were performed in 186 patients with positive findings in 129 (69.4%) of them: acute and/or chronic gastritis in 100% and intestinal metaplasia in 3.8%. The presence of symptoms didn't correlate significantly with the presence of endoscopic or histologic findings.

One hundred and ninety-one proximal gastric bypasses (95.5%) and 9 sleeve gastrectomies were performed. In 4 patients, a hiatal hernia repair was done concomitantly. Postoperative complications occurred in 12 (6%) patients, the most common being anastomotic stricture, without any significant correlation with endoscopic or histologic findings.

Conclusion: Endoscopic and histologic findings were common in preoperative EGD but they did not conditioned significant changings in the planned surgical procedure nor did they correlated with postoperative complications in our study. However, in the absence of correlation between symptoms and endoscopic findings and being EGD an accessible exam, it seems reasonable to perform it in all patients before bariatric surgery.

P0120 GASTRIC PRECANCEROUS CONDITIONS AND LESIONS IN LYNCH SYNDROME PATIENTS

Â. Rodrigues[1], R. Marcos-Pinto[1], D. Libânio[2], M. Dinis-Ribeiro[2], I. Pedroto[1]
[1]*Centro Hospitalar do Porto - Hospital Santo António,* [2]*Instituto Português de Oncologia, Porto, Portugal*

Contact E-mail Address: angelamaria.cr@gmail.com

Introduction: Gastric cancer is the second most frequent extracolonic neoplasm in Lynch syndrome (LS) patients. The majority of them are intestinal adenocarcinomas, consequent to the progression of precancerous conditions and lesions. The main groups recommend performing an upper endoscopy, but with low level of evidence and depending on local context. The objective was to evaluate the prevalence of precancerous conditions and lesions (risk phenotype) in LS patients.

Aims & Methods: Case-control study with evaluation of gastric phenotype (endoscopy with biopsy) and *Helicobacter pylori (Hp)* infection status (histology and serology).

Results

Cases: 36 patients, from 17 families, MSH2 mutations in 58%, MLH1 in 28% and MSH6 in 14%, family history of gastric cancer in 8 families.

Controls: 100 dyspeptic patients. Around 50% males (41% in controls), average age of 53.25 ± 12.62 (42.56 ± 12.34 in controls). LS patients had a higher prevalence of atrophy of the antrum (33.3% versus 19%, OR 2.13 95% CI 0.91-5.01), intestinal metaplasia of the antrum (16.7% versus 13%, OR 1.34 95% CI 0.47-3.83), extensive atrophy (8.3% versus 4%, OR 2.18 95% CI 0.46-10.26) and extensive intestinal metaplasia (2.8% versus 1%, OR 2.82 95% CI 0.17-46.44) than the controls. Patients with LS had a higher prevalence of *Hp* infection (78.8% versus 59%, $p < 0.05$).

Conclusion: Our results suggest that there is a higher tendency to precancerous gastric conditions in LS patients, although with no statistical significance, which can be due to the small sample size. Nevertheless, LS patients were older and had a higher prevalence of *Hp* infection, which can have impact on results. Larger studies are important to define if LS is indeed associated with a risk gastric phenotype and if a systematic and periodic endoscopic surveillance should be recommended.

P0121 ENDOSCOPIC FULL-THICKNESS RESECTION IN THE DUODENUM - A CASE SERIES

A. Schmidt[1], B. Meier[1], K. Caca[1]
[1]*Department of Gastroenterology, Klinikum Ludwigsburg, Ludwigsburg, Germany*

Contact E-mail Address: arthur.schmidt@gmx.de

Introduction: Endoscopic resection of duodenal non-lifting adenomas and subepithelial tumors is challenging and harbors a significant risk of complications. We report on a novel technique for duodenal endoscopic full thickness resection (EFTR) using an over-the-scope device.

Aims & Methods: Aim of this study was to demonstrate feasibility of EFTR in the duodenum using a novel full-thickness resection device (FTRD, Ovesco Endoscopy, Tuebingen, Germany). Data of 4 consecutive patients who underwent duodenal EFTR was analysed retrospectively. Main outcome measures were technical success, R0 resection, histologically confirmed full thickness resection, adverse events.

Results: Four patients (median age: 60 y) with non-lifting adenomas (2 patients) or subepithelial tumors (2 patients) underwent EFTR in the duodenum. All lesions could be resected successfully. Mean procedure time was 67.5 min (range 50-85). Minor bleeding was observend in 2 cases; blood transfusions were not required. There was no immediate or delayed perforation. Mean diameter of the resection specimen was 28.3 mm (range 22-40). Histology confirmed complete (R0) full thickness resection in 3 of 4 cases. Endoscopic follow-up after 2 months could so far be obtained in 2 patients. In both cases, the OTSC was still in place in could be removed without complications, recurrencies were not observed.

Conclusion: EFTR in the duodenum with the FTRD is a promising technique which has the potential to spare surgical resections. Modifications of the device should be made to facilitate peroral introducability. Prospective studies are needed to further evaluate efficacy and safety for duodenal resections.

[2]*Gastroenterology department, Centro Hospitalar de Setúbal, Setúbal, Portugal*

Contact E-mail Address: sergiogiao@hotmail.com

Introduction: The ingestion of caustic substances is one of the major areas of Gastroenterology emergency, and the endoscopic evaluation is the gold standard for assessing the grade of lesions and to define the prognosis. However, in addition to being contraindicated in severe situations, it is not risk-free and its usefulness is debatable in cases of asymptomatic patients without oropharyngeal lesions.

Aims & Methods: (1) To identify clinical and laboratory factors for predicting gastrointestinal caustic injury; (2) creation of a clinical and laboratory model that could identify patients with high-grade gastrointestinal lesions (HGGL) and low-grade gastrointestinal lesions (LGGL), without need of performing an endoscopy.

Multicentric retrospective study, that reviewed all the patients who ingested caustic and were admitted to our centers over a period of 10 years. For defining the grade of lesions, we used Zargar score system (HGGL $\geq$ 2B; LGGL $\leq$2A). We identified clinical and laboratory variables that were statistically significant associated with HGG and we calculated the correlation coefficient.

Results: We identified 133 patients, of whom 65 had a HGGL (Esophagus: 50 patients; Stomach: 43 patients).

When comparing patients with and without HGGL, we identified statistically significant differences for the variables average value of leukocytes (15.3 versus 9600 x10^9/L; p = 0.000) and CRP (73 versus 25 mg/L; p = 0.000). The variables leukocytes (rs = 0.497; p = 0.000), CRP (r = 0.485; p = 0.000) and the number of symptoms (rs = 0.667; p = 0.000) showed a significant moderate correlation to HGGL. In univariate analysis, ingestion of acid (X^2 = 6.881; p = 0.009), ulcers in the oropharynx (X^2 = 18.304; p = 0.000) and hemodynamic instability (X^2 = 19.027; p = 0.000) were also associated with HGGL.

There was no statistical association between HGGL and the variables gender, intentional ingestion, age, previous attempt, psychiatric disease and dependence of toxic substances.

The factors with the strongest relationship to HGGL (leukocytes count; CRP; symptoms; ulcers in the oropharynx and hemodinamic instability) were used to develop an objectively weighted multivariate prognostic score ranging from 0 to 14 points, with a good prognostic discrimination (area under the receiver operating characteristic curve = 0.901). The ROC curve analysis suggests for identification of HGGL, the optimal cut-off of 10 points, with a specificity of 97% and sensitivity of 64%; and for LGGL the cut-off of 5 points, with a specificity of 94% and a sensitivity of 66%.

Conclusion: Our results confirm the model as a good test (AUC = 0.901), but in need of prospective validation, preferably in international multicentric studies.

P0123 DUODENAL ENDOSCOPIC SUBMUCOSAL DISSECTION; SINGLE CENTER EXPERIENCE IN TURKEY

F. Aslan[1], Z. Akpınar[1], M. Arabul[1], H. Çamyar[1], M. Kartal[1], M. Camcı[1], **B. Ünsal**[1]
[1]*Gastroenterology, Katip Celebi University Ataturk Training and Research Hospital, Izmir, Turkey*

Contact E-mail Address: drfatihaslan@hotmail.com

Introduction: Endoscopic Submucosal Dissection (ESD) is an endoscopic treatment modality providing en-block and complete resection of mucosal and submucosal lesions. Duodenal ESD is technically more difficult than gastric and colorectal ESD with longer procedure duration and higher complication risk. Here we present our experience with duodenal ESD.

Aims & Methods: A total of 345 ESD procedures of the esophagus, stomach, colorectum and duodenum had been performed between April 2012 and April 2015 the data of which had been recorded prospectively. During this study the records were searched retrospectively and the results of 8 duodenal ESD were analyzed.

Results: Duodenal ESD had been performed only after performing more than 200 ESD of stomach, esophagus and colorectum. There were 8 patients with duodenal ESD, in 5 patients the lesion was in the duodenal bulb and in 3 patients the lesion was in the second part of the duodenum. The median age of patients was 59.5 years (38-72y), median length of resected tissue was 33.5 mm (14-73), median length of lesion was 16.5 mm (9-67) and median procedure duration was 31.5 min. (16-345).

All the lesions were removed en-block. On histopathological examination both lateral and vertical margins were clear in all patients. During the procedure perforation occurred in patient which was successfully treated medically and with endoscopic clipping. No recurrence was seen during endoscopic follow-up and complete resection was achieved in all patients (Table).

Conclusion: Although duodenum is a difficult localization for endoscopic interventions and duodenal ESD bears higher complication risks because of thin wall, as the guidelines suggest, we believe that after experiencing in stomach and rectal ESD, duodenal ESD can also be performed successfully when needed.

P0124 GRADING ATROPHIC GASTRITIS BY A NEW QUANTITATIVE METHOD USING CONFOCAL LASER ENDOMICROSCOPY PROBE (P-CLE): FIRST RESULTS OF A PROSPECTIVE COHORT STUDY

C. Robles-Medranda[1], M. Puga-Tejada[1], J. Ospina[1], M. Soria[1], G. Bravo[1], R. Del Valle[1], H. Pitanga Lukashok[1]
[1]*Endoscopy, Instituto Ecuatoriano De Enfermedades Digestivas, University Hospital Omni, Espiritu Santo University, Guayaquil, Ecuador*

Contact E-mail Address: carlosoakm@yahoo.es

Introduction: Atrophic gastritis (AG) is a chronic disease, associated to gastric adenocarcinoma moreover if severe AG is present. Sydney system classifies AG as mild, moderate and severe, but with moderate interobserver agreement, as this system is based on a visual analogic scale (qualitative analysis). Confocal endomicroscopy showed an accuracy of 98% for diagnosis of gastric diseases, but when grading AG still remains a qualitative measure. Recently, new software called "Cellvizio® Viewer" (CV) permits to measure in micrometers (μm) the structures observed after p-CLE studies.

Aims & Methods: Based on the hypothesis that AG severity is correlated with crypts size diminution, the ***aim*** of this study is to determine a quantitative way to classify the severity of AG measuring the crypt area and inter-crypt spaces in patients with AG. After approval by the ethics committee 200 consecutive patients that underwent to upper endoscopy (UE) evaluation were included in this prospective study. Inclusion criteria: dyspepsia >12 months, age ≥ 18, no history of UE evaluation, AG at histopathology, acceptance to participate. Exclusion criteria: use of PPIs, antibiotics or NSAIDs, gastric cancer, gastric surgery, pregnancy, contraindication to fluorescein. During UE 5 biopsy sites were performed in accordance to Sydney system first using p-CLE and then by biopsy forceps from the same site. At p-CLE normal crypt was defined by using the classification of Wang et al (1). After histopathology confirm AG, crypts were analyzed using the CV software measuring the crypts diameters, to determine the area by elliptic area formula ($A = \pi.d_1.d_2$) and measuring inter-crypt space. That space was defined as the mean of each measured distance between the studied crypt and its adjacent. The cutoff value between mild, moderate and severe AG, crypts area was classified across tertiles, expressing its distribution using a box-spot graphic. For relationship between crypt area (CA) and inter-crypt space, quadratic polynomial regression was used. Data was processed using IBM® SPSS® Statistics.

Results: 30 patients were identified to have AG, 16 females (55%) with a mean age of 47.82 ± 18.3 and 146 crypts were analyzed. Histopathology showed AG: absent in 10 (38.5%), mild 8 (30.8%), moderate 6 (23.1%) and severe 2 (7.7%) of cases. At p-CLE the mean CA was 4697 (848 – 14794), and average of mean inter-crypt distance was 33.76 (0.00 – 87.45). Minimum normal CA was 10000 μm^2. Classifying AG crypts was established as follow: mild atrophic CA (μm2) range: 5000 and <10000, moderate AG CA: 3000 and <5000. Severe AG CA was <3000. Quadratic polynomial regression established a statistically significant relationship between CA and inter-crypt space

Conclusion: Using p-CLE criteria, severity of AG could be defined through crypt area and inter-crypt space with values of $<3000\mu m^2$ and 40μm respectively.

Introduction: It has been demonstrated that endoscopic and histopathology findings don't have good correlation, leading sometimes to diagnostic and therapeutic doubts. Confocal laser endomicroscopy probe (p-CLE) is a new technology which permits in-vivo cellular view of gastrointestinal mucosa. It includes esophagus, stomach, small intestine, colon, biliary tract and pancreas. Studies showed a diagnostic accuracy above 90% for neoplastic (N) and non – neoplastic (NN) lesions, with specific characteristics and classifications. However, few studies have been oriented to determine the clinical impact of p-CLE for diagnosis and management in patients with diagnostic doubts.

Aims & Methods: The aim of this study is to put in evidence the clinical impact of p-CLE in this group of patients. Prospective study, performed from November 2013 to November 2014, in consecutive patients in whom p-CLE (Cellvizio®, Mauna Kea Technology) was indicated due to diagnostic doubts (absence of endoscopic–histological relationship). Baseline characteristics, indications, previous diagnosis studies, findings at p-CLE, clinical management and histopathological outcomes were evaluated. Indications for p-CLE were N and NN lesions. Lesions include: adenomas, dysplasia or cancer located in any gastrointestinal tract level, Barrett's esophagus, inflammatory bowel disease or pancreatic cysts. Previous diagnostic studies included: high definition magnification with digital chromoendoscopy, ERCP with brushing, EUS. Other studies were: CT-scan, cholangiography by MRI, tumor markers. Interventions based on the findings of p-CLE were analyzed according to the records, and included: drug treatment, other diagnostic studies, endoscopic or surgical treatments. The diagnostic yield was determined thought sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV) and match measurement. Diagnostic and therapeutic management, redirection of biopsies and need of other diagnostic methods were evaluated.

Results: 43 patients were included. 51% were male (22/43) with mean age of 49 ± 19 years. N lesions were 37% (15/43) of cases, located at: stomach (6), esophagus (4), bile duct (3) and colon (2). The sensitivity was 87% and specificity of 93%,(AUC = 0.9582) with a PPV of 87% and NPV 93%. p value <0.05. The observed concordance was 90.6% with a Kappa value of 0.80, corresponding to a force of substantial agreement according to Landis & Koch criteria. Changes in diagnostic and therapeutic approach were evident in 39.5% of cases (17/43), directing the sampling in 100% of cases (17/17) and avoiding diagnostic or therapeutic methods in all cases.

Conclusion: p-CLE is an essential diagnostic tool for patients with diagnostic doubts, as it allows in-vivo display cell and helps to direct biopsies. It has a significant clinical impact on the diagnosis and treatment of patients.

Introduction: Screening endoscopies in individuals 40 years or older in regions where gastric cancer is prevalent increase the diagnosis of gastric cancer at an early stage. However, the benefits of screening endoscopies in a young population (<40 years) have not been evaluated.

Aims & Methods: We reviewed data from patients less than 40 years old who underwent endoscopic submucosal dissection (ESD) or surgery for initial-onset gastric. We also administered a questionnaire to gather information concerning periodic endoscopic inspections and the period from the penultimate endoscopy to diagnosis.

Results: Of the 564 patients in this study, 101 (17.9%) and 36 (6.4%) patients had undergone screening endoscopies within 24 months and 60 months of gastric cancer diagnosis, respectively. The proportion of patients with early gastric cancer (EGC) was 67.6%, 83.3%, and 64.3% in the $\leq$24 months, 24 to 60 months, and >60 months groups, respectively ($P = 0.063$). On multivariable analysis, periodic endoscopies did not influence early diagnosis of gastric cancer (with >60 months as the reference group: $\leq$24 months, odds ratio [OR] = 0.992, 95% CI = 0.614–1.603; 24–60 months, OR = 2.238, 95% CI = 0.891–5.625). However, the proportion of lesions treated with ESD did differ according to the interval between endoscopic examinations ($P = 0.048$).

Conclusion: Although periodic endoscopies increased the proportion of patients with EGC that was treated with ESD, they did not increase the proportion of patients diagnosed with gastric cancer that was determined to be EGC in a young population.

Introduction

Background: The treatment of early gastric cancer (EGC) by endoscopic submucosal dissection (ESD) has been rapidly gaining popularity in Korea. Current guidelines for endoscopic management such as EMR and endoscopic submucosal dissection (ESD) in early gastric cancer (EGC) are in evolution, with broader indication criteria. In Korea, indication of ESD for early gastric cancer have been still one of big issue.

Aims & Methods

Aim: The purpose of this retrospective comparative study was to evaluate clinical outcome of ESD for EGC, based on absolute indication and expanded indication criteria,

Method: ESD was performed on 1102 cases of early gastric neoplasm (cancer: 631, dysplasia: 471) from Jan 2002 to Aug 2011 at Soon Chun Hyang University Bucheon Hospital.

According to final diagnosis, EGCs below were enrolled by two groups (absolute vs expanded) and followed up: absolute: differentiated intramucosal (IM) cancer less than 20 mm, expanded: differentiated-type intramucosal cancer less than 30 mm in diameter or minute sm invasion (<500 μm from the muscularis mucosa) or undifferentiated IM cancer less than 10 mm.

Results: En bloc and complete resection rate in absolute and expanded group were 94.1% vs 90.7%, 93.7% vs 88.5% (*NS*). Size of lesion was 12.7 ± 4.8 mm, 26.6 ± 13.0 mm ($p < 0.05$). Complication such as bleeding and perforation was no statistical difference ($p > 0.05$). There was no between-group difference in the local recurrence rate (1.4% vs1.8%; NS) at a median follow-up period of 28 months (interquartile range 6-48 months).

Conclusion: Higher en bloc resection and complete resection rate, lower complication and recurrence in expanded group of ESD for EGC revealed as absolute group.

We concluded indication of ESD for EGC can be expanded.

Contact E-mail Address: ac.corda.teixeira@gmail.com
Introduction: There is an increasing incidence of caustic substances ingestion in the Western Countries, carrying a high risk of luminal strictures.
Aims & Methods: Identify predictive factors for the development of esophageal stenosis, and evaluate the effect of corticoteraphy and antibiotic therapy in reducing that risk. Multicentric retrospective study, that reviewed all the patients who ingested caustic substances and were admitted to our centers over a period of 10 years. Demographic, clinical, analytical, endoscopic (Zargar score) data were obtained. Univariate and multivariate logistic regression analysis was performed.
Results: 133 patients, 67 females, mean age 49, of whom 100 were hospitalized (median: 6 days). During follow up, 20 patients developed strictures, (esophagus: 90%), predominantly after alkaline substances ingestion (83%). Strong alkali ($p = 0.000$), esophageal lesions Zargar 2B ($p = 0.002$) and Zargar 3A ($p = 0.001$), invasive ventilation ($P = 0.012$), oral feeding after 48h ($p = 0.003$) and total parenteral nutrition (TPN) ($p = 0.000$) were independent risk factors for esophageal stenosis. Delay in the oral feeding had a moderate correlation for stricture development ($rs = 0.422$;$p = 0.00$). Corticotherapy ($p = 0.031$) and antibiotic therapy ($p = 0.001$) were not associated with risk reduction. Age, strong acid, intentionality and recurrence of ingestion were not associated with stricture risk ($p > 0.05$). Multivariate analysis revealed that only strong alkali (OR = 18,81), TPN (OR = 6,6) and esophageal lesions Zargar-2B (OR = 7,18) and Zargar-3A (OR = 12,12) maintained statistical significance.
Conclusion: There was a higher risk of esophageal stenosis with strong alkali ingestion and with higher severity of endoscopic lesions. Corticotherapy and antibiotic therapy were not associated with risk reduction. Our study suggests a potential cytoprotection effect of early oral feeding in esophageal stenosis risk reduction.

Introduction: The number of endoscopic submucosal dissections (ESD), as well as endoscopic mucosal resection (EMR), performed for sporadic non-ampullary duodenal adenoma/carcinoma (SNADA) has recently increased. EMR for SNADA is a comparatively safe procedure, but there are concerns regarding local recurrence, due to a non-R0 resection or piecemeal resection. On the other hand, ESD for SNADA is excellent for en-bloc resection; however, the rate of complications in the duodenum, such as perforation, is much higher than that in the rest of the digestive tracts. Moreover, the indications for duodenal ESD are highly controversial. We therefore analyzed the necessity of ESD for SNADA from the perspective of long-term clinical outcomes and complications.
Aims & Methods: We retrospectively evaluated 82 patients, who underwent endoscopic resection, and who were histopathologically diagnosed as SNADA between May 2004 and February 2015 at our institution. Of 87 lesions, the final pathological diagnoses were low-grade dysplasia, high-grade dysplasia, and adenocarcinoma, in 23, 30, and 34, respectively; in all cases of adenocarcinoma, the disease had invaded up to the mucosal layer. The mean size of the lesions was 10.5 ± 5.7 mm. The numbers of lesions resected by polypectomy, EMR, strip biopsy, EMR with a cap-fitted panendoscope (EMR-C), and ESD were 1, 35, 9, 31, and 11, respectively.
Results: Eighty lesions were endoscopically followed up at least once after endoscopic resection (mean follow up period [months], 32.9 ± 28.5; range, 3–111), and 67 were followed up endoscopically for more than 1 year (mean follow up period [months], 38.2 ± 28.2; range, 12–111). The overall rate of R0 resection was 46.0% (40 of 87), and that of en-bloc resection was 77.0% (67 of 87). The rate of intraprocedural perforation was 3.4% (3 of 87), all of which occurred during ESD; the rate of intraprocedural perforation of ESD was 27.3% (3 of 11), which was significantly higher than that of the rest of the procedures (vs. 0% [0 of 76]; $p < 0.001$, chi-square test). There was only 1 case (1.3%) of local recurrence after resection; this was a case of piecemeal EMR for intramucosal carcinoma in 2 segments, and the recurrent lesion was resected by EMR 3 months after the initial resection, with no re-recurrence. Of the 67 lesions which were endoscopically followed up for longer than 1 year, the recurrence-free rate was 98.5% (66 of 67); the recurrence-free rates for cases of non-R0 and piecemeal resection were 97.5% (39 of 40, 12–95 months) and 91.7% (11 of 12, 12–89 months), respectively. There were no cases of distant recurrence or death from SNADA.
Conclusion: In terms of long-term clinical outcomes, the prognosis of the patients who underwent resection of SNADA with ESD was excellent; the patients who underwent resection of SNADA with non-R0 or piecemeal resection also had a favorable long-term prognosis, because of the rarity of recurrence. We think that reconsideration of the indications for ESD for SNADA is necessary, given the high frequency of complications with ESD.

P0130 INTRAGASTRIC MIGRATION OF LAPAROSCOPIC ADJUSTABLE GASTRIC BANDING. ENDOSCOPIC TREATMENT IS ALWAYS FEASIBLE. THE EXPERIENCE OF A SPANISH NON TERTIARY HOSPITAL

D. Collado[1], L. R. Rábago[1], L. Alonso Castillo[1], A. Ortega[1], M. Perez[1], M. Arias[1], J. Vazquez Echarri[2], N. Herrera[2]
[1]*Gastroenterology,* [2]*surgery, Hospital Severo Ochoa, Leganes, Spain*

Contact E-mail Address: lrabagot@gmail.com
Introduction: Intragastric band migration is an uncommon complication of Laparoscopic Adjustable Gastric Banding (LAGB) (0.5-11%) usually resolved by a surgical approach. We describe our experience .
Aims & Methods: Since 2001 we treated 127 morbid obese patients (pts) by LAGB. Patients with migration of gastric band into stomach more than 50% of circumference were able to be treated. The procedure was performed under general anesthesia. It is not necessary to use fluoroscopy.
Procedure: The band is cut using the wires from mechanical lithotripsy basket (MTW) or a 0.035 standard guidewire. Second the wire is looped about the visible band, grasped by the alligator forceps and brought out through the patient's mouth. Then the guidewire two ends are placed into the metal sheath of the mechanical lithotriptor (MTW) in order to cut it. The surgeon excised and removed the tubing and external port. Finally the split band is removed using a polypectomy snare, usually with a gentle pulling back from the esophagus.
Results: We found that 11 out of 127 LAGB (8.6%) become symptomatic due to gastric migration. 88.8% were females with average age of 42.6 yo. The time between the band placement and endoscopic removal was 60.5 months.
The symptoms were epigastric pain and weight regain as a sign of band dysfunction. Three pts were operated, one refused endoscopic treatment and the others were operated by band dysfunction finding out the gastric migration. 7 out of 9 LAGB (77.7%) were endoscopically removed in one session. We had two failures, 1 out of 9 LAGB (11.1%) was not possible to cut and the other (11.1%) was split but not removed due to difficulties with ventilation by excessive gas insufflation. His recovery from the attempt was uneventful and she remains well after 7 years of follow up, waiting for their possible complete migration. No complications were noticed after the endoscopic removal and pts were discharged in average of 2.6 days (17). The band removal was accomplished in three steps: a) cutting the band of silicone in the middle part avoiding the plastic part near the external tube, b) seizing the end of the split band near the external tube, coming from the port and c) pulling the endoscope out steadily and forcefully to liberate the band from the gastric wall.
Conclusion: More than 8.6% of LAGB will have gastric migration and develop symptoms. The endoscopic removal of LAGB is feasible, safe, but not easy, being a good alternative to surgery. We were able to remove 77.7% of LAGB, but the band should be migrated more than 50%. It is important to know very well the removal technique and their tricks. It is not necessary the use of intraoperative fluoroscopy and it seems to be safe to cut the band without its removal.

P0131 ENDOSCOPIC TREATMENT OF FISTULAS AFTER BARIATRIC SURGERY: EXPERIENCE OF A SINGLE CENTER

D. F. B. Carvalho[1], R. Loureiro[1], P. Russo[1], C. Bernardes[1], I. Seves[1], R. Rio-Tinto[1]
[1]*Gastroenterology, Hospital Santo António dos Capuchos, Lisbon, Portugal*

Contact E-mail Address: dianafbcarvalho@gmail.com
Introduction: Bariatric surgery is the most effective treatment for long-term resolution of obesity and its co-morbidities. The complexity of the procedure and the surgical risk in obese patients is associated with significant morbidity and mortality. Fistulas in suture sites are the most serious complications and their best therapy approach is not yet defined. In the literature there are several small series and descriptions of cases in which self-expandable metallic stents (SEMS) are used for fistulas' treatment, proving to be an effective and safe alternative to surgery.
Aims & Methods: The authors aim to evaluate the efficacy and safety of SMES in the treatment of fistulas after bariatric surgery.
Retrospective analysis of patients who underwent SEMS (uncovered or partially covered) placement for treatment of fistulas after bariatric surgery between 01/01/2010 and 31/12/2014.
Results: Ten patients (p) were included, 80% women, mean age 40 years (26-62). Sleeve was performed in 9p and gastric-jejunal bypass in one. Mean time between the surgery and fistula diagnosis was 34 days (10-67). In 6p uncovered SEMS was used and in 4p partially covered SEMS. Completed fistula closure in 9p (90%), being necessary to relocate the SEMS in one case and to place a second stent in other. Surgery was performed in one patient in which the fistula persisted 49 days after the stent placement. SEMS remained in situ for a mean time of 70 days (24-105). In the patient submitted to gastric-jejunal bypass stent late migration occurred with obstruction and consequent removing by double-balloon enteroscopy. SEMS withdrawal in the remaining cases was performed by traction (5p) or by placement of a plastic stent with extraction in bloc after 2 weeks (3p), without complications.
Conclusion: The endoscopic treatment of fistulas after bariatric surgery is an effective and safe alternative to surgery, with clinical sucess of 90% in this series.

P0132 TOO MANY PREDICTIVE SCORES FOR UPPER GASTROINTESTINAL BLEEDING – SHOULD WE USE THEM AT ALL?

D. Branquinho[1], R. Cardoso[1], C. Gregório[1], C. Sofia[1]
[1]*Gastroenterology, Coimbra University Hospital (CHUC), Coimbra, Portugal*

Contact E-mail Address: diogofbranquinho@yahoo.com

Introduction: Despite the irreplaceable role of esophagogastroduodenoscopy (EGD) in the diagnosis of upper gastrointestinal bleeding (UGB), it is frequently hard to establish the ideal timing to perform it. The need of therapeutic intervention and the risk of relapse are also often difficult to predict. Several scores have been described with this purpose, but a comparison between them is seldom considered.

Aims & Methods: To identify clinical predictors of the need to undertake therapeutic endoscopic procedures, the best timing to execute them and the risk of relapse.

From January to April 2014, all patients submitted to EGD due to suspected UGB were included. Clinical and endoscopic variables from 141 patients were collected. Endoscopic scores such as Rockall, Glasgow-Blatchford and AIMS65 were calculated.

Results: A total of 141 patients were included, with an average age of 68.1 ± 16.3 years old, 65.2% being males. Endoscopic therapeutic intervention was needed in 62 patients (44%), 16 had a relapse (10.6%) and 3 eventually died (2.1%).

The need to perform therapeutic maneuvers was bigger in patients presenting with hematemesis (69.4% *vs*. 38.6%; $p = 0.003$), chronic liver disease (62.2% *vs*.37.5%; $p = 0.009$), hypoalbuminemia (69.4% *vs*. 38.6%; $p = 0.003$) e in those with significant rise in blood urea nitrogen (BUN) levels (41.8 ± 24.1 vs. 34.4 ± 26.0mg/dL; $p = 0.009$). In multivariate analysis, only hematemesis and elevated BUN kept their predictive value. In ROC curves, only pre-endoscopic Rockall score had an acceptable performance: AUC 0.664 (CI:0.561-0.768).

As for relapse, multivariable analysis showed that patients presenting with hematemesis (18.5% vs. 3.9%; $p = 0.005$) and hypoalbuminemia (22.2% vs. 2.9%; $p = 0.001$) had considerably bigger risk of rebleeding.

Conclusion: Clinical presentation with hematemesis, a bigger rise in BUN levels and pre-endoscopic Rockall score showed the ability to predict the need of endoscopic therapy. The best predictors of UGB relapse were AIMS65 score, hypoalbuminemia (< 3g/dL) and altered mental status.

Disclosure of Interest: None declared

P0133 FLEXIBLE ENDOSCOPIC MYOTOMY IS SAFE AND EFFECTIVE FOR ZENKER'S DIVERTICULUM (ZD): RESULTS FROM A TERTIARY REFERRAL CENTER

C. Leberre[1], M. Le Rhun[1], N. Musquer[1], C. Trang[1], S. Bruley des Varannes[1], **E. Coron**[1]
[1]*Institut des Maladies de l'Appareil Digestif, University Hospital, Nantes, France*

Contact E-mail Address: emmanuel.coron@gmail.com

Introduction: Flexible endoscopic treatment for Zenker's diverticulum (ZD) aims at performing a myotomy of the cricopharyngeal muscle on the septum in symptomatic patients. Because this technique is still not widely spread, data regarding its real efficacy in routine practice are still lacking. Our aim was to assess the feasibility, complication rates and the efficacy of flexible endoscopic treatment in patients referred for symptomatic ZD.

Aims & Methods: Medical records of all patients referred to our Department for flexible endoscopic treatment of ZD were retrospectively reviewed. Procedures were performed with a flexible gastroscope (Fujifilm EG530, Japan or Olympus Gif 180/190, Japan). After performing a diagnostic endoscopy, a soft overtube (ZDO-22-30, Cook, Ireland) was inserted over the scope to stabilize the gastroscope over the septum. Under endoscopic surveillance, a myotomy of the cricopharyngeal muscle was performed using a Zimmon needle connected to a surgical generator. After performing the myotomy, 2 clips were placed on the distal edge of the myotomy to prevent leakage into the mediastinum. Patients were discharged on the following day with oral antibiotics and alimentary recommendations. Patients' clinical characteristics, occurrence of complications as well as evolution of digestive symptoms were analysed.

Results: Between 2009 and 2014, 16 patients (8M/7F; mean age 73 years, range 54-97years) underwent flexible endoscopic treatment of ZD at the University Hospital of Nantes, France. Mean size of ZD was 36 mm (range 20-60mm). One case of mediastinitis occurred, which was successfully treated with radiological drainage. No other complication was noted. Prevalence of dysphagia, regurgitation and chronic cough dropped from 80%, 67% and 47% of patients to 27%, 27% and 7%, respectively. Odynophagia and/or dysphonia were initially present in 13% of patients and completely disappeared (0%) after endoscopic treatment. In 3 patients, symptoms recurrence (1 to 7 months) led to further treatment, either by 1-2 endoscopic session(s) ($n = 2$) or surgical ZD resection ($n = 1$).

Conclusion: Flexible endoscopic myotomy was relatively safe and effective for Zenker's diverticulum in this single centre study. Provided multicenter studies confirm these results, flexible endoscopic myotomy might be used as a first-line therapy in symptomatic patients in centers performing interventional endoscopy.

Disclosure of Interest: None declared

P0134 EFFICACY AND SAFETY OF ENDOSCOPIC MUCOSAL RESECTION (EMR) IN SUPERFICIAL OESOPHAGEAL SQUAMOUS CELL CARCINOMA (SCC): RESULTS FROM A MULTICENTER STUDY

M. Jacolot-Benestan[1], N. Etchepare[2], F. Cholet[1], M. Le Rhun[2], J. Jezequel[1], N. Musquer[2], Y. Touchefeu[3], L. Doucet[4], M. Robaszkiewicz[1], **E. Coron**[2]
[1]*Department of Gastroenterology and Hepatology, University Hospital, Brest,* [2]*Institut des Maladies de l'Appareil Digestif,* [3]*Institut des Maladies de l'Appareil Digestif, University Hospital, Nantes,* [4]*Department of Digestive Pathology, University Hospital, Brest, France*

Introduction: Squamous cell carcinoma (SCC) is frequent but data are scarce regarding endoscopic mucosal resection (EMR) in these patients. Data from studies on EMR in Barrett's oesophagus are specifically different and cannot be transposed to SCC because 1) SCC patients generally have severe specific comorbidities and 2) SCC lesions have a higher risk of lymph node invasion. Therefore, our aim was to specifically evaluate the complication rate and efficacy of EMR in a large cohort of patients referred for superficial SCC.

Aims & Methods: We retrospectively selected all patients undergoing esophageal EMR for SCC at the University Hospitals of Nantes and Brest, France. EMR was performed on lugol-negative lesions with previous biopsies showing dysplasia or carcinoma. Clinical, endoscopic and histologic data were analyzed using medical records. Complication rates, recurrence and overall survival were reviewed as the main outcome measurements.

Results: In total, 78 patients (62M/16F; mean age 65 years) with SCC were treated by EMR from 1998 to 2014. Three complications occurred (2 perforations, 1 delayed bleeding), which were all successfully managed by endoscopy. Histological assessment of the EMR specimen confirmed epithelial carcinoma ($n = 27$), intramucosal carcinoma ($n = 8$), muscularis mucosae invasion ($n = 15$) or submucosal invasion ($n = 22$). The deep margin was R0 in 78% of cases. Due to submucosal invasion, 4 and 11 patients underwent subsequent surgery or radiochemotherapy, respectively. During follow-up (mean duration 35 months), recurrence occurred in 24% of cases. Overall survival rates at 1, 3 and 5 years were 90%, 74% and 59%. The 3-year disease free survival was 74%. Only 7.7% of patients died from an evolution of the oesophageal cancer.

Conclusion: In our study, EMR had a very low rate of complications and allowed curative resection in more than 75% of cases, with good long-term overall survival and disease-free survival in patients with SCC. In case of submucosal invasion, EMR was also useful to discuss surgery or radiochemotherapy. Therefore, EMR should be considered as a first-line modality to stage and potentially cure superficial SCC. Future prospective studies should establish the exact role of other promising endoscopic techniques such as endoscopic submucosal dissection in comparison with EMR.

Disclosure of Interest: None declared

P0135 SAFETY AND EFFICACY OF GLYCOPYRROLATE AS A PREMEDICATION FOR ENDOSCOPIC SUBMUCOSAL DISSECTION: A PRELIMINARY REPORT (A RANDOMIZED, DOUBLE-BLIND, PLACEBO-CONTROLLED STUDY)

E. J. Kim[1], S. Y. Kim[1], J. H. Kim[1], J. W. Chung[1], Y. J. Kim[1], K. A. Kwon[1], D. K. Park[1], K. O. Kim[1]
[1]*Department of Gastroenterology, Gachon University, Gil Medical Center, Incheon, Republic of Korea*

Contact E-mail Address: imetkim@gilhospital.com

Introduction: Endoscopic submucosal dissection (ESD) requires a high level of technique as well as a longer procedural time than conventional endoscopic procedures. Occasionally large amount of salivary and bronchial secretion can induce hypoxemia or sudden coughing during endoscopic procedure. Therefore there is a necessity to reduce oral or bronchial secretion. Anti-muscarinic anticholinergics suppress salivary and bronchial secretion and glycopyrrolate is one of the potent anti-muscarinic anticholinergics.

Aims & Methods: In the present study, a double blind, randomized, placebo-controlled trial, we investigated the efficacy and safety of glycopyrrolate premedication for ESD at a single tertiary medical center. A total of 59 patients undergoing ESD at a single tertiary medical center, from December 2014 to April 2015 were randomly allocated to receive one of the two premedications: glycopyrrolate (0.004 mg/kg, IM); or placebo (2.0ml of normal saline solution, IM). All patients received premedication 30 minutes before ESD in double-blind manner. The endoscopist reported the amount of secretions, cough, hypoxemia, procedure time and other procedure related adverse events after the procedure. The secretion assessment of the endoscopist was reported with predefined grading scale from zero indicating no secretion to four indicating large amount of secretion which cannot be controlled with suction.

Results: A total of 28 patients received glycopyrrolate, and 31 patients received placebo. ESD was successfully conducted in all patients without serious adverse events related to sedation or ESD. The proportion of the patients with the secretion score more than three points was lower in the glycopyrrolate group than in control group. (14.3% vs 32.3%), which was not statistically significant ($p = 0.133$). The hypoxemia during ESD was observed in 9.7% of the control group and 10.7% of the glycopyrrolate group, which was not statistically significant ($p = 1.0$). The proportion of the patients with cough during procedure was 41.9% for the glycopyrrolate group and 25% for the control group, which was not statistically significant ($p = 0.170$). No other procedure or premedication related complications were observed in both groups.

Conclusion: In this preliminary report, the use of glycopyrrolate as a premedication for the ESD reduced the salivary and airway secretion, however there was no statistically significant difference between two groups. Similarly incidence of hypoxemia and cough was not significantly different. Further studies with larger sample sizes are necessary to investigate the safety and efficacy of glycopyrrolate as a premedication for endoscopic procedure.
Disclosure of Interest: None declared

P0136 ROUTINE ENDOSCOPIC SCREENING FOR SYNCHRONOUS ESOPHAGEAL NEOPLASM IN PATIENTS WITH HEAD AND NECK SQUAMOUS CELL CARCINOMA: A PROSPECTIVE STUDY

E. J. Gong[1], D. H. Kim[1], J. Y. Ahn[1], K.-S. Choi[1], K. W. Jung[1], J. H. Lee[1], K. D. Choi[1], H. J. Song[1], G. H. Lee[1], H.-Y. Jung[1], J. H. Kim[1]
[1]*Department of Gastroenterology, University of Ulsan College of Medicine, Asan Medical Center, Seoul, Korea, Seoul, Republic of Korea*

Contact E-mail Address: gong-eun@hanmail.net
Introduction: Early detection of synchronous esophageal squamous cell neoplasm (ESCN) in head and neck squamous cell carcinoma (HNSCC) patients can significantly affect their prognosis.
Aims & Methods: Subjects who were diagnosed as HNSCC from May 2010 to January 2014 were eligible. All patients underwent conventional white light endoscopic examinations with narrow band imaging and Lugol chromoendoscopy.
Results: Among 458 subjects screened, 28 synchronous ESCN, including 18 dysplasias and 10 squamous cell carcinomas, were detected in 24 patients (5.2%). The incidence of ESCN was greatest in patients with hypopharyngeal cancer (20.9%), followed by laryngeal cancer (3.8%), oropharyngeal cancer (2.8%), and oral cavity cancer (0.9%). In multivariate analysis, pyriform sinus involvement was independent risk factor for developing synchronous ESCN (odds ratio 171.2, $p<0.001$). Most patients with synchronous ESCN (22/24, 91.7%) were early stage, and 16 patients (66.7%) received treatment with curative intent. During the follow-up period (median, 24 months), the 3-year overall survival rates was significantly lower in patients with ESCN than in patients without ESCN (54.2% *vs.* 78.3%, $p=0.0013$).
Conclusion: Routine endoscopic screening for detecting synchronous ESCN should be recommended for patients with HNSCC, especially those with pyriform sinus involvement.
Disclosure of Interest: None declared

P0137 ENDOSCOPIC PAPILLECTOMY: FEASIBILITY, SAFETY AND EFFICACY DATA FROM A SINGLE UK CENTRE

K. Kandiah[1], **F. Chedgy**[1], A. Kumar[1], R. Bhattacharyya[1], P. Goggin[1], P. Bhandari[1]
[1]*Gastroenterology, Queen Alexandra Hospital, Portsmouth, United Kingdom*

Contact E-mail Address: kesavankandiah@gmail.com
Introduction: Endoscopic papillectomy is an alternative to radical surgery (10% mortality risk) in the management of ampullary adenomas. Very few centres in the UK have the expertise or experience of performing this procedure and there is certainly no published literature from the UK.
Aims & Methods: We aim to report outcomes after endoscopic papillectomy in a single tertiary endoscopy unit in the UK. The prospectively collected data of all patients who underwent endoscopic papillectomy between 2005 and 2015 in Queen Alexandra Hospital, Portsmouth were reviewed. All procedures were carried out by PB (papillectomy) and PG (ERCP) using a standard duodenoscope. The pancreatic and biliary ducts were cannulated. A dilute methylene blue dye was injected into the pancreatic duct prior to papillectomy. Submucosal injection was performed in all cases prior to snare resection of the ampullary neoplasia. 5 Fr pigtail pancreatic stent insertion was attempted in all cases after resection of the neoplasia.
Results: A total of thirty-five patients were referred for papillectomy but only twenty-two patients (13 female, median age 72 years) underwent a total of 24 papillectomies. En-bloc resection was achieved in 17 patients (77%) with lesion sizes ranging from 8 - 25mm (Median 16mm). Pancreatic stent placement was successful in 82% of all papillectomies. Three patients experienced complications (12.5%); 2 bleeding and 1 acute pancreatitis. There was no procedure-related deaths and no one required emergency surgery. There were no local recurrences in 77% of patients. Two patients required 2 attempts to achieve complete clearance of their adenomas. Histology of the resected lesions revealed low grade dysplasia (54.6%), high grade dysplasia (27.2%), cancer (9%), gangliocytic paraganglioma (4.6%), and neuroendocrine tumour (4.6%). Of the two patients who were found to have invasive cancer, the first patient went on to have a pancreaticoduodenectomy and subsequently died of post-operative complications and the second patient was palliated. The total curative resection rate was 86%.
Conclusion: This is the largest reported UK series of endoscopic papillectomy. Our data demonstrates that this method is a feasible, safe and efficacious means of treating ampullary neoplasia in expert hands. It obviates the need for pancreaticoduodenectomy with its inherent morbidity and mortality. Complications can be serious and expertise is required to deal with them.

P0138 DEVELOPMENT AND VALIDATION OF AN ONLINE TRAINING MODULE IN THE USE OF ACETIC ACID TO DETECT BARRETT'S NEOPLASIA

F. J. Q. Chedgy[1], K. Kandiah[1], R. Bhattacharyya[1], H. Barr[2], J. De Caestecker[3], S. Green[4], C. Gordon[5], A. Li[6], G. Sadler[7], G. Longcroft-Wheaton[1], P. Bhandari[1]

Contact E-mail Address: ferguschedgy@yahoo.co.uk
Introduction: Acetic acid enhances the ability to correctly identify Barrett's neoplasia and is increasingly used by both expert and non-expert endoscopists. However, despite its increasing use, there is no validated training strategy to achieve competence.
Aims & Methods: The aim of our study was to develop a validated online training tool for acetic acid assisted Barrett's neoplasia detection and prospectively evaluate its impact and effectiveness. Video libraries of acetic acid assisted chromoendoscopy (AAC) were analysed. The best still images and videos were identified and correlated to histology. These images and videos were validated for quality and accuracy by 3 independent experts in AAC and 3 AAC naïve endoscopists. An online training module was developed.
13 Endoscopists with varying degrees of experience in the use of AAC participated in the study. Participants initially completed an online test consisting of 40 still images and 20 videos of Barrett's oesophagus with and without neoplasia. No feedback was given. Following this, the participants completed an online training module on the use of AAC. Having completed the training module, participants then repeated the test.
Results: We observed a significant difference in accuracy ($p=0.006$) between experts (0.93; 95% CI, 0.84-1.00) and novices (0.76; 95% CI, 0.70-0.82) during the validation exercise. The training tool led to a significant improvement in accuracy for all endoscopists with a mean pre-training score of 76% rising to 83% ($p=0.013$) after training. The training intervention with our tool led to a significant improvement in the confidence of the endoscopist in the use of acetic acid with the mean pre-training confidence level rising from 2.5 (5 point scale) to 3.9 post-training ($p < 0.001$). The training module led to a significant shift to the willingness of the endoscopists in changing practise from Cleveland clinic protocol to acetic acid guided targeted biopsy protocol with mean pre-training score of 2.6 (5 point scale) rising to 3.8 post-training($p < 0.001$).
Conclusion: 1. We were successful in developing and validating an online training and testing tool for acetic acid chromoendoscopy for Barrett's neoplasia.
2. Low pre-training scores amongst users and non-users demonstrated the need for training tool.
3. Training intervention with our tool improves the accuracy of endoscopists in the use of acetic acid to detect Barrett's neoplasia proving the efficacy of this tool.
4. The training tool increases the endoscopist's degree of confidence in the use of AAC.
5. The training tool also leads to shift in attitudes of endoscopists from Cleveland clinic protocol towards AAC guided biopsy protocol for Barrett's surveillance.

P0139 ENDOSCOPIC OVER-THE-SCOPE CLIP SYSTEM FOR TREATMENT OF PERFORATED PEPTIC ULCER: FIRST CLINICAL EXPERIENCES

F. Swahn[1], L. Lundell[2], F. Hammarqvist[2], G. Sandblom[2], U. Arnelo[2]
[1]*Department of Surgery, Skane University Hospital, Clinical Sciences Lund, Lund,* [2]*Center for Digestive Diseases, Karolinska University Hospital, Stockholm, Sweden*

Contact E-mail Address: fredrik.swahn@ki.se
Introduction: Perforated peptic ulcer disease is a severe surgical emergency that carries high mortality and morbidity rates. The standard treatment has been prompt surgical closure of the perforation and control of extraluminal fluid collections. Hereby we report on 12 patients with gastric or duodenal peptic ulcer perforations who were managed by a novel therapeutic concept, i.e. endoscopic over-the-scope clip (OTSC) system.
Aims & Methods: All patients were treated at the OR under general anesthesia with readiness for laparotomy if endoscopic management would fail. The endoscopic OTSC system (10 mm) was combined with a twin-grasper (Ovesco Endoscopy AG, Tübingen Germany) in order to approximate the edges of the ulcer, whereupon the OTSC was applied. The procedure was supplemented with intra-abdominal lavage using 2 litres of lukewarm saline instilled through an infra umbilical drain and subsequently evacuated. The efficacy of the closure was documented by installing some methylene blue through a naso-gastric tube during the procedure and on the first postoperative day (POD). If there were no signs of blue colour in the drainage at POD 1, the drain and the naso-gastric tube were removed and per oral feeding started. A follow-up endoscopy was performed on POD 4. During 2010-2015 we treated 12 patients (median age 72, range, 33-89; 9 men, 3 women) with intention to treat at the time when CT-scan revealed free air in the abdominal cavity.
Results: Ten out of twelve patients (83%) were successfully treated with endoscopic closure at the first attempt. Two patients were directly converted to surgery due to complex perforation and hard surrounding tissue, which made it impossible to grasp the edges. Follow-up endoscopy at POD 4 demonstrated intact closure in all 10 cases.
In patients ($n=5$) with a short perforation history and mild degree of abdominal contamination, the postoperative period was smooth and associated with short hospital stay (4-5 days). In elderly and frail patients and in those with extensive

abdominal contamination a greater need for additional percutaneous drainage of fluid collections, intensive care and prolonged antibiotic treatment were required. No mortality was recorded.
Conclusion: Endoscopic OTSC closure of perforated peptic ulcer disease can be an alternative in selected cases, particularly in patients with short medical history of perforation irrespectively of comorbidity and age.

Contact E-mail Address: gianeugeniotontini@libero.it
Introduction: The Thulium laser system is an established therapeutic technology for surgical resection [1-3]. The wavelength of 2μm is strongly absorbed by water present in soft organic tissues, thereby providing constant speed of cutting and vaporization (i.e. ''vaporesection'') regardless of vascularization, with high degree of control on the penetration depth (0.2-0.4mm) to reduce the risk of inadvertent deep injury. However, no study has yet reported its use for achieving hemostasis in the luminal gastrointestinal (GI) tract.
Aims & Methods: We conducted a pilot study in an established animal model to test for the first time the safety and efficacy of the Thulium Laser system (Cyber TM®, Quanta System, Varese, Italy) for hemostatic treatment in luminal GI-endoscopy. Therefore, various optical fibers (365 and 550 um) were evaluated with different power settings (10, 15, 20, and 25 watts), and diverse configurations (continued laser shaping or pulse modality). Study endpoint was to assess the impact of the device in terms of depth penetration and lateral tissue damage under a laser exposure prolonged for 3, 5 and 7 seconds at fixed distance (0.5-1 cm) from the mucosal surface. Results were compared to the effect of Argon Plasma Coagulation (APC) generated by an established standard electrosurgery system for hemostatic therapy in the luminal GI-tract with a 2.3 mm catheter using 20, 40 and 60 watts. All procedures were performed using a standard video-gastroscope and digitally recorded. Histopathological analysis based on the whole stomach were performed by an expert GI pathologist.
Results: Neither transmural perforation, nor any muscular layer damage was observed with both systems used. A progressive penetration depth and tissue damage was observed with increased laser power and APC settings, as well as with prolonged tissue exposure. Nonetheless, both the fiber diameter and the configuration modality of the laser system were found to have no impact on depth penetration and tissue damage, with only marginal effect on the lateral spread of vaporization. Overall, the laser system has been correlated with comparable degree of vertical tissue injury (from 0.1 to 2.0 mm), with a much more precise effect on target according to a lower lateral spreading damage (0.1-0.3mm and 0.2-0.7mm using the 365 and 550um fiber, respectively) compared to APC (1.1-1.6 mm).
Conclusion: The Thulium laser system appears to be safe and effective for hemostatic therapy in an ex vivo animal model of the upper GI-tract. In vivo studies should now confirm these initial results in a prospective setting.

P0141 ENDOSCOPIC PREDICTION OF RECURRENCE IN PATIENTS WITH EARLY GASTRIC CANCER AFTER MARGIN-NEGATIVE ENDOSCOPIC RESECTION: IS FOLLOW- UP BIOPSY NECESSARY AT ENDOSCOPIC RESECTION SCAR AFTER MARGIN-NEGATIVE RESECTION?

H. K. Na[1], K. D. Choi[1], J. Y. Ahn[1], J. H. Lee[1], D. H. Kim[1], H. J. Song[1], G. H. Lee[1], H.-Y. Jung[1], J.-H. Kim[1]
[1]*Gastroenterology, Asan Medical Center, Seoul, Republic of Korea*

Contact E-mail Address: hkna77@naver.com
Introduction: Although follow-up endosocpy is routinely performed after endoscopic resection for early gastric cancer (EGC), it has not been determined which endoscopic findings are suggestive of recurrence and when we take a biopsy at resection scar.
Aims & Methods: We aimed this study to predict local recurrence at resection scar with endoscopic criteria after margin-negative resection of EGC and to determined the necessity of follow-up biopsy at resection site.
Among 3037 cases of margin-negative endoscopic resection (including endoscopic mucosal resection and endoscopic submucosal dissection) for EGC between June 1995 and December 2011, a consecutive 22 patients with recurrent carcinoma at the site of endoscopic resection were identified. For each case, 4 controls were matched by age, sex and resectability (en-bloc or piecemeal). Endoscopic review was performed by consensus of 2 endoscopists based on the characteristic endoscopic criteria categorized as gross morphology (evenly elevated, unevenly elevated and flat), hyperemic change, mucosal defect (erosion or ulcer) and spontaneous bleeding.
Results: The mean age was 63.8 years and male was 72.9%. En-bloc resection was achieved in 100/110 (90.9%) cases. The mean interval between endoscopic resection and the diagnosis of recurrence was 16.8 months. Using endoscopic criteria of 'elevated gross morphology (both evenly and unevenly) or hyperaemic change at resection scar, the sensitivity, specificity, and positive and negative predictive values of recurrence rate at resection site were 95.5%, 68.2%, 2.6% and 99.94%, respectively. When applying these criteria to histologically differentiated and en-bloc resected EGCs, the values were 100%, 71.4%, 3.0% and 100%, respectively.
Conclusion: Recurrence at endoscopic resection scar after margin negative resection of EGC is very rare. Routine follow-up biopsies may be unnecessary when the follow-up endoscopy shows flat mucosa without hyperaemic changes at the scar especially, for the en-bloc resected and differentiated EGCs.

Contact E-mail Address: gianeugeniotontini@libero.it
Introduction: Therapeutic laser systems are established for surgical and endourological interventions [1-2]. Most recently, a new therapeutic laser system with a wavelength of 2μm has been developed to provide constant speed of cutting and vaporization (i.e. ''vaporesection'') with a precise control on depth and lateral tissue penetration to avoid inadvertent injury. To date, no study has assessed the efficacy of the new device for luminal gastrointestinal endoscopy.
Aims & Methods: We conducted the first pilot study to test the feasibility of the newly introduced Thulium laser system (Cyber TM®, Quanta System, Varese, Italy) for POEM by using an established experimental setting (EASIE model). The POEM procedure was performed in standard technique. All steps were performed just by using the new Laser system. Subsequent to the endoscopic procedure, specimens were evaluated by an expert pathologist.
Results: A complete POEM by using the Thulium laser took approximately 20 minutes. No perforation to the luminal side (i.e. mucosal) occurred. For laser power settings the most effective choice was 25-35 watts for mucosal excision and 15-25 watts for submucosal and muscular excision. Histopathology confirmed a clean and safe cutting of the different layers.
Conclusion: This is the first study of the newly introduced Thulium laser system showing the safety and efficacy of the new device for performing POEM procedures. These initial results should now be confirmed in additional in vivo studies.

P0143 EFFICACY AND LEARNING CURVE OF A NEW SCISSOR-LIKE DEVICE FOR ENDOSCOPIC SUBMUCOSAL DISSECTION (ESD)

H. Neumann[1], S. Löffler[1], M. Neurath[1], A. Nägel[1]
[1]*Department of Medicine I, University of Erlangen-Nuremberg, Erlangen, Germany*

Contact E-mail Address: helmut.neumann@uk-erlangen.de
Introduction: ESD has become the standard technique for early cancerous lesions, particularly in Asian countries. However, current limitations of ESD include the complication rate, a distinct learning curve and the need of various devices, resulting in substantial costs of the procedure.
Aims & Methods: Aim was to prospectively assess the efficacy and learning curve of a new alligator scissor-like device for ESD. Accordingly, a prospective ex vivo study was performed in an established experimental setting. Ex vivo porcine models were utilized in the EASIE endoscopic simulator of interventional endoscopy. First, artificial lesions, each 2x2 cm in size, were created in fresh ex vivo porcine stomachs at the fundus, corpus and antrum. Two beginners with less than 10 ESD procedures each participated in the study. All study parameters were independently recorded. ESD was performed after marking of the lesions with the closed ESD-instrument, followed by lifting of the mucosa with submucosal injection of saline. Afterwards, circumferential incision of the lesions was performed with the new ESD-instrument. For resection, the submucosa was grasped with the scissor-like device, elevated and cut. Resection specimens were retrieved to evaluate if all marks were included (R0).
Results: Average size of removed lesions was 35 mm. En-bloc resection rate was 100% and R0 resection rate was 86%. After the initial three cases, R0 resection was achieved in all cases. The total procedure time improved significantly during the study (52.4 minutes versus 21.10 minutes; $p < 0.05$). One perforation occurred which could be managed with endoclips. Endoscopists satisfaction was high throughout all cases.
Conclusion: The new scissor-like device for ESD appears to be a safe and efficient new instrument for ESD which can relatively easy being learned.

Further studies should now focus on in vivo studies to confirm these initial results.

P0144 CAPNOGRAPHY DURING SEDATION FOR ENDOSCOPIC TREATMENT USING CARBON DIOXIDE SUPPLY SYSTEM

H. Takamaru[1], Y. Kawaguchi[2], I. Oda[1], M. Sekiguchi[1], S. Abe[1], S. Nonaka[1], H. Suzuki[1], S. Yoshinaga[1], Y. Saito[1]
[1]*Endoscopy Division,* [2]*Anesthesiology and Critical Care Medicine, National Cancer Center Hospital, Tokyo, Japan*

Contact E-mail Address: h.takamaru@gmail.com
Introduction: A respiratory monitoring during sedation for endoscopy has an important role. Pulse oximetry is one of the most common ways for respiratory monitoring, however, unexpected adverse effect may occur with pulse oximetry only. In the cases of deep sedation, visual examination, auscultation and monitoring by capnography may be recommended. However, only few studies reported about the capnography during sedation for endoscopic treatment of lesions located in upper gastrointestinal tract using endoscopic submucosal dissection (ESD) or endoscopic mucosal resection (EMR) technique, with deep sedation and carbon dioxide supply system.
Aims & Methods: The aim of this study is to evaluate the stability of respiratory monitoring by capnography during deep sedation for ESD/EMR using carbon dioxide supply system.
Twenty-six patients with successfully monitored both capnography and respiratory monitoring system by breath sounds (Rad87®, Masimo, Japan) among 52 consecutive patients who underwent endoscopic treatment (ESD/EMR) under deep sedation without intubation by anesthesiologist from December 2013 to October 2014 were analyzed. Oxygen saturation (SpO_2) was measured by pulse oximetry. Respiratory rate per minute (RR) was measured by side stream capnography and recorded every 8 seconds. RR was also measured from breath sounds by Rad-87® as gold standard and recorded every 2 seconds. We compared the average value of RR for every 8 seconds with RR by capnography and calculated Pearson's correlation coefficient. We also defined ''outlier'' when the value of RR by capnography was more or less than RR range of ±50% by Rad87®.
Results: In this study, 23 of 26 patients were male and median age was 72.5 years old (IQR: 62.5-80.0). Mean BMI was 22.1(±4.5). Patients who had cardiovascular or pulmonary disease were 26.9% and 19.2%, respectively. Location where patients had the lesions was follows; 17 patients have lesions in esophagus, 5 patients in normal stomach, 2 patients in gastric tube, one patient in gastric remnant. Mean size of the resected specimens was 39.3mm (± 8.8mm). Median time of procedure is 126 minutes (IQR: 91.5 – 167.8 min). Anesthesiologist used fentanyl and propofol for all patients. Mean amount of total administered agent is 0.14mg and 1220mg, respectively. The average of SpO_2, RR by Rad87® and RR by capnography during procedure was 97.6%, 9.6/min and 13.8, respectively. Four cases showed transient hypoxia (SpO2 < 90%). One of four cases showed hypoxemia for few minute, and this adverse effect could be detected by capnography as apnea before pulse oximetry detection. One case showed relatively strong correlation ($r = 0.511$), and three cases showed weak correlation ($0.2 < r < 0.4$), while other 22 cases showed no correlation between RR measured by capnography and by Rad87®. Median frequency of outlier for RR by capnograhpy was 35.2% (IQR: 26.5 – 48.8%).
Conclusion: Respiratory monitoring by capnography during deep sedation for endoscopic treatment with carbon dioxide supply system may be unstable and need some improvement in some situation.
Disclosure of Interest: None declared

P0145 THREAD TRACTION WITH A SHEATH OF POLYPECTOMY SNARE FACILITATES ENDOSCOPIC SUBMUCOSAL DISSECTION OF EARLY GASTRIC CANCERS

H. Noda[1], N. Ogasawara[1], A. Koshino[1], S. Fukuta[1], T. Sugiyama[1], S. Noguchi[1], K. Adachi[1], T. Yoshimine[1], Y. Yamaguchi[1], Y. Kondo[1], Y. Ito[1], S. Izawa[1], M. Ebi[1], Y. Funaki[1], M. Sasaki[1], K. Kasugai[1]

Contact E-mail Address: bisaipan@aichi-med-u.ac.jp
Introduction: Endoscopic submucosal dissection (ESD) has been established as a standard therapy for early gastric neoplasms. During ESD, the mobility of the lesion increases as submucosal dissection proceeds and it becomes difficult to attain effective counter traction. To overcome this problem, various traction methods have been developed. Recently, the thread-traction (TT) method has been developed. However, in TT method, the movement of the thread was interfered with the movement of the endoscopy, and it resulted in disturbing to make the appropriate traction which the operator required. Moreover, in TT method, the lesion can be pulled only to the mouth side but not to the anal side by the thread. Therefore, we modified TT method and developed novel TT method using a sheath of polypectomy snare (TTSPS) method. The TTSPS method enabled the comfortable ESD procedure that did not disturb the thread movement without the interference with the endoscopy and could pull the lesion towards not only to the oral side but also to the anal side regardless of lesion locations.
Aims & Methods: This study aimed to evaluate usefulness of TTSPS method during ESD. Thirty-four consecutive patients who underwent conventional ESD between May 2013 and December 2013 and 54 consecutive patients who underwent ESD with the TTSPS method between January 2014 and March 2015 were included in the study. We compared counter traction ESD with the TTSPS method and conventional ESD that did not involve the new traction system in terms of the duration, the number of times regarding the arterial bleeding and the times regarding the local injection all after completion of circumferential mucosal incision until completion of dissection of the specimen.
Results: The median dissection duration after completion of circumferential mucosal incision until completion of dissection of the specimen for all lesions significantly differed between conventional ESD and ESD with method [conventional ESD, 90 min (range 30-320 min) vs ESD with TTSPS method, 60 min (range 15-160 min); $p = 0.015$]. The median number of times regarding the arterial bleeding after completion of circumferential mucosal incision until completion of dissection of the specimen was significantly less in ESD with TTSPS method than in conventional ESD [conventional ESD, 3 times (range 0-25) vs ESD with TTSPS method, 2 times (range 0-7) ; $p = 0.015$]. The median number of times regarding the local injection after completion of circumferential mucosal incision until completion of dissection of the specimen significantly differed between the two groups [conventional ESD 10 times (range 3-51), vs ESD with TTSPS method, 8 times (range 1-27) $p = 0.04$]. There was no significant difference in complications between conventional ESD and ESD with TTSPS method.
Conclusion: Our study suggests that TTSPS method is straightforward, safe, easy, noninvasive, cost-effective and uses readily available instruments to enhance visualization of cutting lines. Our TTSPS method can be universally applied to conventional ESD.

P0146 DEVELOPMENT OF A NOVEL ENDOSCOPIC SUTURING DEVICE USING NEW RECIPROCATING CURVED NEEDLE: AN EX VIVO COMPARISON STUDY

H. S. Choi[1], H. J. Chun[1], I. K. Yoo[1], J. M. Lee[1], S. H. Kim[1], E. S. Kim[1], B. Keum[1], Y. T. Jeen[1], H. S. Lee[2], C. D. Kim[2], J. J. Park[2], S. W. Lee[2], S. Yoon[3], S.-H. Park[3], Y. Kim[3], B. Kim[3], Y. Song[3], D. Hong[3]
[1]*Internal Medicine, Institute of Gastrointestinal Medical Instrument Research, Korea University College of Medicine,* [2]*Internal Medicine, Korea University College of Medicine,* [3]*Division of Mechanical Engineering, Korea University, Seoul, Republic of Korea*

Contact E-mail Address: mdkorea@gmail.com
Introduction: Endoscopic Suturing Device has been developing rapidly for not only Natural orifice transluminal endoscopic surgery (NOTES) but also minimally invasive obesity treatment. However, some issues remain involving the complex approach to the suturing site and the many additional instruments required that render the procedure more difficult. The complex suturing mechanism and tools not only increase the operation time but also decrease the feasibility of minimally invasive surgery. The authors have developed a novel endoscopic suturing devices to continuously suture a viscerotomy of stomach to overcome limitations of previous suturing devices.
Aims & Methods: The goal of this study is to develop an endoscopic suturing device and to demonstrate the feasibility of the device by showing the strength of closure. New endoscopic suture device is composed of main body, suturing-arms, curved needle, protective tube, and control device. This endoscopic closer (EN-closer) device sutures wound with a curved needle using back and forth movement. The endoscopic suturing device with new closure mechanism was compared with two other closure techniques; endoscopic clips and hand-sewn in porcine stomach. After closure, air leakage pressure was used to determine the strength of the perforation closure by an automated pressure gauge.
Results: After the mechanism design and implementation, we carried out a feasibility study on 10 porcine stomach models. In a comparative experiment, each endoscopic clip (endoclip) method and full-thickness stitches involved hand suturing was used 10 times to increase reliability. The average leakage pressure for the En-closer was 43.25mmHg. The average closer strength of the En-closer does not significantly differ from that of the endoclip, but standard deviation of the En-closer is significantly smaller than that of the endoclip treated stomachs. The En-closer that is capable of multiple stitches with a single endoscope insertion had similar closure strength to that of the endoclips but showed a more consistent sequence than the endoclips.
Conclusion: New suture device competently produced a tight, reliable, and consistent closure. Our instrument platform could be an important basis for future developments of not only gastric NOTES devices but also endoscopic bariatric surgery device. This research showed a new approach for endoscopic suturing devices.

P0147 WHEN SHOULD WE USE HEMOSPRAY? A SINGLE CENTRE EXPERIENCE

I. Nasr[1], S. De Martino[1], D.-M. Borrow[2], J. M. Dunn[1]
[1]*Gastroenterology,* [2]*Gastroenteroloy, Guys and St Thomas' NHS Trust, London, United Kingdom*

Contact E-mail Address: ikram.nasr@gstt.nhs.uk
Introduction: Hemospray is an inorganic nanopowder produced by Cook Medical and is licensed in Europe and Canada for the management of nonvariceal upper gastrointestinal bleed (NVUGIB). The powder adheres to liquid and forms a coagulum which concentrates clotting factors and stimulates the internal clotting cascade. There are numerous reports of successful haemostasis with hemospray, some reporting success rates of 85%[i]. However, the knowledge of which lesion is most suitable for hemospray use remains unclear. We report our experience at Guys and St Thomas' NHS trust to establish the lesions most likely to benefit from hemospray either as a primary intervention or an add-on strategy.
Aims & Methods: A retrospective review of endoscopic procedures that required hemospray was performed and the data was extracted from our endoscopy reporting system between December 2013 and February 2015 (14 months). We

Abstract number: P0147

Results of hemospray use	Procedure induced upper GI	Forrest 1a	Forrest 1b	Forrest 2a	Forrest 2b	Distal ileum (Enteroscopy)	Colonic bleed
Primary haemostasis achieved and sustained	9	0	5	2	3	1	1
Haemostasis not sustained	0	2	5	0	0	1	0
Unsuccessful	0	4	1	0	0	1	1

identified 32 patients who received hemospray, and excluded 2 where hemospray was applied blindly and the bleeding lesion was missed. The primary outcome was achieving primary haemostasis. Cases of recurrent GI bleed requiring further endoscopic or radiological intervention within 72 hours were considered unsuccessful.
Results: The 30 procedures were divided according to the procedure performed.
1. Procedure induced bleeding: 9/30 (7 post Barrett's endoscopic mucosal resection (EMR), 1 post gastric polypectomy and 1 iatrogenic bleed post nasojejunal tube insertion).
2. NVUGIB: 17/30
3. Enteroscopy small bowel bleed: 2/30
4. Colonoscopy: 2/30
Primary haemostasis was achieved in 77%, of which 7% required further endoscopic procedure or interventional radiological intervention within 72 hours (Table). The coagulum was not seen on second endoscopy.
Conclusion: Hemospray provides good hemostasis for post procedure, in particular post EMR bleed, as a single agent or where coagulation alone failed. Bleeding from Forrest 1b, 2a and 2b responded well to hemospray as a second modality, or single modality when the lesion was inaccessible. Forrest 1a had a poor response to hemospray and all cases required further endotherapy or interventional radiology. Further evidence is required to establish the value of hemospray in colonic and variceal bleed.

Introduction: Anastomotic leakages or fistulas are among the most common and severe complications of esophagectomy for esophageal cancer, with high grade of mortality. Recently the endoscopic management has taken a growing place in the treatment of digestive post-operative complications (1). The aim of this study was to evaluate the effectiveness and the characteristics of the endoscopic management in this indication.
Aims & Methods: This is a monocentric study on consecutive patients treated surgically in our institution between 2010 and 2014 for esophageal carcinomas. During this period, on 126 patients operated, 35 developed post-operative fistulas or leakages (27%), endoscopically managed and included in this study. All the procedures were performed in our endoscopy unit, by interventional endoscopists, in intubated patients under general anesthesia, using a large operating channel gastroscope (3.8mm, Pentax, Japan) and fluoroscopy. The patients were systematically controlled endoscopically 6 weeks after the endoscopic treatment to check the efficacy out and to evaluate the need for an additional treatment. The primary or secondary efficacy, the time between surgery, diagnostic and endoscopy, the number of procedures, the material used (stents, clips, or drains), the complications, and the death rate were recorded, and uni- and multivariate analysis was carried out to determine predictive factors of success.
Results: There were 4 women and 31 men, with a median age of 61.7 years $\pm$ 8.9 [43-85]. The surgical techniques were in majority Lewis-Santi for 48.6% of cases, Akiyama for 45.7%. 71.4% patients have undergone neo-adjuvant chemo radiation therapy and 77.1% were hospitalized in intensive care unit. The median delay between surgery and first endoscopy was 8.5 days [6.00-18.25]. 88% of the patients were treated using metallic (double type) esophageal stents, with a removability rate of 100% and a migration rate of 18%. The other ones were treated by Over-the-scope clips, naso-cystic drain or combined approach. The mean number of endoscopy per patient was 2.6 $\pm$ 1.57 [1-10], with a mean number of 1.6 $\pm$ 1.35 [0-7] stents placed. The primary efficacy of the endoscopic treatment was 48.6%, the final efficacy was 68.6%. The mortality rate in patients endoscopically managed was 17%, none being related to procedures. No predictive risk factor of success or failure of the endoscopic treatment (CRT, type of surgery, fistula size, age...) could be identified in univariate as well as in multivariate analysis.
Conclusion: The endoscopic management of leakages or fistulas after esophageal surgery is feasible, and lead to an overall effectiveness rate of 68.8%. There were no significant complications related to the procedures, and the mortality rate was decreased to 17% compared to 40 to 100% rate in the literature (2). Self-expandable metallic stents are the most common used treatment with a removability rate of 100% and a migration rate of 18%.

P0150 CONFOCAL LASER ENDOMICROSCOPY IMAGING OF NEOANGIOGENESIS USING FITC-CD105 ANTIBODIES IN COLORECTAL CANCER: HUMAN IN VIVO TESTING

A. Ciocalteu[1], T. Cartana[1], D. Pirici[2], C. Georgescu[3], I. Cherciu[1], C. Cristea[1,4], A. Saftoiu[1,5]
[1]*Research Center of Gastroenterology and Hepatology, University of Medicine and Pharmacy of Craiova,* [2]*Department of Research Methodology, University of Medicine and Pharmacy of Craiova,* [3]*Department of Pathology, Emergency County Hospital Craiova, Craiova, Romania,* [4]*Hepato-gastroenterologie, Hopital Antoine Beclere, Clamart, Ile de France, France,* [5]*Gastrointestinal Unit, Copenhagen University Hospital Herlev, Copenhagen, Denmark*

Introduction: To date, the determination of neoangiogenic status and its dynamic assessment in real time has been challenging and, therefore, has made treatment optimization in colorectal cancers difficult. One strategy for antiangiogenic therapy is the long-term suppression of forming new blood vessels. Recent developments in endoscopic imaging technologies such as confocal laser endomicroscopy (CLE) have contributed to the progress from macroscopic evaluation to *ex vivo* molecular experiments and consequently to promising *in vivo* imaging by using fluorescently labeled antibodies.
Aims & Methods: The aim of this study was to evaluate the feasibility of *in vivo* acquisition of microscopic images using fluorescent CD105 antibodies for molecular imaging in human colorectal cancer. The current approach builds on our previous study in which we proposed *ex vivo* CLE examination and CD105 immunostaining of fresh tissue samples as a more reliable tool for evaluation of neoangiogenesis in rectal cancer [1]. Tumor was washed with saline solution and it was evaluated from a stable position using an eCLE system, before undergoing surgery. After excluding the presence of tissue autofluorescence, 1 ml fluorescent antibody solution (FITC-labeled anti-CD105/Endoglin antibody, Exbio, 1:5) was topically administered through a spray-catheter. After 10 min of incubation, the targeted area was analyzed by CLE and images were recorded. The fractal dimension of tumor vessels was calculated offline using "fractal box count" tool in Image J software. Grid method was applied to determine the vessel density. Before *in vivo* testing, multiple attempts were made at establishing the optimal antibody-tissue contact time using paraffin-embedded tissue sections under fluorescence microscopy conditions. Immunohistochemistry staining with CD105 was used as a gold standard.
Results: In vivo CLE analysis of CD105 expression in human colorectal cancer enabled the study of vascular network, revealing a chaotic structure. Both good and medium quality images were eligible for clinical analysis. Fractal value was 1.57, indicating the chaotic architecture (with 2 being the fractal value for normal vessels). Average vessel density was 46.09$\pm$ 7.06 vessels/mm^2.
Conclusion: *In vivo* molecular imaging of human colorectal cancer neoangiogenesis using CLE and FITC-CD105 antibodies is feasible. Future *in vivo* applications of immunoendoscopy using CD105 could provide a more specific analysis of tumor microvascular architecture in order to improve diagnosis, patient stratification and monitoring of antiangiogenic therapy.

P0151 THE EFFECTIVENESS OF A CUSTOMIZED MOBILE APPLICATION IN COLONOSCOPY PREPARATION: A RANDOMIZED CONTROLLED TRIAL

A. I. Sharara[1], J. M. Chalhoub[1], M. Beydoun[1], A. H. Harb[1], H. Chehab[1], Z. D. El Reda[1], F. H. Mourad[1], F. S. Sarkis[1]
[1]*Internal Medicine, American University of Beirut Medical Center, Beirut, Lebanon*

Contact E-mail Address: as08@aub.edu.lb
Introduction: Colonoscopy preparations are generally poorly tolerated. Compliance with dietary instructions and proper use of the prescribed purgative solution are essential in achieving an adequate bowel preparation.
Aims & Methods: The study aims at assessing the effect of a customized mobile application (with dietary instructions, illustrations, reminders and push notifications) on the compliance and adherence to instructions and diet and consequently on the quality of bowel cleansing.
Consecutive patients scheduled for elective colonoscopy and having on-hand personal smartphones were randomly assigned to one of two groups. The first group (Paper) received face-to-face detailed paper instructions while the second group (App) received the same paper instructions and had the customized application downloaded onto their phone including the scheduled date and time of their colonoscopy appointment. The preparation consisted of split-dose sodium picosulfate/magnesium citrate (SPS) (Picoprep®, Ferring, Saint-Prex, Switzerland) and a 3-day diet consisting of a low-fiber diet for the first 2 days, and a clear fluid diet on the last day before colonoscopy (day -1). The first dose of SPS was to be taken the eve prior to colonoscopy, and the second dose a minimum of 4 hours before the procedure. Colonoscopy appointments were scheduled between 10 am and 3 pm. Patients were interviewed prior to colonoscopy about compliance with the 3-day diet and use of the SPS solution as well as their assessment of the preparation and the provided instructions. The colonoscopist, blinded to assignment, was asked to grade the bowel cleanliness after the examination using the Aronchick, Ottawa, and Chicago bowel scales. The primary endpoint was overall compliance with dietary and purgative solution instructions. Quality of the preparation was a secondary endpoint.
Results: 160 patients were enrolled (80 in each arm)**.** The average age was 54 (SD = 13), 55.6% were males, and 27.5% of patients had a BMI of $\geq$30. No difference in overall patient compliance and bowel cleanliness (on all 3 scales) was observed between the Paper and App groups. An adequate bowel preparation defined as either excellent or good on the Aronchick scale was noted in 82.5% and 77.2% of Paper vs. App group respectively ($p = 0.68$). Gender, age, BMI, and time of colonoscopy (am vs. pm) did not influence bowel cleanliness or patient compliance. Full compliance with clear fluids on day -1 was seen in 93.9% of patients with a BMI < 30 vs. 77.3% of those with a BMI $\geq$ 30 ($p = 0.009$). SPS was very well tolerated by 81.9% of patients as evidenced by their willingness to use it again in the future. The application was deemed user-friendly and helpful/indispensable by 96.2% and 87.3% of patients in the App group respectively.
Conclusion: Split-dose sodium picosulfate with dietary modification is well tolerated and highly effective for bowel cleaning prior to elective colonoscopy. A detailed face-to-face explanation of bowel preparation instructions leads to comparable results regardless of the instruction method used. Customized smartphone applications may replace traditional paper instructions in this information technology era.

Introduction: ESD for colorectal lesion is well established in Japan while has limited application in western countries.
Aims & Methods: The aim of present study was to report the early and long-term outcome as well the learning curve of a tertiary referral center that has established a database for colorectal ESD since 2008. Information on all patients who underwent ESD for colorectal lesions at our institution since 2008 have been prospectively collected in a database and patients followed-up with endoscopy on regular basis according to the lesion histology and standard guidelines. Collected data included size, morphology, location, technique of ESD, en-bloc rate, R0 rate, complication and recurrence. Part of these data have been previously reported in 2 papers. Results were compared between three consecutive study periods (2 years each until end of 2014) in order to determine the effect of learning curve on outcome.
Results: Overall data on 286 patients (167M, mean age 68.3 y) were recorded in the data base. Lesions were located in the rectum in 187 cases (68.8%) and mean diameter was 3.9 mm (range 15 to 110). ESD was aborted because of technical difficulties in 29 (10.1) with 12 of these patients switched to multipiece EMR and 17 referred for surgery. Hybdrid-knife technology was used in 105 cases (36%) while different types of knife (Flush-knife, Hook-knife, Dual-knife and Flex-knife) have been used in the remaining cases. Median operative time 108 minutes. En-bloc resection and R0 resection were respectively 82% (235 out of 286) and 72% (208 out of 286). Perforation occurred in 20 patients (6.9%) while bleeding occurred in 7 (2.4%) with all bleeding cases successfully treated with conservative management in 2 cases or endoscopic intervention in 5. Perforation required surgery in 7 cases while was managed conservatively in the remaining. No mortality associated to the procedure was observed. Histology has demonstrated intramucosal cancer or submucosal cancer in 110 cases (38.4%) and surgery was required because of advanced histology in 26 patients (9%). The mean follow-up was 32.7 months with 11 patients lost during follow-up and 4 patients died because of unrelated disease. The overall recurrence rate was 6.2% with most of these patients successfully treated with additional endoscopic therapy and 2 patients requiring surgery. Mean operation time (152 minutes vs 88 minutes, $p = 0.001$), en-bloc resection (62% to 92%, $p = 0.05$), R0 (56% to 85%, $p = 0.001$) significantly improve from period 1 (2008-2010) to period 3 (2012-2014). Perforation rate decreased from 11% in period 1 to 6.5% even though did not reach the statistical significance.
Conclusion: Data coming from a single European center experience confirm that ESD for colorectal lesions can be safely and effectively performed in western setting. However a long-training period with progressive learning curve is required to obtain results comparable with Japanese experts in terms of efficacy and perforation rate.

P0153 NON-ANESTHESIOLOGIST ADMINISTERED PROPOFOL SEDATION IN COLONOSCOPY – RESULTS OF A RANDOMIZED CONTROLLED TRIAL

A. O. Ferreira[1], J. Torres[1], E. Barjas[1], J. Nunes[1], L. Glória[1], C. Fidalgo[1], R. Ferreira[1], S. Pereira[2], M. Rocha[2], S. Dias[1], A. A. Santos[1], **M. Cravo**[1]

Contact E-mail Address: alex.gastrohep@gmail.com
Introduction: Propofol allows the best sedation in colonoscopy. There is only one Randomized Controlled Trial (RCT) comparing Non-Anesthesiologist Administered Propofol Sedation (NAAPS) to sedation by an anesthesiologist.
Aims & Methods: Our goal was to compare the incidence of sedation related adverse events (AE), colonoscopy quality and patient satisfaction between NAAPS and anesthesiologist sedation. We performed a single blinded RCT with two parallel intervention groups (group A – NAAPS; group B – anesthesiologist sedation). The primary endpoint was the incidence of AE as defined by the World SIVA International Task Force on Sedation. Secondary endpoints were propofol dose, patient satisfaction and pain assessed by a 10 point visual analogue scale, procedure and recovery time and colonoscopy quality indicators (cecal intubation rate, withdrawal time, adenoma detection rate). Based on the AE incidence of our preliminary experience a sample size of 320 (1:1) was calculated with a non-inferiority margin of 15% for a power of 90% at a 5% level of significance. Patients aged 18-80 with low anesthetic risk (ASA I-II) were included. Statistical analysis was performed with SPSS version 21. Chi-square, Fischer's exact, t-tests and logistic regression were used as indicated.
Results: A total of 277 colonoscopies were performed (table 1). The incidence of AE was 39.3% on group A and 39.0% on group B (OR1.013; IC95% 0.622-1.651; $p = 0.959$). There were no severe (sentinel) AE events. The following interventions were necessary: atropine administration (0% vs 5.5%; $p = 0.004$); airway repositioning (8.7% vs 4.7%; $p = 0.196$); increase in O2 administration (6.7% vs 4.2%; $p = 0.317$); increase in fluids rate (2.6% vs 0.8%; $p = 0.242$). Mean propofol dose: group A 215 ± 92 mg vs group B 230 ± 97 mg ($p = 0.205$). Procedure times was 21.59 ± 12.967 and 18.64 ± 9.859 min ($p = 0.033$), withdrawal time was 11.37 ± 9.839 vs 9.84 ± 7.509 min ($p = 0.154$) and recovery time was 58 ± 33 min vs 67 ± 29 min ($p = 0.032$). Patients had no pain (0) in 83.5% vs 88.9% ($p = 0.208$) and reported complete satisfaction with the sedation in 82.4% vs 85.1% ($p = 0.887$). Procedural amnesia was reported in 83.9% vs 90.8% ($p = 0.093$). All but 2 patients (group B) were willing to repeat the colonoscopy under propofol sedation. Cecal intubation rates were 94.7% vs 96.1% ($p = 0.584$), adenoma detection rates were 28.4% vs 23.2% ($p = 0.331$).

	Group A (n = 150)	Group B (n = 127)
Male sex, n(%)	61 (40.7)	50 (39.4)
Mean age, years(sd)	58.6 (13.8)	55.4 (15.4)
ASA I/II, n	13/137	18/107
Cardiovascular disease, n(%)	20 (13.4)	12 (10.4)
Smoking, n(%)	24 (18.0)	20 (17.5)
Snoring history, n(%)	17 (13.1)	24 (21.8)

Conclusion: NAAPS is equivalent to anesthesiologist sedation in the rate of adverse events in a low risk population. Clinicaltrials.gov (NCT02067065).

Introduction: Colonoscopy is the most sensitive method for colorectal cancer screening, but inadequate bowel preparation can result in both missed pathological lesions and cancelled procedures.

Aims & Methods: We prospectively followed up the quality of colonic preparation at screening colonoscopy and tried to establish if there is a potential association between the bowel preparation and the polyp detection rate in screening colonoscopy.

We evaluated prospectively the bowel preparation during colonoscopy, using the Boston bowel preparation scale (BBPS) (a scoring system applied to the 3 broad regions of the colon: right colon, transverse colon and left colon, each part being evaluated from 0 and 3 as follows: 3 = entire mucosa of the segment seen well, 2 = minor amount of residual staining, 1 = segments not well seen due to residual stool or/and opaque liquid, 0 = unprepared segment), with a maximum of 9 points (perfectly cleaned colon). The bowel preparation was performed either with split or non-split regimens using PEG solution.

Results: We evaluated 2412 patients in whom screening colonoscopy was performed: 1377 women (57%) and 1035 men (43%). The mean BBPS score was 6.6 ± 1.3. Considering an excellent bowel preparation for the colonoscopy a BBPS score of 8 or 9 points, a good bowel preparation a BBPS score ≥ 7 points, and a score of ?5 points as an inadequate bowel preparation, we obtained the following BBPS score distribution: excellent preparation in 634 (26.3%) patients, good preparation in 1232 (51%) patients, and an inadequate preparation in 144 (6%) patients. In 450 (18.6%) patients we found one or more colonic polyps and in 166 (6.8%) patients significant polyps (polyp $\geq$1cm). We compared the polyp detection rate and significant polyp detection rate in relation with the BBPS score and we obtained the following results:

Conclusion: The polyp detection rate increased with the increasing of BBPS score; for significant polyps this association was not found.

Contact E-mail Address: amitchattree@nhs.net

Introduction: The use of endoscopic mucosal resection (EMR) is established as first-line treatment for the treatment of large non-pedunculated colorectal polyps (LNPCP), with practice now widespread in both the district general and tertiary setting. A large proportion of LNPCPs in the UK are managed within the Bowel Cancer Screening Programme (BCSP)[1] and recent data demonstrating increased variation in endoscopic polypectomy outcomes with increased polyp size[2] has led to concerns that the quality of endoscopic LNPCP management also varies widely between BCSP clinicians and centres, irrespective of procedure volume, with many patients potentially subject to suboptimal therapy.

Aims & Methods: Retrospective analysis was conducted on LNPCPs [MDR1] managed using EMR in the England Bowel Cancer Screening Programme (BCSP) within the North East region between 2011-14. A comparison of 12 month recurrence, an internationally recognised marker of successful endotherapy[3], was made between the four North East screening centres. Statistical analysis was performed using the Fisher's exact test.

Results: A total of 135 lesions were subject to 12 month surveillance with recurrent/residual polyp (RRP) identified in 8.1% of cases. RRP incidence was 8.4%, 0%, 29.2% and 3.9% at the 4 screening centres respectively, with screening centre location strongly associated with the probability of a finding of unsuccessful endotherapy (p = 0.001).

		12 month recurrence (%)		Total (n)
		n	y	
Screening Centre	A	91.6	8.4	24
	B	100	0	36
	C	70.8	29.2	24
D	96.1	3.9	51	
Total		**91.9%**	**8.1%**	**135**

Conclusion: A vast difference was demonstrated in the quality of endotherapy undertaken within a wide geographical area, with 12 month RRP varying between 0% and 29.2%. The results from this series are especially noteworthy given that the endoscopists concerned were all BCSP accredited, and therefore highly experienced and subject to a strict certification process. These findings indicate that advanced polypectomy is not a universal skill and that endoscopist quality varies markedly irrespective of experience. In addition, they highlight the importance of accurate lesion management and the identification of endoscopists with the requisite expertise to manage these complex lesions.

P0156 CAECAL LOCATION IS ASSOCIATED WITH INCREASED LESION RECURRENCE FOLLOWING ENDOSCOPIC MUCOSAL RESECTION OF LARGE NON-PEDUNCULATED COLORECTAL POLYPS

A. Chattree[1,2], M. D. Rutter[1,2]
[1]*Gastroenterology, North Tees and Hartlepool NHS Foundation Trust, Stockton on Tees,* [2]*School of Health Sciences, University of Durham, Durham, United Kingdom*

Contact E-mail Address: amitchattree@nhs.net

Introduction: Large caecal polyps over 2cm in size are considered amongst the most complex lesions to achieve successful endoscopic resection, with recent data suggesting a significantly increased risk of post procedure bleeding and perforation associated with their endoscopic removal compared with elsewhere in the colon.[1,2] There is however a paucity of data assessing whether caecal location affects successful (R_0) clearance of lesions.

Aims & Methods: Retrospective analysis was conducted on large non-pedunculated colorectal polyps (LNPCPs) managed with endoscopic mucosal resection in the English Bowel Cancer Screening Programme (BCSP) between 2011-14. A comparison of 12 month recurrence rates, an internationally recognised marker of treatment success,[3] was made between caecal and non-caecal LNPCP groups. Statistical analysis was performed using the chi-squared test.

Results: A total of 135 lesions were identified, with 12 month recurrence identified in 8.1% of cases. Caecal location demonstrated a strongly significant association with recurrence compared with non-caecal location (27.8% vs 5.1%, p = 0.007)

	12 month recurrence (%)		Total (n)
	no	yes	
Caecal location?	94.9	5.1	117
	72.2	27.8	18
Total	**91.9%**	**8.1%**	**135**

Conclusion: Caecal location was associated with over a 5-fold increase (28.7% vs 5.1%) in the incidence of 12 month recurrence. The results from this series confirm the increased technical demands associated with the endoscopic resection of caecal LNPCPs, and are especially noteworthy considering that our study involved experienced BCSP endoscopists only. In view of the increased risk of endoscopic treatment failure, in addition to the established increased risk of adverse endoscopic events, caecal LNPCPs may benefit from multidisciplinary discussion and managed by a select group of advanced endoscopists.

P0157 THE DEVELOPMENT OF A MINIMUM DATASET PROFORMA FOR THE MULTIDISCIPLINARY ASSESSMENT AND MANAGEMENT OF LARGE NONPEDUNCULATED COLORECTAL POLYPS

A. Chattree[1,2], J. A. Barbour[3], S. Dolwani[4], M. D. Rutter[1,2], on behalf of British Society of Gastroenterology Large Polyp Working Group
[1]*Gastroenterology, North Tees and Hartlepool NHS Foundation Trust, Stockton on Tees,* [2]*School of Health Sciences, University of Durham, Durham,* [3]*Gastroenterology, Queen Elizabeth II Hospital, Gateshead,* [4]*Gastroenterology, University Hospital of Wales, Cardiff, United Kingdom*

Contact E-mail Address: amitchattree@nhs.net

Introduction: The lack of any structured framework internationally for the assessment and management of large non-pedunculated colorectal polyps (LNPCPs) appears to have resulted in a wide variation in decision making with regards to endoscopic and surgical management and suboptimal outcomes.[1] Multidisciplinary team discussion has been advocated to better coordinate management. The development of an evidence based and expert approved minimum dataset proforma may complement this process and encourage optimal management resulting in improved outcomes.

Aims & Methods: Following an extensive literature review, various patient and polyp parameters relevant to LNPCP assessment and management were selected. A 14 person British Society of Gastroenterology (BSG) approved multidisciplinary panel participated in Delphi consensus methodology to vote anonymously on the proposed parameters with ≥80% agreement required for consensus to be achieved. The draft proforma was then assessed on a sample of 20 LNPCP cases, resulting in modification after a further voting round.

Results: The final proforma comprised of 17 parameters encompassing all patient and lesion factors considered essential to the decision making process in LNPCP management. Patient parameters included patient symptoms, treatment preferences and comorbidity. Lesion parameters included morphology and surface characteristics (e.g. Paris classifications and Pit pattern) and the specification of any lesion features associated with increased complexity such an increased risk of malignancy, unsuccessful endoscopic resection or adverse endoscopic events[2]. Parameters regarding relevant histology and radiology results and guidance on obtaining adequate lesion imaging were also agreed.

Conclusion: The development and validation of a BSG/ACPGBI minimum dataset proforma allows for structured and comprehensive multidisciplinary discussion in LNPCP management, ensuring that all important factors are discussed and resulting in more coordinated and robust decision-making. This proforma can be used to structure discussions during a multidisciplinary team meeting and all related discussions such as referral to the tertiary setting, in addition to being used as a checklist for comprehensive lesion assessment.

Introduction: Confirmation of lesion eradication at least 12 months after endoscopic mucosal resection (EMR) of large non-pedunculated colorectal polyps (LNPCPs) is an internationally recognised marker of therapeutic success[1]. Variable outcomes have been reported in international case series, with reported figures of up to 10% recurrent/residual polyp (RRP)[2]. Whilst various technical factors been attributed to the variable outcomes in treatment success, there is a paucity of evidence linking endoscopist advanced endotherapy procedure volume with successful curative resection of LNPCPs.

Aims & Methods: Retrospective analysis was conducted on LNPCPs managed with endoscopic mucosal resection in the North East NHS Bowel Cancer Screening Programme (BCSP) between 2011-14. A comparison of 12 month RRP was made between high volume (≥30 procedures per year) and low volume (<30 procedures per year) endoscopist groups. Statistical analysis was performed using the chi-squared test.

Results: A total of 135 lesions were identified, with 12 month RRP identified in 8.1% of cases. The incidence was higher in the low volume endoscopist group (12.3% (9) vs 3.2% (2),p = 0.064).

		12 month recurrence (%)		Total (n)
		no	yes	
Endoscopist procedure number	≥30	96.8	3.2	62
	<30	87.7	12.3	73
Total		**91.9**	**8.1**	**135**

Conclusion: A level of 12-month RRP comparable with international series (8.1%), suggests effective LNPCP management within the NHS BCSP. Whilst no statistical association was found between endoscopic volume and curative resection, an almost four-fold increase in failed curative resection was seen in the low volume endoscopist group (12.3% vs 3.2%). It can be argued that our study may be underpowered and that the results indicate clinical relevance. These outcomes also indicate that limiting advanced endotherapy to a select number of experienced therapeutic endoscopists may result in a further improvement in outcomes.

Introduction: Endoscopic mucosal resection [(EMR) en-block and piecemeal] has been recognized as an effective and less invasive curative endoscopic treatment procedure for large and nonpedunculated colorectal lesions (LNLs) > 20 mm.

Aims & Methods: The aims of the current study were to evaluate EMR complete resection and complication rate for LNLs > 20 mm and to estimate the long-term local recurrence rate afterwards. Data were collected retrospectively by use of the Electronic Endoscopy Report Data Base at our center. A total of 158 patients (84 men, 71.1 ± 7.52 years and 74 women, 70.58 ± 7.49 years) with 158 LNLs > 20 mm were enrolled. All endoscopic resections were performed by experienced endoscopists. All patients underwent standardized follow-up colonoscopy after 3.23 ± 2.43 months and 9.58 ± 6.26 months based on the lesion diameter, location, configuration, histopathology, type of EMR and endoscopic assessment of complete resection, respectively. The resection was regarded as incomplete if histopathologic examination revealed a residual/recurrent adenomatous tissue at the EMR scar site.

Results: En block resection was performed in 43/158 LNLs (27.21%) and piecemeal resection in 115/158 LNLs (72.78%). LNLs mean size was estimated at 34.9 ± 14.5 mm. Histological examination of LNLs showed 30 tubular adenomas (18.98%), 5 villous adenomas (3.26%), 102 tubular-villous adenomas (64.55%), 1 serrated adenoma (0.63%) and 20 adenocarcinomas (12.65%). High-grade

dysplasia was detected in 35 LNLs (22.15%) and low-grade dysplasia in 123 LNLs (77.84%). The first follow-up demonstrated 40/102 LNLs (39.21%) with residual/recurrent adenomatous tissue at the EMR scar site while the second revealed 23/87 LNLs (26.43%). The overall post-polypectomy complication rate was 4.43% (major complications 0.63%, one case of bowel perforation, minor complications 3.79% two cases of minor bleeding and three cases of postpolypectomy syndrome). Although, there was no statistically significant correlation between the size of the LNLs and the rate of residual/recurrent neoplasia after the first surveillance colonoscopy (t-test, $P = 0.052324$, $p < 0.05$), subsequent statistical analysis showed a strong correlation between the initial size of LNLs and the total rate of late recurrent and residual lesions after the second follow-up examination (t-test, $P = 0.0249$, $p < 0.05$). Finally, the use of chi-square test indicated that piecemeal resection is equally effective to en-block resection in LNLs related to recurrent/residual lesions at the previous EMR scar site ($\chi 2$ test, $P = 0.083$, $p < 0.05$).

Conclusion: EMR is safe and effective for treatment of LNLs > 20 mm. Nonetheless, a substantial portion of residual/recurrent adenomas at the previous EMR scar site can be detected. Therefore, an appropriate very strict follow-up surveillance colonoscopy protocol is necessitated in order to obtain biopsies from previous polypectomy scar sites.

Introduction: Colorectal cancer is a major cause of morbidity and mortality worldwide. Colonoscopy remains the investigation of choice for both diagnosis and screening, and many countries have implemented screening programmes to allow for early detection. The European Society of Gastrointestinal Endoscopy quality in colonoscopy position statement highlights key quality indicators in colonoscopy and concluded that the success of screening programmes is related to the prompt provision of high quality, patient centred colonoscopy service. The European Colonoscopy Quality Investigation (ECQI) group of leading European clinicians developed a practical tool to enable audit of current clinical practice across Europe to assess whether quality standards are being achieved, and to identify, test, and implement practical ways of improving quality in colonoscopy.

Aims & Methods: The aim was to understand how quality is evaluated in current clinical practice via the development and implementation of an online tool to audit colonoscopy practice. At the inaugural meeting in 2013, the ECQI group recommended a clinical practice level audit tool to be developed to enable colonoscopists to audit their own practice. The audit tool was designed to encourage improvement in overall outcomes (e.g. adenoma detection rate), and to ensure consistency and high standards across clinical practice, within countries and across Europe, and was validated by the group in September 2014. A phase 1 pilot to test this tool was performed in November 2014, with early outputs discussed by the group in December 2014. The audit tool was further revised to improve usability via a collaborative iteration process.

Results: The online audit tool was piloted at centres across 10 European countries with 313 patient visits recorded on the initial questionnaire during a 1-week period. Questions included: patient demographics, the status and experience of the practitioner performing the endoscopy, details of the bowel preparation procedure used and the quality of bowel cleansing achieved, colonoscopic findings, and follow up arrangements. Following the review of the phase 1 pilot, consensus from the ECQI group resulted in the refinement of the tool to create an updated version which included three separate sections: Practitioner, Centre and Patient level questionnaires to improve efficiency of use. This will form part of a second phase pilot planned for 2015.

Conclusion: The creation of the ECQI Group enabled the development of a validated, practice level audit tool to enable clinicians to audit their own practice. This tool will be tested in a second pilot phase, and its value will be further evaluated by the Group in order to make recommendations for its use across Europe. The range of experience and geographical spread of the participants allows for quality evaluation to be compared across practices and countries. The longer term aim of this project is to enhance the quality of colonoscopy at a practice level by enabling clinicians to be involved in improving their own practice.

P0161 UNDERWATER ENDOSCOPIC MUCOSAL RESECTION: THE THIRD WAY FOR EN BLOC RESECTION OF COLONIC LESIONS? A CASE SERIES

A. Amato[1], F. Radaelli[1], S. Paggi[1], E. Rondonotti[1], G. Spinzi[1]
[1]*Gastroenterology, Valduce Hospital, Como, Italy*

Contact E-mail Address: arnamato@gmail.com

Introduction: Underwater endoscopic mucosal resection (UEMR) has been described since 2012 for removing large colorectal non polypoid lesions[1,2,3,4]; it is based on filling the colonic lumen with water and it differs from traditional endoscopic mucosal resection since it does not require sub-mucosal injection.

Aims & Methods: To evaluate the reproducibility of this new endoscopic technique in terms of ease of implementation, safety and efficacy. UEMR prospectively performed in a community hospital were gathered.

Results: From September 2014 to February 2015 20 colorectal non polypoid lesions (median size 24.7 mm, range 10-50mm) have been removed in 20 patients (12 women; median age 62.2 years). Two of the lesions were adenomatous recurrences on scar of previous resection and one was a recurrence located on a surgical anastomosis. Five lesions were located in the cecum, seven in the ascending colon, two in the transverse colon, one in the descending colon, one in the sigmoid colon and three in the rectum.

In 16 lesions (80%) the resection was performed en bloc, whereas 4 (20%) were removed by piece-meal resection. At the pathological examination six lesions had non advanced histology, 10 lesions had advanced histology and 4 were SSA, one of which with high grade dysplasia.

Complete resection was observed in all the sixteen lesions removed en bloc.

A complication (intra-procedural bleeding, endoscopically managed with no consequences) was observed in the first two UEMR.

Conclusion: UEMR appears an easy, safe and effective technique also in community setting. Further studies comparing UEMR and conventional EMR in terms of complete resections and evaluating the early and late recurrence are needed.

P0162 IS WATER-ASSISTED COLONOSCOPY SUPERIOR TO CARBON DIOXIDE ASSISTED STANDARD COLONOSCOPY: RESULTS OF AN OBSERVATIONAL STUDY

A. K. Kurup[1], S. Shetty[1], S. Ishaq[1]
[1]*Gastroenterology, Russells Hall Hospital, Dudley, United Kingdom*

Contact E-mail Address: drarunkumar_uk@hotmail.com

Introduction: Water-assisted colonoscopy [WAC] is known to reduce patient discomfort and improve the adenoma detection rate [ADR] [1]. In this retrospective observational study, we compared water assisted colonoscopy against standard colonoscopy [SC] using CO2 in a bowel cancer screening positive population.

Aims & Methods: This was a retrospective review of prospectively collected data. The population studied was undergoing colonoscopies following a positive faecal occult blood test as part of the bowel cancer screening programme [BCSP]. Endoscopist A preferred to intubate the caecum using the water exchange method and endoscopist B would insufflate the bowel using carbon dioxide. Sedation and analgesic use was at the discretion of the endoscopist. The primary outcome was the adenoma detection rate and the comfort scores in the two groups. Secondary outcomes included caecal intubation rate, mean withdrawal time, sedation use and polyp retrieval rate.

Results: Data from two hundred and seven colonoscopies performed from April 2014 to December 2014 [9 months] were analyzed. 102 colonoscopies were performed using the water exchange method [group A] and 105 colonoscopies were performed using CO2 [group B].

Primary outcomes:

Adenoma detection rate [ADR] in group A was 53% compared to of 36% in group B.This was statistically significant [difference in rate = -0.1868 [95% CI 0.0052- 0.3685 $p = 0.0438$].

The proportion of patients experiencing none [score 1] or minimal [score2] discomfort [based on modified Gloucester comfort score] were more in group A [n = 74] compared to group B [n = 62]. This was found to be statistically significant [$Z = 2.046$, $p = 0.0408$].

Secondary outcomes:

Indicator	Group A	Group B
Caecal intubation rate	95%	97%
Mean withdrawal time	8.4 minutes	7 minutes
Polyp retrieval rate	93%	95%
Intravenous sedation	68	87
Entonox only	30	13

Conclusion: Our finding of a significant improvement in ADR and better tolerability in the WAC group supports similar conclusions by Hsieh et al. This may have potential implications for the bowel cancer screening programme since the perception of colonoscopy can influence public participation and improve uptake in the BCSP. Improved ADR may be due to combination of factors like improved bowel preparation, flattening of mucosal folds and floating effect of polyps with water irrigation.

P0163 EFFECT OF HIGH BMI ON ADEQUACY OF BOWEL PREPARATION & COLONOSCOPY PERFORMANCE

A. Hussain[1], **M. Al-Ansari**[1], N. Smith[1], A. Zad[1], A. Tung[1]
[1]*Gastroenterology, Ballarat Hospital, Ballarat, Australia*

Contact E-mail Address: drasifhussain@hotmail.com

Introduction: There is limited evidence regarding the effect of high body mass index (BMI) on colonoscopy performance. Given the prevalence of high BMI in regional communities, this association may impact on the already limited resources within regional hospitals [1,2].

Aims & Methods

Objective: To determine if there is an effect of high BMI on bowel preparation and colonoscopy performance.

Design: A single centre prospective study at a teaching hospital in Ballarat, Victoria, Australia between May 2012 and November 2014. Patients undergoing colonoscopy for any indication were included.

Method: Patients were divided into two groups, BMI $\geq$25 or BMI $<$25. Colonoscopies were performed by 17 experienced endoscopists and the data collected by trained endoscopy nurses. Bowel preparation was assessed using the Ottawa Bowel Preparation Scale. Colonoscopy performance was assessed using caecal intubation times (short up to 6 minutes, intermediate = 7-9 minutes and long $\geq$ 10 minutes). Chi-square statistical analysis was used to determine significance ($p = <0.05$).

Main outcome measurements: Adequacy of bowel preparation and caecal intubation time.

Results: A total of 2026 colonoscopies were performed during the study period. 74% of participants had a BMI $\geq$25. Both the low BMI and the high BMI groups has similar adequacy of bowel preparation (93%, $p = 0.16$). Short caecal intubation time (up to 6 minutes) was 29% for patients with normal BMI, and 35% for patients with high BMI. 28% of patients with a normal BMI had an intermediate caecal intubation versus 23% for patients with high BMI. For patients with a long caecal intubation time, 41% had a normal BMI, compared to 42% of patients with a high BMI, which was not statistically significant ($p = 0.37$).

Discussion: In this study we found that high BMI is extremely prevalent in the Ballarat population. However, high BMI did not contribute to a statistically significant difference in the quality of bowel preparation or colonoscopy performance. This prospective study, showing important negative results, has a good sample size and was conducted by 17 experienced colonoscopists. However being a single-centre study, the generalizability of the results is limited.

Conclusion: The study has shown that there is no correlation between high BMI and colonoscopy performance. A multicentre study may be helpful in further establishing significance of high BMI and colonoscopy performance.

P0164 PROSPECTIVE RANDOMIZED COMPARISON OF THE SAFETY AND EFFECTIVENESS OF ANESTHESIOLOGIST-ADMINISTERED PROPOFOL ALONE VERSUS PROPOFOL AND NALBUPHINE DEEP SEDATION FOR OUTPATIENT COLONOSCOPY

B. Gellert[1], L. Madacsy[2], M. Murányi[2], I. Hritz[2]
[1]*Department of Gastroenterology, Semmelweis University, Budapest,* [2]*Department of Gastroenterology, Endo-Kapszula Endoscopy Unit, Székesfehérvár, Hungary*

Contact E-mail Address: endomabt1@gmail.com

Introduction: Colonoscopy is nowadays routinely carried out under propofol deep sedation. Nalbuphine is a widely used major analgetics and is an ideal drug to reduce the given propofol dose during outpatient colonoscopy. The aim of our present prospective, randomized study was to evaluate the safety and effectiveness of 397 ambulatory colonoscopies carried out under propofol versus propofol and nalbuphine deep sedation with respect to endoscopic success rate, complications and patient satisfaction.

Aims & Methods: 190 patients received nalbuphine and propofol and another 207 patients received propofol alone in a randomized manner. The cecal intubation rate, the incidence of major and minor cardiovascular and respiratory complications during deep sedation in terms of the mean of the highest and lowest blood pressure and heart rate values were prospectively measured (BPmax and BPmin mean, Pmax and Pmin mean) as well as changes in oxygen saturation (SpO2) were calculated. The propofol induction and total dose, the time from induction to spontaneous awakening, the recovery time and Post Anesthetic Discharge Scoring System (PADSS) were also compared.

Results: No significant differences in the cecal intubation rate was demonstrated in the nalbuphine and propofol vs. propofol groups: 98.4% vs. 96.8% ($p = 0.4$). No major cardio-respiratory complications lasting more than 2 minutes occurred. The induction propofol dose was 40 ± 13 mg vs. 74 ± 45 mg, and the corresponding mean total doses of propofol was 80.5 ± 32.7 mg and 142.9 ± 88.1 mg in the two groups, respectively ($p < 0.05$). Comparison of patients groups with nalbuphine and propofol versus propofol administration alone depicted no significant differences regarding to the mean awakening time 30.4 min $\pm$ 10.7 vs. 29.3 min $\pm$ 9.4, ($p = 0.3$), and the mean recovery time 51.7 min $\pm$ 23.3 vs. 68.1 min $\pm$ 29.5 ($p = 0.4$). However, and the results of PADSS was significantly different, and demonstrated more gastrointestinal symptoms to prevent timely patient discharge in some of patients in the nalbuphine group ($p < 0.05$).

Conclusion: Colonoscopy procedures implemented in propofol deep sedation administered by an anesthesiologist turned out to be completely safe procedure, with excellent coecum intubation rate and optimal patient satisfaction. Low-dose nalbuphine combined with propofol is an effective and economic alternative in the reduction of propofol needs, but gastrointestinal side effects of morphine agonists significantly reduce the PADSS and may prevent timely patient discharge.

Disclosure of Interest: None declared

P0165 RELATIONSHIP BETWEEN THE POSITION OF THE ILEOCAECAL VALVE IN THE COLONIC CIRCUMFERENCE AND THE FEASIBILITY OF ITS INTUBATION

B. Velayos[1], L. Del Olmo[1], N. Alcaide[1], M. F. Muñoz[2], J. M. González[1]
[1]*Department of Gastroenterology,* [2]*Investigación Unit, Hospital Clínico de Valladolid, Valladolid, Spain*

Contact E-mail Address: benitovelayos@hotmail.com

Introduction: Ileal intubation is an important goal in colonoscopy practice.
We have studied if the position of the ileocaecal valve in the colonic circumference can determine a feasible and prompt ileal intubation.

Aims & Methods: We randomized 177 consecutive patients (mean age: 56 yrs; range: 13-87 yrs; 52% males) in which we reached a clean caecum to supine (62.7%) and right-lateral decubitus posture (37.3%).
This two postures resulted in different positions of the ileocaecal valve: 5.7% in the quadrant I (2 o'clock: 2.3%, 3 o'clock: 1.1% and 4 o'clock: 2.3%); 20.3% in the quadrant II (5 o'clock: 3.4%, 6 o'clock: 5.6% and 7 o'clock: 11.3%); 43.5% in the quadrant III (8 o'clock: 7.9%, 9 o'clock: 15.3% and 10 o'clock: 20.3%) and 30.5% in the quadrant IV (11 o'clock: 20.9%, 12 o'clock: 7.3% and 1 o'clock: 2.3%).
With the scope shortened and de-looped we moved it back to the ileocaecal valve, trying to get into the ileum (at least 3 cm) with the tip.

Results: Successful ileal intubation was achieved in the first attempt (16.9%), in the first three attempts (71.7%), or in the first five attempts (89.2%).
We did not find statistically significant difference in accomplishment ileoscopy in the first attempt depending on quadrant ($p = 0.158$) nor o'clock position ($p = 0.189$), because of the low percentage of success in this case, but we did for the first three attemps ($p = 0$ for quadrant; $p = 0$ for óclock position) and for the first five attemps ($p = 0.005$ for quadrant; $p = 0$ for o'clock position).
Quadrant III and 10 o'clock position were the best locations for a quick ileoscopy.

Conclusion: The exact position of the ileocaecal valve in the colonic circumference, a modifiable condition by changing the patient's posture, can determine success in its intubation and promptness to get it.
This is a scarcely analyzed point that could improve safety and comfort for patients undergoing in colonoscopy.

P0166 PREDICTORS OF INADEQUATE BOWEL PREPARATION FOR COLONOSCOPY: A PROSPECTIVE STUDY

C. Leitão[1], H. Ribeiro[1], J. Pinto[1], A. Caldeira[1], R. Sousa[1], J. Tristan[1], A. Banhudo[1]
[1]*Serviço de Gastrenterologia, Hospital Amato Lusitano - Unidade Local de Saúde de Castelo Branco, Castelo Branco, Portugal*

Contact E-mail Address: catia.f.leitao@gmail.com
Introduction: Inadequate bowel preparation remains a common problem on our daily clinical practice and is associated with canceled procedures, prolonged procedure time, incomplete examination, but most importantly, with missed pathology.
Aims & Methods: This prospective study was designed to assessment the quality of intestinal preparation and evaluate potencial factors associated with an inadequate level of bowel preparation.
Methods: We prospectively studied consecutive outpatients who had colonoscopies performed at our hospital between March and December 2013. Patients' data were analyzed and a questionnaire was applied to the gastrenterologist after the examination. The grade of intestinal preparation was evaluated using the Aronchick preparation assessment scale.
Results: A total of 196 patients were enrolled into the study (51.2% male; with a mean age of 64 ± 13 years). Only 10.6% of patients were not able to follow the bowel preparation instructions and 34.0% described a poor tolerability to the bowel preparation. An excellent or good bowel preparation was achieved in 61.7% and a fair, poor or inadequate intestinal preparation was reported in 38.3% of observed colonoscopies. An earlier colonoscopy start time ($p < 0.034$), age greater than 65 years ($p < 0.014$), male gender ($p < 0.001$) and higher weight ($p < 0.034$) were independent predictors of an inadequate intestinal preparation. There was no significant difference in the quality of bowel preparations among the types of bowel preparations administered to the patient, the tolerability of bowel preparation and the quality of preparation instructions ($p > 0.05$).
Conclusion: This prospective study identified several factors that may predict inadequate bowel preparation irrespective of bowel preparation type, compliance with preparation instructions and tolerability. This information may help to identify patients at an increased risk for inadequate colonic preparation for whom the personal education would be appropriate.

P0167 COLORECTAL ENDOSCOPIC SUBMUCOSAL DISSECTION IN A WESTERN TERTIARY REFERRAL CENTRE. ANALYSIS OF 173 CASES: LONG-TERM RESULTS AND IDENTIFICATION OF POSSIBLE RISK FACTORS FOR TECHNICAL DIFFICULTY

C. Snauwaert[1], H. Piessevaux[1]
[1]*Gastroenterology and Hepatology, Cliniques Universitaires Saint-Luc, Brussels, Belgium*

Contact E-mail Address: christophe.snauwaert@hotmail.com
Introduction: Colorectal endoscopic submucosal dissection (CR-ESD) enables en-bloc resection of lesions > 2 cm which would otherwise require piecemeal removal. However, CR-ESD is still considered as a technically challenging procedure and is not widespread outside Asian expert centres.
Aims & Methods: Our aim was to assess efficacy, safety and long-term results for CR-ESD and identify possible risk factors for technical difficulty. We analysed charts from 173 consecutive patients who underwent CR-ESD between May 2006 and July 2013. Efficacy and safety endpoints were complete en-bloc resection rates, endoscopic and histological remission and post-procedural complications.
Results: Median age of patients was 67 years (IQR 58-76). Lesions were located throughout the colon with predominance for the caecum and rectum: ileo-anal pouch (1.2%), ileo-caecal valve (4.6%), caecum (21.4%), ascending colon (11.6%), hepatic flexure (6.9%), transverse colon (4%), splenic flexure (2.3%), descending colon (1.7%), sigmoid colon (6.4%) and rectum (39.9%). Median longest and perpendicular diameter of lesions was 35mm (range 10-150mm) and 30mm (range 8-130mm) respectively. Most lesions were classified as Paris 0-IIa (45.1%), 0-Is (29.5%) and 0-IIb (17.3%). Forty-eight percent of lesions were classified as LST-NG according to the Japanese classification. In 15.6% of cases a previous resection had been attempted elsewhere. Full ESD was performed in 117 (68%) patients; the remainder was treated using a hybrid technique of circumferential submucosal incision, dissection and finally followed by en-bloc snare resection. Median procedure duration was 109 minutes (IQR 70-157). The en-bloc resection rate was 74.6% (129/173). Previous attempt at resection was a significant risk factor for en-bloc resection failure (40.8% vs. 22.7%; $p < 0.05$). Twenty-one (12.1%) perforations occurred during ESD, which were all successfully managed by endoscopic clip closure. One or more post-procedure complications occurred in 46 patients (26.9%) of which 15 delayed perforations (8.6%). The complication rate decreased significantly with growing experience (e.g. 14 delayed perforations for the first 87 cases vs. 1 for the last 86 cases; 16% vs. 1%; $p < 0.05$). Two patients required surgery for post-procedural perforation salvage. Median hospital stay was 2 days (IQR 2-2). The majority of lesions (114/173; 65%) contained high-grade dysplasia or more advanced histopathology (Table 2). Free vertical margins were achieved in 92% (160/173) of patients. Fourteen patients underwent additional surgical resection because of incomplete resection or unfavourable histology. Endoscopic follow-up was available in 154 patients. During the median follow-up period of 13 months (IQR 3-24), 2 small mucosal recurrences occurred which were resected endoscopically.
Conclusion: CR-ESD is effective with very low local recurrence rates. Previous attempts at snare resection are predictive for en-bloc resection failure. In general, post-procedural course is favourable with short hospitalisation stays. Complications (especially delayed perforation) have to be considered, but usually can be managed conservatively. A growing level of experience significantly reduces the post-procedural complication rate.

P0168 THE USEFULNESS OF BALLOON OVERTUBE-ASSISTED COLORECTAL ENDOSCOPIC SUBMUCOSAL DISSECTION WITH A RUBBER BAND TISSUE TRACTION DEVICE

D. Ide[1], S. Saito[1], S. Kamba[1], H. Inomata[1], N. Tamai[1], K. Sumiyama[1]
[1]*The Jikei University Hospital, Tokyo, Japan*

Contact E-mail Address: dei0405@jikei.ac.jp
Introduction: The gastroscope is often used even for colorectal ESD on a priority basis because operational performance is suitable to procedure in our facility. However, anatomic variability in the colon may hinder any endoscopic intervention. In cases which access to the lesion with a gastroscope was difficult, we used a balloon overtube as an endoscopic channel for colorectal ESD. In addition, to enable a more safe and efficient procedure, we combined balloon overtube- assisted ESD with a rubber band tissue traction device (RTD), designed to be fixed on freed edges of a mucosal overlay with clips to deflect the diseased mucosa away from the dissection plane.
Aims & Methods: We aimed to evaluate the utility of balloon overtube- assisted colorectal ESD with a RTD as needed. At The Jikei University Hospital from April 2012 to December 2014, we performed ESD in colorectal lesion for 311 patients. In the preoperative evaluation of accessibility with a gastroscope, thirty one patients were identified as difficult, and were enrolled in the balloon overtube- assisted ESD and retrospectively examined.
Conclusion: There were little practical differences between the standard ESD method using a gastroscope without the overtube and the balloon-assisted ESD method in term of outcome for therapy. This result suggested that use of the balloon overtube is an effective for colorectal ESD, when lesions are located at difficult positions in the right side colon. Furthermore, as the situation demands, using the RTD for colorectal ESD was also suggested to effective procedure.

P0169 CECAL INTUBATION RATE (CIR) CORRELATES WITH ADENOMA DETECTION RATE (ADR) BUT HAS NO IMPACT ON ADVANCED ADENOMA DETECTION RATE (AADR)

D. Sallinger[1,2], E. Waldmann[1,2], P. Jeschek[1,2], I. Gessl[1,2], M. Britto-Arias[1,2], B. Majcher[1,2], A. Dokladanska[1,2], M. Gschwantler[2], M. Trauner[1,2], M. Ferlitsch[1,2]

Contact E-mail Address: daniela.sallinger@meduniwien.ac.at

Introduction: Incomplete screening colonoscopy can result in missing precancerous lesions, such as adenomas. By a study of Kaminski et al., cecal intubation rate (CIR) as a major quality indicator, showed to be not associated with higher risk of interval cancer.

Adenoma detection rate (ADR) is considered a main quality measure in screening colonoscopy and should be at least 20%. Advanced adenomas (AA) carry greater risk for progression to cancer than non-advanced adenomas and should be detected early.

Because of lack association between CIR and the risk of interval cancer, our primary aim was to investigate whether there is a correlation between CIR and ADR. Further we wanted to assess if CIR correlates with AADR and if findings differ between high (≥95%) and low CIR-group (<95%).

Aims & Methods: Within the Austrian quality assurance program, 148.284 colonoscopies performed by 197 endoscopists were analyzed. Spearman rank-order was used to assess correlation between CIR and ADR, as well as AADR.

Results: Median CIR was 97.38% [Interquartile range (IQR) = 94.24% > 98.65%] and ranges from 72.95% > 100%. Median ADR was 21.37% (IQR = 16.25% > 27.78%) with a minimum of 4.45% and a maximum of 43.06%. Median AADR was 5.43% (IQR = 3.71% > 8.40%) with a range from 0.00% to 20.93%.

Spearman rank order coefficient (r_s) of 0.222 showed a significant correlation between CIR and ADR ($p < 0.001$). AADR was independent of CIR ($R_s = -0.024$; $p = 0.735$) within both groups of endoscopists, those with CIR <95% ($r_s = 0.152$; $p = 0.251$; $n = 59$) as well as within high (≥95%) CIR-group ($r_s = -0.036$; $p = 0.679$; $n = 138$).

Conclusion: CIR correlates with ADR but has no impact on participants' detection of advanced adenomas, which could explain the lack of impact of CIR and the risk of interval cancer in the study of Kaminski et al.

Asistenciales, Canarias,* [5]*DG. Salud Pública, Murcia,* [6]*P.Director Oncología, Cataluña, Spain*

Contact E-mail Address: salas_dol@gva.es

Introduction: In Spain, colorectal cancer screening programmes (CRCSP) are being progressively implemented, with 28% coverage (for all Spanish population) in 2014. The regions of Canarias, Cantabria, Cataluña, Murcia, País Vasco and Valencia participate in the CRIBEA Project with the aim to identify CRC screening benefits and warms (FIS PI12/00944, financed by FEDER funds). The programmes are directed at men and women between 50 and 69 years of age with the aim to reduce CRC incidence and mortality. The screening test is a biennial faecal occult blood test (FOBT), and the confirmation test is a colonoscopy. Colonoscopy complications are one of the adverse effects of screening, and could be immediate (during the exploration) or deferred (post-exploration). Immediate complications are easy to identify and register but deferred ones not, because of ignorance of the time that occurs.

Aims & Methods

Aim: To estimate the severe complications rate (immediate and deferred at 30 days) in the context of further investigation colonoscopies (after positive FOBT) in the context of 6 Spanish CRCSP according to the European definition of severe complication (severe bleeding that requires transfusion, intestinal perforation, severe vagal syndrome, similar to peritonitis syndrome).

Method: Retrospective population-based cohort study, defined by the population with colonoscopy performed in 6 regions of Spain with CRCSP from 2000 to 2012. Information sources: the screening information system and the Minimum Set Basic Data (MDS) information system (mandatory in all hospitals). The identification process of complications is managed by crossing the personal identifiers of people with screening colonoscopy and the hospital admissions 30 days after the colonoscopy performance. Matched people are identified using CIE-9 codes.

Results: A total of 2.15413 million invitations and 959 249 people participated in these regions. People with positive FOBT were 52.913, and 47.008 colonoscopies were performed. The complication rate for both sexes was 5.02 per thousand colonoscopies (236/47008), men being 5.51% (151/27402) and women 4.34% (85/19606). Complication rate for the age group 50-59 was 3.76%, and for 60-69 was 4.57%.

Conclusion: A significant number of deferred screening colonoscopy complications need to be identified in hospital registries. The severe complications rate is 5.02 per 1000 colonoscopies. The complication rate was higher in men versus women and in the age group of 60-69 years versus 50-59.

Introduction: The Third Eye Retroscope, Full Spectrum Endoscope (FUSE) and EndoRings have been developed to improve visualization behind colonic folds and have individually been shown to reduce overall adenoma miss rates. Using a pooled analysis, we evaluated for which adenoma characteristics and in which patient subgroups "behind folds visualizing" techniques are most optimal to reduce miss rates.

Abstract number: P0171

Table. Ade: noma miss rate per adenoma characteristic and patient subgroup.

Adenoma characteristics		Standard colonoscopy	"Behind folds visualizing" technique	
		Missed/total (%)	Missed/total (%)	P-value[a]
All adenomas[b]		93/255 (36)	37/264 (14)	<0.001
Localization	*Proximal colon*	51/135 (38)	21/156 (13)	<0.001
	Distal colon	42/119 (35)	16/108 (15)	<0.001
Adenoma size	*≤5mm*	71/189 (38)	34/203 (17)	<0.001
	6-9mm	19/43 (44)	3/38 (8)	<0.001
	≥ 10mm	3/23 (13)	0/23 (0)	0.233
Morphology	*Pedunculated*	3/24 (13)	1/39 (3)	0.150

	Flat	14/27 (52)	1/11 (9)	0.014
Histology	*Tubular (Tubulo) villous*	84/223 (38)	35/238 (15)	<0.001
		4/19 (21)	0/16 (0)	0.109
Advanced adenomas[c]		6/35 (17)	1/32 (3)	0.108
Serrated lesions[d]		4/8 (50)	1/14 (7)	0.039
Patient subgroups				
Gender	*Female*	27/61 (44)	11/61 (18)	0.002
	Male	66/194 (34)	26/203 (13)	<0.001
Age	*<50 years*	4/11 (36)	3/18 (17)	0.375
	50-60 years	40/103 (39)	14/102 (14)	<0.001
	> 60 years	49/141 (35)	20/144 (14)	<0.001
Indication	*Screening*	30/103 (29)	18/113 (16)	0.020
	Surveillance	43/98 (44)	15/111 (14)	<0.001
	Diagnostic workup	20/54 (37)	4/40 (10)	0.003

[a]Calculated using chi-square or Fisher's exact test where appropriate. [b]Including 2 adenocarcinomas. [c]Any adenoma with villous features, high-grade dysplasia or ≥10mm. [d]Serrated lesions are counted separately from adenomas.

Aims & Methods: Data of three independent multicentre randomized trials (NCT01044732; NCT01549535; NCT01955122) were combined. Patients underwent same-day, back-to-back tandem examinations with both standard colonoscopy and Third Eye Retroscope, FUSE or EndoRings colonoscopy, respectively. In a pooled analysis we determined adenoma miss rates stratified by adenoma characteristics and patient subgroups.
Results: A total of 650 patients (60% male, mean age 57.5 ± 9.7 years) were randomized, of which 320 patients underwent standard colonoscopy first and 330 patients underwent ''behind folds visualizing'' colonoscopy first. Adenoma miss rates with ''behind folds visualizing'' colonoscopy were significantly lower compared to standard colonoscopy for proximally and distally located adenomas, for ≤5mm and 6-9mm adenomas, for sessile, flat and tubular adenomas, and for serrated lesions (Table). The miss rates were not statistically significantly different for ≥10mm, pedunculated, (tubulo)villous and advanced adenomas. Adenoma miss rates were significantly lower with ''behind folds visualizing'' colonoscopy independent of gender and indication, and in all persons ≥50 years.
Conclusion: ''Behind folds visualizing'' colonoscopy reduces miss rates in all segments of the colon for 1-9mm adenomas; no significant differences were found for larger (≥10 mm) and advanced adenomas. Whether the detection of more small (<10mm) adenomas indeed reduces CRC incidence and mortality remains to be determined.

P0172 ENDOSCOPIC SUBMUCOSAL DISSECTION LEARNING CURVE: EXPERIENCE OF A LARGE VOLUME COLONOSCOPY CRC ITALIAN SCREENING CENTER

E. Rosa-Rizzotto[1], E. Guido[1], D. Caroli[1], A. Dupuis[1], M. Lo Mele[2], M. Rugge[2], P. Pilati[3], F. De Lazzari[1]
[1]*Gastroenterology Unit,* [2]*Surgical Pathology and Cytopathology Unit,* [3]*Surgery Unit, Padova, Italy*

Introduction: endoscopic submucosal dissection (ESD) is an advanced endoscopic technique that allows for curative resection of superficial neoplasms in GI tract. The vast majority of experience and guidelines for ESD resection comes from Japan, where this technique was developed more than 10 years ago. In East countries the training curve is done on gastric GI lesions with expert supervision before starting on esophageal and colon lesions. In West countries EGC is a rare desease and expert guidance is not commonly available, so the learning courve of this tecnhique has to be developed in a different way.
Aims & Methods: To demonstrate that the ESD learnig curve performed on rectal lesions is a good way to practice on these difficult procedure in European countries. We retrospectovely included in the study all the ESD performed in our Endoscopy Unit in Padua from february 2012 to april 2015. None neplastic lesions come frome other endoscopy units. We considered the learning curve of a single dedicated endoscopist that before starting on humans performed 10 ESD on in vivo animal models under expert guidance. All the dissections were performed using Hybridknife needle and ERBEJET2 (ERBE®). Complications after procedure like bleeding and perforation were managed with hemoclips, Over the scope clips and hemostatic forceps. ESD was performed if the neoplastic lesion was considered susceptible to ESD regardless to the size. T test for unpaired data and Pearson chi-test were used for ststistical analysis.
Results: 40 ESD were performed, 22M(55%) and 18F(45%), mean age 63yr. 27 rectum (68%), 9 sigmoid tract (23%), 1 trasverse colon (2%), 3 ascending colon (7%). The neoplastic lesions were: 31 laterally spreading tumors (77%), 2 polipoid lesions 0-Is (5%), 3 recurrent tumor on scar (8%), 4 polipoid lesion 0-Isp(10%). Mean polyp area was 17.5 cm^2. Mean intervention time 107 min. En-bloc dissection was successful in 25/40 (63%) and R0 was reached in 18/24 (75%). Polyps hystological features were: 10 LGD (25%), 21 HGD (53%), 6 pT1 (15%), 3 pT2 (7%). Procedural complications accurred in 12/40 (30%): perforation in 8/40(20%), delayed bleeding 2/40(5%), rectal stenosis 2/40(5%). No deaths or surgical interventions followed the procedural complications. From the 12th procedure onwards the en-bloc performance became acceptable 22/27(81%) vs 3/12(25%) ($p < 0.001$). From the 30th procedure onwards the en-bloc performance became good 9/10 (90%, $p < 0.05$) and the mean execution time was significantly lower 55 vs 122 min ($p < 0.0001$) with no significant difference in the mean area of the lesions 15.6 vs 18.2 cm^2 (p = ns). Only 1 complication occurred after the 30th procedure (p = ns).
Conclusion: In our experience to reach an acceptable confidence with ESD procedure starting the training from in vivo animal model (at least 10 procedures) and then to colo-rectal neoplasms no less than 12 procedures had to be performed, but we still probably havent yet reached the learning curve plateau also after 40 procedures.

P0173 A NEW TECHNIQUE IN TREATMENT OF GIANT LATERAL SPREADING TUMORS WITH ENDOSOCPIC SUBMUCOSAL DISSECTION; POCKET CREATION TUNNELING METHOD

F. Aslan[1], Z. Akpınar[1], E. Alper[1], B. Ünsal[1]
[1]*Gastroenterology, Katip Celebi University Ataturk Training and Research Hospital, Izmir, Turkey*

Contact E-mail Address: drfatihaslan@hotmail.com
Introduction: Endoscopic submucosal dissection (ESD) has been widely accepted as an effective and minimally invasive treatment for patients with premalignant lesions. ESD allows en-bloc resection of a lesion, irrespective of the size lesion. However, en-bloc resection of large laterally spreading tumors (LST) with ESD is difficult technically because of anatomical features of the colon including its longer length, narrower lumen, and thinner walls and needs longer procedure time in the colon. The pocket-creation method (PCM) is a new technique in overcoming these difficulties of ESD in the treatment of colorectal lesions ≥3cm in size. But for larger lesions both the vascular structures and submucosal area to be dissected is larger. We investigated the efficacy of pocket creation tunneling method (PCM-t) in giant (≥5 cm) LSTs.
Aims & Methods: A total of 345 ESD procedures, which were performed in the esophagus, stomach, colorectum and duodenum between April 2012 and April 2015, were recorded prospectively before and after the procedure. 191 ESD procedures were performed in the colorectum. Lesions <5 cm in size and those removed with PCM were excluded from the study. The data of the rest 35 patients with lesion size ≥5cm were analyzed retrospectively. The patients were divided in to two groups; namely the ESD and PCM-t, according to the technique performed. The en-bloc and complete resection rates,complications, size of lesions, pathological results, length of procedure and dissection speed, and frequency of hemostatic forceps use in both groups were compared.
Results: Standard ESD was performed in 20 patients and PCM-t in 15 patients. There were no statistically significant differences between the two groups regarding age, gender, duration of procedure, size and type, endoscopic view, localization and pathological results of the lesions ($p > 0.05$).The dissection rate was higher in the PCM-t group and the frequency of hemostatic forceps use was less (p = 0.046 and 0.044, respectively). En-bloc and complete resection rates were higher in PCM-t group and complication rate was less.
Conclusion: The dissected lesion can completely block the lumen as the diameter of colon is small and generally the lesions are more vascular. This may lead to difficult dissection and a long procedure time.When the lesion diameter is large, dissection of the submucosal area as a tunnel helps in dissecting with control by providing a better notice of the vascular area.Using PCM-t in giant colorectal lesions can increase en-block resection rate, help in controlled dissection, decrease use of forceps besides decreasing the length of duration and increasing dissection rate.

Contact E-mail Address: drfatihaslan@hotmail.com

Introduction: Endoscopic submucosal dissection (ESD) is a minimally invasive technique, providing en-bloc resection of premalignant lesions and early stage gastrointestinal (GI) cancers. This procedure is commonly used in Far East countries like Japan and Korea; however, it has come into use in western countries in recent years. Additionally, ESD is not as widely performed in the colorectum compared with gastric ESD. In the present study, we present our results of colorectal ESD procedures.

Aims & Methods: A total of 345 ESD procedures, which were performed in the esophagus, stomach, colorectum and duodenum between April 2012 and April 2015, were recorded prospectively before and after the procedure. Patient data were analyzed retrospectively. We began to perform colorectal ESDs after 30 gastric ESD procedures and proximal colon segment procedures were performed only after 15 rectal ESD procedures had been completed. The results of 191 ESDs performed in colon and rectum were analyzed retrospectively.

Results: In a total of 185 patients, 191 colorectal ESDs were performed. The overall en-bloc and complete resection rates were 90.1% and 88.5%, respectively. Histopathology revealed carcinoma in 80, adenoma in 108 and neuroendocrine tumor in 3 patients. Complete resection was not achieved in 8.4% patients with positive vertical border. Perforation occurred in 4 patients which were treated successfully with endoscopic clip without the need for surgery except for one patient with delayed perforation (Table). Although cover type knife was generally preferred during the first cases non-cover type knife was used for later procedures. Surgical treatment was performed in all patients with deep submucosal (sm2) invasion, however neoplasia was observed in none of these patients.Table.Demographic data and colorectal ESD results Lesion (**N**) = 191

Conclusion: ESD is a safe and effective method to provide en-bloc and curative resection of premalign or malign colorectal lesions.

P0175 SALVAGE ENDOSCOPIC RESECTION OF SCARRED POLYPS AFTER FAILED PREVIOUS ENDOSCOPIC RESECTION ATTEMPT: SENSE STUDY

F. J. Q. Chedgy[1], R. Bhattacharyya[1], K. Kandiah[1], G. Longcroft-Wheaton[1], P. Bhandari[1]
[1]*Gastroenterology, Queen Alexandra Hospital, Portsmouth, Portsmouth, United Kingdom*

Contact E-mail Address: ferguschedgy@yahoo.co.uk

Introduction: Current standard of care for recurrent/residual polyps after previous endoscopic resection is surgery which can be associated with significant morbidity and cost.

Aims & Methods: This study analyses the outcomes of salvage endoscopic resection of polyps with severe scarring following a previously failed endoscopic resection. Prospective cohort study of patients referred to a Tertiary-centre for resection of scarred polyps with failed previous endoscopic resection attempts. Resection techniques: ESD knife & Snare combination (Knife Assisted Resection, KAR) or Snare & APC assisted resection (SAR).

Results: We identified 64 consecutive patients referred to us following a previously failed endoscopic resection attempt. All these patients had severely scarred polyps which were being considered for surgery at the referring centre. The mean polyp size 46mm (20-150mm). 83% were left-sided and 17% right–sided. 67% of resections were performed by KAR with mean polyp size 50mm. 33% of resections were by SAR with mean polyp size 38mm.

Referral to surgery: 2/64 for technically difficult so no attempt made, 5/64 for cancer.

Endoscopic follow up & cure: mean follow up of 3 years (range: 1-8 years), 97% overall cure rate which was the same for left and right sided lesions as well as KAR and SAR. The only complication was bleeding seen in 3 patients (4.6%).

Cost saving: Had all 64 patients been sent for surgery the total cost would have been £343,224. The total cost of the endoscopic approach, including the cost of patients requiring surgery, was £149,820 representing an average cost saving of £3021.94 per patient.

Conclusion: Severely scarred polyps due to failed previous endoscopic mucosal resection attempts can be successfully treated by experts. The techniques of KAR and SAR are equally effective when used for appropriate polyps. The complication rate is low. Further recurrence after first salvage resection can be treated successfully. Surgery can be avoided in most patients and an endoscopic approach is very cost effective. We would therefore, advocate an aggressive endoscopic resection strategy over surgery when dealing with severely scarred polyps.

P0176 COLON CLEANSING FOR COLONOSCOPY IN PATIENTS WITH IBD COLITIS: EFFICACY AND ACCEPTABILITY OF 2 LITER PEG VS 4 LITER PEG

G. Manes[1], P. Fontana[2], G. de Nucci[1], F. Radaelli[3], C. Hassan[4], S. Ardizzone[5]
[1]*Gastroenterology, G. Salvini Hospital, Garbagnate Milanese, Milano, Italy,* [2]*Gastroenterology, Sacco University Hospitla, Milano,* [3]*Gastroenterology, Valduce Hospital, Como,* [4]*Gastroenterology, Nuovo Regina Margherita Hospital, Roma,* [5]*Gastroenterology, Fatebenefratelli Hospital, Milano, Italy*

Contact E-mail Address: gimanes@tin.it

Introduction: Low-volume preparations are gaining attention for higher acceptability, but their use in IBD patients has never been evaluated. This study compares the efficacy, safety and tolerability of a 2L PEG solution plus bisacodyl with a 4L PEG solution in patients with ulcerative colitis.

Aims & Methods: This is a multicenter, randomized, single-blind, non-inferiority study. Adult outpatients with ulcerative colitis undergoing colonoscopy received either 2L PEG plus bisacodyl or 4L PEG. Bowel cleansing was assessed using the Ottawa Scale and rated as adequate if the score was ≤ 2 in each colon segment. Patient acceptance, satisfaction, and related symptoms were recorded.

Results: 211 patients were included. Overall, preparation was adequate in 80% patients without any differences between groups. Mean Ottawa scores for whole and right colon were similar in the two groups. As concern tolerability, 83% patients in 2L PEG bisacodyl arm and 44.8% in 4L PEG arm reported no/mild discomfort ($p < 0.0001$) and 94.3% and 61.9% expressed their willingness to repeat the preparation ($p < 0.001$). Palatability was better with 2L PEG-bisacodyl, whereas related symptoms occurred more frequently with 4L PEG. Regardless of preparation, split dosage was associated to better cleansing. Further predictors of poor cleansing were moderate/severe discomfort during preparation, and more than 6 hrs between end of preparation and colonoscopy. Extension and severity of colitis did not influence quality of preparation.

Conclusion: Low-volume PEG plus bisacodyl is not inferior to 4L PEG for bowel cleansing in IBD, but it is better tolerated and accepted by patients. The time interval from solution intake and colonoscopy is the most important factor affecting quality of cleansing also in IBD.
(ClinicalTrial.gov number NCT02248337).

P0177 COMPUTER-ASSISTED INSTRUCTION BEFORE COLONOSCOPY IS AS EFFECTIVE AS NURSE COUNSELLING, A CONTROLLED TRIAL

G. Veldhuijzen[1], M. Klemt-Kropp[2], C. Noomen[2], T. van der Ploeg[3], J. Drenth[4]
[1]*Gastroenterology, Radboudumc, Nijmegen,* [2]*Gastroenterology, Medical Center Alkmaar,* [3]*Foreest Medical School, Alkmaar,* [4]*Gastroenterology, Radboudumc, Nijmegen, Netherlands*

Contact E-mail Address: Govert.Veldhuijzen@radboudumc.nl
Introduction: Better patient education prior to colonoscopy, for instance through nurse counselling, improves adherence to instructions for bowel preparation and probably leads to cleaner colons. We hypothesized that computer assisted instruction (CAI) supported by video and 3D animations improves the effectiveness of nurse counselling, with potential operational advantages.
Aims & Methods: To assess the effectiveness of CAI for patient education prior to colonoscopy in terms of bowel cleanliness and patient knowledge, comfort and anxiety.
We included patients > 18 years who were referred for colonoscopy in an endoscopy unit in a general teaching hospital in the Netherlands. Exclusion criteria were illiteracy in Dutch and audiovisual handicaps. Patients were divided into two consecutive groups, one which received nurse counselling and one which received CAI, followed by a brief contact with a nurse shortly before colonoscopy. The CAI had been reviewed by expert endoscopists. For the main outcome measure, cleanliness of the colon during examination, data was collected using a physician questionnaire including the Ottawa Bowel Preparation Scale (OBPS) and the Boston Bowel Preparation Scale (BBPS). We assessed patient anxiety, patient comfort and general information using three questionnaires validated by expert consensus, which were issued after counselling or CAI and shortly before and after colonoscopy. We assessed knowledge of information provided earlier through a pre-colonoscopy test consisting of 10 questions. Statistical analyses were performed, including Mann-Whitney and T-test.
Results: We included 385 patients, 197 in the nurse counselling group and 188 in the CAI group. Overall response rates for the three patient questionnaires were 99%, 76.4% and 69.9% respectively. The physician questionnaire had an overall response of 60.8%. Baseline characteristics were similarly distributed among groups. Bowel cleanliness did not differ significantly between the two groups; on the OBPS, the counselling group scored 6.07 (SD 2.53) and the CAI group 5.80 (SD 2.90), and on the BBPS the scores were 6.54 (SD 1.69) and 6.42 (SD 1.62) respectively. Anxiety scores did not differ significantly. Patient comfort scores were significantly lower after CAI only. But in combination with a brief nurse contact comfort scores were significantly higher shortly before the colonoscopy. Scores on the knowledge test were similar, with 7.08 (SD 1.17) and 7.31 (SD 1.11).
Conclusion: CAI is a safe and practical modality for instructing patients before colonoscopy. This study found no difference in bowel cleanliness and patient knowledge with respect to the two groups. However, brief personal contact yielded significantly better patient comfort scores. We therefore recommend the combination of CAI with a brief nurse contact for daily practice.

Introduction: Colonoscopy is the gold standard for colorectal cancer screening. However, total colonoscopy may be impeded by several factors, including extensive diverticulosis, elongated transverse colon, female gender, low body mass index, or prior abdominal or pelvic surgery.
Aims & Methods: Aim was to evaluate the safety and efficacy of a novel balloon system which will be introduced at UEGW 2015 for difficult colonoscopy. Therefore, patients (mean age 75 years; Range 21-78 years; 40% female) referred for colonoscopy after failure of previous colonoscopy were prospectively enrolled in a pilot cohort study whose primary end point was device safety. Other study endpoints included success rate and time of cecum intubation, withdrawal times, total procedure times, and success of therapeutic procedures.
Results: Among the enrolled patients one was excluded due to a technical problem of the device. Ileocolonoscopy was performed in all (100%) patients using the novel balloon-system without any complications. Cecal intubation rate was 100%. Mean times to reach the cecum, withdrawal, and total procedure times were 11.05 minutes, 15 minutes, and 32 minutes, respectively. All therapeutic endoscopic interventions that were required were performed without any complications. Success rate of therapeutic procedures was 100%.
Conclusion: The novel introduced balloon-system for difficult colonoscopy appears safe and effective to use. Final data will be presented at UEGW.

P0179 PROSPECTIVE 1:1 RANDOMIZED STUDY TO ASSESS THE PERFORMANCE CHARACTERISTICS OF COLORECTAL FULL SPECTRUM ENDOSCOPY (FUSE)

H. Neumann[1], G. Tontini[1], M. Vieth[2], T. Rath[1], M. Grauer[1], I. Gralnek[3], M. Neurath[1]
[1]*Department of Medicine I, University of Erlangen-Nuremberg, Erlangen,* [2]*Institute of Pathology, Klinikum Bayreuth, Bayreuth, Germany,* [3]*Department of Gastroenterology, Technion-Israel Institute of Technology, Haifa, Israel*

Contact E-mail Address: helmut.neumann@uk-erlangen.de
Introduction: The newly introduced Full Spectrum endoscope (FUSE) provides a 330° field of view thereby potentially allowing endoscopists to see more anatomy of the colon as compared to standard forward viewing endoscopes (FVE). Recent data has indicated that FUSE significantly reduced adenoma miss rates.
Aims & Methods: The aim of this prospective randomized study was to assess the performance characteristics of FUSE in comparison to FVE. Therefore, patients were randomly assigned at a one-to-one ratio to undergo colonoscopy with FUSE or FVE after a previous sample size calculation. Performance characteristics including time to cecum, withdrawal time, total examination time, medication, patient and endoscopists' satisfaction, and polyp detection rates were recorded.
Results: Among 109 patients, 19 patients were excluded (11 inadequate bowel preparation; 5 hemicolectomy, 2 stenosis, 1 severe inflammation). 90 patients were finally randomized at a 1:1 ratio to undergo FUSE or FVE. Time to cecum (minutes, mean ± SD) was 4.05 ± 0.68 minutes for FUSE and 5.48 ± 0.67 minutes for FVE ($P < 0.001$). Withdrawal times were 12 ± 4.16 minutes and 15 ± 4.28 minutes for FUSE and FVE, respectively ($p < 0.01$). Total examination time was 16.30 ± 4.72 minutes in the FUSE group and 20.48. ± 4.39 minutes in the FVE group ($p < 0.001$). Sedation was less required in the FUSE group as compared to FVE (mean propofol dosage, 170 mg vs. 200 mg). Significantly more patients needed analgesia in the FVE group (meperidine; $P = 0.002$). Patient and endoscopists satisfaction were high throughout the cases and not different between both groups. Polyps were detected in 36% and 24% of patients in the FUSE and FVE group, respectively.
Conclusion: Advancement times of the scope to the cecum and withdrawal times were faster with the FUSE scope as compared to standard FVE. Satisfaction rates of patients and endoscopists were similar in both groups while patients needed more sedation and analgesia in the FVE group. Although more polyps were found in the FUSE group the study was not designed to compare adenoma detection rates between both groups.

P0180 RISK FACTORS FOR POSTPOLYPECTOMY BLEEDING AND ITS ASSOCIATION WITH HEPARIN BRIDGE THERAPY

H. Ishigami[1], M. Arai[1], K. Okimoto[1], D. Maruoka[1,2], T. Matsumura[1], T. Nakagawa[1], T. Katsuno[1], O. Yokosuka[1]
[1]*Gastroenterology and Nephrology, Graduate School of Medicine, Chiba University,* [2]*Clinical Research Center, Chiba University Hospital, Chiba, Japan*

Contact E-mail Address: the-god-of-stone14@nifty.com
Introduction: Postpolypectomy bleeding (PPB) is the most common complication of colonic polypectomy. The risk of PPB is associated with increasing age, anticoagulation therapy, hypertension, large polyp size, proximal location, and polyp morphology. According to American Society for Gastrointestinal Endoscopy (ASGE) and Japanese Society of Gastrointestinal Endoscopy (JSGE) guidelines, for patients taking anticoagulants (e.g. warfarin), bridge therapy with unfractionated heparin (UFH) or low molecular weight heparin (LMWH) is recommended to reduce the risk of thromboembolic events during high-risk procedures like polypectomy. However, little is known about the risk of PPB with heparin bridge (HB) therapy. We investigated the association between HB therapy and PPB.
Aims & Methods: We retrospectively reviewed 1659 polypectomies performed on 906 patients from January 2007 to December 2014 at our institution. A total of 728 patients did not take any antithrombotic agents (control group), and 45 patients underwent colonic polypectomy while receiving HB therapy (HB group). We analyzed the risk factors for PPB related to both the patients and the polyps, and we determined the rate of PPB in the HB group.
Results: PPB occurred in 33 lesions (2.0%) of 30 patients (3.3%). Eleven of 30 (36.7%) PPB patients were in the HB group ($p < 0.0001$), and the incidence of PPB in the HB group was 24.4% (11 of 45 patients). Polyp size ≧10 mm (20 of 33 [60.6%] vs. 639 of 1626 [39.3%], $p = 0.015$), pedunculated polyps (12 of 33 [36.7%] vs. 288 of 1626 [17.7%], $p = 0.012$), and location in the cecum (10 of 33 [30.3%] vs. 111 of 1626 [6.9%], $p < 0.0001$) were significant risk factors for PPB. In the control group, size ≧10 mm, pedunculated polyps, and location in the cecum were also significant PPB risk factors ($p = 0.0042$, $p = 0.014$, and $p = 0.0029$, respectively), although in the HB group, these were not significant ($p = 0.39$, $p = 1.0$, and $p = 0.053$, respectively). PPB in small polyps (≧10 mm) was higher in the HB group (15.4%, 10 of 65 lesions) than in the control group (0.73%, 7 of 963 lesions) ($p < 0.0001$), as was the recurrent bleeding rate (27.3% [3 of 11 patients] vs 0% [0 of 15 patients], respectively) ($p = 0.064$).
Conclusion: HB therapy, polyp size ≧10 mm, pedunculated polyps, and location in the cecum are risk factors for PPB. The incidence of PPB was higher in the HB group, and PPB occurred even if the polyp size was small (≧10 mm).

P0181 THE VALIDITY AND SAFETY OF THE COLORECTAL ESD FOR THE LESIONS SPREADING TO THE APPENDICEAL ORIFICE

H. Chiba[1], D. Kurihara[1], T. Suto[1], N. Kawano[1], M. Kaai[1], K. Ashikari[1], S. Seki[1], A. Takahashi[1], I. Tomonori[1], T. Morohashi[1], T. Goto[1]
[1]*Gastroenterology, Omori Red Cross Hospital, Tokyo, Japan*

Contact E-mail Address: h.chiba04@gmail.com

Introduction: Colorectal ESD has not been widely performed for colorectal tumors because of the high frequency of complications. Especially, ESD for the lesions spreading to the appendiceal orifice needs higher skill because of the confrontation to the muscle layer, narrow working space or spontaneous fibrosis. It is still unknown about the validity or effective strategy for these lesions.

Aims & Methods: 163 consecutive cases who underwent ESD in Omori Red Cross Hospital from 2012 April to 2015 March were analyzed. We use needle knife (Flex or Dual knife, Olympus Co Tokyo, Japan) for colorectal ESD. The main strategy for the lesions in the appendiceal orifice was shown as follows; we do the first injection from the tip of the vermiform appendix so that the tumor does not sink to the end of the vermiform appendix. This first injection should be minimum volume, and we make an enough endpoint around the appendiceal orifice as soon as possible. After this, we can continue ESD while using a counter traction of the gravity. We assessed the clinical findings and outcomes of ESD for the 6 lesions spreading to the appendiceal orifice (group A), compared to the other 157 lesions as control (group B).

Results: Mean age, sex, antithrombotic agents and past history were similar between two groups and there was no case of post appendicitis in group A. All ESD in group A was performed by one experienced endoscopist (≧150 colorectal ESD cases).Tumor shape was Is0/LST-G5/LST-NG1 in group A, and Is8/LST-G58/LST-NG84/SMT4 in group B, respectively. In addition, tumor size, specimen size, the area of the resected specimen, rate of en-bloc resection, and rate of curative resection were also similar: 35.8mm, 41.8 mm, 1187.9 mm^2, 6/6(100%), and 6/6(100%) in group A, and 28.4mm, 36.8mm, 1022.7mm^2, and 156/157 (99.4%) in group B, respectively. The number of mild or sever fibrosis was more often in group A (non; 3, mild; 3) than in group B (non; 127, mild; 25, severe; 5) ($p = 0.077$), but the mean operation time (group A: 42.5min, group B: 42.9min) was about the same. Pathological findings were adenoma2/M3/SM-slight 1 in group A, and adenoma71/M73/SM-slight3/SM-massive6/SMT4 in group B, respectively. The number of post bleeding or perforation was no case in group A and 2 perforations in group B. After ESD, WBC(/μl), CRP(mg/dl), a number of having a high fever(≧38°C), and taking a painkiller had no significant difference.

Conclusion: ESD for the lesions spreading to the appendiceal orifice was safe and there were no significant differences of outcomes, compared to the lesions in the other positions. Our strategy for these lesions will be appropriate. However, the existence of the spontaneous fibrosis around appendiceal orifice is not a little and the working space is very narrow, so we have to understand the characteristics of the appendiceal orifice.

Disclosure of Interest: None declared

P0182 PITFALL OF PIT PATTERN DIAGNOSIS AND MAGNIFYING ENDOSCOPY WITH NARROW BAND IMAGING -PREDICTION OF THE DEPTH OF SUB MUCOSAL INVASION FOR COLORECTAL NEOPLAS

H. Osumi[1], Y. Tamegai[1], T. Kishihara[1], A. Chino[1], M. Igarashi[1]
[1]*Department of Gastroenterology, Cancer Institute Hospital, Japanese Foundation for Cancer Research, Tokyo, Japan*

Contact E-mail Address: hiroki.osumi@jfcr.or.jp

Introduction: In Japanese Society for Cancer of the Colon and Rectum guidelines 2014, the intramucosal or superficial submucosal (depth of invasion < 1000 μ m:T1a) invasion is important to determine appropriate for ESD. On the other hand, size and macroscopic type both do not matter. So it is important for us to evaluate the depth of submucosal invasion because there have been reports of significantly increased risk factors for lymph node metastasis of early colorectal cancers in cases where the lesions invaded the deep submucosa (depth of invasion $\geq 1{,}000$ μ m:T1b). When we evaluate the depth of invasion for colorectal cancer, we usually use pit pattern classification and magnifying narrow band imaging (NBI) adding white light observation and magnifying chromo-endoscopy.

Aims & Methods: The aim of this study is to evaluate diagnostic accuracy in estimating the depth of submucosal invasion of colorectal neoplasms using both pit pattern classification and NBI, and to extract endoscopic features for misdiagnosis patients. We enrolled the 522 patients who performed colorectal ESD from January 2011 to December 2014. Among them, 286 patients (57.3%, 164 men, 42.7%, 122 women, Median age ±SD: 66 ±11.3 years) that we could confirm type V pit pattern were enrolled for this study. Type V pit patterns include areas with irregular crypts (type V_I) and areas of apparent non-structure (type V_N). Type V_I pit patterns are further subdivided into areas of mild irregularity (type V_I mild) and areas of severe irregularity, which exhibit destroyed and damaged pits (type V_I severe). We evaluated the ability of differential diagnosis between Tis-T1 cancer and T1b cancer using type V pit pattern and NBI, and extract endoscopic features for misdiagnosis patients.

Results: In macroscopic type, polyploid type was 31.1% (88/286), and depressed or laterally spreading type were 68.9% (LST-G:106?LST-NG and depressd:92). In the relationship between type V pit pattern and the depth of invasion, sensitivity, specificity, and accuracy were 96.0%, 33.3%, and 88.1%, respectively. On the other hand in the relationship NBI and the depth of invasion, sensitivity, specificity, and accuracy were 89.4%, 32.3%, and 82.5%, respectively. Endoscopic features of misdiagnosis patients of type V mild shrunk in size of villous component, depressed area, and more than 30mm in max diameter. Furthermore, expansiveness, constitutive of the focal fold, and white spots in the polyploid type appeared with higher frequency than in the depressed or laterally spreading type. In contrast, the frequency features of a large nodule in the depressed lesion or laterally spreading type was higher than in the polyploid type. For the patients of type V severe, 5 patients had loss of dyeing and this was the factor of over diagnosis. The remaining 5 patients high frequency of endoscopic features were severe redness, elevation, depressed component, and the area of type V severe within 5mm in diameter.

Conclusion: Endoscopic findings suggest that there are some limitations of the diagnosis of the depth of submucosal invasion for colorectal cancer using pit pattern classification and NBI. We should utilize the findings of the lesions invaded with deep submucosa in the white light and chromo-endoscopic observation and evaluate submucosal fibrosis of the cancer when performing ESD.

Disclosure of Interest: None declared

P0183 A VISIBILITY STUDY USING NARROW BAND IMAGING IN THE COLORECTAL FLAT AND DEPRESSED LESIONS

H. Nakamura[1], H. Ikematsu[1], S. Osera[1], K. Shinmura[1], T. Hombu[1], K. Takashima[1], M. Imajo[1], T. Kadota[1], T. Katoh[1], H. Morimoto[1], Y. Yoda[1], Y. Oono[1], M. Kojima[2], A. Ochiai[2], K. Kaneko[1]
[1]*Department of Gastroenterology, Endoscopy Division,* [2]*Pathology Division, Research Center for Innovative Oncology, National Cancer Center Hospital East, Kashiwa, Japan*

Contact E-mail Address: hirosnak@east.ncc.go.jp

Introduction: Background: In conventional observation using white light, miss rate of adenoma was 10–30% through colonoscopy. It is difficult to detect flat lesions, especially laterally spreading tumors of non-granular type (LST-NG) and depressed lesions with higher malignant potential. In many detection studies for all colorectal lesions including polypoid, flat, and depressed lesions, no significant difference as seen in detection rate between narrow band imaging (NBI) and white light imaging, however, there have been no reports regarding visualization of LST-NG and depressed lesion in NBI observation.

Aims & Methods

Aim: To investigate the visibility of LST-NG and depressed lesions by using NBI.

Methods: We intended consecutive patients with LST-NG and IIc lesions that were endoscopically or surgically resected in our hospital between August 2011 and July 2013. These lesions were classified into four groups as followed: ''Brownish area (BA)'', ''Brown of only margins (O-ring sign)'', ''Same color as normal mucosa (SC)'' and ''Whitish area (WA)'' by appearance of NBI, and reveal each ratio. Furthermore, we compared pathological findings in individual groups of LST-NG and IIc lesions.

Results: Result: A total of 19 IIc lesions and 180 LST-NG lesions were analyzed. In IIc lesions, BA was 6 lesions (31.5%), O-ring sign was 11 lesions (57.9%), SC was 1 lesion (5.3%) and WA was 1 lesion (5.3%). In LST-NG lesions, BA was 120 lesions (66.7%), O-ring sign was 26 lesions (14.4%), SC was 34 lesions (18.9%) and WA was no lesions. The pathological findings of IIc lesions as followed: in BA, 1 lesion (16.7%) of high grade dysplasia (HGD), and 5 lesions (83.3%) of low grade dysplasia (LGD). In O-ring sign, 2 lesions (18.1%) of invasive cancer, and 9 lesions (81.9%) of LGD. In SC and WA, LGD were 1 lesion (100%). The pathological findings of LST-NG lesions as followed: in BA, 25 lesions (20.8%) of invasive cancer, 45 lesions (37.5%) of HGD, and 50 lesions (41.7%) of LDG. In O-ring sign, 8 lesions (30.8%) of invasive cancer, 4 lesions (15.4%) of HGD, and 14 lesions (53.8%) of LGD. In SC, 3 lesions (8.8%) of invasive cancer, 8 lesions (23.6%) of HGD, and 23 lesions (67.6%) of LGD.

Conclusion: Conclusions: Since most of IIc lesions were visualized as brown by NBI, there would be clinical benefit for the visibility. On the other hands, approximately 20% of LST-NG lesions were recognized in same color as surround normal mucosa, so the visibility was inferior to that of IIc lesions.

Disclosure of Interest: None declared

P0184 USEFULNESS AND SAFETY OF COLD SNARE POLYPECTOMY FOR REMOVING COLONIC POLYPS IN JAPANESE PATIENTS

H. Noda[1], N. Ogasawara[1], H. Hoshino[1], T. Nagoya[1], A. Koshino[1], Y. Kondo[1], Y. Ito[1], S. Izawa[1], M. Ebi[1], Y. Funaki[1], M. Sasaki[1], K. Kasugai[1]
[1]*Gastroenterology, Aichi Medical University School of Medicine, Nagakute, Japan*

Contact E-mail Address: bisaipan@aichi-med-u.ac.jp

Introduction: Colorectal cancer is a major health problem worldwide. Polypectomy of small colonic polyps has been an effective procedure for reducing the risk of colon cancer development by interrupting the progression of adenoma to carcinoma. Cold snare polypectomy (CSP) which can treat small colonic polyps without electrocautery has been recently reported to be useful for removing small colonic polyps in European countries, and CSP has become one of the common procedures for resecting colonic polyps. In Japan, CSP has been gradually utilized although endoscopic mucosal resection (EMR) has been a most common method for removing small colonic polyps. However, there has been few reports regarding the usefulness and safety of CSP in Japanese patients.

Aims & Methods: To verify the usefulness of CSP, we analyzed the complete resection rate and the complication between EMR and CSP. Subjects were 423 consecutive patients with 1010 lesions (ranges of polyp sizes, 3 mm-15 mm; average of polyp size, 6.8 mm; macroscopic type, Is or Isp) resected by EMR, and 106 patients with 175 lesions (ranges of polyp sizes, 3 mm-10 mm; average of polyp size, 5.0mm; macroscopic type, Is or Isp) resected by CSP at Aichi Medical University School of Medicine between May 2014 and February 2015. Moreover, 175 lesions resected by CSP were divided into two groups; 58 lesions resected by CSP using short snare (diameter of the snare, 13 mm) and 117 lesions resected by CSP using long snare (diameter of the snare, 27 mm). The complete resection rate was histologically compared between the two groups.

Results: There was no significant difference in complete resection rate between EMR (99.5%) and CSP (99.4%). There were no significant difference related with complications such as perforation and post-operative bleeding between EMR (perforation: 0, post-operative bleeding: 2) and CSP (perforation: 0, post-operative bleeding: 0). Histological examination revealed that complete resection rate of CSP using short snare (60.3%) is significantly higher than that of CSP using long snare (33.7%) ($p < 0.05$). There were no significant difference in complications between CPS using short-snare and CPS using long-snare.
Conclusion: CSP is a safe method for removing colonic polyps without complication. The complete resection rate in CPS using short snare is significantly higher than that in CPS using the long snare. Our study demonstrates that the short snare is considered to be useful for removing colonic polyps compared with the long snare in CPS. Thus, CSP using the short snare should become widely applicable to Japanese patients.

P0185 DEVELOPMENT OF NOVEL TECHNIQUE FOR IDENTIFICATION OF COLONOSCOPE SHAPE USING ULTRATHIN SHAPE SENSOR: A PILOT STUDY

I. K. Yoo[1], H. J. Chun[1], S. H. Kang[1], J. H. Lee[1], S. H. Kim[1], J. M. Lee[1], H. S. Choi[1], E. S. Kim[1], B. Keum[1], Y. T. Jeen[1], H. S. Lee[1], C. D. Kim[1]
[1]*Department of Internal Medicine, Korea University College of Medicine, Institute of Gastrointestinal Research and Medical Device Development, Division of Gastroenterology, Seoul, Republic of Korea*

Contact E-mail Address: ikyoo82@hanmail.net
Introduction: During colonoscopy, procedural completion, accuracy, comfort, and safety are important factors. Uncontrolled looping of the colonoscope shaft during insertion can cause abdominal pain and could lead serious complications. Scope guided endoscopy using ultrathin shape sensor can reduced unnessessory tactile pressure or torque.
Aims & Methods: The aim of this study is to simulate 3D structure of colonoscope using ultrathin shape sensor. We conducted a prospective pilot study. Three-dimensional (3D) shape of the colonoscope shaft was obtained by using ultrathin shape sensor of fiber Bragg gratings. It detect strains and bending angles and provides real-time continuous 3D imaging of the colonoscope without radiation hazard. We reconstructed the shape of colonoscope and measured bending curvature and error of tip position.
Results: Total 10 patients underwent colonoscopy using ultrathin shape sensor. The results show that the shape sensor is reliable at a maximum bending curvature of $80mm^{-1}$. The average tip position error was 1.722 ± 1.678mm, which corresponds to $1.50 \pm 1.46\%$ of the total length of the sensor.
In this approach, the endoscopists performance may enhanced by providing using a kinetic model that provides information such as the shape of the scope, direction of the colon and forces.
Conclusion: Scope guided endoscopy using FBG sensor can be successfully used to display colonoscope configuration by reconstruction of the high curvature bending and low tip position error. This Flexible, thin and almost weightless shape sensor would be a novel technique for identification of colonoscope shape.

Introduction: Accurate detection and characterization of colorectal lesions are important for optimal treatment and follow-up strategies. Electronic chromoendoscopy may be helpful in this setting, but scientific evidence is inconclusive. The usefulness of chromoendoscopy may differ according to the expertise of endoscopists. We hypothesized that i-Scan, the electronic chromoendoscopy available in Pentax endoscopes, improves the characterization of colorectal lesions in non-expert hands.
Aims & Methods: Aim of the present study was to assess the impact of different iScan profiles for the accurate characterization of colorectal lesions in non-expert hands.
Material and methods: A prospective, observational study of colorectal lesions detected in patients referred to our Endoscopy Unit for diagnostic colonoscopy from February to April 2015 was designed. Three experienced endoscopists collected four images from every lesion by applying HD-white light (HDWL) and three different iScan profiles (iScan1, iScan2 and iScan3), respectively before endoscopic removal for histological evaluation. Total collected images from all lesions were presented unlabeled in a randomized order to a young staff member with a two years' experience in diagnostic and therapeutic endoscopy, and with a limited experience in advanced imaging, for predicting histological diagnosis. The accuracy to predict histology with the different iScan profiles compared to HDWL was calculated according to the size of the lesions. The prediction confidence was also evaluated and classified as low and high. Statistical analysis was performed using the chi-square test and Fisher exact test, as appropriate.
Results: A total of 444 images from 111 lesions were analyzed. Final histological diagnosis was adenoma in 73 cases and serrated lesions in 38 cases. Global accuracy for predicting histology increased from 69.4% with HDWL to 85.6% with iScan ($p < 0.05$). Accuracy was similar with any of the three iScan profiles (75.7%, 80.2% and 82.9% for iScan 1, 2 and 3, respectively) (n.s.). For non-serrated adenomas, accuracy to predict histology was 57.5% for HDWL compared to 82.2% with iScan ($p < 0.05$). Again, no statistical difference was observed among different iScan profiles, although accuracy tended to be higher with iScan3 (69.8%, 76.7% and 79.4% for i-Scan1, 2 and 3, respectively) (n.s.). Accuracy for serrated lesions was equal with HDWL and i-Scan (92.1% in both cases). Usefulness of iScan was greater for predicting histology in case of diminute and small lesions (19.3% and 11.9% diagnostic improvement with regard to the accuracy with HDWL, respectively) ($p < 0.05$). iScan also allowed to increase significantly the prediction confidence, and high prediction confidence was more frequent with iScan (78.4%) than with HDWL (51.3%) ($p < 0.05$).
Conclusion: i-Scan allows improving significantly the accuracy of optical diagnosis of colorectal lesions compared to HDWL in non-expert hands. This is mainly true for diminute and small adenomatous lesions. iScan also helps to increase the prediction confidence of these lesions.

Introduction: The complete removal of adenomatous polyps is important for reducing the incidence and mortality of colorectal cancer. However, little information is available on the rate of incomplete polypectomy for intermediate sized lesions (5–20 mm) in clinical practice and on the affecting factors, and there are no guidelines addressing the issue of incomplete resection.
Aims & Methods: The aims of this study were to identify factors affecting the completeness of colonoscopic polypectomies and to evaluate the experience level of fellows who achieve competence compared with that of experts. Medical records of the patients who underwent at least one polypectomy for an adenomatous polyp at a single tertiary hospital between March 2011 and February 2013 were retrospectively reviewed. The lateral and deep margins of the resected polyps were evaluated to check the resection completeness.
Results: A total of 3,671 adenomatous polyps from 1,945 patients were included. Of these polyps, 1,591 (43.3%) were removed by three experts and 2,080 (56.7%) were removed by seven fellows. In the expert-treated group, polyp size ≥ 20 mm (odds ratio [OR] 3.07, 95% confidence interval [CI] 1.87-5.05, $P < 0.001$), right-sided location (OR 1.35, 95% CI 1.09-1.67, $P = 0.006$), and sessile type (OR 1.67, 95% CI 1.10-2.54, $P = 0.017$) was associated with incomplete resection. In the fellow-treated group, not only polyp characteristics (right-sided location [OR 1.41, 95% CI 1.18-1.69, $P < 0.001$]), but the cumulative number of procedures was also related to resection completeness. After 300 consecutive polypectomies, the complete resection rate of the fellows was comparable to that of the experts.

Conclusion: In the fellow-treated group, the level of procedure experience was closely associated with the outcome of colonoscopic polypectomy. Meticulous attention is critical to ensure the completeness of polypectomies performed by trainee endoscopists during the training program.

Contact E-mail Address: johann.dreanic@cch.aphp.fr
Introduction: The accuracy in the differentiation of colonic polyps would allow a ''resect and discard'' strategy for small colonic lesions. Recently, the ESGE suggested ''that virtual chromoendoscopy can be used for real-time optical diagnosis of diminutive (< 5 mm) colorectal polyps to replace the histopathological diagnosis''. Blue Laser Imaging (BLI), is a new endoscopic system (Fujifilm-Japan) associated with magnification, which can potentially further improve the differentiation of polyps. The aim of this study was to measure the diagnostic accuracy of polyp assessment (adenomatous versus hyperplastic) in small (6-9mm) and very small polyps (≤5mm), to allow a ''resect and discard strategy'' predict using BLI and zoom magnification.
Aims & Methods: Colonic polyps < 10 mm were prospectively included in the study. Each polyp was evaluated with white-light, standard BLI, BLI-bright, with and without magnification (Zoom). Photos and video were performed for each polyp. Expert endoscopists reviewed all pictures and videos blindly, and classified polyps using size and the Paris, NICE, WASP and Sano classifications. Histological findings were correlated with clinical and endoscopic findings. Polyps were classified according the histopathological diagnosis between neoplastic lesions (adenoma n = 46, Sessile Serrated Adenoma SSA/Ps n = 4, and no invasive carcinoma) and non-neoplastic lesions (hyperplastic polyps n = 11 and polypoid expansion of normal colonic mucosa n = 15).
Results: A total of 76 lesions < 10mm (n = 33 of 6-9mm; n = 43 of ≤5mm) were detected in 29 patients, and their median size was 5mm (IQR 3-7). Morphologies of the lesions were: 19 polypoid (0-I) and 57 slightly elevated (0-IIa). No slightly depressed without ulcer lesion (0-IIc) was observed. Pathological type of the polyp was predicted and polyp management decided upon for all 76 detected lesions. Polyps' location was splenic flexure to cecum (proximal colon) and rectum to descending colon (distal colon) in 56% and 44% respectively. The overall sensitivity, specificity, positive and negative predictive value, and diagnostic accuracy of BLI with magnification for the endoscopic diagnostic of neoplastic polyps were 0.88 (95% CI = 0.76-0.95), 0.58 (95% CI = 0.37-0.77), 0.80, 0.71 and 88%, respectively. Diagnostic accuracy of in vivo polyp assessment in 6-9mm and ≤5mm polyps were 92% and 83% respectively. Considering the adenoma detection, the accuracy of the NICE, Sano and WASP classifications was 64%, 64% and 92% (p = 0.0013) respectively.
Conclusion: At the era of BLI and zoom magnification, small polyps identification using NICE and Sano classifications was not sufficient to allow a ''resect and discard'' strategy. The 90% agreement in assignment of post-polypectomy surveillance intervals recommended by the ESGE was not reached with NICE and SANO classifications. The diagnostic accuracy using the WASP classification is a promising technique to pass the 90% cut-off identified by the ESGE.
Disclosure of Interest: None declared

P0189 OPTICAL DIAGNOSIS OF COLONIC POLYPS: WHICH CLASSIFICATION SHALL WE USE AT THE EDGE OF THE BLUE LASER IMAGING (BLI) TECHNIQUE? THE WASP AND THE SANO CLASSIFICATION' ACCURACY

J. Dreanic[1], R. Coriat[1], S. Leblanc[1], F. Prat[1], V. Abitbol[1], M. Dhooge[1], M. Camus[1], E. Sion[1], M. Barret[1], S. Chaussade[1]
[1]*Gastroenterology and endoscopy unit, Hopital Cochin - APHP, Paris, France*

Contact E-mail Address: johann.dreanic@cch.aphp.fr
Introduction: Accurate endoscopic differentiation of colonic polyps would allow resect and discard strategy for small colonic lesions. Blue Laser Imaging (BLI), a new endoscopic system has been validated to detect adenoma. The accurate endoscopy differentiation remained a challenge and new classifications have been developed to better identify adenoma from hyperplastic polyps. Recently, a classification system based on narrow band imaging (NBI) was validated for endoscopic differentiation of small and diminutive adenomas, hyperplastic polyps and Sessile Serrated Adenoma/polyps (SSA/Ps): the Workgroup serrAted polypS and Polyposis (WASP) classification. In addition, the SANO classification was validated in the same conditions using the pit pattern and the vascularization of the lesion. We herein stressed the WASP and the SANO classifications in optical diagnosis polyps using BLI and magnification.
Aims & Methods: 117 colonic polyps were studied in 45 patients in real-life colonoscopy, and prospectively included in the study. Each polyp was evaluated with white-light, standard BLI, BLI-bright, with and without magnification (Zoom). Experts endoscopists reviewed all pictures and videos blindly using WASP and Sano classifications. Polyps were classified according the histopathological diagnosis between adenoma (n = 72), hyperplastic polyps (n = 13), SSA/Ps (n = 14), polypoid expansion of normal colonic mucosa (n = 15) or invasive lesion (n = 3). Histological findings were correlated with clinical and endoscopic findings. The diagnosis accuracy was evaluated considering histology, size, WASP and SANO classifications. A discrepancy between SANO and WASP classification was considered as the most advanced type of lesions.
Results: 117 polyps were resected by endoscopic submucosal resection (EMR) with a mean size of 12.8mm (1–60mm). Polyps location was splenic flexure to cecum (proximal colon) and rectum to descending colon (distal colon) in 57% and 43% respectively. The overall sensitivity, specificity, positive and negative predictive value, and diagnostic accuracy of BLI with magnification using WASP classification for the endoscopic diagnostic of colorectal adenomas were 0.76 (95% CI = 0.66-0.85), 0.42 (95% CI = 0.25-0.63), 0.80, 0.36 and 76%, respectively. The overall sensitivity, specificity, positive and negative predictive value, and diagnostic accuracy of BLI with magnification using SANO classification for optical diagnosis of advanced polyps were 0.91 (95% CI = 0.84-0.96), 0.67 (95% CI = 0.51-0.81), 0.86, 0.78 and 90%, respectively. The diagnostic accuracy of SANO and WASP classifications to predict SSA/Ps were 79% and 85%, respectively. Neither SANO nor WASP classifications were superior to detect SSA/Ps from adenoma (p = 0.82).
Conclusion: BLI and magnification are advanced endoscopic images that challenges optical diagnosis. SANO classification permits better endoscopic differentiation of small adenomas and non-neoplastic lesions than WASP classification. We observe a trend to better optical diagnosis of SSA/Ps by WASP classification. Acquisition of basic knowledge in BLI and magnification endoscopy could permit to improve endoscopic optical diagnosis of SSA/Ps using the new WASP classification.

P0190 CONSTIPATION; TO SCOPE OR NOT TO SCOPE? THAT IS THE QUESTION: A LARGE DISTRICT GENERAL HOSPITAL STUDY

J. Segal[1], C. Kanagasundaram[1], A. Vaziri[1]
[1]*Gastroenterology, Lister Hospital, Stevenage, United Kingdom*

Contact E-mail Address: jonathansegal@doctors.org.uk
Introduction: The European Society of Gastrointestinal Endoscopy and the British Society of Gastroenterology offer no specific guidelines on performing colonoscopy for constipation. The American guidelines advise to colonoscope those with constipation if new onset and over 50 years of age without prior bowel screening or in those with other alarm features (1). In Two US-Based Population retrospective case control studies, one suggested constipation had an increase Odds Ratio of 2.36 for colorectal cancer in those with bowel opening less than 3 times a week (2). The other study suggesting an increase Odds Ratio of 2.0 if needed laxatives 12-51 times in a year to 4.4 if laxative use was greater than 52 times in a year (3). A meta analysis of 8866 patients found that constipation as a primary indication was associated with colorectal cancer in 5.2% of patients which had a lower odds ratio of 0.56 when compared with other indications (4).
Aims & Methods: To determine if performing endoscopy in patients with constipation could detect cancers. All colonoscopies and flexible sigmoidoscopies performed for '' constipation'' between January 2012 and December 2014 at the East and North Hertfordshire NHS trust were looked at using an endoscopy database. Cancer pick-up rate in this cohort was assessed with histology followed up following the procedure for confirmation of cancers. Cancer detection rates were then compared with the 4 most common other indications for colonoscopy at the NHS trust. Two tailed T tests were used to compare cancer detection rates with p value set at (< 0.05).
Results: There were 298 endoscopies performed (165 Colonoscopies, 133 Flexible Sigmoidoscopies). There were 5 new cancers found on colonoscopy (3%) and 6 cancers found on flexible sigmoidoscopy (4.5%). When compared to the other top 4 indications for undergoing a colonoscopy there was no significant differences in cancer detection rate at (p < 0.05). ''Diarrhoea'' had a cancer detection rate of 0.8% which was significantly lower than for constipation detection rates. 3 New cancers were found with constipation as the primary indication with 5 cancers found for constipation with an abnormal CT scan.
Conclusion: As an indication for endoscopy, the indication ''Constipation'' remains a contentious issue without clear guidelines of when it is appropriate to scope. Our study has highligted that constipation as an only indication can still yield cancers as a rate similar to other important indications. This study has also highlighted the importance of imaging in those that are constipated. In those presenting with constipation a non invasive test first such as a CT scan to help rule out significant pathology.

Contact E-mail Address: josecarlos.marin@salud.madrid.org

Introduction: To improve the quality of ESD outcomes with the initial cases, it is crucial that factors predicting the need to end the procedure with a piecemeal endoscopic mucosal resection (pEMR) are evaluated.

Aims & Methods: The aim of our study was to prospectively assess what factors were associated with changing the initially planned ESD to pEMR and to develop a predictive model to anticipate the need for a piecemeal resection. We prospectively enrolled the first 122 cases referred for an ESD from September 2008 to April 2015.

Results: Endoscopic treatment was aborted in five cases. Finally, 117 lesions were included in the *intention-to-treat* analysis (95.9%). A pEMR was necessary in 40 (34.2%). Factors significantly associated with the need for a pEMR were: experience $\leq$ 40 ESDs (OR: 4.01; IC 95%: 1.77 – 9.06; $p =$ 0.001), location out of the stomach (OR: 3.93; CI 95%: 1.55 – 9.63; $p =$ 0.003), procedure time- $>$ 180 minutes (OR: 2.62; CI 95%: 1.16 – 5.92; $p =$ 0.03) and size $>$ 3 cm (OR: 5.15; CI 95%: 2.24 – 11.82; $p <$ 0.0001). In the logistic regression model, the factors independently associated with changing technique to a pEMR were: size of the lesion $>$ 30 mm (OR: 4.80; CI 95%: 1.81 – 12.72; $p =$ 0.002) and experience $\leq$ 40 ESDs (OR: 5.98; CI 95%: 2.18 – 16.42; $p =$ 0.001). The value of the area under the ROC curve of the predictive model for a pEMR [logodds = 1.87 x (size $>$ 3 cm) + 1.66 x (first 40 cases) + 1.07 x location out of the stomach – 2.90] was 0.81 (CI 95%: 0.73 – 0.89). A cut-off point of $\geq$ 0.34 for predicting pEMR showed the following diagnostic performance: sensitivity: 82.5% (CI 95%: 81.2 – 83.8); specificity: 70.1% (CI 95%: 69.4 – 70.8).

Age (mean ± SD)	**69.8** ± 11.9
Male / Female n;%	**67 / 50** (57.3 / 42.7)
Tumor location n; %	
Esophagus	**1** (0.85)
Stomach	**42** (35.9)
Rectum	**45** (38.4)
Colon	**29** (24.8)
Mean tumor size, mm (mean ± SD)	**31.6** ± 16.1
En bloc resections (n; %)	**77** (65.8)
Piecemeal resections (n; %)	**40** (34.2)
Histopathology (n; %)	
Mucosal low grade neoplasia	**31** (26.5)
Mucosal high grade neoplasia	**71** (60.7)
Curative submucosal invasion	**3** (2.5)
Non-curative submucosal invasion	**7** (0.6)
Other (subepithelial tumors, carcinoids...)	**5** (4.3)
Procedure time (mean ± SD)	**190** ± 82
Delayed bleeding (n;%)	**12** (10.3)
Perforations (n;%)	**17** (14.5)

Conclusion: A scoring system combining the size and location of the lesion and the experience in ESD provided good diagnostic performance to predict the need for a p-EMR.

P0192 EFFECTIVENESS OF A SOFTWARE APPLICATION IN IMPROVING APPROPRIATENESS OF COLONOSCOPY PRESCRIPTION

J. Díaz-Tasende[1], J. C. Marín-Gabriel[1], P. Cancelas-Navia[1], P. Ruiz-López[2], J. Ferrándiz-Santos[3], S. Rodríguez-Muñoz[1], M. Pérez-Carreras[1], F. Sánchez-Gómez[1], A. Del Pozo-García[1], G. Castellano-Tortajada[1]
[1]*Gastroenterology,* [2]*Quality and Patient¨s Safety, Hospital Universitario 12 de Octubre,* [3]*Primary Care Management, Comunidad de Madrid, Madrid, Spain*

Contact E-mail Address: jose.diazta@salud.madrid.org

Introduction: There is evidence that a significant proportion of colonoscopies performed worldwide do not comply with clinical guidelines. This inadequacy on the medical prescription has important consequences on its diagnostic performance, the patients safety and costs. Results of educational interventions have been inconsistent in previous studies. The development of software tools, incorporated in the electronic medical record, might have a role in improving prescriptions' appropriateness.

Aims & Methods

Aims: To evaluate the effectiveness of a software application, integrated in the colonoscopy electronic request form of an university hospital and designed as prescription aid, to decrease colonoscopy prescription inadequacy.

Methods: Observational prospective study. An electronic colonoscopy request form has been designed including the algorithms and the recommendations for follow up on its most relevant indications and providing real time information on the procedures appropriateness on each clinical context. Six hundred colonoscopy prescriptions were evaluated before (PRE period) and after (POST period) software implementation. The colonoscopy was considered "appropriate" if it met the recommendations of any of the following guidelines with a six month difference or less: Spanish Gastroenterological Association Colorectal Cancer Prevention Guideline, European Guidelines for Quality Assurance in Colorectal Cancer Screening and Diagnosis or European Panel on the Appropriateness of Gastrointestinal Endoscopy (EPAGE II) categories "appropriate and necessary", "appropriate" or "uncertain".

Results: 1084 prescriptions were included in the analysis, 519 PRE / 565 POST, (average age 59.5 +- 14.6 y.o., 49.32% females). There is a significant reduction in the inapropriateness rate after the implementation of the software: PRE 21.19% VS POST 9.20% ($p < 0.001$). This improvement is statistically significant in the follow-up after surgical treatment of colorectal cancer and endoscopic resection of early colorrectal neoplasia (table).

TABLE: INAPPROPRIATENESS in PRE (n = 519) and POST (n = 565) PERIODS, disaggregated by indication. Data are shown as n(%).

Indication	PRE	POST	p
Anemia	1 (2.70)	0 (0)	0.21
Hematochezia	1 (3.23)	2 (3.03)	0.96
Constipation	1 (5.56)	2 (7.41)	0.81
Abdominal pain	2 (11.76)	3 (37.50)	0.13
Diarrhea	3 (8.11)	0 (0)	0.01*
Inflammatory bowel disease	4 (5.71)	1 (2.17)	0.36
Surveillance after endoscopic resection	59 (49.17)	26 (33.33)	0.03*
Surveillance after surgical resection of cancer	21 (35.00)	7 (15.22)	0.02*
Screening (high risk population)	6 (13.04)	5 (10.64)	0.72
FOBT +	0 (0.00)	1 (2.94)	0.48
Others	12 (18.18)	5 (6.42)	0.03*

Conclusion: The implementation of a decision-making aid software tool improves appropriateness of colonoscopy prescription.

P0193 IMPACT OF BOWEL PREPARATION QUALITY ON ADENOMA IDENTIFICATION DURING COLONOSCOPY AND OPTIMAL TIMING OF SURVEILLANCE

J. S. Kim[1], S. H. Kang[1], H. S. Moon[1], S. H. Kim[1], J. K. Sung[1], H. Y. Jeong[1]
[1]*Internal Medicine, Chungnam National University School of Medicine, Daejeon, Republic of Korea*

Contact E-mail Address: showsik@hanmail.net

Introduction: Present guidelines stating the surveillance interval after index colonoscopy are all based on optimal bowel preparation. However, in the case of poor bowel preparation, appropriate timing of repeat colonoscopy is not clear.

Aims & Methods: We compared adenoma detection rate and missing rate according to the status of bowel preparation in order to determine the appropriate timing of repeating colonoscopy in cases of poor bowel preparation. The medical records of patients who underwent colonoscopy in the last 5 years were retrospectively analyzed. Index colonoscopy was defined as the first colonoscopy in patients who received at least twice during the study period. Adenoma miss rate (AMR) was calculated by dividing the number of patients where at least one adenoma was detected during repeated colonoscopy by the total number of patients who received repeated colonoscopy. Bowl preparation quality was defined as optimal, fair, and poor.

Results: The overall adenoma detection rate (ADR) was 39.1% (95% confidence interval [CI], 38.0–40.1). However, the detection rate was significantly different based on bowel preparation status (optimal; 46.8%, fair; 25.6%, poor; 21.6%, $P < 0.001$). AMR was also significantly increased with poor bowel preparation (optimal; 27.3%, fair; 48.1%, poor; 69.6%, $P < 0.001$). We compared the AMR of optimal bowel preparation group with fair and poor bowel preparation groups on the basis of the repeat colonoscopy interval. When compared with the optimal bowel preparation group, AMR was significantly increased in both the poor and fair bowel preparation group for repeated colonoscopy within 2 years (poor group: OR 6.25; 95% CI, 3.76–11.83, fair group: OR 3.67; 95% CI, 2.19–6.16); however, there was no difference after 2 years.

Conclusion: Bowel preparation quality significantly affects AMR. Repeated colonoscopy should be performed within 2 years in patients who have received colonoscopy under suboptimal bowel preparation conditions.

P0194 ENDOSCOPIC MUCOSAL RESECTION OF COLORECTAL LESIONS LARGER THAN 2 CM: THE EXPERIENCE IN A DISTRICT HOSPITAL

J. Pinho[1], D. Martins[1], P. Sousa[1], E. Cancela[1], R. Araújo[1], A. Castanheira[1], P. Ministro[1], A. Silva[1]
[1]*Centro Hospitalar Tondela Viseu, Viseu, Portugal*

Contact E-mail Address: julianapinho18@gmail.com

Introduction: Endoscopic mucosal resection (EMR) has been shown to be useful in the removal of large lesions of the gastrointestinal tract. The aim of this study was to evaluate the experience of our hospital on the efficiency and safety of EMR in colorectal lesions, using inject and cut technique.

Aims & Methods: We did a retrospective study based on the EMR performed between June 2009 and June 2013. Resected lesions ≥20 mm in diameter were selected. The histological characteristics, complications, follow up and surgical needs were evaluated.

Results: During the study period, we performed 266 EMRs; 114 EMRs were performed in lesions ≥20 mm in diameter among 110 patients (64 men and 46 women) with an average age of 67.7 ± 11.8 years. The lesions average size was 30.9 mm, having 58% been located in the colon and 42% in the rectum. According to the Paris classification, the lesions were classified as: Is-77; IIa-33; IIb-3; IIa + IIc-1. Piecemeal resection was performed in 76% of cases. A complete endoscopic resection was achieved in 93% of the cases. Post-EMR argon plasma coagulation was applied in 18 lesions (16%). The histopathological results revealed: adenoma with high-grade dysplasia - 57; adenoma with low-grade dysplasia - 34; adenoma with focal adenocarcinoma - 13; invasive adenocarcinoma - 5; serrated adenoma - 6. Complications occurred in 4.4% of the procedures (1 intra-procedural bleeding; 2 delayed bleedings; 2 perforations). Until now, 226 follow up colonoscopies were performed in 94 patients. The average follow up time was 21.2 months, with endoscopic control ranging from 1 to 64 months post-EMR. Local recurrence occurred in 25 patients (22%), and the majority (88%) was managed with polypectomy or new EMR. Ten patients (8.8%) were referred for surgery, 50% because of histological evidence of invasive adenocarcinoma.

Conclusion: EMR is a safe and effective technique for colorectal lesions larger than 2 cm, with low risk of recurrence and complications. Local recurrences were successfully treated with endoscopic resection, avoiding the need for surgery in 88% of cases.

P0195 INCREASED INSULIN RESISTANCE IS AN INDEPENDENT RISK FACTOR FOR POST-ERCP PANCREATITIS

A. R. Koksal[1], **S. Boga**[1], H. Alkim[1], M. Bayram[1], M. Ergun[1], C. Alkim[1]
[1]*Gastroenterology, Sisli Etfal Education and Research Hospital, Istanbul, Turkey*

Contact E-mail Address: arkoksal@gmail.com

Introduction: The relationship between insulin resistance and post-ERCP pancreatitis (PEP) was not known. We aimed to determine whether increased pre-ERCP insulin resistance is associated with an increased risk of PEP or not, and to evaluate the relationship of insulin resistance with well-established risk factors of PEP.

Aims & Methods: Consecutive patients who underwent ERCP with the diagnosis of choledocolithiasis between July and December 2013 were enrolled to this prospective study. Pre-procedural insulin resistance state and other risk factors were evaluated according to PEP development.

Results: Pancreatitis developed in 16 (11.3%) of 141 ERCP procedure. HOMA-IR (3.37 ± 0.8 vs 2.38 ± 1.4, $p < 0.001$) levels was found statistically significantly higher in patients who developed PEP than the ones who didn't. According to logistic regression analysis HOMA-IR ≥ 2.5 (OR:3.92), pancreatic duct cannulation (OR:4.09), procedure time (per minute OR:1.09), common bile duct diameter (per millimeter OR:0.80) and age (per year OR:1.05) were the important factors increasing PEP risk.

	PEP	Non-PEP	p value
Age	60 ± 15	58.8 ± 16.1	0.97
BMI kg/m^2	29.8 ± 3	27.9 ± 4.4	0.44
ALT (U/L)	99.6 ± 83	72.9 ± 71.7	**0.03**
MPV (fl)	8.9 ± 0.9	9.7 ± 1.2	**0.01**
Platelet Count (/mm^3)	237168 ± 68029	294259 ± 112605	**0.05**
Total Bilirubin (mg/dl)	1.5 ± 0.9	1.8 ± 1.8	0.69
HOMA IR	3.37 ± 0.8	2.38 ± 1.4	**<0.001**
Procedure time (min.)	33.5 ± 9	27.9 ± 7.2	**0.006**
CBD diameter (mm.)	10.1 ± 4	13.4 ± 4.5	**0.01**

Conclusion: According to our results, presence of insulin resistance is an independent risk factor for the development of PEP and increases the risk at least similar to the known risk factor of pancreatic canal cannulation.

P0196 COMPARATIVE STUDY ON THE SAFETY AND EFFICACY OF PROPOFOL INDUCED CONSCIOUS SEDATION DURING ERCP BETWEEN ANAESTHESIOLOGIST AND OTHER (NON - ANAESTHESIOLOGISTS) APPROPRIATELY TRAINED PHYSICIANS

A. Koutsoumourakis[1], G. Lazaraki[1], D. Tzilves[1], I. Pilpilidis[1], K. Soufleris[1], O. Abraam[1], S. Anisoglou[2], A. Tarpagkos[1]
[1]*Department of Gastroenterology,* [2]*Department of Anaesthesiology, Theagenio Cancer Hospital, Thessaloniki, Greece*

Contact E-mail Address: koutsoumourakis@gmail.com

Introduction: During the last years, propofol has become the preferred short-acting sedation agent offering an alternative to the benzodiazepine midazolam anaesthetic induction agent during diagnostic and therapeutic endoscopic retrograde cholangiopancreatography (ERCP).

Aims & Methods: The aim of this retrospective study was to compare the safety and efficacy of propofol-induced conscious sedation in patients class I (normal healthy subjects), II (subjects with mild systemic disease) and III (subjects with non-incapacitating severe systemic disease,) according to the American Society of Anaesthesiologists ASA Physical Status Classification, undergoing ERCP administered either by anaesthesiologists or other (non-anaesthesiologists) appropriately trained physicians. Data from 2012-2014 were collected retrospectively by use of the Electronic Endoscopy Report Data Base at our center. A total of 195 patients (98 men, 69.61 ± 14.05 years and 97 women, 69.21 ± 13.78 years, respectively) were divided into propofol sedation group A under the supervision of the anaesthesiologist (N = 122, 62 men, 69.21 ± 13.78 years and 60 women, 69.73 ± 13.36 years, respectively) or into propofol sedation group B under the supervision of the non-anaesthesiologist appropriately trained endoscopist (N = 73, 36 men 70.77 ± 13.40 years and 37 women, 68.24 ± 14.51 years, respectively). Blood pressure, pulse, and oxygen saturation were measured. Propofol was administered either by the anaesthesiologist or by the endoscopist and titrated to the patients' response during ERCP to a maximum dose of 1-2 mg per kg.

Results: There was no significant statistical differences between two groups with respect to median age ($p = 0.618$), to sex ($p = 0.639$), to ASA classification ($p = 0.612$), to indication for ECP ($p = 0.451$), to serum bilirubin level ($p = 0.984$) and to endoscopist experience ($p = 0.538$). The mean required propofol during the procedure in the group A and B were 354.15 ± 210.74 mg and 217.5 ± 93.3 mg, respectively (t-difference: 7.342; $p > 0.05$). Furthermore, there was no statistical difference in selective cannulation of the common bile duct (86% versus 89%, $p = 0.597$) between the two groups. Only three patients (1/62 men and 2/60 women) developed sedation-related cardiorespiratory complications in group A and no patient in group B ($p = 0.14$).

Conclusion: Appropriately trained endoscopist-directed administration of propofol is totally safe and effective for providing propofol sedation in patients ASA Class I, II and III during ERCP.

Introduction: Pancreatitis is the most common and serious complication of diagnostic and therapeutic endoscopic retrograde cholangiopancreatography (ERCP). Prevention strategies targeting risk factors could be important to reduce the rate of post-ERCP pancreatitis. However, the risk factors for post-ERCP pancreatitis (PEP) are still debated.

Aims & Methods

Aim: This systematic review ananalysis was performed to determine the prevalence of PEP and to identify its risk factors.

Methods: We conducted a retrospective study in a single center by reviewing all consecutive cases in which ERCP was performed between January 2010 and January 2015. The existence of pancreatitis before the procedure was an exclusion criteria. All patients remained in the hospital for at least 24 hours after the procedure to monitor them for clinical manifestations of pancreatitis. Serum amylase and lipase levels were measured at 4 and 24 hours (the next morning) after ERCP. We evaluated 8 variables, including patient-related factors and procedure related factors that could be analyzed in detail based on information in the patients' charts.

Results: A total of 1794 patients were included in our study.Therapeutic ERCP had been performed in all cases. 73% of cases were for common bile duct stones and in 27% of cases for biliary stent . Thirty five patients developed PEP with a prevalence of 1.95%. On univariate analysis, precut sphincterotomy ($p = 0.008$) and pancreatic duct cannulation ($p = 0.002$) were found to be significantly associated with PEP. On multivariate analysis, significant risk factors were: at least two pancreatic duct injections ($p = 0.05$) and age younger than 75 years ($p = 0.01$).
Conclusion: History of acute pancreatitis, precut sphincterotomy and pancreatic duct cannulation were all identified as independent risk factors for PEP.

P0198 PRECUT FISTULOTOMY: CANNULATION EFICIENCY AND RISK OF POST ERCP COMPLICATIONS IN A NOVEL TERTIARY HOSPITAL IN LIMA PERU

C. F. Gutierrez[1], V. F. Parra[1], H. Nuñez[1], J. R. Flores[1]
[1]*Gastroenterologia, Hospital Nacional Hipolito Unanue, Lima, Peru*

Contact E-mail Address: fernagut@hotmail.com
Introduction: Precut sphincterotomy (PS) has controversial data about its performance and complications that are not fully elucidated. There are different types os PS. Precut Fistulotomy (PF) is a type of PS that employs a needle knife to create an incision at the level of the intraduodenal segment of the common biliary duct avoiding papillary orifice. Recent data show low risk of PEP for this technique in expert hands.
Aims & Methods
Aims: To evaluate success and safety of Precut Fistulotomy(PF), and the risk of complications, specially post ERCP pancreatits (PEP).
Methods: Between June 2012 and November 2013 a single-center prospective cohort study with retrospective analysis on 167 consecutive patients with native papillas referred for ERCP was conducted. Patients elegible were those referred for first ERCP at hospital over 18 years old. All patients were hospitalized 48h before and at least 48h after procedure. The major Indication for ERCP were choledocolithiasis suspected (88%). We intent a selective wire guided cannulation (WGC) in all patients. After 15 minutes of unsuccessfully cannulation or 2 unintentional guidewire advance into pancreatic duct (PD) the endoscopist realize PF by protocol. Success in cannulation was defined as deep placement of a catheter into the common bile duct. A diagnosis and severity of complication was made according to Cottońs classification. 4 endoscopists were involved in study (more than 200 ERCP each one 50 ERCP per year) but less than 5 year of experience. Complications were retrospectively evaluated.
Results: We collect 167 patients in the study time with a median age of 49.18 + 18.27. Female patients were 118 (72.39%).The main diagnosis post ERCP were: choledocolithiasis 114 (69.93%) oddities 22(13.50%) stone migration (6.13%) benign biliary stricture or bile leak 11 (6.75%) biliary malignancy (1.78%). WGC was successful in 119 patients (71.25%). Success cannulation with PF was reach in 163 patiens (97.6%). The overall incidence of PEP for PF patients was 20.5% vs 3.5% in those without PF ($p = 0.001$ RR 6.03). Unintentional pancreatic cannulation was the other significant factor for PEP (40.8% vs 4% $p < 0.001$ RR 8.40). These factors maintain its relation with PEP in de logistic regression model. There is no difference about bleeding rate between patients with PF or not (2.33% vs 2.52% $p = 0.59$).
Conclusion: Precut Fistulotomy is a useful technique that importantly improve successful cannulation. PF does not increase bleeding risk in our cohort but in this novel center we found a slightly increased risk of PEP. Future trials must evaluate if PF could be a risk factor for PEP in centers with low-volume ERCP biliary endoscopists.

Contact E-mail Address: edu.gil.pinto@gmail.com
Introduction: Pancreatic fistulas (PF) may result from surgical resection, pancreatic trauma or chronic pancreatitis. Endoscopic retrograde cholangiopancreatography (ERCP) allows a faster resolution of PF, by performing pancreatic sphincterotomy (S) and/or placement of pancreatic stents (PS) with 5/7Fr.
Aims & Methods: Assess the role of ERCP in the treatment of PF. Cross-sectional study of patients referred for ERCP due to PF.
Results: Fifteen patients (10 males) had PF in pancreatogram, 5 in the cephalic portion, 1 in the neck, 6 in the body and 3 in the tail. Ten patients (66.7%) had undergone previous surgery, with the remaining being secondary to pancreatitis ($n = 3$; 20%) or traumatic transection ($n = 2$; 13.3%). Six of the operated patients had splenectomy. Median time to ERCP was 23 days. Fourteen patients (93.3%) placed PS and 8 (53.3%) performed S. Eleven patients (73.3%) resolved PF endoscopically, 24 days (8 – 401) after ERCP; 1 patient repeated ERCP, with the 3 remaining requiring surgery. Splenectomy was associated with endoscopic failure (50% *vs* 0%, $p = 0.048$). PS > 5cm and/or 7Fr were associated with a trend towards higher endoscopic resolution, respectively, 87.5% *vs* 66.7% ($p = 0.348$) and 100% *vs* 72.7% ($p = 0.198$). Time till endoscopic resolution was tend shorter when surgical fistulas (28 days *vs* 34 days, $p = 0.270$), when PS with 7Fr (22 days *vs* 28 days, $p = 0.203$) or > 5cm (14 days *vs* 34 days, $p = 0.301$).
Conclusion: ERCP with PS and S is effective in 75% of patients with PF. PS > 5cm or 7Fr may be more effective. Associated splenectomy is associated with endoscopic resolution failure.

Contact E-mail Address: edu.gil.pinto@gmail.com
Introduction: Plastic stents (PS) are cheaper, however, have lower patency than metal stents in pancreatic adenocarcinoma (PA).
Aims & Methods: Assess patency of different stents in biliary drainage of biliary obstruction condition by PA. Cross-sectional study of patients referred for endoscopic retrograde cholangiopancreatography (ERCP) for biliary drainage of biliary obstruction conditioned by PA.
Results: Seventy-nine patients underwent biliary drainage. Adjuvant therapy was performed in 49%, carried out prior to drainage in 41% of cases. PS were placed in 57% of patients, of which, 82% were 10Fr/11.5Fr and 22% were > 7cm. ERCP was repeated in 29% of the patients. In patients with survival longer than 30 days, ERPC was repeated when adjuvant therapy was performed after ERCP (45% *vs* 7%, $p = 0.009$, OR 10.8) and when PS were placed (49% *vs* 10%, $p = 0.001$, OR 8.3). There was a tendency to repeat ERCP when stents had a smaller caliber (83% *vs* 43%, $p = 0.067$). In the multivariate analysis, ERCP repetition was higher in PS (OR 9.5, $p = 0.002$). Stents patency was 76 days (IQR: 42 – 164), being lower in PS ($p = 0.001$) and in these, when smaller caliber (42 days *vs* 133 days, $p = 0.017$) or bigger dimensions (59 days *vs* 133 days, $p = 0.024$). Number of hospital admissions and ERCP repetition due to stent dysfunction was higher in PS (respectively, 49% *vs* 12%, $p < 0.001$, OR 7.2 and 42% *vs* 6%, $p < 0.001$, OR 11.6).
Conclusion: ERCP repetition is more common in PS. Patency is lower in PS, and in these, when smaller caliber or bigger dimensions.

Introduction: Plastic biliary stenting in patients with choledocholithiasis is suitable until a second ERCP or surgery. This option has demonstrated the fragmentation and dissapearence of large size bile duct stones. Also, it is a simple and safe method for high-risk surgical patients.
Aims & Methods
Objective: To study the effectiveness of plastic biliary stenting in patients with incomplete choledocholothiasis removal, as final technique or as a bridge for additional endoscopic or surgical intervention.
Materials and Methods: Retrospective and multicentric study based on a review of ERCP performed between October 2005 and January 2015.
Results: 72 ERCP were enrolled (52 patients), 26 male and 26 female (50%). The therapeutic indications were: incomplete removal (n43, 82.69%), intradiverticular papilla (n4, 7.7%) and others (n5, 9.6%). In most cases, they had

anaesthetic risk (n36, 69.23%) and the endoscopic procedure was suspended due to severe oxygen desaturation in 3 patients.
The size of plastic biliary stent usually used was 7 or 10 cm and 8,5Fr or 10Fr. In general, patients with 10Fr stent showed less complications than patients with 8,5Fr stent (38.8% vs 62.5%)
We established three groups of patients:
1. Plastic biliary stenting as definitive technique (n15, 28.8%) with an average age of 82.07 ± 12.38. 33.3% of patients delivered biliary disease (4 cholangitis, 1 biliary colic) in an average time of 15.6 months, without migration of stent. In these cases, we changed the stent in 3 patients and stone clearance with removal the stent in 2. After this, these patients were asymptomatic. Five patients died of causes not related and carried the stent during an average time of 10.6 months.
2. Plastic biliary stenting as a brigde for surgical intervention (n9, 17.3%). 33.3% of patients showed biliary disease (1 cholecystitis 6 months after initial placement, 1 pancreatitis 1 month after placement and 1 biliary colic, 18 months after). These patients underwent elective cholecystectomy. Surgical intervention was carried out in an average time of 2.75 months.
3. Patients with additional ERCP (n28, 53.8%). 22 patients (78.2%) needed 2 ERCP getting stone fragmentation and/or removal in most cases (n17, 77.2%). 6 patients (21.5%) needed more than 2 ERCP to successfully resolve the bile duct obstruction in 83.3% (n5). Only 3 patients (10.7%) required a surgical intervention for the resolution of choledocholithiasis.
Conclusion: According to these results, the effectiveness of plastic biliary stenting are directly related with placement time. Plastic stent as a final option needs to be replaced annually. As a bridge for surgical intervention, this procedure should be carried out before 3 months. In patients with additional ERCP, it is an effective measure. However further studies are required to confirm this data.

P0202 POST-ERCP PANCREATITIS (PEP) – DOES ROUTINE USE OF RECTAL INDOMETHACIN AFFECT OUTCOMES? A HIGH-VOLUME SINGLE-CENTRE EXPERIENCE FROM THE UK

F. Abid[1], M. T. Huggett[1], J. M. Hutchinson[2], S. M. Everett[1], M. H. Davies[2], R. E. England[3]
[1]*Gastroenterology,* [2]*Hepatology,* [3]*Radiology, St James University Hospital, Leeds, Leeds, United Kingdom*

Contact E-mail Address: faisal.abid@nhs.net

Introduction: Post-ERCP pancreatitis (PEP) is a common but potentially life-threatening complication of ERCP with an incidence of up to 10% in unselected patients in large international series[1]. A number of prospective trials have shown that administration of rectal indomethacin is beneficial in reducing the incidence of PEP in high-risk patients[2]. We aimed to compare the rate and severity of PEP in an unselected group during the pre and post-indomethacin era at our hospital, which has one of the largest ERCP practices in the UK.
Aims & Methods: A retrospective analysis of a prospectively-collected ERCP database in all adult patients undergoing ERCP from January 2011 to December 2014. In 2011 no rectal indomethacin was given, whilst in 2014 all patients recieved it. In 2012-13 only high-risk patients recieved indomethacin. Therefore, the unselected patient cohorts from 2011 (pre group) and 2014 (post group) were compared. PEP was diagnosed and categorised into mild, moderate and severe according to Cotton's 1991 consensus guidelines[3].
Results: 1432 patients were included. Of 717 patients in the pre group, 27 (3.7%) developed pancreatitis, 11 (1.5%) mild, 10 (1.4%) moderate and 6 (0.8%) severe with 4 deaths. Of 715 patients in the post group, 21 (2.9%) developed PEP; 15 (2%) mild, 4 (0.6%) moderate and 2 (0.3%) severe with 1 death. There was no difference in the overall incidence of pancreatitis between the post and pre groups [OR 0.77; p = 0.38], but the combined incidence of moderate and severe PEP was significantly lower in the post group [OR 0.37; p = 0.03]. There was no difference in haemorrhage rates in post 7 (0.9%) vs pre group 5 (0.7%)[OR 1.45; p = 0.56].
Conclusion: We observed that in our cohort of patients the unselected use of rectal indomethacin did not significantly reduce the incidence of PEP, however there was a significant reduction in moderate to severe PEP. This study therefore suggests a beneficial effect of the routine use of rectal indomethacin in unselected patients, consistent with current European Society of Gastrointestinal Endoscopy (ESGE) recommendations.

P0203 COMPARISON OF CONVENTIONAL DUODENOSCOPE AND SINGLE-BALLOON ENTEROSCOPE TO PERFORM ERCP IN PATIENTS WITH BILLROTH II GASTRECTOMY

G. Mbatshi[1], T. Aouattah[1], R. Yeung[1], E. Macken[2], B. Roth[2], H. U. De Schepper[2], H. Piessevaux[1], P. H. Deprez[1], T. G. Moreels[1]
[1]*Gastroenterology & Hepatology, Cliniques Universitaires Saint-Luc, Brussels,* [2]*Gastroenterology & Hepatology, Antwerp University Hospital, Antwerp, Belgium*

Contact E-mail Address: tmoreels@gmail.com

Introduction: Billroth II partial gastrectomy precludes conventional endoscopic retrograde cholangiopancreatography (ERCP) because of altered anatomy. It renders ERCP more difficult because of the intubation of the afferent limb and the orientation of the intact papilla.
Aims & Methods: Comparison of ERCP procedures performed with the conventional duodenoscope and the single-balloon enteroscope (SBE) in Billroth II patients in 2 university endoscopy units. 34 Billroth II patients underwent 64 ERCP procedures between 2006 and 2014. Technical aspects, therapeutic success and complications were recorded.
Results: Male/female ratio was 20/14 (59/41%) with a mean age of 72 ± 1 (48-91) years. The initial choice of endoscope type was at the endoscopist's discretion. 29 (45%) ERCPs were started using a duodenoscope of whom 25 (86%) were successful and 3 were completed using SBE. 21 (33%) ERCPs were started using SBE of whom 16 (76%) were successful and 2 were completed using a pediatric colonoscope. 5 (8%) ERCPs were started using a pediatric colonoscope of whom 4 were completed with a duodenoscope and 2 with the SBE. In total 9 (14%) procedures needed a change of endoscope type in order to complete the procedure. Overall therapeutic success rate using a duodenoscope was 87% vs 81% using SBE ($P > 0.05$; Chis-square), whereas success rate using a pediatric colonoscope was only 43% ($P < 0.05$; Chi-square). Complication rate using a duodenoscope was 7% (pancreatitis; embolism) vs 14% (pancreatitis; biliary leak) using SBE ($P > 0.05$; Chi-square), without mortality. The use of a duodenoscope allowed complete sphincterotomy and both plastic and metallic stent placement, whereas the use of SBE often needed to combine sphincterotomy with additional sphincteroplasty (8-15 mm) and only 7 Fr plastic stent placement was possible due to the 2.8 mm working channel diameter. However, SBE allowed easy access to the papilla in the afferent limb and sphincteroplasty often allowed direct cholangioscopy using SBE. Indications were bile duct stones (55%), chronic pancreatitis (26%), cholangitis (16%), livertransplantation (3%).
Conclusion: Therapeutic ERCP success rate is high in patients with Billroth II gastrectomy using either a conventional duodenoscope or the SBE, with an acceptable and comparable complication rate. The choice of endoscope may depend on the endoscopist's experience, postoperative anatomy (gastrojejunostomy and length of afferent limb) and therapeutic indication (metallic stent placement and direct cholangioscopy).

Introduction: Endoscopic bile duct stone (BDS) removal using the basket or balloon catheter is a well-established treatment. However, the choice of extraction devices depends on the operator's preference because there has been no study comparing outcomes with the two catheters.
Aims & Methods: We conducted a non-inferiority trial to investigate the performance of individual catheter for stone extraction. Patients with a BDS diameter ≤10 mm and common bile duct diameter ≤15 mm were enrolled in this study. The participants were randomly assigned to groups that were treated with the basket or the balloon catheter at 12 hospitals from October 2013 through September 2014. After stone extraction with the assigned catheter was completed, balloon occlusion cholangiography was performed in both groups to confirm the clearance of the duct. Primary endpoint was the rate of complete clearance of the duct by the assigned catheter. Secondary endpoints were the rate and time of complete clearance in one endoscopic session.
Results: We initially enrolled 172 consecutive patients, but 14 patients were excluded after randomisation. The total number of patients available for analysis was 158. The rates of complete clearance by the assigned catheter were 92.3% (72/78) in the balloon group and 80.0% (64/80) in the basket group. The difference of the rates between the two groups was -12.3%, indicating failure of non-inferiority of the basket catheter (non-inferiority limit 10%; $p = 0.17$ for non-inferiority). However, the results revealed superiority of the balloon over the basket catheter ($p = 0.037$). There were no significant differences in secondary endpoints.
Conclusion: The balloon catheter is recommended for a first-line device of endoscopic BDS removal. This study was registered on the UMIN Clinical Trial Registry (UMIN000011887).

Introduction: Although increasing evidence of the usefulness of single-balloon enteroscopy (SBE) for endoscopic retrograde cholangiopancreatography (ERCP) has been reported in postoperative patients with altered gastrointestinal anatomy, no short-type SBE has been made available in the market. Thereafter, the technical limitations or parameters of SBE (working length, 200 cm; working channel diameter, 2.8 mm; SIF-Q260, Olympus Medical Systems Corp., Tokyo, Japan) necessitate the use of prototype endoscopic instrumentation or the replacement of SIF-Q260 with another endoscope through the overtube.

Aims & Methods: We evaluated the efficacy of a novel SBE approach by using PCF-PQ260L (with passive bending and high-force transmission; working length, 168 cm; working channel diameter, 2.8 mm; Olympus Medical Systems Corp.) in patients with an altered gastrointestinal anatomy, without the use of special or prototype instrumentation or an enteroscope replacement. Between February 2012 and March 2015, 38 modified SBE-assisted ERCP procedures were performed in 24 postoperative patients (15 men and 9 women; mean age, 64.7 years [range, 25–93 years]) with altered gastrointestinal anatomy (Roux-en-Y hepaticojejunostomy, 16 procedures in 6 patients; Roux-en-Y gastrectomy, 9 procedures in 7 patients; Billroth-II gastrectomy, 7 procedures in 5 patients; pancreatoduodenectomy, 4 procedures in 4 patients; and gastrojejunostomy, 2 procedures in 2 patients). In all of the cases, a side hole was made 110 cm from the distal end of the overtube. ERCP was performed by inserting a PCF-PQ260L through the side hole of the overtube and then into the gastrointestinal tract. We retrospectively evaluated the success rate of reaching the blind end, the mean time required to reach the blind end, the diagnostic success rate, the therapeutic success rate, the mean procedure time, and the complications.

Results: Endoscopic therapeutic procedures were performed as follows: plastic biliary stent (ERBD) insertion, 15 times in 10 patients, including endoscopic sphincterotomy (EST) performed 4 times; balloon dilatation for stenosis of hepaticojejunal anastomosis, 5 times in 2 patients; choledocholithiasis extraction, 5 times in 5 patients, including EST performed 4 times; removal of ERBD, 3 times in 2 patients; endoscopic nasobiliary drainage, once; and removal of debris from the bile duct, once. In the remaining 4 patients, brush cytology of the pancreatic duct and cholangiography were performed. The success rate of reaching the blind end was 97.4% (37/38 patients). The mean time required to reach the blind end was 28.3 ± 24.0 min. The diagnostic success rate was 92.1% (35/38 patients). The mean procedure time was 59.4 ± 39.5 min. The success rate of the overall modified SBE-assisted ERC was 89.5% (34/38 patients). The complication rate was 23.7% (hyperamylasemia in 9 patients).

Conclusion: Diagnostic and therapeutic ERCP using our novel approach of modifying SBE without the use of a special or prototype instrumentation, or an enteroscope replacement is sufficiently safe and effective. It may potentially serve as an alternative to the SBE-assisted ERCP with SIF-Q260.

Introduction: Post-endoscopic retrograde cholangiopancreatography (ERCP) pancreatitis (PEP) is the most common major complication of ERCP. Its incidence has substantial variations ranging from 5.1% to more than 25% of all ERCP procedures. In some cases pancreatitis is followed by severe course with pancreatic necrosis and multiorgan failure. Diclophenac sodium together with indometacine is currently standard treatment in prevention of PEP while ceftazidime is possible alternative treatment for patients with contraindication for nonsteroidal anti-inflammatory drugs (NSAID).

Aims & Methods: The primary aim of this study was to determine whether prophylactic, parenteraly administered ceftazidime reduces the frequency of PEP compared to rectally applied diclofenac sodium. All eligible patients who underwent ERCP in tertiary care center during a 20-month period (June 2013 to February 2015) were enrolled in this study. Estimating the prevalence of PEP of 10% and reduction of incidence of 50% ($\alpha = 0.02$, beta $= 0.95$) calculated total sample size was 248. In a double-blinded randomized controlled trial, patients received a suppository containing a 100 mg of diclofenac sodium rectally and placebo intravenously (group A) or 1g of ceftazidime intravenously and placebo rectally (group B) immediately before the procedure. PEP was diagnosed according to the standardized criteria (Cotton criteria). The study was registered at Clinical Trial.gov (NCT01784445)

Results: We included 272 patients, mean age of 71.9 years ($SD \pm 12.2$), female 128 (47%). There were 129 (47.4%) patients in the diclofenac sodium group and 143 (52.6%) in the ceftazidime group. The occurrence of post-ERCP pancreatitis (PEP) in complete sample was 11.8% (32/272). There was no statistical difference in occurrence of PEP between diclofenac and ceftazidime group (RR = 1.72; 95%CI = 0.86-3.43, P = 0.17). PEP incidence in females was similar in booth groups 7(11.7%) in diclophenac sodium and 11(16.2%) in ceftazidime group (RR = 0.7212; 95%CI 0.29 to 1.74, P = 0.46).

Conclusion: There are no statistically significant difference in incidence of PEP among patients who received ceftazidime or diclophenac potassium. Ceftazidime may be used as alternative treatment for prevening PEP in patients with contraincidations for NSAID.

Introduction: Main pancreatic duct (MPD) strictures due to chronic pancreatitis (CP) may be treated endoscopically by insertion of single or multiple plastic stents. MPD stricture resolution after plastic stents removal occurs in near 60% of the cases.

Aims & Methods: We evaluate the use of removable fully covered, self expandable metal stents (FC-SEMS) to dilate MPD strictures secondary to CP. Patients with CP and symptomatic MPD strictures in the head of the pancreas that persisted >3 months after placement of a single plastic stent, were enrolled into a prospective single arm trial. The protocol was approved from the Ethic Committee of our University. A Nitinol FC-SEMS (Bumpy stent, Taewoong) was inserted and removed after 6 months. FC-SEMS diameter (6 or 8 mm) and length (3, 4, 5 cm) were chosen according to stricture anatomy and MPD diameter above the stricture. Stricture resolution was defined as a satisfactory pancreatico-duodenal contrast medium outflow and absence of pain during continuous flushing with saline (1000ml/day) for 24 hours through a 6 french naso-pancreatic drain. Primary objective was FC-SEMS removability. Secondary objectives were MPD stricture resolution rate and complications. Follow-up was planned every 6 months during a 2 year. Pancreatic pain episodes and recurrence of pancreatitis were recorded.

Results: Between Dec 2012 and Oct 2014, 15 patients (10M, mean age 60 y) were enrolled. Pancreatic calcifications were present in 6(40%) and ESWL was performed in 4. Four patients (27%) had a history of alcohol abuse. In 10 cases the FC-SEMS was inserted through the major papilla (7 had a previous biliary sphincterotomy, 2 had pancreatic sphincterotomy alone, 1 had choledochoduodenostomy), while 5 patients (3 pancreas divisum, 2 dominant dorsal duct) received the FC-SEMS through the minor papilla. One patient developed cholangitis after 24 hours due to occlusion of the biliary sphincterotomy from the FC-SEMS; cholangitis resolved after insertion of a plastic biliary stent. During stenting period 13 patients (87%) were asymptomatic while 2 had recurrent pancreatitis after 4 and 5 months; the FC-SEMS had migrated and the persistent MPD stricture was treated with a plastic stent. FC-SEMS completely migrated in 7 patients and could be removed endoscopically in the remaining 8 cases. Four patients (27%) developed a tight stricture induced by FC-SEMS at the level of its proximal end; in one case the stricture was overcome only after EUS-guided pancreatic rendez-vous. Follow-up is ongoing. Results are summarized in the table.

	N	%	Follow-up,mean months (range)
Patients	15	-	-
FC-SEMS removability	8/8	100	-
Complete FC-SEMS distal migration	7/15	47	-
FC-SEMS proximal migration	1/8	12	
MPD stricture resolution	10/15	67	-
SEMS ''induced'' MPD stricture	4/15	27	-
Asymptomatic	8/14*	57	12 (5-18)

*One patient excluded from follow-up (pancreatic cancer diagnosed 6 months after stent removal).

Conclusion: FC-SEMS removability from the MPD in chronic pancreatitis was feasible in all cases. After 1-year follow-up 57% of the patients were asymptomatic; this figure is similar to those obtained with plastic stents. Occurrence of FC-SEMS induced pancreatic strictures is a major issue and deserves further assessment. According to our experience the use of FC-SEMS in the MPD needs careful evaluation in the setting of clinical trials.

Abstract number: P0209

Biliary condition	n	CBD deep cannulation	Biliary sphincterotomy	Balloon dilation	Stent insertion	Successful biliary drainage	mortality

8.Billroth II anatomy	28	26 (93%)	0	16/16 (100%)	12/12 (100%)	26 (93%)	0
TOTAL	363	346 (95.3%)	254 (100%)	81(95%)	222 (98%)	336 (94%)	3/363 (0.8%)

CBD = Common Bile Duct. EPBD = endoscopic papillary balloon dilation. For small CBD stone extraction it was employed up to 10 mm. For larger CBD stones, 12-18 mm balloon diameter was used. In Billroth II balloon dilation and stent insertion were always performed after inserting a plastic stent in the Main Pancreatic Duct without previous sphincterotomy.

P0208 FEASIBILITY AND PRELIMINARY SAFETY STUDY OF A NEW NITINOL "SOFT" FULLY COVERED SELF-EXPANDING PANCREATIC METAL STENT IN CHRONIC PANCREATITIS

J. Deviere[1], M. Fernandez[1], J. Peetermans[2], A. Lemmers[1]
[1]*Ulb Erasme, Brussels, Belgium,* [2]*BSCI, Marborough, United States*

Contact E-mail Address: jacques.deviere@erasme.ulb.ac.be

Introduction: Multiple plastic stents are used for calibrating distal stricture in severe chronic pancreatitis. A single metal stent which does not require exchanges would be useful in this setting.

Aims & Methods: Document feasibility and preliminary safety in ongoing pancreatic endotherapy in patients (pts) with painful chronic pancreatitis (CP) of Cremer Type IV using a new Nitinol "Soft" fully covered (6 mm diameter) self-expanding metal stent (Panc SEMS) (Pancreatic WallFlex, Boston Scientific Corporation, Marlborough, USA). Ten (10) patients enrolled. Intended Panc SEMS indwell 3 mo in 5 pts and 6 mo in 5 pts. Follow-up to 24 mo ongoing. Interim results reported on ITT basis.

Results: 10 pts (mean age 48, 60% male). CP etiology 60% alcoholic, 10% hereditary, 30% unknown. Calcific CP in 70% of pts. All pts had prior plastic stent placement(s) during a mean of 3 yrs (range 4 mo to 6 yrs). No pts had a prior Panc SEMS. At time of interim analysis, all pts were stent free with mean time on study 262 d (range 218-326 d) and mean stent-free period of 95 d (range 22-193 d). In total 14 stents were placed, with 2 pts having immediate removal and replacement of the initial stent due to deployment in unsatisfactory position and 2 pts needing a second stent placement after premature complete distal migration. Stent migration without symptoms, thought to be a reflection of adequate calibration of the benign stricture, occurred in 6 stent placements, not requiring restenting. Clinically meaningful complete distal migration (CDM) with symptoms occurred in 21% (3/14) stent placements. There were no proximal stent migrations. Endoscopic stent removal was performed per-protocol easily in one pt after 3 mo indwell and in 2 pts after 6 mo indwell without stent removal-related adverse events (AEs). To date 80% (8/10) pts remain stent free and follow-up is ongoing. One pt had premature CDM followed by placement of plastic stents. One pt had no pain relief after SEMS placement and had subsequent pancreatic diversion surgery which did not provide pain relief either. Mean Izbicki pain scores were 59 (range 15-86) at baseline, 42 (range 0-88) at time of SEMS removal or observation of complete distal migration, and 44 range (0-90) at last visit. AEs occurred in 50% (5/10) of pts, with 7 AEs (2 pain associated with premature CDM, and at time of SEMS placement 3 transient pain, 1 bacterial infection, and 1 mild acute pancreatitis). No SEMS needed to be removed due to intolerable pain after SEMS placement. There were no stent-induced ductal changes.

Conclusion: Feasibility of FC SEMS implantation and removal in pts undergoing pancreatic endotherapy was confirmed. Preliminary safety was acceptable with only mild adverse events, represented mainly by anticipated pain after implantation. SEMS removability was achieved without adverse events in all patients, either per protocol or by spontaneous complete distal migration. No stent induced ductal changes were observed at the time of removal. Further study to assess effectiveness of pancreatic endotherapy

P0209 ERCP QUALITY EVALUATION THROUGH SELF-ASSESSMENT AND OUTCOMES

J. García-Cano[1], M. A. Godoy-López[2], L. Taberna-Arana[3]
[1]*Department of Digestive Diseases,* [2]*Department of Radiology, Hospital Virgen de la Luz,* [3]*Family Practice, Health District of Cuenca, Cuenca, Spain*

Contact E-mail Address: jgcl7@live.com

Introduction: ERCP is one the most difficult gastrointestinal endoscopic procedures, therefore monitoring and enhancing the quality of this interventionn is of paramount importance.

Aims & Methods: All ERCPs performed in our center from January 2009 to September 2014 were prospectively included in a specific ERCP database. Procedures were analyzed retrospectively with a modification of the Rotterdam Assessment Form for ERCP (RAF-E) [1] that has proven to provide insight into the quality of individual ERCP performance and can be used to assess and set standards for quality control in ERCP. Only naïve papillae were considered as it is well known that after biliary sphincterotomy, cannulation and ERCP completion is usually easier. MRCP was routinely performed before ERCP.

Results: A total number of 363 ERCPs with naïve papilla were performed in this period of time by a single endoscopist. Results according to the retrospective appraisal using the modified RAF-E are shown in the table.

According to degrees of difficulty based on Schutz's classification [2], ERCP indications 1-5 correspond to level 1, 6-7 to level 2 and 8 to level 3. Diagnostic cholangiography or pancreatic procedures were never performed. For CBD cannulation a sphincterotom loaded with a guidewire was used.

Conclusion: Self-assessment is a valuable method to gain insight in ERCP performance. Outcomes can be compared with those obtained in centers of excellence to promote improvement. It appears that CBD deep cannulation can be considered as a surrogate for successful biliary drainage because it was accomplished in 97% of occasions after cannulation in the eight biliary scenarios reported in this study.

Introduction: Transmission of Multi-Drug Resistent Organisms (MDROs) has recently been linked to duodenoscopes. The epidemiology of this potentially serious problem is poorly understood. Variability across Units in endoscope cleaning and disinfection methods has received limited attention to date.

Aims & Methods: To survey the incidence of duodenoscope-transmitted infection overall and of MDRO in particular in Spain. Members of the Sociedad Española de Endosocopia Digestiva (SEED) registered at institutions offering ERCP were sent a questionnaire about disinfection standards and instances of duodenoscope transmitted infection in their Units. Self-reported recall data were pooled for analysis.

Results: Seventy one hospitals from across Spain participated in the study. The total estimated procedure volume covered by respondents was 70,000 ERCPs

over a 5-yr period. 3/71 (4.2%) centres performed manual cleaning of the duodenoscopes. No infection transmission was reported from any of these hospitals. 68/71 (95.8%) units had automatic washing methods for cleaning. Thirteen infectious outbreaks linked to duodenoscopes were reported from 13 different centres. Only four of these outbreaks were related to MDRO. Three MDRO outbreaks involved multiple patients (Klebsiella Carbapenemase in two centers and Escherichia Coli producing extended-spectrum beta-lactamases in another) and a single patient in another (MDR Klebsiella). Microbiological genotyping revealed a common MDRO in patients referred from different hospitals to a single referral Unit. Clinical course ranged from fever to severe sepsis requiring ICU admission. MDRO was judged a potentially contributing factor in two postoperative deaths. A single patient was infected in the remaining 9 outbreaks. Isolated microorganisms were: Klebsiella species (4), Escherichia Coli (1), Enteroccocus (1), Pseudomonas (1), Serratia (1), Candida (1). No patient died. Routine microbiologic assessment of disinfections practices had only been performed in 2/13 centers with outbreaks. Corrective measures were implemented in all cases with MDRO
Conclusion: Duodenoscope transmitted infection was observed in 13 out of 71 centers (18.3%), with MDRO identified in 30% of outbreaks, typically involving multiple cases. Despite the limitations of this survey, it provides further evidence of duodenoscope-transmitted MDRO as an emerging problem. There is a need to address critical cleaning steps in the chain-of-transmission, pending future improvements in scope design.

P0211 SMALL PAPILLA OF VATER AS A RISK FACTOR FOR POST-ERCP PANCREATITIS

J. García-Cano[1], M. A. Godoy-López[2], L. Taberna-Arana[3]
[1]*Department of Digestive Diseases,* [2]*Department of Radiiology, Hospital Virgen de la Luz,* [3]*Family Practice, District Health of Cuenca, Cuenca, Spain*

Contact E-mail Address: jgcl7@live.com
Introduction: The pathogenesis of Post-ERCP pancreatitis (PEP) is multifactorial; mechanical injury, hydrostatic injury, chemical and thermal injury, have been postulated as factors for PEP development. Uchino et al. [1] suggested that a small papilla can also be considered as a risk factor for PEP. A small papilla makes the pancreatic orifice susceptible to trauma, which ultimately leads to pancreatitis.
Aims & Methods: A small papilla of Vater was defined as having less than 3 mm in size and/or the absence of a caudal fold (plica papillae). These criteria were applied retrospectively to a series of ERCP with naïve papilla with detailed reports. Common Bile Duct (CBD) drainage was the purpose of all ERCPs. CBD cannulation was always attempted with a sphincterotome loaded with a guidewire
Results: Main results are shown in the table.

Table: Pancreatitis rate according to papilla of Vater size

	n	PostERCP pancreatitis rate	Mortality
Normal papilla	94	8 (8.5%)	0
Small papilla	18	4 (22%)	1/18 (5.5)

Both groups were matched in terms of age, gender, ERCP indication, easy or difficult cannulation, precut use and stent insertion without biliary sphincterotomy.
Both pancreatitis and mortality rate showed a $p < 0.05$ between normal and small size papillas. The patient who died was an 80-yr old woman who had a very easy procedure. A 10 french biliary stent was inserted without sphincterotomy for CBD drainage. Biliary sphincterotomy to remove CBD stones was not attempted because of a small papilla of Vater with no clear landmarks for cutting. The patient suffered from a severe pancreatitis and died 72 hours later.
Conclusion: In this small series study, it appears that a small size papilla is a risk factor for PEP. Pancreatitis severity appears to be also greater when biliary sphincterotomy is not performed [2]. Further studies are warranted to confirm these results.

P0212 PARTIALLY COVERED VERSUS UNCOVERED SELF-EXPANDABLE NITINOL STENTS WITH ANTI-MIGRATION PROPERTIES FOR THE PALLIATION OF MALIGNANT DISTAL BILIARY OBSTRUCTION: A RANDOMIZED CONTROLLED TRIAL

J. H. Kim[1], M. J. Yang[1], B. M. Yoo[1], J. C. Hwang[1]
[1]*Gastroenterology, Ajou University School of Medicine, Suwon, Republic of Korea*

Contact E-mail Address: jinhkim@ajou.ac.kr
Introduction: Covered self-expandable metal stents (SEMSs) are increasingly used as alternatives to uncovered SEMSs for the palliation of inoperable malignant distal biliary obstruction to counteract tumor ingrowth.
Aims & Methods: The aims of this study were to compare the outcomes of partially covered and uncovered SEMSs with identical mesh structures and anti-migration properties, such as low axial force and flared ends. One hundred and three patients who were diagnosed with inoperable malignant distal biliary obstruction between January 2006 and August 2013 at a single tertiary center were randomly assigned to either the partially covered (n = 51) or uncovered (n = 52) SEMS group.
Results: There were no significant differences in the cumulative stent patency, overall patient survival, stent dysfunction-free survival, and overall adverse events, including pancreatitis and cholecystitis, between the two groups. Compared to the uncovered group, stent migration (5.9% vs. 0%, $P = 0.118$) and tumor overgrowth (7.8% vs. 1.9%, $P = 0.205$) were non-significantly more frequent in the partially covered group, whereas tumor ingrowth showed a significantly higher incidence in the uncovered group (5.9% vs. 19.2%, $P = 0.041$). Stent migration in the partially covered group occurred only in patients with short stenosis of the utmost distal bile duct (two in ampullary cancer, one in bile duct cancer), and did not occur in any patients with pancreatic cancer.
Conclusion: For the palliation of malignant distal biliary obstruction, endoscopic placement of partially covered SEMSs with anti-migration designs and identical mesh structures to uncovered SEMSs failed to prolong cumulative stent patency or reduce stent migration.

Contact E-mail Address: jhmoon@schmc.ac.kr
Introduction: Direct peroral cholangioscopy (DPOC) using an ultraslim endoscope has been increasingly applied for diagnosis and treatment of diverse biliary diseases. However, the usefulness of DPOC is limited by low, inconsistent success rates. The success rate can be increased by assistance of several accessories, but it's technically demanded and cumbersome. In addition, maintenance of desired scope position during interventional procedure is difficult.
Aims & Methods: The aim of this study was to evaluate the success rate of free-hand direct insertion into the bile duct using a newly developed multibending ultraslim endoscope as for a dedicated cholangioscope for DPOC. A total of 52 patients with biliary disease were prospectively enrolled. Each patient was performed two trials of DPOCs using a multibending ultraslim endoscope (Olympus Co., Tokyo, Japan) after a conventional ultraslim scope (GIF-XP290N, Olympus) without assistance of accessories. If a DPOC using multibending ultraslim endoscope without accessory failed, an intraductal balloon-guided DPOC was performed. The success was defined as successful advancement of the endoscope into the bifurcation or the obstructed segment of the biliary tree within 15 minute without accessory.
Results: The success rate of a DPOC using multibending endoscope without accessory was significantly higher than a DPOC using a conventional endoscope (90.4% vs. 28.8%; $p < 0.001$). The 5 patients failed in DPOC using multibending endoscope without accessory were all success with an intraductal balloon-guided DPOC using multibending endoscope. The success of interventional procedures was achieved with 36 of 37 (97.8%) trials including 11 intraductal biopsies, 9 intraductal lithotripsy. Adverse event was observed in one patient of mild hemobilia.
Conclusion: A high success rate of free hand direct insertion of a scope into the bile duct was achieved with newly developed multibending ultraslim endoscope with experienced endoscopist. DPOC without assistance of accessories can be possible with further development.

Introduction: Endoscopic biliary sphincterotomy has been commonly used for biliary and pancreatic duct diseases, in cases of difficult biliary duct canulation, various methods like precut and endoscopic pancreatic sphincterotomy (EPDS) has been used. Various studies have reported variable rate of complications

after doing EPDS. Thus, we examined the indications and rate of complications in one of the largest center for endoscopic retrograde cholangiopancreatograph.
Aims & Methods: Among patients who underwent endoscopic retrograde cholangiopancreatography (ERCP) between January 2012 and December 2014, 40 patients who underwent endoscopic pancreatic duct sphincterotomy (EPDS) were included in this retrospective study. We examined the indications, complications and safety of procedure.
Results: Out of 40 patients 52.5% were female and 47.5% were male. Diagnostic and therapeutic indications for ERCP were recurrent pancreatitis (10 cases), pancreatic pseudocyst (2 cases), and mass at porta hepatis (1 cases) pancreatic duct leakage (2 cases), cbd stone (3 cases), biliary stricture with obstructive jaundice (12 cases). The success rate of EPDS was 100% (40/40). Acute complications of EPDS included three cases (7.5%) of mild pancreatitis and no other complication was noted.
Conclusion: EPDS showed a very low incidence of complications and a high rate of treatment success; thus, EPDS is a relatively safe procedure when performed by an expert endoscopist

P0215 AN OBJECTIVE APPROACH TO QUANTIFY TISSUE OBTAINED FROM ENDOSCOPIC ULTRASOUND GUIDED FINE NEEDLE BIOPSY (EUS-FNB): A POTENTIALLY IMPORTANT TOOL FOR FUTURE EUS-GUIDED BIOPSY TRIALS

A. V. Phan[1], A. Ruszkiewicz[2], N. Q. Nguyen[1]

Introduction: Endoscopic ultrasound (EUS) guided tissue acquisition, with a fine needle, allows cytologic and/or histologic diagnosis of lesions within or adjacent to the gastrointestinal tract (GIT). Given most needles used so far are fine needle aspiration (FNA), the ''traditional'' primary outcome has been a cytological diagnosis. The recent development of core-like needles aims to increase the amount of tissue acquired for ''histological'' assessment. Apart from the conventional ''tissue diagnosis'', there has been no method or criteria to objectively quantify the tissue obtained from different EUS FNA needles. This may explain for the indifferences in trials that compared FNA versus FNB needles.
Aims & Methods: The aim was to evaluate an objective method to quantify the tissue acquired by EUS-guided biopsy using core needles.
Methods: Tissue acquired from biopsy of pancreatic mass by EUS-FNA technique was prospectively obtained from 18 subjects with suspected pancreatic malignancy. In each case, all material from two needle passes of either 22G or 25G Procore needle were flushed into a 5ml-bottle of formalin for direct histological processing, which involved extracting the material from the bottle (without spinning) for routine paraffin processing and generating slides as if the specimen was a ''histological specimen''. One of every 3 slides will be reviewed for presence of diagnostic material by a dedicated cyto-pathologist. In order to objectively quantify the tissue acquired from the needle, the slides will be scanned using the NanoZoomer (Hamamatsu Phototonic, Japan) and high definition images will be stored electronically. Using the associated software (NDP.view2, Phototonic, Japan), the characteristics of the diagnostic tissue will be further quantified by objectively assessing the length, width, presence of tissue-core (defined as tissue showing preserved architectural integrity, in which the length of the core is at least twice of the nominal inner diameter of the used needle), and the total surface area of diagnostic tissue.
Results: This approach was used to examine EUS guided biopsied specimens from 18 subjects with pancreatic mass, using 22-G Procore needle ($n = 10$) and 25-G Procore ($n = 8$). The final pathological diagnoses were achieved in all cases, with 16 invasive adenocarcinomas and 2 neuroendocrine tumour with Ki67 determination. When compared the tissue characteristics between the 22G and 25G Procore needle, both needles were able to acquired tissue-cores, but the cores were larger (376 ± 9.72 vs.262 ± 16.01 μm; $P < 0.0001$) and longer (1.93 ± 0.22 mm vs. 0.96 ± 0.18 mm; $P < 0.02$) with the 22G than the 25G Procore needle. Most importantly, the 22G Procore needle able to acquire more diagnostic material than the 25G needle, as quantified by the total surface area of diagnostic tissue (1.67 ± 0.51 mm^2 vs. 0.52 ± 0.14 mm^2; $P = 0.05$).
Conclusion: The characteristic and amount of tissue acquired from EUS guided biopsy can be objectively quantified by using the direct histological processing and NanoZoomer assessment. This method has great potential for research use, especially in the evaluation the outcome of different types of needles in practice of EUS guided biopsy.

P0216 SINGLE SESSION EUS-RENDEZVOUS ERCP VERSUS PERCUTANEOUS BILIARY DRAINAGE IN PATIENTS WITH FAILED COMMON BILE DUCT ACCESS AFTER ERCP

A. Y. B. Teoh[1], T. Iwashita[2], V. Dhir[3], T. Mukai[2], A. Maydeo[3], F. K. L. Chan[4], J. Y. W. Lau[1]
[1]*Surgery, Chinese University of Hong Kong, Hong Kong, Hong Kong,* [2]*Gastroenterology, Gifu University Hospital, Gifu, Japan,* [3]*Gastroenterology, Baldota Institute of Digestive Sciences, Mumbai, India,* [4]*Gastroenterology, Chinese University of Hong Kong, Hong Kong, Hong Kong*

Contact E-mail Address: anthonyteoh@surgery.cuhk.edu.hk
Introduction: Common bile duct access (CBD) may fail in less than 5% of the patients undergoing ERCP. Traditionally, these patients will require percutaneous biliary drainage. However, the advent of EUS-biliary drainage provides another endoscopic means of achieving CBD access at the same session of failed ERCP. However, how single session EUS-rendezvous ERCP (ERV) compares to percutaneous biliary drainage is not known.
Aims & Methods: This was a multicentre study (3 Asian hospitals, 2 university affiliated) of all patients that underwent single session EUS-rendezvous ERCP after failed CBD access by ERCP, performed between January 2012 and October 2014. The outcomes of these patients were retrospectively compared to those that received percutaneous-rendezvous ERCP or antegrade stenting (PTBD) prior to the introduction of the EUS technique. These procedures were believed to be comparable as the goal of the procedures was to achieve transpapillary CBD access for subsequent interventions. The main outcome parameters included the success rate in gaining CBD access, adverse event rates, the number of sessions of interventions required in each patient to obtain CBD access and luminal drainage.
Results: A total of 128 patients were included (ERV:PTBD = 64:64). There were no differenced in background demographics (table 1). A high success rate in obtaining CBD access (92.2% vs 100%, $P = 0.056$) and achieving luminal drainage (93.8% vs 85.9%, $P = 0.241$) was observed in both groups. This was possible in a single session in all patients within the ERV group. Whilst, the median (range) number of sessions required to obtain CBD access in the PTBD arm was 2 (1-2), $P < 0.0001$. Similarly, significantly more interventions were required in the PTBD group to achieve transluminal drainage (3 [2-9] sessions, $P = 0.032$). The adverse events rates were comparable between the 2 groups (17.2% vs 23.4%, $P = 0.510$). The most common adverse events were cholangitis (6.2%) in the ERV arm and tube dislodgement (9.4%) in the PTBD group.
Conclusion: Single-session EUS-rendezvous ERCP may replace PTBD as the procedure of choice in patients with failed ERCP. The procedure allows same session CBD access and luminal drainage with avoidance tube related adverse events.

Introduction: There is concern about the safety of endoscopic ultrasound-guided fine needle aspiration of pancreatic cystic lesions. The aim of this study is to assess the incidence of adverse events of the technique in this setting using the lexicon recommended by ASGE.
Aims & Methods: Patients with pancreatic cystic lesions undergoing an endoscopic ultrasound-guided fine needle aspiration were prospectively included. A 22 gauge-needle was used in all patients. The procedure was performed under conscious sedation. A complete cystic fluid evacuation with a single needle pass was attempted in all cases. Patients received ciprofloxacin during the procedure and 3 days after. Adverse events were defined and graded following the lexicon recommended by ASGE. Patients were followed at 48 hours, one week and day 30 after the procedure. Potential predictive factors for adverse events were analyzed.
Results: A total of 132 patients were included and 7 adverse events (5.3%) were recorded: fever ($n = 3$, 2.3%); acute pancreatitis ($n = 3$, 2.3%) and cholangitis ($n = 1$, 0.75%). All adverse events had an early presentation (before 48 hours post-procedure) and resolved with medical therapy. All the episodes of pancreatitis were observed in patients with chronic pancreatitis or with a previous episode of acute pancreatitis ($p < 0.05$). We did not find any other variable related with the development of adverse events.

Conclusion: Endoscopic ultrasound-guided fine needle aspiration of pancreatic cystic lesions has a rate of adverse events slightly higher than that of solid masses, but small enough to consider this procedure a secure way to guide management of these patients.

Contact E-mail Address: sergiogiao@hotmail.com
Introduction: Gastrointestinal stromal tumors (GISTs) are the most common mesenchymal gastrointestinal tumors (MTs), corresponding in most *post-mortem* studies, to less than 3% of gastrointestinal malignancies. Although its relatively indolent course, all GISTs are considered as potentially malignant, and so, its essential to stratify the tumors according to the relative risk of progression.
Aims & Methods: (1) Descriptive analysis of the experience of our center in the diagnosis and monitoring of MTs with the main focus on GISTs; (2) to assess the role of endoscopic ultrasonography in the identification of high risk-stigmata, and the correlation between endosonographic features and histological predictors of malignancy.
Retrospective analysis of all new cases of MTs, in the period between 2010 and 2014. We recorded demographic, clinical, pathological and radiological data. Risk stratification was performed according to the TNM classification and the Miettinen criteria. Endosonography high-risk stigmata was defined as presence of heterogeneous echopattern, cystic spaces, irregular extra-luminal margin and large tumor (≥ 4 cm). Histological malignancy was defined as > 5 mitoses on a total area of $5mm^2$
Results: We identified 54 patients with mesenchymal tumors, 37 with immunohistochemistry confirmation of being a GIST. There was equal distribution between genders, with a mean age of 68 years. At diagnosis, 5 patients had a synchronous tumor (3 colorectal cancer). The mean size was 5.7 cm, being the spindle cell (81%) the most common subtype. Stomach was the most frequent localization (70%), followed by the small bowel. Concerning clinical presentation, in 50% it was an incidentaloma, gastrointestinal bleeding happened in 20% and in 10%, the diagnosis was established during the management of acute abdomen.
According to TNM classification, 83% were classified as localized disease and 24% as having high-risk of progression.
Endoscopic ultrasound was performed in 25 patients. At the first endosonography examination, 8 presented endosonographic high-risk stigmata, and were refer to surgery. In all cases, their histological analysis revealed a low mitotic index (≤ 5 mitoses on a total area of $5mm^2$). During the ecoendoscopic follow-up, none of the patients in the low-risk group, developed high-risk features or metastatic disease.
The mean follow-up was 24 months and the median overall survival at 2 years was 81% (localized disease: 82%; advanced disease: 63%).
Conclusion: Endoscopic ultrasound was a good method for following lesions with less potential for malignancy, avoiding the morbidities associated with an aggressive strategy. The presence of high-risk features in endoscopic ultrasound, did not correlate with the presence of histological malignancy (increased mitotic index). We identified a high prevalence of synchronous tumors.
Our data outlines the need of new prospective studies to create and validate new ecoendoscopic features for predicting histological malignancy.

Introduction: Endoscopic ultrasound (EUS) elastography is a recent ultrasound method used for the real-time visualization and evaluation of tissue elasticity. Qualitative and quantitative methods have been used, in particular in evaluation of pancreatic diseases and malignant lymph nodes, with interesting results regarding the accuracy and the differential diagnosis between malignant and benign masses. No consensus has been reached with regard to the superiority of different quantitative methods, but strain ratio and strain histogram (SH) remain the most used. SH corresponds to a graphical representation of the color distribution in a region of interest (ROI), and mean SH (mSH) value is a SH-derived quantitative measure of the global hardness in the evaluated ROI.
Aims & Methods: The aim of the present study was to describe the different elastographic patterns of solid pancreatic masses and malignant lymph nodes using the mSH value. This is a prospective, observational, monocentric study. One experienced EUS examiner performed the endoscopic procedure and elastographic measures. SH was calculated automatically by machine integrated software in a ROI manually selected by the operator. Four parameters were calculated using the histogram to quantify the elasticity of the pancreas: the mSH, the standard deviation of the histogram, the kurtosis and the skewness. Three different measures were performed by the same operator and the mean value of the previous described values was evaluated. After the elastographic measure a FNA was performed when a lesion was observed. We used the histology obtained by FNA or surgical specimens or the global assessment of cytology and imaging as reference standard for the diagnosis, except in case of normal examinations.
Results: A total of 42 patients were included (23 F/19M): 8 normals, 22 pancreatic adenocarcinoma, 4 neuroendocrine tumors (NET), 6 malignant lymph nodes and 2 benign lymph nodes. Compared with normal patients, we found a statistically significant difference in mSH value in both patients with pancreatic adenocarcinoma (111.13 vs. 29.9, $p < 0.05$) and malignant lymph nodes (111.13 vs. 63.52, $p < 0.05$), but not in NET lesions (111.3 vs 72.9, $p = 0.07$). A statistically significant difference was found in mSH between pancreatic adenocarcinoma and NET (29.9 vs. 72.9, $p < 0.05$), suggesting that mSH value could help in differential diagnosis between malignant pancreatic masses. Similarly, malignant and benign lymph nodes presented a statistically significant difference in mSH (63.52 vs 4.9, $p < 0.05$).
Conclusion: Mean strain histogram value seems an interesting quantitative tool to differentiate between different malignant pancreatic masses and between benign and malignant lymph nodes. A larger number of patients is needed to confirm our data.

Introduction: Endoscopic ultrasound (EUS) elastography represents a new imaging procedure that allows quantification of tissue stiffness, with a high degree of accuracy for the differential diagnosis of pancreatic disease.
Aims & Methods: The aim of this study was to evaluate the efficiency of quantitative EUS elastography for the differentiation of chronic pancreatitis (CP) and pancreatic cancer (PC). Between August 2014 and April 2015, 54 patients with PC, 39 patients with CP who underwent EUS were prospectively enrolled. EUS elastography was performed using linear Pentax EUS and Hitachi HI VISION Preirus. The quotient B/A (strain ratio; SR) is considered as the measure of the elastographic evaluation. Area A is representative of the pancreatic lesion strain. Area B refers to a soft peripancreatic tissue strain. The SR results were measured at the head and body, respectively.
Results: A total of 93 patients (mean age 60.2 years, 58 male) were included. The mean SR was 8.96 ± 6.05 for CP, 22.04 ± 13.57 for PC. The SR was different significantly in two groups respectively (CP vs. PC; $p < 0.001$). The area under the curve (AUC) of EUS elastography for diagnosing CP was 0.811 (95% confidence interval (CI) 0.746-0.858), the sensitivity and specificity was 71.8% and 80.2% (cut off SR of 5.81). The AUC of EUS elastography for PC was 0.983 (95% CI 0.971-0.995), the sensitivity and specificity was 94.4% and 97.4% (cut off SR of 9.15).
Conclusion: In our study, we provided the reference range of SR value of normal pancreas, CP, and PC respectively as well as good parameters of the AUC analysis. Also, EUS elastography is a promising useful method for differentiating CP and PC. Further prospective and multicenter research in this method is needed.

Contact E-mail Address: Gabriele.Delconte@istitutotumori.mi.it
Introduction: Endoscopic Ultrasound-Guided Fine Needle Aspiration (EUS-FNA) is the procedure of choice to differentiate pancreatic tumors. EUS-FNA has a good diagnostic yield particularly when procedure is performed with on-site pathologist. However, cytology alone may be not sufficient to perform immunohistochemical studies and therefore to individualized the therapy.
Aims & Methods: We evaluated the diagnostic yield of EUS-FNA on pancreatic masses using both cytological and histological approach. To do that, we retrospectively identified 122 consecutive patients (67 males, mean age 64 ± 13.7 years) who underwent EUS-FNA for solid pancreatic masses from August 2012 to January 2015. In forty-five subjects synchronous or metachronous malignancies other than pancreatic cancer were present at the time of endoscopic procedure. In most cases (115/129, 89.1%) a 22 G standard needle was used with a mean number of passes of 2.1. Obtained material was recovered in cytolit by flushing the needle with saline. There was no pathologist present in the endoscopy room. Fragments of tissue, when present, were embedded in paraffin and processed for mini-histology, whereas residual material was cytospinned and processed for cytology. Whenever collected material was adequate for that, molecular profiling was studied mainly using immunohistochemical staining.
Results: A total of 129 procedures were performed and the material collected was judged adequate for diagnosis in 112 cases. In 5 subjects with no evidence

of cancer on FNA, diagnosis was supported by negative follow-up in 4 cases and by definitive histology in 1 resected lesion. A metastatic pancreatic lesion was detected in 10 out of 107 patients. Resective surgery was performed in 32 patients and initial diagnosis was confirmed in all of them but one in whom an acinar cell carcinoma resulted a mixed type tumor (endocrine and acinar). In 7 cases the procedure was repeated two times and in all of them definitive diagnosis was obtained at the second exam (overall diagnostic accuracy: 112/122, 91.8%). Cytology was judged adequate for diagnosis in 74 out of 112 cases, whereas mini-histology in 102 out of 112 cases. Adequate material for immunostaining was obtained in 84 (9 cytological and 75 mini-histological, $p < 0.001$) samples. In 49 patients molecular profiling was considered to be essential for a definitive diagnosis: 32 patients with other malignancies, 11 primary neuroendocrine tumors, 2 pseudopapillary solid tumors, 1 adenosquamous carcinoma, 2 acinar cell carcinoma and in one case of mixed-type carcinoma.
Conclusion: Trying to collect material for both cytology and mini-histology helps to increase the diagnostic yield of EUS-FNA, especially when on-site pathologist is not available. In our experience immunostaining is feasible in a consistent number of FNA specimens. Mini-histology is more suitable than cytology for tissue profiling and the former should be preferred when a firm diagnosis is required to target the therapy.

P0222 A NOVEL PIG MODEL OF BILE AND PANCREATIC DUCT DILATATION FOR EUS TRAINING

H. Shiomi[1], M. Sugimoto[1], Y. Shiomi[1], M. Takenaka[1], A. Masuda[1], Y. Arisaka[1], Y. Okabe[1], T. Azuma[1]
[1]*Kobe University, Kobe, Japan*

Contact E-mail Address: hshiomi@med.kobe-u.ac.jp
Introduction: It is known that obtaining skills of endoscopic ultrasonography is difficult, especially in the field of pancreatic and biliary disease. However, there are few animal models suitable for training in diagnostic and interventional EUS of the pancreaticobiliary field. It is not ethically acceptable that endoscopists perform practical training in patients in order to learn EUS procedure. EUS training model could help alleviate these problems.
Aims & Methods: The purpose is to develop the pig model for the training of diagnostic and interventional EUS. Abdominal operation was performed on a pig (n = 8) under endotracheal general anesthesia. The external catheters were introduced into orifice of bile and pancreatic duct. The EUS model of both biliary dilatation and pancreatic duct dilatation was established. We evaluated feasibility of the model of the pancreaticobiliary disease for EUS imaging and intervention.
Results: In all pig models, EUS image showed the dilation of bile duct and pancreatic duct at 3 days after surgical procedure. Moreover, using this model, the puncture for the biliary duct and the pancreatic duct were performed under EUS and fluoroscopic guidance (n = 8 success rate 100%). After puncture, a displacement of the duct diameter could be adjusted by control amount of injecting water to external catheters. Ducts were able to be dilated, and diameter of CBD and MPD were able to be controlled 10mm and 6mm respectively. In this way, our pig model was available more than ten times for puncture of these ducts. It is possible for 10 beginner endoscopists to confirm the bile and pancreatic duct, and then to perform the puncture for the bile and pancreatic duct.
Conclusion: We developed successfully the innovative model which has variable-sized ducts and repeatability of interventional EUS procedure in pancreaticobiliary field. The unconventional novel model will be very valuable for EUS training, and will surely contribute to development of interventional EUS-guided technology.

P0223 DIAGNOSTIC ACCURACY OF 22/25-GAUZE CORE NEEDLE IN ENDOSCOPIC ULTRASOUND-GUIDED SAMPLING OF SOLID PANCREATIC LESIONS: SYSTEMATIC REVIEW AND META-ANALYSIS

H.-C. Oh[1], H. Kang[2], J. H. Do[1]
[1]*Gastroenterology,* [2]*Anesthesiology, Chung-Ang University College of Medicine, Seoul, Republic of Korea*

Contact E-mail Address: ohcgi@cau.ac.kr
Introduction: It is uncertain if novel core needle increases the diagnostic accuracy by obtaining sufficient amount of tissue. The aim of this study was to use systematic review and meta-analysis to define the diagnostic accuracy of EUS-guided core needle aspiration.
Aims & Methods: Studies were identified by searching medical databases for reports published between 1994 and 2015, using a reproducible search strategy comprised of relevant terms. Studies using 22/25G core needles, irrespective of comparison with standard fine needles, that used surgical histology or at least 6 months clinical follow-up. Pooled sensitivity, specificity, diagnostic odds ratio (DOR) and summary receiver operating characteristic (SROC) curves for the diagnosis of pancreatic malignancy were used to estimate the overall diagnostic efficiency.
Results: Eleven studies involving 929 subjects met the defined inclusion criteria. Of the 929 patients, 583 were in the core group and 346 were in the standard needle (both needles were used in 242 patients). The pooled sensitivity, specificity and diagnostic odds ratio (DOR) of the core needle were 0.88 (95%CI 0.85–0.91), 0.99 (95%CI 0.96–1) and 167.68 (64.53-435.77) respectively. The pooled sensitivity, specificity and diagnostic odds ratio (DOR) of the standard needle were 0.84 (95%CI 0.78–0.88), 1 (95%CI 0.97–1) and 129.77 (34.00-495.35) respectively. The core and standard needles were comparable in the sensitivity and specificity. In addition, the area under the curve (AUC) of core needle and standard needle in the diagnosis of pancreatic malignancy were 0.9748 and 0.9555, respectively. There were no significant differences in accuracy (RR 0.98, 95% CI 0.92, 1.04) and technical failure (RR 5.07, 95%CI 0.68-37.64). There was lower procurement of histologic core in core needle (RR 0.81, 95% CI 0.72-0.92).
Conclusion: The core and standard needles were comparable in terms of diagnostic accuracy, technical performance and safety profile. However, there was lower procurement of histologic core in the core needle group.

Introduction: Endoscopic ultrasound (EUS)-guided fine needle aspiration has become an accurate technique for obtaining tissue acquisition from upper gastrointestinal (GI) subepithelial lesions. However, the diagnostic yields for small lesions were relatively low. To increase the diagnostic yield, we developed EUS-guided cutting biopsy (EUS-CB) using a forward-viewing echoendoscope.
Aims & Methods: We evaluated the feasibility of EUS-CB for tissue acquisition from upper GI subepithelial lesions. This study was a prospective case series and approved by the institutional review board of the Nagoya University. Between January 2015 and April 2015, ten patients with upper gastrointestinal subepithelial lesions underwent EUS-CB by using a hot biopsy forceps. After mucosal cuts, several specimens were taken within the lesion using this forceps under real-time EUS visualization. Finally, the incision site was closed using hemoclips. The following points were assessed; (1) diagnostic yield, (2) number of samples, (3) procedure time, and (4) adverse events.
Results: Ten patients (median lesion size 16mm, range 15-44 mm) were enrolled. The overall rate of histological diagnosis of EUS-CB was 100% (10/10). The median number of samples within tumor was 4.5. The procedure times for EUS-CB and complete closure were 28.5 and 4.5 minutes. Adverse events did not occur.
Conclusion: This newly developed EUS-CB is feasible and allowed forceps biopsy from upper GI subepithelial lesions under EUS visualization.

P0225 EUS-GUIDED BILIARY DRAINAGE VERSUS PERCUTANEOUS TRANSHEPATIC BILIARY DRAINAGE AFTER FAILED ERCP IN MALIGNANT BILIARY OBSTRUCTION

N. Alcaide[1], L. Fernández Salazar[1], **I. Peñas**[2], M. A. Udaondo[3], B. Velayos[1], C. de la Serna[2], L. del Olmo[1], J. Trueba[3], J. M. González Hernández[1], M. Pérez-Miranda[2]

Contact E-mail Address: noelialcaide@hotmail.com
Introduction: Percutaneous transhepatic biliary drainage (PTBD) is the method of choice for the palliative relief of malignant biliary obstruction in cases where ERCP is not feasible. EUS-guided biliary drainage (EUSBD) is purported to be an alternative to PTBD in this setting. However, evidence to back this claim is still limited.
Aims & Methods
Aim: To compare safety and efficacy of EUSBD and PTBD.
Methods: Records from 40 consecutive patients with unresectable malignant biliary obstruction undergoing PTBD after failed ERCP over a 5-year period at one tertiary hospital and from 40 age and sex matched controls undergoing EUSBD for the same indication at another tertiary center in the same city were reviewed. Baseline bilirubin values, days from admission until drainage, number of sessions required, technical success rate (drain/stent placement), internal biliary drainage rate, type of stent, clinical success (80% decrease in serum bilirubin values from baseline), adverse events, procedure-related deaths, stent dysfunction, need for reinterventions, hospital stay, stent patency and overall survival were compared between the two groups. Chi-squared and Fisher's test were used where appropriate.

Results: EUSBD: age, mean (range)= 68.12 (40-92) years; 60% male. Pancreatic cancer, 40%; Metastasis, 22.5%; Cholangiocarcinoma, 22.5%; Other, 15%. Hilar biliary obstruction in 37.5%. PTBD: age, mean (range)=72.6 (50-93); 55% male. Pancreatic cancer, 30%; Cholangiocarcinoma, 32.5%; Metastasis, 15%. Hilar biliary obstruction in 32.5%. No statistically significant differences in baseline features, including serum bilirubin, days from admission to drainage were noted between the two groups. Regarding treatment outcomes, rates of technical success, type of stent, clinical success, adverse events, stent dysfunction, stent patency, reinterventions, hospital stay, overall survival and procedure-related deaths were no different between the two groups (Table). The rate of internal biliary drainage was significantly higher in EUSBD (39 versus 32, p=0.029) and the number of sessions to obtain it was significantly lower (1.32 in EUSBD versus 2.2 in PTBD; $p < 0.001$).

	DBUSE	CTPH	p
Baseline Bilirubin (mg/dL)	10.65	13.64	0.077
Time from Admission to Drainage (days)	8.95	9.28	0.816
Treatment sessions (n)	**1.35**	**2.2**	**0.000**
Technical Success (n)	39	40	1.000
Internal biliary drainage (n)	**39**	**32**	**0.029**
Metal Stent (n)	32	32	0.610
Clinical Success (n)	27	25	0.750
Adverse Events (n)	6	10	0.586
Procedure-realted deaths (n)	1	2	0.215
Stent dysfunction (n)	10	7	0.586
Reinterventions (n)	22	11	0.738
Hospital Stay (days)	11.63	9.53	0.397
Stent patency (days)	89.45	111.83	0.477
Survival (days)	212	149	0.265

Conclusion: The safety and efficacy of EUSBD is comparable to that of PTBD in patients with unresectable malignant biliary obstruction and failed ERCP. The number of treatment sessions is lower with EUSBD, and the rate of internal biliary drainage higher than that of PTBD.
Disclosure of Interest: None declared

P0226 FACTORS PREDICTIVE OF CLINICAL OUTCOME FOLLOWING BILIARY DRAINAGE IN PATIENTS WITH UNRESECTABLE MALIGNANT BILIARY OBSTRUCTION AND FAILED ERCP

N. Alcaide[1], L. Fernández Salazar[1], M. A. Udaondo[2], **I. Peñas**[3], B. Velayos[1], C. de la Serna[3], L. del Olmo[1], J. Trueba[2], J. M. González Hernández[1], M. Pérez-Miranda[3]

Introduction: Unresectable malignant biliary obstruction (MBO) carries a poor prognosis. Biliary stent insertion achieves adequate palliation. Predictive factors of clinical success, procedural complications and long-term survival require further elucidation, specifically in the setting of novel procedural approaches to drainage.
Aims & Methods
Aims: To identify predictive factors of clinical outcome after technically successful biliary drainage following either percutaneous transhepatic (PTBD) or endoscopic ultrasound-guided (EUSBD) access in patients with unresectable MBO and failed ERCP.
Methods: Baseline features and clinical course of 80 patients with unresectable MBO drained by PTBD or EUSBD at two tertiary centers were retrospectively analyzed. Binary uni- and multivariate logistic regression analysis was carried out for the following dependent variables: technical success, clinical success, complications, in-hospital death, stent dysfunction, 3 and 6-month survival. Uni- and multivariate Cox proportional hazard model was performed. Independent variables analyzed were: age, sex, tumor etiology, level of obstruction, baseline bilirubin, reason for failed ERCP, days from onset of jaundice to drainage, days from failed ERCP to drainage, number of attempts, stent type, rate of internal biliary drainage, postprocedure chemotherapy. $P < 0.05$ was considered significant.
Results: Demographics: 57.5% male; mean (SD) age, 72.8 (13.9) years; 76.2% primary MBO vs 23.8% metastatic; 35% hilar vs 65% distal MBO. Mean survival was 161 days. Failed access to the papilla as a reason for failed ERCP was an independent predictive factor of decreased postprocedure complication risk (OR 0.178, IC 95% 0.045-0.700, p=0.014). Time from failed ERCP to final drainage procedure was an independente predictive factor of increased in-hospital death risk (OR 1.121, IC 95% 1.005-1.250, p=0.040). Hilar location was an independent predictive factor of decreased 3 and 6-month survival (OR 0.155, IC 95% 0.029-0.819, p=0.028, and OR 0.155, IC95% 0.029-0.821, p=0.028). Reintervention because of sent dysfunction was a predictor for increased 6-month survival (OR 5.839, IC 95% 1.296-26.312, p=0.022). Hilar location and reintervention for stent dysfunction were independent predictors of mortality over time (HR 1.969, IC 95% 1.037-3.737, p=0.038 y HR 0.476, IC 95% 0.254-0.890, p=0.020). PTBD versus EUSBD were not predictors for any of the dependent variables at uni- or multivariate analysis.
Conclusion: Hilar location, reason for failed ERCP, days between failed ERCP and final drainage procedure, and reintervention caused by stent dysfuncion are predictors of clinical outcome in the subset of patients with MBO and failed ERCP. These data warrant confirmation, as they are potentially relevant to improve current practice patterns.

P0227 THE DIAGNOSTIC YIELD OF ENDOSCOPIC ULTRASONOGRAPHY IN PATIENTS WITH SUSPECTED CHOLEDOCHOLITHIASIS

I. Hritz[1,2], J. Basha[2], R. Kalapala[2], M. Ramchandani[2], R. Gupta[2], N. Reddy[2], S. Lakhtakia[2]
[1]*Department of Gastroenterology, Bács-Kiskun County University Teaching Hospital, Kecskemet, Hungary,* [2]*Asian Institute of Gastroenterology, Hyderabad, India*

Contact E-mail Address: istvan.hritz@gmail.com
Introduction: Choledocholithiasis is the most common cause of biliary obstruction, which occurs in 10-20% of patients with cholelithiasis. Management of suspected choledocholithiasis requires confirmation of stones in the common bile duct (CBD). The diagnosis is based on clinical signs and symptoms, laboratory- and imaging examination findings. Likelihood of CBD stones can be prognosticated by the presence of various clinical predictors, however the sensitivity and specificity of these factors is moderate. Endoscopic ultrasonography (EUS) has been shown to be a non-invasive precise test for the detection of CBD stones.
Aims & Methods: Our aim was to assess the diagnostic yield of EUS in patients with suspected choledocholithiasis in a high-volume center during the period of one-month. Prospective study of patients with cholelithiasis and clinical symptoms or abnormal liver function tests who underwent transabdominal ultrasonography (USG) that could not detect CBD stones (except in one case) were categorized and divided into an intermediate- and high likelihood groups according to the clinical predictors (i.e. serum bilirubin, age, CBD diameter) defined by the American Society of Gastrointestinal Endoscopy (ASGE) guidelines and referred for radial EUS.
Results: Total of 26 patients, 14 females and 12 males (average age of 40.8 ± 17.3 and 51.1 ± 14.9, respectively) were assessed. CBD stones were detected by EUS overall in 17 (65.4%) patients: 61.5% of patients (8/13) in the intermediate likelihood- and 69.2% of patients (9/13) in the high likelihood group. The size and the number of detected CBD stones in all patients were confirmed by the followed therapeutic endoscopic retrograde cholangio-pancreatography (ERCP) except in one case where a preampullary calcific stenosis was described as a calculus during the EUS. Two-month follow up of those patients with no CBD stones detected on EUS revealed no clinical findings suspicious for biliary obstruction.
Conclusion: EUS is a highly sensitive and accurate diagnostic tool for the detection and evaluation of CBD stones also in patients with previous normal USG findings. Further study is needed to assess the potential correlation of clinical data with EUS findings in the detection of suspected choledocholithiasis.

Introduction: EUS-guided FNA is the standard of care for tissue sampling of pancreatic lesions. It has some limitations such as lack of proper histology sample, low sensitivity for malignancy in the presence of chronic pancreatitis, low diagnostic accuracy in the absence of on-site cytopathologist and false-positive rates up to 5-7%. The new Echo Tip ProCore biopsy needle (Cook Medical) was developed to obtain core tissue specimens improving the diagnostic yield and potentially obviating the need for onsite cytopathologist.
Aims & Methods: To compare the standard Echo tip ultra FNAC needle with the new Echo Tip Ultra ProCore FNAB needle in the sampling of solid pancreatic lesions. Sampling time, number of passes and sample adequacy were compared. Randomized multicenter trial in a tertiary university hospitals setting approved by the National Research Ethics Service (NRES). All patients referred for EUS guided tissue sampling of a solid pancreatic mass were invited to participate. Informed consent form was obtained from every participant. Linear EUS (Aloka-Olympus, Hitachi-Pentax) was performed and patients were randomised to either FNAC or FNAB. Due to the nature of the study the endoscopist could not be blinded. A 22G needle was used when sampling from the stomach and a 25G from the duodenum. A maximum of 5 passes[o] were allowed. Sampling time from first insertion of the needle into the lesion to the time the last sample is transferred into the histology pot, number of passes and adequacy for diagnosis reported by the pathologist were recorded and

included for analysis. Immediate and delayed complications between days 8-30 post procedure were also recorded.
Results: 266 patients were recruited (median age 67 years, 52% men); 142 were randomized to FNAC and 124 to FNAB. Two were excluded after randomization; no mass lesion was seen in 1 patient randomized to FNAC and the needle failed in 1 patient in the FNAB group and FNAC was performed. A total of 264 patients were analyzed, FNAC = 141 (22G = 83 and 25G = 58. Median lesion size 34 mm, range 10-87 mm) and FNAB = 123 (22G = 53 and 25G = 71. Median lesion size 33 mm, range 8-85 mm). There was no statistical significant difference in number of passes (median 4, range 1-5 in the FNAC group vs. median 3, range 1-5 in the FNAB group, p = 0.126), required time to obtain adequate samples (median 13 min, range 1-32 min vs. median 13 min, range 2-42 min, p = 0.636) and adequacy of the specimen for diagnosis (90.8% vs. 87%, p = 0.33). Three technical failures were observed in the FNAB cohort, 2 different needles had to be used in two patients as first was faulty and in 1 patient the needle did not come out from the scope (excluded for analysis). No technical failures noted in the FNAC cohort (1.6% vs. 0%, p = 0.998). No immediate or delay complications reported in either group.
Conclusion: FNAC and FNAB needles were comparable in terms of sampling time, number of passes, sample adequacy for diagnosis and safety. Technical failure was higher in the FNAB arm but not statistically significant.

Introduction: Capsule enteroscopy (CE) allows the evaluation of the entire small bowel, representing an important tool in the management of obscure gastrointestinal bleeding (OGIB).[1,2,3] Nevertheless, the real impact of CE in the management of active overt OGIB (OOGIB) lacks evidence.[1] The aim of this study was to evaluate the diagnostic yield of CE and its therapeutic impact in patients with active OOGIB.
Aims & Methods: Between April 2005 and January 2015, all patients with active OOGIB who underwent emergency CE in the first 48 hours after a negative esophagogastroduodenoscopy and ileocolonoscopy were included. Severe active OOGIB was classified as persistency of melena or hematochezia despite an initial negative endoscopic assessment, resulting in hemodynamic instability (systemic arterial pressure < 100 mmHg and pulse > 100 beats/min) and/or the need for ≥2 units of packed red blood cells (PRBC). Patients with active OOGIB not fulfilling the preceding criteria were classified as mild-to-moderate. Descriptive analysis was performed.
Results: 42 patients underwent emergency CE, 50% were men with a mean age of 61.7 years. The mean hemoglobin at admission was 9.0+/-2.9 g/dL and 59.5% (n = 25) required PRBC transfusion, with a mean number of 1.4 units. OOGIB manifested with melena in 59.5% (n = 25) of patients and with hematochezia in 40.5% (n = 17) and was classified as severe in 59.5% (n = 25) and as mild-to-moderate in 40.5% (n = 17). CE identified a lesion in 52.4% (n = 22) patients with active OOGIB (n = 14 severe; n = 8 mild-to-moderate) and identified the location of bleeding in 38.1% (n = 16) of active OOGIB (n = 9 severe; n = 7 mild-to-moderate), totaling a diagnostic yield of 90.5% in active OOGIB (92% in severe; 88.3% in mild-to-moderate). Findings included active bleeding (n = 15); ulcers/erosions (n = 7); angiodysplasias (n = 6); tumors (n = 4); Meckel's diverticulum (n = 2); polyps (n = 2); signs of recent bleeding (n = 1); varices (n = 1). Further diagnostic and therapeutic procedures were performed in 73.8% patients, including endoscopy in 38.1%, surgery in 19%, endoscopy/surgery in 7.1%, endoscopy/radiology in 4.8%; radiology/surgery in 2.4% and radiology in 2.4%.
Conclusion: The diagnostic yield of emergency CE was 90.5%, establishing the diagnosis in 52.4% of the patients and identifying the location of bleeding in more 38.1%, resulting in a specific management in 73.8% of cases. This study highlights the importance of emergency CE in the diagnostic approach and subsequent therapeutic management in active OOGIB.

Introduction: Capsule endoscopy (CE) is a diagnostic method that enables visualization of intraluminal bowel, diagnosing disorders not diagnosed effectively.
Aims & Methods
Aim: To demonstrate the utility and diagnostic effectiveness of CE in patients with diarrhea and initially diagnosed and treated as irritable bowel syndrome and abdominal pain.
Methods: Retrospective study (03-2012 / 03-2014) in patients who underwent CE for abdominal pain and / or diarrhea, normal studies: gastroscopy, colonoscopy and laboratory; patients without improvement, previously treated as IBS according to Rome III criteria. We used 2 type of capsules: Mirocam (Intromedic) and SB2 (Given-Imaging).Readings were performed by a single physician who is blinded for the study.
Results: 216 CE were reveiwed. 65 (30%) subjects met the criteria. (35/65) or 53.8% were women. Median age was 50 years. Diarrhea was present in 33.8% (22/65) and abdominal pain in 66.1% (43/65). CE with diarrhea subjects showed: atrophy of the villi in 18.1% (4/22), and ulcers compatible with inflammatory bowel disease (IBD) 36.3% (n = 8/22), normal study in 45.4% (n = 10/22). CE in -abdominal pain subjects detected: ascaridiasis 2.3% (n = 1/43), atrophy of villi in 23.2% (n = 10/43), IBD in 25.5% (n = 11/43), gastroparesis in 6.9% (n = 3/43), submucosal tumor 2.3% (n = 1/43), nonspecific erythema 4.65% (n = 2). In total, the CE detected 48% more lesions that had a clinical impact of 100%.
Conclusion: The CE showed an important role in managing IBS patients with no response to treatment.

P0231 PREDICTING INFLAMMATORY PATHOLOGY AT CAPSULE ENTEROSCOPY: WHAT IS THE UTILITY OF A RAISED FAECAL CALPROTECTIN?

C. Parker[1], C. Lamb[1], M. Robinson[1], J. Mansfield[1], M. Gunn[1]
[1]*Gastroenterology, Royal Victoria Infirmary, Newcastle upon Tyne, United Kingdom*

Contact E-mail Address: clare.e.parker@doctors.net.uk
Introduction: Faecal Calprotectin (FCP) is a widely used biomarker of gastrointestinal (GI) mucosal inflammation. Many capsule enteroscopy (CE) services are receiving increased referrals of patients with abdominal symptoms combined with an elevated FCP (> 50μg/g) but normal gastroscopy, colonoscopy or radiology. There is little data on using FCP levels as a screening tool for selecting patients in whom CE will lead to a definitive diagnosis. Elevated FCP levels may indiscriminately drive investigations in endoscopy and imaging-negative patients who subsequently have normal findings at CE. We aimed to determine the incidence of inflammatory pathology on CE in patients with a raised FCP, and if a suitable concentration of the biomarker could be identified as a screening tool to avoid unnecessary CE.
Aims & Methods: A single centre retrospective review of The Newcastle upon Tyne Hospitals CE database was conducted (Feb 2012-Feb 2015). Patients with GI symptoms (abdominal pain, diarrhoea, bloating, vomiting, weight loss) and a raised FCP (> 50μg/g) were identified. Findings at CE considered to be inflammatory were: erythema, ulceration, erosions and fissuring.
Results: 35 patients were identified with elevated FCP and GI symptoms. 45.7% (n = 16) had inflammation identified by CE and in 54.3% (n = 19) no inflammatory pathology was identified. The mean (+/-SE) FCP was higher in patients with evidence of inflammation at CE in comparison to those with no inflammation: 452.1(95.8)μg/g vs. 206(20.8)μg/g; p = 0.01. Stratifying patients according to FCP revealed that only 8.3% of patients (n = 1/12) with a FCP of 50-200μg/g had inflammatory findings at CE. This rose to 58.3% of patients (n = 7/12) with a FCP of 201-300μg/g, and 72.7% of patients (n = 8/11) with a FCP > 300μg/g. A threshold of 200μg/g FCP revealed a sensitivity of 94.1% to predict inflammation at CE, with a specificity of 55.6%. This FCP threshold had a negative predictive value of 90.9%, and positive predictive value of 66.7% for CE inflammation.
Conclusion: In this small retrospective analysis of a sub-group of patients referred for CE with a FCP of > 50μg/g the likelihood of identifying inflammatory pathology at CE increased with rising FCP concentrations above 200μg/g. A threshold of 200μg/g provided a high negative predictive value for CE inflammation and may be a useful screening tool to reduce the requirement for CE in select patient groups. This retrospective analysis should be confirmed in a larger prospective cohort.

P0232 ROLE OF SECOND-GENERATION COLON CAPSULE ENDOSCOPY FOR WHOLE GUT EVALUATION

C. Spada[1], C. Hassan[1], M. Campanale[1], L. Petruzziello[1], G. Costamagna[1]
[1]*Digestive Endoscopy Unit, Catholic University of Rome, Rome, Italy*

Contact E-mail Address: chiaracampanale@hotmail.com

Introduction: Although colon capsule endoscopy (CCE) was developed for evaluation of the colon, it can be used to assess the entire GI tract since it offers excellent images also of the esophagus and the small bowel (SB), with the exception of the stomach that remains poorly evaluated. Usually, after the firsts 3 min of running, CCE slows down the frame rate to 14 images/min. When SB is detected CCE automatically restarts using the Adaptive Frame Rate (AFR) technology. Nevertheless, CCE can be also "activated" to the AFR mode prior to the ingestion allowing the whole gut evaluation at a high frame rate acquisition.

Aims & Methods: Aim of this preliminary, feasibility study was to evaluate the ability of CCE to evaluate esophagus, small bowel and colon if patients take CCE after early, manual activation. Methods: 19 pts (8F, mean age 58 yrs, R 31-78 yrs) were enrolled. All pts underwent second-generation CCE. Pts were invited to follow the standard regimen of preparation for CCE. It consists of the regimen recommended by the ESGE guidelines with the inclusion of Gastrografin in adjunct to sodium phosphate booster. The day of the procedure all CCE were manually activated to AFR before the ingestion. Pts were asked to swallow CCE following the recommended procedure for ESO capsule. They remained in hospital until CCE transit into the SB was confirmed. They were, then, invited to drink the first booster and leave the hospital. Esophageal, SB and colonic transit times (TT) were evaluated. Esophagoscopy was defined complete when Z line was visualized. Completeness and cleansing level of SB and colon were evaluated. Significant findings were defined as findings that could explain the reason for referral and/or that had any effect on the medical decision making.

Results: Indication for CE was: incomplete colonoscopy (n = 7), OGIB (6), colonoscopy refusal (4), iron deficiency anemia (2). A total evaluation of the entire GI tract was possible in 14 out of 19 pts (74%): Z line was not visualized in 4 pts and colonoscopy was incomplete in 1. Overall the Z line was visualized in 15/19 (79%) pts. Mean esophageal capsule TT was 69 sec (R 5-497). 1 (5%) pt had esophagitis. Complete capsule enteroscopy and SB adequate cleansing level was achieved in all pts. Mean SBTT was 106 min (R38-231). Significant SB findings were diagnosed in 3 (16%) pts and included diverticula (1), ulcerations (1) and large bleeding polyp (1). Colon TT was 104 min (R 10 734). CCE was complete and cleansing level was adequate in 18/19 (95%) pts. Significant findings were diagnosed in 6 (31%) pts: ≥6mm/≥3 polyps (5) and caecal angiodysplasia (1).

Conclusion: Second-generation CCE is feasible for whole GI evaluation and it has a relevant impact on medical decision making. The indications for a pan-endoscopy, however, need to be clarified and the procedure should be validated.

P0233 UPPER AND LOWER GASTROINTESTINAL LESIONS OVERLOOKED AT CONVENTIONAL ENDOSCOPY AND FURTHER DIAGNOSED WITH SMALL BOWEL CAPSULE ENDOSCOPY: THE CRUCIAL ROLE OF ENDOSCOPIC EXPERIENCE IN PATIENTS WITH OBSCURE GASTROINTESTINAL BLEEDING

D. Moneghini[1], G. Missale[1], L. Minelli[1], R. Cestari[1]
[1]*Digestive Endoscopy, Spedali Civili - University of Brescia, Brescia, Italy*

Contact E-mail Address: dario.moneghini@spedalicivili.brescia.it

Introduction: The role of small bowel capsule endoscopy (CE) in the investigation of obscure gastrointestinal bleeding (OGIB) is well established, with a mean diagnostic yield of 60%. However, in up to 20% of patients the cause of OGIB is located within the reach of upper and lower endoscopy. No data are available regarding the impact of endoscopic experience on the rate of lesions missed by previous esophagogastroduodenoscopy (EGDS) or ileocolonoscopy (ICS) and further found with CE. The aim of this series is to clarify if the experience of the endoscopy units could influence the rate of overlooked lesions.

Aims & Methods: We retrospectively reviewed the charts of 584 patients who underwent CE at Endoscopy Unit between October 2008 and March 2015 for OGIB. The CE-derived data are recorded and analyzed in terms of non-small-bowel CE findings (gastric, duodenal and colonic lesions) overlooked at previous upper and lower endoscopy. The type of endoscopic units who performed the conventional endoscopy (tertiary referral centres or primary level centres) and the respective lesions miss rate was recorded. The Given M2A video capsule system (Pillcam; Given Imaging Ltd, Yoqneam, Israel) was used. The day before the exam bowel preparation with 2L of polyethylene glycol solution was administered. Capsule ingestion was performed in the morning after a overnight fast. All the patients gave their written informed consent.

Results: 547 patients were enrolled for the final investigation (41 cases were excluded from further analysis because of the capsule did not reach the colon). In 35 patients (6.4%) one or more lesions previously missed by conventional endoscopy were diagnosed at CE. 20 of these 35 cases were males. The mean age was 72.8 years (range 51-89). 77.1% of lesions were overlooked at primary level endoscopy units; 22.9% at tertiary level units ($p < 0.01$). The overlooked lesions are reported in the table according to the type of endoscopic centre. The most frequently missed lesions were located in stomach and duodenum (66.6%); primary centres missed lesions mostly during EGDS (71.4%); tertiary centres miss lesions during EGDS and ICS equally. Both types of centres can miss neoplasias (66.6% at primary centres): tertiary centre overlooked a gastric GIST (gastrointestinal stromal tumor); primary centres overlooked a non invasive intraepithelial gastric haemorrhagic neoplasia and an ascending colon adenocarcinoma.

Conclusion: Our results suggest that endoscopic experience, in terms of number of referral patients, can significantly reduce the miss rate of lesions located in upper or lower gastrointestinal tract, avoiding unhelpful CE.

P0234 COLON CAPSULE TRANSIT TIMES AND IMAGE QUALITY IN PATIENTS PREPARED WITH POLYETHYLENE GLYCOL + ASCORBATE (PEG + A) AND BOOSTER OF EITHER PEG + A OR GASTROGRAFIN AND LOW DOSE SODIUM PHOSPHATE (NAP)

D. Nastou[1], H. Palmer[1], J. Lewandowski[1], O. Epstein[1]
[1]*Minimally Invasive Gastroenterology, Royal Free Hospital, London, United Kingdom*

Contact E-mail Address: desnastos@yahoo.gr

Introduction: Successful colon capsule endoscopy (CCE) requires high capsule excretion rates and high-quality bowel cleansing. Most cleansing regimens are based on polyethylene glycol (PEG) supplemented with a booster of NaP to accelerate transit time. Because of potential renal toxicity associated with NaP, we have piloted two novel CCE cleansing regimens.

Aims & Methods: *Prep1* was designed as a NaP free regimen comprising 2L PEG + Ascorbate (PEG + A) administered as a split dose, with an additional 1L booster after capsule ingestion. *Prep2* comprised identical split dose 2L PEG + A, but the post capsule ingestion booster was low dose NaP (30-45ml) and gastrografin (50-100ml), a contrast medium known to accelerate bowel transit. 34 CCEs were reviewed, 17 from each group. Oro-caecal, caeco-rectal transit times and capsule excretion rates were measured. Quality of bowel cleansing was assessed by two independent observers, using a modified small bowel cleansing scale grading from the first caecal image and every 15 minutes until the end of the study. At each time point the assessors graded each of the two static images recorded by the CCE cameras. The proportion of visualised mucosa was graded as M3 (>75% of mucosal surface visualised), M2 (50-75%), M1 (25-49%) and M0 (<25%). Obscuration was graded as O3 (<5% of the image obscured by bubbles, debris or unclear fluids), O2 (5-24%), O1 (25-50%) and O0 (>50%). If capsule remained stationary more than 15 minutes, the time was extended to the frame 15 minutes following onward movement of capsule.

Results: In 6 of the 17 CCEs (35.29%) assessed in *prep1* group, the capsule camera was excreted, providing a complete assessment of the colonic mucosa. The excreted capsule cameras for the *prep2* group were 15 of 17 (88.23%) ($p = 0.001$).

Three hundred seventy five frames were assessed and graded from the group that received *prep 1*. Three hundred sixty six frames were assessed and graded from the group that received *prep 2*.

In total 55.4% of frames in *prep1* group scored M2/M3 for mucosal visualisation (equivalent to good/excellent bowel preparation as described by standard CCE grading scores), whilst in *prep2* group 82.23% of frames scored M2/M3 ($p < 0.001$).

In *prep1* group 24.53% of frames scored O3 for obscuration (equivalent to insignificant obscuration with standard CCE scores), whilst in *prep2* group 40.71% of total frames scored O3 ($p < 0.001$).

Conclusion: *Prep1* assessed whether a PEG + A booster could produce a "tsunami" prokinetic cleansing effect and *Prep2* examined boosting with a combination of gastrografin and low-dose NaP. Failure of capsule excretion occurred in almost two thirds *of Prep1* patients, whilst with *Prep2* the 88.2% completion rate was similar to that expected in standard colonoscopy. In *Prep1* group 55% of frames examined scored M2/M3 for mucosal visualisation and 43% O2/O3 for obscuration, whilst in *Prep2* group 82% of frames scored M2/M3 and 72% O2/O3.

PEG + A is an ineffective booster and fails to achieve adequate cleansing whilst the booster combination of gastrografin and low dose NaP appears to offer both excellent excretion rates and enhanced bowel cleansing.

Introduction: Colon capsule endoscopy (CCE) is an attractive alternative for the patients who refuse the standard colonoscopy.
Aims & Methods: To evaluate technical aspects and feasibility of CCE in the daily clinical practice. From I.2014 to XII.2014 we performed 57 CCE (PillCam Colon2) in 56 patients (m-26, f-30, mean age 51.4 ± 11.7 years, range 26-75). In 1 (2.7%) case the capsule retained in the stomach for 10 hours, so we repeated CCE once more. The main indication for colonoscopy was CRC screening – 37 (66.1%) patients; complaints of pain and constipation – 18 (32.1%); surveillance – 1 (1.8%) patient. The majority (96.4%) of patients refused to perform conventional, including sedated, colonoscopy. For the bowel preparation, we used regimen recommended by ESGE guidelines; for the evaluation of preparation – J.A.Leighton scale.
Results: Total CCE was performed in 52 (92.8%) patients. Slow capsule transit in sigmoid colon (until the battery exhausted) was observed in 3 (5.3%) patients, in transverse colon – in 1 (1.8%) patient. The mean transit time of the colon-capsule through the gastrointestinal tract was 7 hours 58 min ± 3 hours 33 min. The mean colon transit time was 6 hours 18 min ± 3 hours 04 min. Only 64.3% of the capsules were excreted in conditional 10 hours after ingestion. Colon preparation in 20 (35.7%) patients was excellent, in 25 (44.6%) - good, in 8(14.3%) – fair, in 3(5.4%) – poor. Colon abnormality was detected in 48 (85.7%) patients: polyps in 29 (60.4%), in 13 cases the size of polyps ranged from 1 to 6 mm, in 16 - was more than 6 mm; diverticulosis in 14 (29.1%) patients; erosions in 5 (10.4%); focal inflammation in 8 (16.6%); angioectasias in 6 (12.5%); melanosis in 1 (2.1%); aphtous ulcers in 7 (14.6%); anal fissure in 1 (2.1%) and hemorrhoids in 11 (22.9%) patients. No adverse events related to CCE were revealed. After CCE we recommended colonoscopy for 23 patients, but at the moment only 7 (30.4%) agreed. Results of CCE were completely confirmed in 3(42.8%) patients, partially – in 3(42.8%) and non-confirmed in 1(14.4%).
Conclusion: CCE was able to examine the whole large bowel in 92.8% of patients and to detect abnormalities in 85.7%, including polyps in 60.4% of patients. With reduced rates CCE could become the method of choice for CRC screening and incomplete colonoscopy.

Introduction: Polyethylenoglucol has been widely used as bowel preparation before small bowel capsule endoscopy.
Aims & Methods
Aim: To determine risk factors those affect small bowel preparation with polyethilenoglycol.
Methods: 1030 patients undergone small bowel capsule endoscopy, gastroscopy and colonoscopy were evaluated. 165 with inflammatory bowel disease, 11 with celiac disease and 124 with underlined neoplasia were excluded from the analysis. 401 were evaluated for iron deficiency anemia, 149 for undefined gastrointestinal bleeding, 178 for diarrhea, 102 for other causes. Bowel preparation quality was defined as adequate (good, fair) or inadequate (poor). Stat: t-test, X2, logistic regression analysis.
Results: Bowel preparation was adequate in 533 (64.2%) patients. Mean age: adequate preparation: 63 ± 18 years, inadequate preparation: 63 ± 19 years ($p = 1.00$); Preparation was adequate in: Gastrointestinal bleeding: 93 (62.4%), anemia: 249 (62.1%), other indications for capsule endoscopy: 191 (68.2%, not statistical difference for capsule endoscopy indication); Male gender: 277 (59%, $p = 0.004$), active smoking: 119 (69%, $p = 0.20$), alcohol consumption: 46 (55%, $p = 0.08$); Small bowel polyps: 49.3%), small bowel ulcerative lesions: 142 (67.3%, $p = 0.28$), small bowel ulcers: 36 (59%, $p = 0.37$), angiodysplasias: 154 (57.5%, $p = 0.005$); Diabetes mellitus: 107 (55.7%, $p = 0.005$), motility disorders 12 (60%, $p = 0.69$), ischemic heart disease 150 (58.8%, $p = 0.03$), stroke 21 (60%, $p = 0.59$), hypothyroidism 74 (66.1%, $p = 0.66$), chronic renal failure 21 (48.8%, $p = 0.03$), use of antidepressants 42 (63.6%), use of tranquillizers: 78 (63.9%, $p = 0.005$). Moreover in patients excluded preparation was adequate in 7 (53.8%, $p = 0.44$) of patients with small bowel cancers. Small bowel transit time in patients with adequate preparation was 332 ± 142 min, while in those with inadequate preparation was 355 ± 137 min ($p = 0.02$). Capsule study completion was 78.2% in those with adequate preparation and 77.1% with those with inadequate ($p = 0.71$). In logistic regression analysis: male gender ($p = 0.009$), presence of angiodysplasias ($p = 0.048$) and presence of small bowel polyps ($p = 0.03$) predispose to inadequate bowel preparation.
Conclusion: Inadequate preparation is related with male gender, presence of angiodysplasias and small bowel polyps. The former possibly due to underline pathologies like diabetes or ischemic heart disease, while the latter two as they predispose to slower bowel transit. More thorough preparation is needed for those patient groups.

Introduction: Capsule endoscopy is a non-invasive method that enables excellent visualization of the small-bowel mucosa. The method has been evaluated for detection of Crohn's lesions in the adult population but data about the method's clinical value for diagnosing Crohn's disease in a large pediatric clinical material is still scarce.
Aims & Methods: The aim of our study was to examine the impact and safety of capsule endoscopy performed in children and adolescents being investigated for established and suspected Crohńs disease (CD) at a tertiary academic hospital in Scandinavia.
A retrospective, single-center study included 180 capsule endoscopy examinations in 169 consecutive patients between October 2003 and December 2014. Patients had a median age of 13 years (range 3-17 years) and the indications for capsule endoscopy were clinically suspected (125 cases, 69%) and established (55 cases, 31%) CD. Capsule endoscopy was performed with PillCam™ SB (Given Imaging) capsule endoscopy system with 8-12 hours of registration without bowel preparation.
Results: 26 of 180 (14%) capsules were endoscopically placed in the duodenum. Patency capsule examinations were performed in 47 (26%) cases.
Capsule endoscopy detected findings consistent with CD in 71 (40%) examinations, 17 (9%) procedures showed minor changes but were not diagnostic for CD. 92 (51%) examinations displayed normal intestinal mucosa. In 30 of 180 (17%) procedures the capsule did not reach the colon during recording time and were defined as incomplete examinations.
A change in therapy was recommended in 53/180 (29%) patients based on capsule endoscopy results.
The most feared complication, capsule retention, occurred in only one (0.6%) patient with established CD.
Conclusion: Capsule endoscopy is a safe method in children with suspected and established CD. The result of capsule endoscopy often leads to a definitive diagnosis and have significant impact on the clinical management of pediatric patients with CD.

Introduction: CapsoCam® SV1 (CapsoVision Inc, Saratoga, USA) is a new small bowel capsule (SBC) with "panoramic view", wire-free technology, and a long-lasting battery life. It is equipped with 4 high frame rate cameras (3-5 frames/second/camera), located at the side of the capsule, resulting in a very high number of acquired frames. Previous studies, comparing this device with frontal view SBCs, showed comparable operative and diagnostic performance [1-2].
Aims & Methods: Accordingly, we conducted a multicenter, observational study to assess the performance of CapsoCam® SV1 in real-life clinical setting. Between January 2014 and April 2015, all consecutive patients undergoing SBC with CapsoCam® SV1 in four Italian and two British Institutions were enrolled. All the identified findings were classified according to their bleeding probability and clinical significance, in line with Saurin classification [3], as **P0**: low probability; **P1**: intermediate probability; **P2**: high probability. Capsule endoscopy was defined as "positive" if at least one P2 finding was identified.
Results: Eighty-nine patients underwent SBC (49 men; median age ± SD: 66 ± 17 years, range: 15-86 years). 70/89 were referred for obscure GI bleeding (18 with overt and 52 with occult OGIB) and 19/89 for suspected (17) or established (2) Crohn's disease (CD). One technical failure occurred - due to short battery life (270min) - leading to incomplete enteroscopy. 88/89 patients excreted and retrieved the capsule. One capsule was retained due to a neoplastic stricture, no acute obstruction occurred and retrieval was done at time of surgery.
The overall diagnostic yield (rate of positive tests) was 42.5%, whereas it was 43.5% for OGIB (50% for overt bleeding) and 38.8% for CD. The ampulla of Vater was identified in 40% of patients and the capsule explored the entire small bowel in 91% of patients.
In a per-lesion analysis, overall 328 findings were detected (P0: 43, P1: 119, P2: 166). Most of the lesions were located in the small bowel (273/328: 83.2%) and 55% of them were classified as P2. Interestingly, 47/328 (14.3%) and 8/328 (2.4%) lesions were detected in the upper and in the lower GI tract, 22 and 6 of them were classified as P2 respectively.
Conclusion: Our data suggest that even when used in the everyday clinical practice, CapsoCam® SV1 has a detection rate and a safety profile comparable to other SBCs with frontal view.

Introduction: Colon capsule endoscopy (CCE) is a valid, non-invasive method to detect colon polyps. However, CCE is time consuming. We evaluated a software algorithm that might reduce investigation time.
Aims & Methods: 29 CCE videos (CCE-2, Covidien®) were analysed by blinded investigators using the "collage mode" (Rapid 8 software, Covidien®) by experienced (n = 3; two-day training course for detecting polyps in CCE and experience of at least 50 CCE investigations) and unexperienced investigators (n = 3, twenty minute briefing about morphology of polyps and technique of CCE). Gold standard was the finding of an experienced extern investigator (> 100 CCE) and results of subsequent flexible colonoscopy. Localisation of the entry to the colon and all detected polyps were marked. Videos were assessed under standardized conditions without interruption.
Results: Evaluation of CCE videos took 7.1 and 7.7 min for experienced and unexperienced investigators, respectively.
Sensitivity of experienced investigators was significantly higher than sensitivity of unexperienced investigators to detect at least one polyp, but specificity was similar in both groups see table 1.

Table 1: Sensitivity and specificity of using the collage mode for detecting at least one colonic polyp per patient.

n = 29	experienced investigators	unexperienced investigators
Sensitivity	88.1+/-8.25%	56.96+/-30.82%
Specificity	84.86+/-7.36%	86.67+/-11.54%
Investigation time per CCE video	424+/-198 sec.	458+/-229 sec.

Conclusion: The use of collage mode reduces the time to investigate colon capsule videos to less than eight minutes. Experienced investigators using this tool are able to achieve excellent sensitivity.

Introduction: Symptoms related to intestinal motility are common in irritable bowel syndrome and even inflammatory bowel disease. Patient symptoms of bloating and nausea are typically worse post-prandially but clinical investigations to date are carried out fasting or after aggressive and unpleasant bowel preparations likely to alter physiology. Moreover, different appointments necessitating multiple patient visits are usually needed to assess motility across different segments of the gastrointestinal (GI) tract.
Aims & Methods
Aims: We describe here a novel paradigm to assess fasting and postprandial motility in a single visit and assess its feasibility in healthy volunteers. The paradigm uses a validated soup meal[1], and MRI to measure gastric emptying[2], gall bladder contraction[3], small bowel motility[4], small bowel water content[5] and whole gut transit[6] in this cohort.
Methods: Ten healthy participants (5 male, age 32 (11) yrs) were recruited for this study MRI scanning was carried out on a 1.5T Philips Achieva scanner. The subjects were asked to swallow five MRI transit marker capsules (20 mm x 7 mm) at 09:00 am, 24 h before undergoing an MRI scan[6] and fasted from 2000 h the night before. On the day of the scan, a baseline fasting scan at 0900 hours was acquired. At 0925 hours, subjects were asked to consume a soup meal (Heinz cream of chicken 204 kcal, 11.8g fat or mushroom soup 214 kcal, 11.4g, 400g) within 20 min with the first immediate postprandial scan acquired at 0945 hours. Data collection time points were every 15 min for the first 60 min and every 30 min up to 270 min. At each time point scans were acquired to assess gastric volume, gall bladder volume, small bowel water content and small bowel motility, 2 additional scans were acquired at baseline to determine the position of the transit pills.
Results: Data is presented as mean (standard deviation (SD)). All participants completed the study. In the immediate postprandial state, the gastric volume was 416 (73) mL. The mean half-life of the meal in the stomach was 41 (20) min. The gall bladder maximum ejection fraction was 59 (19) % which occurred within the first 60 minutes postprandially. The fasted small bowel contained a total volume of 41 (27) mL of resting water. Postprandially this small bowel water content rose to a maximum value of 107 (46) mL. Across the 10 volunteers, a motility index based on the SD of signal intensity across the small bowel rose by 47 (30) % postprandially . The mean whole gut transit as measured through a weighted average position score[6] was 1.9 (1.5).
Conclusion: This novel paradigm is feasible and well tolerated by participants. The soup meal challenge was effective in inducing a change in multiple measured end-points, monitoring markers of GI motility in a single visit. This methodology may be applied to a variety of disease groups to understand alterations in GI physiology, allowing us to identify symptom biomarkers to target pharmacologically.

Introduction: Multiphoton endomicroscopy is the recentely updated technique for endoscopy and virtual image and optical sectioning. However optimized probe has not been established for multiphoton endomicroscopic image. Therefore we developed novel probe for mitochondria and applied for colon neoplasm tissues. In cancer cell, abnormally increased mitochondrial replication is related mitochondrial dysfunction and Warburg effect.[1]
Aims & Methods: We used newly developed multiphoton probe for micochondria imaging which are made using benzofuran derivative (BFP, maximal multiphoton fluorescence at 570 nm). Fresh mucosal tissues of colonic adenoma and adenocarcinoma were obtained from endoscopic biopsy. Multiphoton probe BFP for mitochondria was stained for tissues and imaging performed using multiphoton microscopy.
Results: BFP shows high enhancement factor upon binding mitochondria, good selectivity, cell permeability, and can readily detect mitochondria in human tissues by multiphoton microscopy. Mitochondria were detected in human colon mucosa tissues. Calculated mitochondria area were increased in adenocarcinoma tissues compared to normal mucosal tissues.
Conclusion: Newly developed multiphoton probe for mitochondria are usable to image human live colon tissues. Mitochondrias are increased in colon cancer tissues compared to normal colon mucosa tissues.

Ospedali Galliera, genoa,* [5]*Unit of Gastroenterology, Department of Surgery, Oncology and Gastroenterology, university of Padua, Padua, Italy*

Introduction: Abdominal CT may have a role in the loco-regional evaluation of rectal cancer, besides systemic staging. The discrimination between intra- and extraperitoneal rectal cancer has important implications for both oncologic and surgical grounds. Indeed, based on intra- and extraperitoneal location the therapeutic approach may change because of the different risks of local recurrence and different prognosis.
Aims & Methods: Aim of the study was to compare the diagnostic performance of CT with that of MRI to determine the intra- or extraperitoneal location of rectal cancers, using surgical exploration as reference standard. We

Abstract number: P0243

Sensitivity	Specificity	Post-test probability for positive US result at prevalence 76.4%	Post-test probability for negative US result at prevalence 76.4%
69% (95% CI 59% to 78%)	81% (95% CI 73% to 88%)	92% (95% CI 88% to 95%)	55% (95% CI 46% to 63%)

retrospectively evaluated MRI and CT examinations of patients with rectal cancer defining the extra- or intraperitoneal location of tumor's inferior edge with respect to the anterior peritoneal reflection (APR). We assessed the quality of identification of the APR according to a 4-point confidence scale and we measured the distance from the inferior edge of tumors to the anal verge and from the APR to the anal verge.

Results: Thirty-eight patients were included: 24 men and 14 women with a mean age of 68.8 ± 9.4 years. The APR was appreciable in all MRI examinations and in 36/38 patients on CT images. Mean distances from the APR to the anal verge were 98.97 ± 18.8 mm at MR and 100.6 ± 12.9 mm at CT ($p = 0.6653$, t-test for independent samples). MR showed sensitivity of 100% (95% CI: 89.62-100.00%), specificity of 75% (95% CI: 20.34-95.88%), positive predictive value of 97.14% (95% CI: 85.03-99.52%), negative predictive value of 100% (95% CI: 30.48-100.00%). Diagnostic performance of CT was: sensitivity 100% (95% CI: 89.32-100.00%), specificity 60% (95% CI: 15.40-93.51%), positive predictive value 94.29% (95% CI: 80.81-99.13%), negative predictive value 100% (95% CI: 30.48-100.00%). The mean distance from the inferior edge of tumors to the anal verge was 62.3 ± 21.2 mm at MR and 62.5 ± 20.1 mm at CT ($p = 0.8181$ Mann-Whitney test for independent samples), with a strong correlation (Spearman's coefficient of rank correlation (rho): 0.995; $p < 0.0001$).

Conclusion: The results of our study confirm the great clinical value of MRI in determining the location of rectal cancers by direct visualization of APR in preoperative setting; CT demonstrated a potential supporting role in the evaluation of rectal cancer, showing a strong correlation with MRI in regarding measurements of the distance betweenthe tumor's inferior edge and the anal verge.

P0243 ABDOMINAL ULTRASOUND FOR DIAGNOSIS OF ACUTE APPENDICITIS: SYSTEMATIC REVIEW AND META-ANALYSIS OF DIAGNOSTIC ACCURACY STUDIES

V. Giljaca[1], T. Nadarevic[2], G. Poropat[1], D. Stimac[1]
[1]*Gastroenterology,* [2]*Radiology, University Hospital Centre Rijeka, Rijeka, Croatia*

Introduction: Acute appendicitis (AA) is one of the most frequent causes of acute abdominal pain (1, 2). Clinical signs of AA have overall diagnostic accuracy for the disease of about 80% (3). Reported sensitivity and specificity of abdominal ultrasound (US) for diagnosis of AA is up to 92% and 96%, respectively (4, 5). The reported negative appendectomy rate is up to 34% (6, 7).

Aims & Methods: The aim of this systematic review was to determine diagnostic accuracy of US for diagnosis of AA. Medline, Embase, The Cochrane library and Science Citation Index Expanded from January 1994 to October 2014 were systematically searched. The reference standard for evaluation of final diagnosis was pathohistological report from the tissue obtained on appendectomy. Summary sensitivity, specificity and post-test probability of AA after positive and negative result of US with corresponding 95% confidence intervals (CI) were calculated. The pre-test probability was defined as the prevalence of AA in the population of included studies. Review Manager 5 (8) and METADAS macro for SAS were used for statistical analysis (9). Methodological quality of included studies was evaluated using Quality Assessment in Diagnostic Accuracy Studies 2 (QUADAS-2) tool (10).

Results: There were 3,306 references identified through electronic searches. Full-texts of 296 reports were assessed for inclusion, out of which 17 reports met the inclusion criteria. A total of 2,841 participants were included in the analysis. None of the included studies were of high methodological quality. The results of meta-analysis are presented in the Table. The result of sensitivity analysis did not significantly influence summary results of the main analysis.

Conclusion: Abdominal ultrasound does not seem to have a role in the diagnostic pathway for acute appendicitis. The sensitivity and specificity of US do not seem to exceed that of clinical examination. Patients with lower clinical probability of having AA that require additional diagnostic workup should be referred to more sensitive and specific diagnostic procedures, such as computed tomography.

Introduction

Background/Aims: Benign biliary strictures (BBSs) have been endoscopically managed with plastic stent placement. Fully covered self-expandable metal stents (FCSEMSs) are gaining acceptance for the treatment of BBSs. We performed a large prospective study to analyze the clinical outcomes; following endoscopic treatment data regarding fully covered self-expandable metal stents (FCSEMSs) in BBS patients remain scarce in Rio de Janeiro.

Aims & Methods: Methods: In a nonrandomized study a single center, 263 patients (145 men, 55%) with BBSs underwent FCSEMS placement between January 2012 and March 2015. Efficacy and safety were evaluated retrospectively. Patients were considered to have resolution if they showed evidence of stricture resolution on cholangiography and if an inflated retrieval balloon easily passed through the strictures at FCSEMS removal.

Results: The mean FCSEMS placement time was 6.2 (1.0-12.2) months. Patients were followed for a mean of 10.2 (1.0-36.0) months after FCSEMS removal. The BBS resolution rate was confirmed in 241 of 263 (92%) patients who underwent FCSEMS removal. After FCSEMS removal, 36 of 241 (15.8%) patients experienced symptomatic recurrent stricture and repeat stenting was performed. When a breakdown by etiology of stricture was performed, 17 of 20 (85%) patients with chronic pancreatitis, 53 of 53 (100%) with gall stone-related disease, 57 of 61 (93%) with surgical procedures, pancreatic collections 45 of 47 (93.3%), Endoscopic complications (perforation and bleeding) 14 of 14 (100%) and 55 of 68 (80%) with BBSs of other etiology had resolution at FCSEMS removal. Complications related to stent therapy occurred in 40 (15%) patients, including pain (n = 23), proximal migration (n = 10), cholecystitis (n = 1), distal migration (n = 2), and occlusion (n = 4).

Conclusion: Endoscopic treatment of temporary FCSEMS placement in BBS patients is safe and effective and can be considered a first-choice alternative to surgical and/or plastic stenting. The potential benefits and risks should be evaluated in further investigations.

P0245 USE OF PARTIALLY COVERED AND UNCOVERED METALLIC PROSTHESIS (GIOBOR STENT) FOR ENDOSCOPIC ULTRASOUND-GUIDED HEPATICOGASTROSTOMY: RESULTS OF A RETROSPECTIVE MONOCENTRIC STUDY

C. De Cassan[1], **E. Bories**[1], C. Pesenti[1], F. Caillol[1], S. Godat[1], J. P. Ratone[1], J. R. Delpero[1], M. Giovannini[1]

Introduction: Endoscopic ultrasound-guided hepaticogastrostomy (EUS-HGS) represents an option to treat obstructive jaundice when endoscopic retrograde cholangio pancreatography (ERCP) fails, in alternative to surgery or percutaneous transhepatic biliary drainage (PTBD). The success rate of this technique has been shown to be very high, with resolution of jaundice in up to 98.5% of cases. Up to now plastic and covered or uncovered self-expandable metallic stents (SEMS) have been used, each of them presenting some limitations.

Aims & Methods: Aims of this study were to evaluate the technical and functional success of EUS-HGS using a dedicated biliary SEMS with a half covered part (GioBor stent- Taewoong Medical ®). We retrospectively reviewed data of patients who underwent EUS-HGS at our centre, with at least 6 months of follow up. Demographics, clinical and laboratory data were extracted from the patient's charts and electronic records. Technical success was defined as the passage of the GioBor stent across the stomach, along with the flow of contrast medium and/or bile through the stent, while functional success as the decrease of bilirubin value of at least 25% of the pre-treatment value within the first week. The rate of early (in the first month after EUS-HGS) and late (at 6 months follow up) complications was assessed.

Results: A total of 41 patients were included (21F/20M, mean age 66, range 45-65). Obstructive jaundice was due in most of patients (39/41, 95%) to a malignant disease. Reasons to EUS-HGS were failed biliary cannulation in 18 patients (44%) and failed bile duct decompression in 24 patients (56%). Technical success was obtained in 37/41 patients (90%), while functional success, measurable in only 29 patients, was obtained in 19/29 patients (65%). Thirteen patients (33%) presented an early complication, mostly represented by infectious complications. At six months follow up, 10/37 patients (27%) required a new biliary drainage and 11/37 (30%) died because of their disease.

Conclusion: EUS-HGS using GioBor stent is technically feasible, clinical effective, safe and may be an alternative to PTBD in case of ERCP failure for biliary decompression. Randomized controlled studies comparing GioBor prosthesis with "classical" SEMS are needed to confirm these preliminary results.

Introduction: Although covered self-expandable metallic stent (SEMS) has longer patency than uncovered SEMS in patients with unresectable malignant distal biliary obstruction, the complication rate of covered SEMS are quite different among the stents due to their mechanical properties. Niti-S SUPREMO (Tae Woong Medical) is a newly developed fully-covered SEMS with lower axial force than a standard Covered WallFlex (Boston Scientific) stent.
Aims & Methods: We retrospectively analyzed the outcome of both types of covered SEMS in patients with unresectable malignant distal biliary obstruction. Medical records were retrospectively reviewed for consecutive patients with unresectable malignant distal biliary obstruction who underwent placement of Covered WallFlex between April 2009 and March 2011 (group W) and Niti-S SUPREMO 10 between April 2011 and June 2014 (group S). Background characteristics, procedure-related complications and long-term stent dysfunction were compared between the groups.
Results: Seventy-one patients were analyzed (25 vs. 46 in group W vs. group S, respectively). There were no significant differences in patient characteristics; median age of 65 vs. 67, male gender in 52% vs. 52%, perfomance status of 0 in 64% vs. 67%, pancreatic cancer in 93% vs. 94%, and receiving chemotherapy in 78% vs. 93%. Procedure-related complications were significantly higher in group W; acute pancreatitis in 8% vs. 0% ($p = 0.04$) and acute cholecystitis in 12% vs. 0% ($p = 0.01$). Stent dysfunction were seen in 16% vs. 28% ($p = 0.27$) and median time to stent dysfunction by Kaplan-Meier method were 196 days vs. 150 days ($p = 0.50$ by log-rank test). The median overall survival time were 259 days vs. 244 days ($p = 0.84$).
Conclusion: Niti-S SUPREMO, a newly developed covered SEMS with lower axial force, decreased the risk of procedure related complications of acute pancreatitis and acute cholecystitis compared with covered WallFlex without significant differences in long-term outcomes.

Contact E-mail Address: m-kitano@med.kindai.ac.jp
Introduction: Endoscopic placement of self expandable metal stents (SEMSs) has been pivotal in providing relief from obstructive jaundice in patients with biliary stricture. Covered SEMSs tend to show a higher rate of stent migration than uncovered SEMSs, which is the most important issue to be resolved during deployment of the covered SEMSs for biliary stricture. Stent properties such as the stent framework, flare structure and radial force (RF) may prevent stent migration.
Aims & Methods: The purpose of the study was to measure the anti-migration potential of 6 different covered SEMSs including 5 braided types and one laser-cut type using a phantom model inducing migration of biliary SEMSs, and to evaluate whether RF and flare structure contribute to the anti-migration potential.
Anti-migration potential was measured using a phantom model for migration. The metal stents were fixed at a round hole of silicone walls of three types of hole diameter, 6, 8 and 10 mm. The distal end of the stent was fixed at a force gauge device. During experiments, the distal end of the stent with the force gauge device was retracted at a speed of 1mm/sec. using the retraction robot. The force of the resistance of the stent to the retraction (resistance force to migration; RFM) was measured from starting retraction of the stent to dislocating the distal end of the stent from the silicone wall.
The RF was measured by using a radial force measurement machine when the stent was compressed to 6, 8 and 10 mm in outer stent diameter.Three variables of stent flare structure including outer diameter of the flare (ODF), height of the flare (HF) and taper angle of the flare (TAF) were measured. The correlations between RF and RFM as well as between variables of the stent flare structure and RFM were analyzed.
Results: The smaller the compressed outer diameter of the stent (CODS), the higher the RFM and RF exhibited for all the 6 SEMSs. The laser-cut SEMS has higher RFM than any braided SEMSs whether the stent fully expands or not. A strong correlation between RF and RFM was observed when CODS was 6 mm ($r = 0.849$), but there was no strong correlation when the CODS was 8 or 10 mm. In addition, when the stent fully expanded (CODS was 10 mm), only TAF ($r = 0.837$) closely correlated with RFM in all the 6 SEMSs, and ODF ($r = 0.952$), HF ($r = 0.943$) and TAF ($r = 0.906$) closely correlated with RFM in 5 braided SEMSs. When the stent not fully expanded state (CODS was 6 or 8 mm), there was no strong correlation between three variables of stent flare structure and RFM.
Conclusion: The RF plays an important role in anti-migration when the covered SEMS not fully expanded state. In the fully expanded covered SEMS, the stent flare structure is strongly related to the anti-migration potential. The laser-cut stent potentially possesses extremely higher resistance force to migration whether the stent fully expands or not. The stent properties including radial force, flare structure and stent framework should be considered before selecting covered SEMS for biliary stricture.

P0249 EFFICIENCY AND SAFETY IN CASE OF TECHNICAL SUCCESS OF EUS-GUIDED TRANSHEPATIC ANTEGRADE BILIARY DRAINAGE. REPORT OF A MONOCENTRIC STUDY

S. Godat[1], E. Bories[1], F. Caillol[1], C. Pesenti[1], J.-P. Ratone[1], C. De Cassan[1], M. Giovannini[1]
[1]*Gastroenterology, Paoli-Calmettes, Marseille, France*

Contact E-mail Address: tagodat@gmail.com
Introduction: EUS-guided biliary drainage like choledochoduodenostomy, hepaticogastrostomy, antegrade stenting and rendezvous are alternative procedures in case of obstructive jaundice and altered anatomy or failed endoscopic-retrograde-cholangiography (ERCP). Complications related to EUS-guided antegrade drainage (EUS-GAD) are still described as substantial in up to 10%. Combination of procedures is sometimes suggest to avoid adverse events like biliary leakage, even in case of primary successful EUS-GAD.
Aims & Methods: Aims of this study were to evaluate the efficiency and safety of EUS-GAD with transhepatic access in case of technical success. We retrospectively reviewed computer data collected between 2006 and 2015 of patients with malignant and non-malignant biliary obstructive lesions who underwent EUS-GAD in a single, tertiary care center.
Results: A total of 20 patients were included (9F/11M, mean age 68, range 40-90, mean ASA score 2). Obstructive jaundice was due in most case to a malignant disease (19/20 patients, 95%). Reasons for EUS-GAD was failed ERCP in 13/20 (65%), duodenal stenosis in 4/20 (20%), altered anatomy after surgical intervention in 3/20 (15%). Intrahepatic biliary duct puncture was done with a 19G EchoTip® Ultrasound Needle in 16/20 (80%), with an EchoTip® Ultrasound Access Needle in 7/20 (35%). The hepaticogastric tract was performed in 20/20 with a cystostoma 6 fr, without puncture site closure at the end of procedure. Stenosis dilatation was done in 3/20 (15%) and calibration with cystostoma 6 fr in 9/20 (45%). SEMS was transpapillary in 19/20 (95%) and non transpapillary in 1/20 (5%). Drainage was completed in intraoperative stage in 2/20 (10%), once by hepaticogastrostomy and once by percutaneous drainage of the right liver. Clinical success was 17/20 (85%). 1/20 (5%) patient presented a persistent obstructive infectious cholangitis treated by another SEMS via ERCP. 2/20 (10%) patients died of infectious complication and incomplete drainage in case of advanced cancerous disease. One of these 2 patients was treated by EUS-GAD and hepaticogastrostomy in same time. None patients developed bilioma or bile leakage. 2/20 patients were treated later by an endoscopic duodenal SEMS for a duodenal obstruction.
Conclusion: EUS-GAD by transhepatic way is clinical effective and a safety method to treat biliary obstructive disease, in case of technical success. Closure of the gastric puncture site is not mandatory if drainage is efficient. Complementary method for biliary decompression should be combined in case of incomplete drainage and not to prevent potential adverse events. Additional studies are needed to target the most appropriate patient's characteristics to undergo this type of intervention.

Contact E-mail Address: takuji@w7.dion.ne.jp
Introduction: Therapeutic ERCP for malignant biliary obstruction (MBO) in patients with surgically altered anatomy (SAA) is challenging even with application of enteroscopies. Percutaneous transhepatic biliary (PTB) or surgical approach is common alternatives for failed enteroscopy-based ERCP, but is associated with considerable complications.
Aims & Methods: The aim of this study was to evaluate the feasibility and safety of EUS-antegrade biliary stenting (EUS-ABS) for MBO in patients with SAA in prospective cohort.
EUS-ABS for unresectable MBO was attempted in 20 patients with SAA between 8/2012 and 2/2015. EUS-ABS was performed as follows: The left intra-hepatic bile duct (IHBD) was initially punctured from the intestine followed by cholangiography and antegrade guidewire manipulation. ABS with uncovered metallic stent was performed. A naso-biliary drainage tube (NBD) was placed if necesssary.
Results: SAAs were gastrectomy with Roux-en-Y reconstruction in 18, BillrothII reconstruction in 1, and hepatectomy with biliary reconstruction in 1. Biliary puncture was successful in 95% of the patients (19/20). In the patient with failed biliary puncture, inadequate biliary dilation did not allow EUS-guided puncture. The guidewire placement and subsequent ABS were successful in 19. Therefore, the overall technical success rate was 95% (19/20). NBD was placed in 3 and was removed in a median of 7 days. A median procedure time was 37 min (22-80). Adverse events were recognized in 20% of the patients (4/20) and were fever-up in 1 and mild pancreatitis in 3.
Conclusion: EUS-ABS for MBO in patients with SAA is feasible and can be an option as a safe and effective alternative. Further studies are warranted.

Introduction: Laparoscopic Sleeve Gastrectomy (LSG) is a bariatric procedure with documented efficacy at short and midterm follow-up but there are only few data at long term follow-up.
Aims & Methods
Aim: To evaluate the long-term results of LSG describing the effect on GERD symptoms.
Methods: 105 obese patients eligible for bariatric surgery underwent LSG. According to the preoperative BMI obese patients were divided in two Groups: Group 1 (N = 61, patients with preoperative BMI $\leq$ 50 Kg/m^2) and Group 2 (N = 44, patients with preoperative BMI > 50 Kg/m^2). All underwent a preoperative assessment including evaluation of comorbidities, standardized GERD questionnaire, a double-contrast barium swallow, an upper-gastrointestinal endoscopy. At 5 years after LSG the following data were collected: BMI, GERD symptoms, modification of comorbidities, complications. The adopted criteria of surgical success were BMI $\leq$ 35 kg/m^{2}in patients of Group 1 and BMI $\leq$ 40 kg/m^{2}in patients of Group 2.
Results: Table 1 showed the demographic characteristics and prevalence of some comorbidities in the two groups of the study before LSG

	Group 1 N = 61/105 (58.1%)	Group 2 N = 44/105 (41.9%)	p
Weight, kg	**114.2 ± 19.0**	**161.70 ± 19.76**	**< 0.001**
BMI, kg/m^2	**41.2 ± 4.7**	**57.25 ± 5.60**	**< 0.001**
Age, yr	**39.9 ± 10.1**	**38.5 ± 11.5**	**0.51**
Women, n (%)	**44 (72,1)**	**23 (52,3)**	**0.04**
Hypertension	**19 (31.1%)**	**14 (31.8%)**	**0.88**
Hyperlipidemia	**20 (32.8%)**	**22 (50%)**	**0.11**
Type 2 diabetes	**11(18%)**	**9 (20%)**	**0.9**
Typical GERD symptoms	**19 (31%)**	**11 (25%)**	**0.6**

At 5 years of follow-up, the success rate (BMI < 35) was achieved in 85.5% of Group 1 and in 62.9% of Group 2 (p = 0.01). Among the patients of Group 1: 73.3% referred the resolution, 26.7% the persistence and 15% the new onset of GERD complaints. Among the patients of Group 2, 44.4% referred the resolution, 55.6% the persistence and 7.7% the new onset of GERD complaints. Patients of Group 1 that did not meet the criteria of surgical success (BMI < 35) at 5 years of follow-up showed a similar prevalence of postoperative GERD symptoms compared to patients who showed a surgical success according to the adopted success criteria (p = 0.52). On the other hand, the patients of Group 2 that did not meet the criteria of surgical success (BMI < 40) at follow-up reported an higher prevalence of GERD symptoms (p = 0.03).
Conclusion: LSG is an effective treatment and showed good weight loss outcome and resolution of comorbidities also on long term follow-up; although the success rate was significantly lower in pazients with preoperative BMI > 50. A good percentage of patients with resolution of GERD symptoms was observed. However in patients with preoperative BMI > 50 who failed to reach the success criteria, there was a high percentage of GERD persistence or new onset.

P0252 CLINICOPATHOLOGIC PROFILES AND CLINICAL OUTCOMES OF RECURRENCE AND MORTALITY OF PATIENTS WITH GASTROINTESTINAL STROMAL TUMORS AT THE PHILIPPINE GENERAL HOSPITAL

A. Q. Taguba[1], J. M. L. Balbuena[2], G. C. O. Floro[3], E. I. Q. Villanueva[4], M. A. A. De Lusong[1]
[1]*Department of Medicine, Section of Gastroenterology,* [2]*Department of Medicine, Section of Medical Oncology,* [3]*Department of Medicine,* [4]*Department of Laboratories, University of the Philippines - Philippine General Hospital, Manila, Philippines*

Contact E-mail Address: aubreytaguba@gmail.com
Introduction: Gastrointestinal stromal tumors (GIST) occur in less than 1% of all digestive tumors, but are the most common mesenchymal neoplasms of the gastrointestinal tract. This is the first study that described the clinicopathologic profiles and clinical outcomes of recurrence and mortality of GIST patients at the Philippine General Hospital (PGH).
Aims & Methods: This was a retrospective, descriptive study including all biopsy-proven GIST cases in PGH from 2009 to 2014. Data from the review of hospital records were encoded and analyzed using Microsoft Excel.
Results: A total of 58 patients were included. Median age at diagnosis was 50 years, with female to male ratio of 1.3. Most common primary site was stomach (39.7%). Median duration of symptoms prior to first consult was 6 months. Most common presenting symptom was abdominal pain (37.9%). Mean size of primary tumor was 7.6 cm. Immunohistochemical staining result for CD 117 was positive in 63.8%. Five percent was noted to have unresectable metastatic disease at presentation. Liver was the site of metastasis for all these cases. Ninety-five percent underwent surgery and 100% of which was reported to have R0 resection. Majority were stratified as low risk (46.6%), followed by high risk (43.1%), then moderate risk (8.6%). After a median follow up of 32.5 months, 7.3% developed local recurrence and 5.1% was reported as mortality.
Conclusion: This hospital-based study showed that the clinicopathologic profile of GIST in PGH is comparable to other population-based studies. Survival was favorable in completely resected cases and in lower-risk groups.
Disclosure of Interest: None declared

P0253 NON-EXPOSURE ENDOSCOPIC FULL-THICKNESS RESECTION WITH SIMPLE SUTURE TECHNIQUE, A PRELIMINARY RANDOMIZED COMPARATIVE ANIMAL STUDY

C. G. Kim[1], H. M. Yoon[1], J. Y. Lee[1], S.-J. Cho[1], B. W. Eom[1], K. W. Ryu[1], Y.-W. Kim[1], I. Choi[1]

Contact E-mail Address: glse@ncc.re.kr
Introduction: Recently, endoscopic full-thickness resection (EFTR) with simple suture technique which did not expose gastric mucosa to peritoneum was developed. This new technique includes the steps of laparoscopic seromuscular suturing with a barbed suture thread (V-Loc), which results in inversion of the stomach wall; EFTR of the inverted stomach wall from inside the stomach; and finally, endoscopic mucosal suturing with endoloops and clips.
Aims & Methods: The aim of this study was to assess the outcome of EFTR using simple suture technique compared with that of laparoscopic wedge resection using linear stapler in animal model.
Preliminary analysis of prospective, randomized, controlled animal study. EFTR group (n = 4) use the method of EFTR with simple suture technique and linear stapler group (n = 4) use laparoscopic linear stapler for resection and suturing. Locations were cardia, upper body anterior side, upper body greater curvature, and antrum lessor curvature side of stomach. Successful complete resection (en-bloc resection with clear resection margin) rates and successful closure rates and complications of each group were evaluated.
Results: Complete resections rates were 100% of EFTR group and 50% of linear stapler group. Successful closure rates were 100% in both groups. Complications were developed in only linear stapler group (a leakage at cardia and a stenosis at antrum). The procedure time were significantly shorter in linear stapler group (mean ± SD; 29.5 ± 12.7 min) than EFTR group (112.3 ± 27.4 min, p = 0.002). The sizes of resected tissue were significantly larger in linear stapler group (mean ± SD; 7.4 ± 0.9 cm) than EFTR group (4.6 ± 0.7 cm, p = 0.002).
Conclusion: Outcome of non-exposure EFTR with simple suture technique was compatible with that of laparoscopic wedge resection using linear stapler in preliminary study. Completion of study is needed.

P0254 RISK FACTORS FOR MARGINAL ULCER AFTER GASTRIC BYPASS SURGERY FOR OBESITY

E. Sverdén[1,2], F. Mattson[2], A. Sondén[1], T. Leinsköld[1], W. Tao[2], Y. Lu[2,3], J. Lagergren[2,4]
[1]*Department of Upper Gastrointestinal Surgery, South Hospital,* [2]*Upper Gastrointestinal Surgery, Department of Molecular Medicine and Surgery, Karolinska Institutet, Stockholm, Sweden,* [3]*Department of Epidemiology and Biostatistics, Imperial College,* [4]*Division of Cancer Studies, Kings College, London, United Kingdom*

Contact E-mail Address: emma.sverden@sodersjukhuset.se
Introduction: Marginal ulcer (MU) is a common and potentially serious complication of gastric bypass surgery (GBP) for obesity, but little is known about its etiology.
Aims & Methods: The study aimed to asses risk factors for MU. This population-based cohort study of GBP in Sweden in 2006-2011 evaluated MU in relation to exposure to diabetes, hyperlipidemia, hypertension, chronic obstructive pulmonary disease (COPD), ulcer history, and use of proton pump inhibitors (PPIs), aspirin, non-steroidal anti-inflammatory drugs (NSAIDs), and selective serotonin re-uptake inhibitors (SSRIs). Multivariable Cox proportional hazard regression models estimated hazard ratios (HRs) and 95% confidence intervals (CIs), adjusted for confounding.
Results: Among 20,294 GBP patients 2006-2011, diabetes and peptic ulcer history entailed statistically significantly increased risk of MU (HR = 1.26, 95%CI 1.03-1.55 and HR = 2.70, 95%CI 1.81-4.03), while hyperlipidemia, hypertension and COPD did not. PPI users had an increased HR of MU (HR = 1.37, 95%CI 1.17-1.60). Aspirin and NSAID consumption $\leq$median entailed decreased HRs of MU (HR = 0.56, 95%CI 0.37-0.86 and HR = 0.30, 95%CI 0.24-0.38), while aspirin and NSAID users > median had an increased risk and no association with MU, respectively (HR = 1.90, 95%CI 1.41-2.58 and HR = 0.90, 95%CI 0.76-1.87). SSRI use $\leq$median had a decreased risk of MU (HR = 0.50, 95%CI 0.37-0.67), while use > median entailed increased HR (HR = 1.26, 95%CI 1.01-1.56).
Conclusion: Diabetes and peptic ulcer history seem to be risk factors for MU, but not hyperlipidemia, hypertension, or COPD. Limited doses of aspirin, NSAIDs and SSRIs might not increase the risk of MU, while higher doses of aspirin do. The association with PPI could be due to confounding by indication.

P0255 PREDICTING DIETARY INTAKE AFTER DISCHARGE FOLLOWING UPPER GASTROINTESTINAL SURGERY USING DIET DIARIES AND A GASTRIC ACCOMMODATION TEST PRIOR TO HOSPITAL DISCHARGE

F. Froghi[1], G. Sanders[1], T. Wheatley[1], R. Berrisford[1], P. Peyser[1], J. Rahamim[1], S. Lewis[2]
[1]*Upper GI Surgery,* [2]*Gastroenterology, Derriford Hospital, Plymouth, Devon, UK, Plymouth, United Kingdom*

Contact E-mail Address: farid.froghi@nhs.net

Introduction: Patients undergoing upper gastrointestinal surgery are often malnourished and following hospital discharge eat poorly despite dietetic input. The 'slow satiety' drinking test has been used to assess impaired gastric accommodation in functional dyspepsia. We examined if a drinking test done along with a 2 day diet diary could predict dietary intake post hospital discharge.

Aims & Methods: Prior to discharge, patients undergoing an oesophagectomy or total gastrectomy for cancer completed a 2-day dietary diary and underwent a gastric accommodation test. The accommodation test comprised of drinking 20ml/min of polymeric sip feed until they felt comfortably full. After hospital discharge patients completed 2 day dietary diaries at 3, 6 and 12 weeks. The diaries were analysed using Dietplan 6 and tabulated. We calculated energy intake as absolute intake (Kcal) and % of calculated requirement (using the Harris-Benedict formula). The accommodation test (volume of feed taken and time taken) were correlated (pearsons) with energy intake at hospital discharge. The accommodation test results and energy intake at hospital discharge were also correlated with energy intake at 3, 6 and 12 weeks post discharge.

Results: 28 patients (22 men), median age 66 (IQ range 60, 74) were recruited, oesophagectomy = 18 Gastrectomy 10.

There was no correlation between the accommodation test and actual energy intake or % of required energy intake at hospital discharge.

Accomodation test		Energy (Kcal) intake as % of calculated requirements			
Volume (ml)	Time (min)	Discharge	3 weeks	6 weeks	12 weeks
106 (72, 140)	389 (244, 534)	66 (58, 74)	78 (69, 87)	79 (71, 88)	90 (77, 102)
	Correlation coefficient		0.34	0.43	0.40
	P value		0.078	0.023	0.034

Dietary energy intake (Kcal) at hospital discharge did not correlate with post discharge energy intake, but when expressed as a % of calculated requirements there was a correlation at 6 and 12 weeks. The volume of feed consumed and time taken to drink the sip feed for the accommodation test did not correlate with post discharge dietary intake.

Conclusion: Energy intake at hospital discharge was modest and increased slowly to reach 90% of requirements at 12weeks. There was only a weak correlation between dietary records done just prior to hospital discharge and those done at 6 and 12 weeks. There was no correlation between the gastric accommodation test and post discharge dietary intake. Neither the gastric accommodation test or 2 day dietary records done just before hospital discharge after upper gastrointestinal surgery predicted post discharge dietary intake.

Contact E-mail Address: h.t.kunzli@amc.uva.nl

Introduction: The distribution of lymph node metastases in oesophageal adenocarcinoma is not well studied. LN status is an important prognostic factor in oesophageal carcinoma. Distribution of metastatic LN may be influenced by tumor location, invasion depth and neo-adjuvant chemoradiation therapy. For the extent of the radiation field, as well as the extent of the lymphadenectomy it is essential to elucidate the distribution pattern of lymph node metastases.

Aims & Methods: To describe the distribution pattern of lymph node metastases in oesophageal adenocarcinoma and to identify lymph node echelons with high risk of metastases, adjusted for primary tumor location.

Between April 2014 and April 2015, all patients with an oesophageal adenocarcinoma undergoing transthoracic oesophagectomy with a complete 2 field lymphadenectomy were reviewed. In all patients the lymph node stations according to the 7th edition of the AJCC classification were excised and separately sent for histopathological examination. Patients were excluded if they were diagnosed with an oesophageal squamous cell carcinoma, or when a salvage resection was performed.

Results: 43 patients (36 male, mean age 64 years) were included. An adenocarcinoma of the distal oesophagus was diagnosed in 40 patients, while 3 patients were diagnosed with an adenocarcinoma of the mid-oesophagus. 84% of patients were neo-adjuvantly treated with chemoradiation. A median of 36 (IQR 27-44) lymph nodes were resected.

Lymph node metastases were found in 22/43 (51%) patients, of which 2 patients (9%) were not treated with neo-adjuvant chemoradiation therapy. A median of 3 (IQR 1-10) tumour-positive lymph nodes were found.

Lymph node metastases were observed most frequently in the paracardial lymph node stations (9/22 patients, 41%: right vs. left = 4 vs. 5 patients), in lymph nodes around the left gastric artery (7/22, 32%), and in station 2R (paratracheal: 6/22, 27%). Ten out of 22 patients (45%) diagnosed with lymph node metastases, had tumour-positive lymph nodes above and below the diaphragm.

Conclusion: Oesophageal adenocarcinoma frequently metastasizes to both the mediastinal and abdominal lymph node stations. Paracardial lymph nodes, in close proximity to the primary tumor, have the highest risk of lymph node metastases.

P0257 SURVIVAL AFTER OESOPHAGECTOMY FOR CANCER PRE- AND POST- COMPUTED TOMOGRAPHY- POSITRON EMISSION TOMOGRAPHY (CT-PET) INCEPTION

J. Wheat[1], P. Blake[1], A. Karran[1], D. Chan[1], K. Foley[1], A. Roberts[1], W. Lewis[1]
[1]*University Hospital of Wales, Cardiff, United Kingdom*

Contact E-mail Address: Wyn.Lewis4@wales.nhs.uk

Introduction: CT-PET is indicated and funded in the UK for staging potentially curable oesophageal cancers in order to identify those patients with occult distant metastases. It has become an integral component of the staging pathway. The aim of this study is to analyse the effect of CT-PET use on overall survival and assess the patterns of recurrence before and after CT-PET inception.

Aims & Methods: Consecutive 424 oesophagectomies performed for cancer [median age 62 (24-80) yr; 337 male; 360 Adeno, 64 Squamous cell carcinoma; 254 neoadjuvant therapy] were recorded in a prospectively-maintained database. 169 were performed after the routine use of CT-PET began. Primary outcome measure was overall survival based on intention to treat.

Results: Overall 5-year survival pre-CT-PET was 37%, post-CT-PET was 49% (Chi^2 4.991, df 1, $p < 0.025$). On multivariable analysis, pT stage (HR 1.497 [95% CI 1.344-1.667], $p < 0.001$) and pre- or post- CT-PET (HR 0.509 [95% CI 0.352-0.735], $p < 0.001$) were independently associated with survival. There were 119 (46.7%) recurrences in pre-CT-PET patients: 24.4% local; 58.8% distant; 16.8% both. Post-CT-PET patients had 33 (19.5%) recurrences: 27.3% local; 57.6% distant; 15.1% both.

Conclusion: The use of staging CT-PET independently improves overall survival in patients undergoing oesophagectomy for oesophageal cancer, although the patterns of recurrence remain unchanged.

Introduction: Sentinel node is defined as the first draining lymph node from the primary tumor, and sentinel node navigation surgery (SNNS) is a procedure in which the extent of surgery will be planned according to the metastatic status of sentinel node. Recently, SNNS has been investigated to avoid unneccesary extensive lympg node dissection in surgery for early gastric cancer (EGC). Various dyes and detecting methods were evaluated to acquire the accuracy of detecting sentinel nodes in SNNS for EGC.

Aims & Methods: The aim of this study is to investigatethe safety and feasibility of sentinel node mapping with a fluorescent dye and visible rayin the patients with gastric cancer.

Nineteen patients with gastric cancer, in whom laparoscopic distal gastrectomy with standard lymphadenectomy, were enrolled in this study. Before lymphadenectomy, they underwent endoscopic peritumoral injection of Fluorescein solution. The sentinel basin was investigated through inspecting the laparoscopic fluorescent imaging under a blue ray (wave length of 440-490 nm) emitted from a LED curing light.The detection rateand lymph node status were analyzed in the enrolled patients. In addition, short-term clinical outcomes were also investigated.

Results: Sentinel nodes were detected in18of 19enrolled patients (94.7%). Metastatic lymph nodes were found in two enrolled cases. These lymph nodes belonged to sentinel basin of each patients. Meanwhile, a patient (5.3%) underwent postoperative complication that had little relation with the sentinel node mapping. In all enrolled cases, nomortality was recorded.

Conclusion: The sentinel node mapping with visible light fluorescence was safe and effective at visualization of sentinel node. In addition, this method is superior than other fluorescent imaging techniques in visualizing the concrete correlation of sentinel node and surrounded structures.

P0259 WHAT IS THE BEST PROCEDURE FOR T1 TUMORS OF ESOPHAGO-GASTRIC JUNCTION ?

K. Noma[1], Y. Shirakawa[1], Y. Tsukumo[1], Y. Katsura[1], N. Maeda[1], S. Tanabe[1], K. Sakurama[1], M. Nishizaki[1], S. Kagawa[1], T. Fujiwara[1]
[1]*Gastroenterological Surgery, Okayama University Medical School, Okayama, Japan*

Contact E-mail Address: knoma@md.okayama-u.ac.jp
Introduction: There is still no consensus of surgical strategy for early stage tumor at esophago-gastric junction (EGJ). It is urgent issues to establish which stations of lymph node (LN) should be resected and to discuss which reconstruction is adequate for such patients that postoperative QOL is considered for their promised long-term survival.
Aims & Methods: The aim of this study is firstly to analyze our experienced 36 cases of pT1 EGJ tumor clinicopathologically and discuss appropriate LN resection fields and adequate reconstruction. Second is to introduce our novel reconstruction after lower esophagectomy and proximal gastrectomy, which is hand-sewn valvuloplastic esophagogastrostomy using ''double flap technique''.
This study included 36 patients with pT1 tumor from total 131 patients with EGJ tumors. LN stations are reviewed by Japanese classification of esophageal cancer 2nd English edition (1).
Results: A total of 36 patients, consisting of 28 with adenocarcinoma (AC), 6 with squamous cell carcinoma (SCC) and 2 with other subtypes were enrolled in the study. Location of tumors was E: 21, EG: 4, E=G: 2, GE: 4 and G: 5 patients. pT1b was noted in 27 patients and LN metastasis was observed in 13.9% (5/36). Lower mediastinal LN metastasis (#110) was observed in only 1 patient, who had sm3 tumor and 3cm of esophageal invasion (EI). Abdominal station (#1, #3) was observed in other 4 patients. Only 2 patients both of who were of subtypes tumors were died of the illness. One was a patient of malignant melanoma, who had 5 LNs metastasis in #1, #3 and was died of liver metastasis. The other was a patient of basaloid, who had vascular invasion without any LN metastasis and was died of liver metastasis and mediastinal recurrence after 48 months. 32 patients (88.9%) survived without any recurrence.
As consideration, pT1a was noted in 9 patients, suggesting the difficulty of preoperative accurate diagnosis. For tumors located mainly in G, LN dissection should be performed in stations conformed to the guideline of proximal gastrectomy (Japanese gastric cancer treatment guideline ver. 4), but for tumors located mainly in E #110 station should be resected in addition. With regard to prognosis, AC or SCC groups showed radical cure and will be expected long-term prognosis. For reconstruction, we have adopted the hand-sewn morphological and functional valvuloplastic esophagogastrostomy with ''double flap technique'' since 2011, which showed excellent clinical outcome without any medication for reflux esophagitis even when anastomosis was located in lower mediastinum. So far, as our department policy proximal gastrectomy with D1+ is standard and if EI is more than 2cm we performed intently #110 dissection in addition. Reconstruction is the ''double flap technique'' for first choice regardless of the anastomosis site.
Conclusion: In conclusion, in cT1 tumors it is important to set the appropriate LN dissection stations. In addition, since there is expectation of long-term prognosis, there also need to be considered suitable reconstruction for long-term postoperative QOL.

P0260 ENDOSCOPIC TREATMENT OF GASTRIC ANASTOMOTIC LEAKS AND FISTULAS SECONDARY TO BARIATRIC SURGERY: SINGLE-CENTER EXPERIENCE

A. Belaïd[1], N. Kouinche[1], Y. Hoebeke[2], F. Corbisier[2], P. Warzee[1]
[1]*Gastroenterology Unit,* [2]*Surgical Unit, Grand Hôpital de Charleroi, Charleroi, Belgium*

Contact E-mail Address: belaidaimen@gmail.com
Introduction: One of most feared complications of modern bariatric surgery is gastric anastomotic leak (GL). First-line treatment of leaks is external drainage collection and antibiotics. Treatment of the GL used clips, tissucol, Self-Expanding Metal endoprothesis (SEMS) and later pigtails. Endpoint of treatment is absence of contrast agent leakage on RX or CT.
Aims & Methods: We reviewed retrospectively 1794 cases of bariatric surgery performed in our hospital between 2008 and 2015 (Sleeve gastrectomy and Roux-en-Y gastric bypass). 19 patients were referred to gastro-enterologists for GL. Following treatments were used: SEMS exclusively (n:12), SEMS plus pigtails (n:1), SEMS then pigtails (n:2),double pigtails (n:3), clip (n:1).
Results: In SEMS group, the fistulas disappeared in most patients (12/13, 92.7%). In one patient, endoclip needed to be placed after removing the stent.
In the pigtails group, all patients responded (4/4,100%) to treatment.
Median hospitalization stay was 3.5 weeks in the SEMS group (n:13, 0.6-7.1w) and 1.1w in the pigtail group (n: 5, 1.1-4.42w).
Nineteen prosthesis (Ultraflex 3, Endoflex 11, Taewoong Medical 4, Life Partners Megastent (Barthet) 1) were used. Two patients were lost for follow up. Early migration occurred in 6/13 (46.1%) patients with SEMS. Longstanding nausea, vomiting, retrosternal pain and gastro oesophageal reflux occurred in more than half of patients with SEMS (8/13, 61.5%) vs none in the pigtail group (0/4).
Conclusion: SEMS are effective in treatment of GL. Tolerance is usually bad, especially after Sleeve gastrectomy. More recently, endoscopic placement of double pigtails was introduced for treatment of GL. Early results in selected patients are promising in terms of fistulas closure and tolerance. Further studies are required to confirm these preliminary results.

P0261 EVALUATION OF THE CLINICAL EFFICIENCY OF THE INTESTINAL BLOOD FLOW QUANTIFICATION BY USING INDOCYANINE GREEN (ICG) AS A NEAR-INFRARED FLUORESCENT IMAGING SYSTEM

D. Nakano[1], T. Yamaguchi[1], H. Matsumoto[1], K. Takahashi[1], Y. Nakayama[1], M. Amaki[1], S. Natsume[1]
[1]*Surgery, Tokyo Metropolitan Cancer and Infectious Diseases Center Komagome Hospital, Tokyo, Japan*

Introduction: Anastomotic leakage (AL) is one of the frequent complications in colorectal surgery. Although a principal factor of AL is thought to be vascular compromise, there is currently no accepted method to assess blood flow. To prevent AL, surgeons had to rely on the color of the intestine and the pulse of the marginal artery.
Aims & Methods: The aim of this study was to evaluate the clinical efficiency of the intestinal blood flow quantification by using indocyanine green (ICG) as a near-infrared fluorescent imaging system (NIFI). From May 2013 to April 2015, we enrolled patients who underwent low anterior resection (LAR). After 1.0 ml of ICG solution (2.5mg/ml) was injected intravenously by the anesthetist just before formation of the anastomosis, the blood flow was visualized in real time by NIFI.
Results: The median (range) age of the patients was 70 (38-81) years. The median (range) BMI was 23.7 (15.4-30.6) kg/m^2. Forty-six percent of patients were female. In all cases, the evaluation of the blood flow distribution of intestinal wall was clearly achieved. After ICG injection, median (range) time to visualize the blood flow was 35 (22-105) seconds. The occurrence of delay in the blood flow distribution to the anastomotic site compared to the proximal side of intestine was observed in 3 cases. In 2 of the 3 cases, revision of the intestinal transection point was done before formation of the anastomosis. In the other 1 case, AL due to bowel ischemia occurred.
Conclusion: The intestinal blood flow can be evaluated by ICG fluorescence by NIFI. The occurrence of delay in the blood flow distribution may cause AL due to ischemia. By using ICG fluorescence, intestinal ischemia of the anastomotic site of LAR might be avoided.

Contact E-mail Address: a.p.van.beek@umcg.nl
Introduction: Dumping syndrome is a prevalent complication of gastric bypass surgery, characterised by early (cardiovascular and gastrointestinal response, along with rise in haematocrit [Ht] and pulse rate [PR]) and late (hypoglycaemia due to excess insulin) postprandial symptoms. Only a subset of patients (pts)

responds to treatment based on dietary measures, off-label use of acarbose and somatostatin analogues (SSA). Pasireotide (PAS), a next-generation SSA with high affinity to 4 of the 5 somatostatin receptor subtypes (sst), being a potent inhibitor of incretin and insulin secretion (via sst_2 and sst_5), prevents postprandial hypoglycaemia.

Aims & Methods: This is a single-arm, open-label, multicentre, intra-patient dose escalation, phase 2 study to evaluate the preliminary efficacy, safety and pharmacokinetics of PAS subcutaneous (s.c.) and long-acting release (LAR) in pts with dumping syndrome. The 6-month (mo) core period included a 3-mo s.c. phase followed by a 3-mo LAR phase. Eligible pts started treatment with PAS s.c. 50μg tid (before meals); dose could be increased by increment of 50μg up to 200μg tid based on the presence of hypoglycaemia (plasma glucose <60mg/dL) during an oral glucose tolerance test (OGTT) in the s.c. phase. In the LAR phase, pts received a fixed dose of PAS LAR 10 or 20mg based on the dose at the end of s.c. phase. Primary endpoint was the proportion of pts with no hypoglycaemia during an OGTT (ie, response rate [RR]) at the end of s.c. phase (mo 3). A RR of ≥50% was considered to be clinically relevant. Secondary endpoints included RR at the end of LAR phase (mo 6). The Ht levels and PR were evaluated at all OGTT time points.

Results: Of the 43 pts enrolled, 33 and 31 pts completed the s.c. and LAR phase, respectively. Main reason for discontinuation was adverse events (AEs; 11.6% [n = 5]). The RR in terms of prevention of hypoglycaemia was 60.5% (26/43; 95% CI: 44.4% > 75.0%) and 36.4% (12/33; 95% CI: 20.4% > 54.9%) in the s.c. and LAR phases, respectively. Notably, plasma glucose levels during OGTT were higher at all time points with s.c. dose vs baseline and vs LAR dose. Fewer pts had an increase in PR of ≥10 beat/min and an increase in Ht level of ≥3% (from pre-OGTT to 30 min post-OGTT) at mo 3 than at the baseline (18.6% vs 60.5% and 16.3% vs 27.9%, respectively). Overall, the most frequent (>15% of pts [N = 43]) AEs were headache (32.6%); diarrhoea, hypoglycaemia (25.6% each); abdominal pain (18.6%); upper abdominal pain and nausea (16.3% each). Grade 3/4 AEs occurred in 32.6% pts; most frequent (≥2 pts) were hypoglycaemia (9.3%); diarrhoea, upper abdominal pain, dizziness and small intestinal obstruction (4.7% each).

Conclusion: These results suggest that PAS s.c. effectively controls postprandial hypoglycaemia and improves changes in PR and Ht in pts with dumping syndrome. PAS s.c. and LAR were well tolerated; no new safety signals were identified in this population. A phase 3 study is warranted to confirm the effects of PAS in dumping syndrome.

Contact E-mail Address: kanefumi0519@yahoo.co.jp

Introduction: Colorectal surgery continues to have the highest rate of surgical site infections (SSIs) of all surgical procedures, accounting for 5–45% of all SSIs. Triclosan-coated sutures were developed to prevent bacterial colonisation of the suture material, and consequently to impair the local mechanisms of wound decontamination. We aimed to assess the effectiveness of triclosan-coated sutures used for skin closure on the rate of SSIs in colorectal cancer surgery.

Aims & Methods: We aimed to assess the effectiveness of triclosan-coated sutures used for skin closure on the rate of SSIs in colorectal cancer surgery. Until August 2012, our centre (Department of Gastroenterological Surgery, Fukuoka University Faculty of Medicine) used conventional methods for skin closure in colorectal cancer surgery. We were therefore able to retrospectively collect surveillance data from a 1.5 year period, which formed the control group. From September 2012, we began to use triclosan-coated polydioxanone antimicrobial sutures (PDS plus) for skin closure. We collected data for the study group from September 2012 until August 2013. Using propensity score matching, the control and study group cases were matched based on the following variables: patient age, sex, body mass index (BMI), medication use, complications, lifestyle-related factors, American Society of Anesthesiologists (ASA) physical status score as determined by an anaesthesiologist, type of surgery, operation time, quantity of blood lost, quantity of blood transfused, surgical wound classification, and method of skin closure. The baseline differences and selection bias were adjusted using the propensity score-matching method.

Results: A total of 374 colorectal cancer surgery patients were included in this study (control group, 221 patients; study group, 153 patients). Of all cases, 76 pairs were matched using the propensity score-matching method. Baseline patient characteristics were similar in the propensity score-matched groups. The incidence of SSIs within 30 days of the index operation, before matching, was 14.0% (31/221) in the control group and 7.2% (11/153) in the study group; the difference was statistically significant (p = 0.030). After matching, the incidence of SSIs was 23.7% (18/76) in the control group and 5.3% (4/76) in the study group; the difference was statistically significant (p = 0.001). Multivariable logistic regression analysis revealed that type of surgery was an independent factor affecting the incidence of SSIs prior to propensity score matching (p = 0.032). Emergent surgery (p = 0.017) and PDS plus (p = 0.002) were independent factors affecting the incidence of SSIs following propensity score matching.

Conclusion: Use of triclosan-coated sutures was associated with a significant decrease in the risk of SSIs following colorectal surgery.

P0264 THE IMPORTANCE OF BEING HONEST. METICULOUS REGISTRATION OF FOLLOW-UP DATA IN QUALITY REGISTERS INCREASE DATA VALIDITY - A STUDY OF 94185 CHOLECYSTECTOMIES

L. Enochsson[1,2], A. Wallin[3], J. Österberg[3]
[1]*Center for Digestive Diseases, Karolinska University Hospital,* [2]*CLINTEC, Karolinska Institutet, Stockholm,* [3]*Department of Surgery, Mora Hospital, Mora, Sweden*

Contact E-mail Address: lars.enochsson@ki.se

Introduction: The Swedish national registry of gallstone surgery and endoscopic retrograde cholangiopancreatography, GallRiks, was founded in May 2005 and by the end of 2014 includes 98677 cholecystectomy registrations. The cholecystectomies are registered online by the surgeons immediately after surgery and then there is a 30-day postoperative follow-up (1). However, the hospitals participating in GallRiks have different complete 30-day follow-up frequencies.

Aims & Methods

Aim: The aim of our study was to analyze if these differences affect the frequency of reported adverse events.

Methods: 98677 cholecystectomy registrations were included. A total of 4492 registrations were excluded due to being non-index procedures, the cholecystectomy being part of major surgery or registrations with missing data. A total of 94185 cholecystectomies were included in the analysis (2.8% with complete 30-day follow-up of ≤90 (Group A) and 97.2% with a complete 30-day follow-up of >90% (Group B).

Results: The frequency of complete 30-day follow-up (≤90%) has increased somewhat from 0.2% (2005) to 4.1% (2014). The patients in Group A were somewhat older, included more urgent operations and slightly more males. The reported 30-day postprocedural adverse event rate was significantly less in Group A (OR 0.82; 95% CI 0.75-0.89) as well as the pancreatitis rate (OR 0.55; 95% CI 0.38-0.78) (Table 1). However, the perforation rate was significantly higher (OR 2.29; 95% CI 1.55-3.30) compared to Group B.

	Adverse events ≤90% 30d follow up vs. >90% 30d follow-up			
	Univariate		Multivariate	
	OR	95%CI	OR	95%CI
Intraprocedural	0.96	(0.85-1.09)	0.95	(0.84-1.07)
Postprocedural	**0.86**	(0.79-0.93)	**0.82**	(0.75-0.89)
Pancreatitis	**0.58**	(0.39-0.82)	**0.55**	(0.38-0.78)
Cholangitis	1.01	(0.54-1.73)	0.95	(0.51-1.62)
Bleeding	1.04	(0.81-1.32)	1	(0.78-1.27)
Perforation	**2.28**	(1.54-3.28)	**2.29**	(1.55-3.30)
Infection	1.09	(0.91-1.30)	1.04	(0.87-1.24)

Conclusion: The lower frequency of postoperative adverse events and pancreatitis in Group A could indicate that a lower frequency of 30-day follow-up registrations risk to miss cholecystectomies with adverse events whereas serious complications like perforation of the gut are seldom missed. The importance of a meticulous registration in quality registers in order to get valid data cannot be overstated.

Horovice, Department of Surgery, Prague, Czech Republic*

Contact E-mail Address: martakostrejova@seznam.cz

Introduction: Restorative proctocolectomy with ileal-pouch anal anastomosis (IPAA) has become the surgical procedure of choice in patients with UC.

Aims & Methods: The aim of the study was to assess the long-term functional results and quality of life in those UC (n = 138) patients, who underwent IPAA from 1993-2013 in two Czech referral centers. In 129 of patients had been perfomed three-stage procedure, using stapled anastomosis. Qualite of life (QoL) was evaluated by using the Medical Outcome 36 item Health Survey, and Wexner Continence Grading Scale.The outcome of SF-36 item questionnaire has been compared with the Oxford study for the European. Statistical significance in all tests set to p,0.05, a Cronbachs alpha reliability of psychometrics tests was from 0.737-0.917.

Results: A total of 114 out of 119 pts completely answered the questionnaires. 62% of whom were male, a median of age (interquartile range) at proctocolectomy was 34 (27-44) years. During a median (range) follow-up of 7.9 (2.1–20.7) years. In 28% of these patients developed septic and/or obstructive and perianal complications. In 8.7% resp. 10.2% of patients anastomotic stricturae and complete fistula have been detected. Pouch failure occured in 7.9% of the patients and in 5.5% of pts '' re-do'' puche was done and in 2 pts continent ileostomy was done. One female patient developed carcinoma in IPAA seventeen months after poctocolectomy.

24% of pts developed at least one episode acute pouchitis, 15.0% had recurrent pouchitis. In majority of patients (63%) the median of functional outcome was 2 (0-4), according to the Wexner continence score. The median range of bowel moments was 5 (1-8) during the day, and 1 (0-3) at night. 24% had episodes of soiling, 11% urgency defecation, in 2/1.7% was seen true faecal incontinence. Nevertheless, 50% of patients occasionally had to change daily activities, and up to 62% of patients were taking antidiarrheal medications.

In patients after IPAA were observed slightly but significantly lower mean of QoL overall, and in five of eight SF-36 health dimensions than general population.The HRQoL was mainly impaired in the psychological and social areas and to a lesser degree in physical area. Physical Component Summary (PCS) and Mental Component Summary (MCS) were 46.37 and 46.55 (both are 50 in general population), respectively ($p < 0.001$). Patients with a certain degree of defecation function damage with a median Wexner score 9 (6-17) had a significantly lower quality of life in majority of dimensions of SF-36 than patients with perfect continence ($p < 0.001$). Regarding pouchitis in female significantly was affected all dimensions of MCS (median score 37, $p < 0.028$). On the other hand pts with perfect continence had normal QoL in all dimensions.

Conclusion: The ileal – pouch anal anastomosis in patients with ulcerative colitis confers a good quality of life. The majority of patients are fully continent. Subjective assessment of QoL and overall satisfaction was very high (98.3%).

Introduction: Esophagogastric anastomotic stenosis is the most common cause of dysphagia after esophagectomy with esophagogastroplasty for esophageal cancer.

Aims & Methods: To evaluate the results of endoscopic dilation therapy for esophagogastric anastomotic stenosis.

Retrospective analysis of prospectively collected database of patients who underwent subtotal esophagectomy for cancer and developed dysphagia due stenosis of the esophagogastric anastomosis, at the Cancer Institute of the University of São Paulo.

Results: From May 2010 to May 2014, a total of 32 patients were included, with dysphagia and stenosis of the esophagogastric anastomosis, and a median of 3 months after surgery (ranging from 0.5 to 19 months). Mean age was 58 years (range: 40 – 72 years), with male predominance (78.1%). Eight (25%) patients had fistulas or anastomotic leakage in the postoperative period. A 9.8mm endoscope could not traverse the stricture in 18 cases (56%). For endoscopic dilation, guidewire-assisted bougies (Savary-Gilliard; Wilson-Cook Medical) were used in 17 cases (56%), guidewire-assisted bougies or hydrostatic balloons (CRE-TTS, Boston Scientific) in 14 cases (43%), and hydrostatic balloons alone in 1 case. The maximum diameter of 16 mm was achieved in 31 patients (96%), with a median of 5 sessions per patient (range: 1 – 25 sessions per patient). There were no major complications, such as perforation or massive bleeding. Triamcinolone injections were performed in 22 cases (69%), with a mean of 2.1 sessions per patient (range: 1 – 5 sessions per patient), removal of sutures in 7 (22%), incisional therapy using electrocautery in 2 (6%), and placement of self-expanding metallic stent in 1 case. Therapeutic success rate, defined as clinical improvement without further dilation for a period of at least 6 months, was obtained in 28 patients (87.5%).

Conclusion: When patients undergoing esophagectomy and esophagogastric anastomosis develop symptomatic stenosis, they usually present dysphagia in the first 3 months after the operation. The endoscopic dilation carried out with bougies or balloons, associated with corticosteroid injection, is successful in almost 90% of the patients with no life-threatening related complications.

Introduction: Resection is the only curative treatment option for patients with pancreatic and periampullary cancer. After pancreatoduodenectomy (PD) patients are at risk of developing new-onset diabetes mellitus (NODM). The exact risk of NODM after PD is relevant when counseling patients, but it is currently unknown since systematic reviews are lacking. The aim of this study is to determine the risk of new-onset diabetes mellitus (NODM) after pancreatoduodenectomy (PD) performed for benign and malignant diseases.

Aims & Methods: A systematic literature search was performed up to October 1st 2014 in PubMed, Embase (Ovid) and the Cochrane Library in accordance with the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines. All studies reporting on the incidence of NODM following PD for benign or (pre)malignant pancreatic or periampullary tumors were included. Studies of patients undergoing PD for chronic pancreatitis were excluded. Primary outcome was incidence of NODM.

Results: Of the 1863 studies identified, 13 studies (715 patients) fulfilled the eligibility criteria. Patients underwent PD for cancer (n = 602), benign disease (n = 62), or neoplasm from unclear origin (n = 51). The weighted mean percentage of NODM was 11.6% (±11.2). Only 4 studies, comprising 34 patients with NODM, reported the incidence of insulin-dependent diabetes mellitus (IDDM). The weighted mean post-PD percentage of IDDM among these patients with NODM was 20.5% (±6.02).

Conclusion: Incidence of NODM following PD for pancreatic or periampullary tumors is 11.6%. Routine postoperative screening for NODM seems advisable. More research into the risk of IDDM following PD is needed.

P0268 PERITONEAL IRRIGATION DOES NOT REDUCE RATE OF POST-OPERATIVE FORMATION OF INTRA-ABDOMINAL ABSCESS AFTER PERFORATED APPENDECTOMY

S. Groen[1], L. de Nes[2], H. Barton[1], S. Donkervoort[1], S. Festen[1], on behalf of Dirty Belly Working Group
[1]*Surgery, Onze Lieve Vrouwe Gasthuis, Amsterdam/Netherlands, Amsterdam, Netherlands,* [2]*Surgery, Humanitas Research Hospital, Milano, Italy*

Contact E-mail Address: syl.groen@gmail.com

Introduction: Annually 16,000 appendectomies are performed in the Netherlands. Although the overall rate of post-operative intra-abdominal abscess (PIAA) formation is small, there is a potential significant effect on mortality, morbidity, duration of hospital-admission and costs. Largest risk in developing PIAA is after perforated appendicitis (20%). Peritoneal-irrigation during surgery is frequently used as preventive procedure, however literature is lacking supporting evidence. The only available prospective study describes an increase of abscess-formation in a pediatric study-group. Primary objective of our study was to determine the efficacy of peritoneal-irrigation in perforated appendicitis on PIAA in adults.

Aims & Methods: All patients undergoing appendectomy for acute appendicitis from January, 2008, until December, 2013, were included in a database. Exclusion-criteria were age < 18yrs, incidental and interval-appendectomy. PIAA is used as primary outcome measure.

Results: 1163 of 1467 appendectomies were included. PIAA was diagnosed in 61 patients (5.2%). There were 245 (22.1%) appendix-perforations during surgery in which 37 patients (15.1%) developed PIAA, versus 24 of 917 patients in the non-irrigation group (2.6%). Between the peritoneal-irrigation and non-irrigation group were no significant differences in patient-characteristics. In the irrigation-group a greater risk in developing PIAA is shown versus non-irrigation (18.6% vs. 6.8%, OR 3.6, BI 0.9–13, p = 0.082). Additionally, irrigation is

associated with a longer hospital-admission, on an average of 1.7 days (OR 1.1, BI 1.0-1.4, P = 0.004).
Conclusion: Peritoneal-Irrigation during surgery in perforated appendicitis does not significantly reduce the rate PIAA formation in this retrospective study and probably increases the rate of this complication. Furthermore, patients in the irrigation group were admitted significantly longer.

P0269 STAGE APPROACH TO MEDICAL MANAGEMENT OF INTRA-ABDOMINAL HYPERTENSION

V. Teplyi[1], **I. Kolosovych**[1], S. Tarasenko[1], A. Kolosovych[1]
[1]*Surgery #2, O.O. Bogomolets National Medical University, Kyiv, Ukraine*

Contact E-mail Address: teplyy@ukr.net
Introduction: Intra-abdominal hypertension (IAH) may lead to the development of abdominal compartment syndrome (ACS) – potentially lethal complication. The experts proposed IAH/ACS medical management algorithm which on our point of view is something general (1).
Aims & Methods: The purpose of this study was to detail the stage approach to the management of IAH/ACS in the patients with general surgical pathology. The monitoring of intra-abdominal pressure (IAP) was performed by transbladder technique. In 7 operated patients (group 1) the volume of abdominal cavity was decreased by the abdominal wall surgery (5 – abdominoplasty, 2 – ventral hernioplasty). In 25 other patients (group 2) IAH was caused by the increase of the volume of abdominal content (14 – acute pancreatitis, 5 – paralytic ileus secondary to diffuse purulent peritonitis and in 2 – because of uremia and 4 – cirrhosis with progressive ascites). Taking into account that the rise of IAP always is a result of the disproportion of the ratio of the abdominal content volume to the volume of the abdominal cavity, management was focused on the decrease of the former or enlargement of the latter one. The first stage measures in the group 1 were focused on the improving of the abdominal wall compliance. In all patients receiving mechanical ventilation we started from the adjustment of the ventilator settings (decrease of tidal volume and increase of the respiratory rate). In parallel the adequacy of sedation and analgesia were checked, constricting dressings and bandages were removed. The same management was hold at the 1 stage in all patients of the group 2 on mechanical ventilation. But the main efforts were directed to reduce the volume of abdominal content. Thus in 8 non-operated patients of the group 2 with severe abdominal accumulations primary stage included their percutaneous drainage under ultrasound control. The main cause of the increase of the abdominal content volume in 15 patients was paralytic ileus. Here the first stage was focused on the evacuation of the gastro-intestinal content. If it was not effective, on the second stage enteral nutrition was minimized or even discontinued and fluid administration was optimized. The 3 stage treatment for these patients was neuromuscular blockade.
Results: The adjustment of the ventilator setting sand removing of compressive garments permitted to decrease IAP in 16 patients (including all patients of group 1) on 18.8 ± 2.6 mm H_2O. Thus there was no necessity to go to the next stage. But if abdominal wall compliance cannot be improved, neuromuscular blockade should be considered. Drainage of severe abdominal accumulations permitted to decrease IAP to less than 200 mm H_2O in 6 of 8 patients. In remaining 2 patients therapy was escalated to the second stage.
Conclusion: In 68.8% of cases it was enough the first stage measures to stabilize and decrease IAP. Described approach permitted to escape the decompressive laparostomy in 93.8% of patients without redundant manipulations.

IBD I – HALL 7

P0271 RISK OF THROMBOEMBOLIC DISEASE IN INFLAMMATORY BOWEL DISEASE

A. Kumar[1], B. Disney[1], L. Wood[1], J. Slater[1], S. de Silva[1]
[1]*Gastroenterology, Russells Hall Hospital, Birmingham, United Kingdom*

Contact E-mail Address: aditikumar@nhs.net
Introduction: Patients with inflammatory bowel disease (IBD) are thought to be associated with an increased risk of developing venous thromboembolic (VTE) disease and arterial thombi (AT). There is conflicting data on the prevalence of VTE disease and AT in IBD, varying between 1.2% and 6.7% in clinical studies, which rises to 39% in postmortem studies. Our aims were to evaluate the rate and risk factors of VTE and AT in a large cohort of IBD patients.
Aims & Methods: We performed a retrospective review between the years 1984 to 2014 of all patients with IBD. These patients were identified from the IBD database and cross-referenced with the online electronic reporting system, patient notes and clinic letters.
Results: There were a total of 1678 patients with IBD, with 47 found to have VTE and AT, giving a prevalence rate of 2.8%. Of these 47 patients, 8 (17%) patients had recurrent disease with 6 (12.8%)patients having 2 incidents and 2 (4.2%) patients having 3 incidents of VTE disease. The median age was 60.2 years old with a greater risk for males than females (55% versus 45%) and with ulcerative colitis than Crohn's disease (2.8% versus 0.87%). A total of 6 patients were inpatients, unrelated to their IBD, and a diagnosis of VTE/AT was confirmed within 5 days of admission.
36 (2.1%) patients were diagnosed with deep venous thrombosis (DVT) and 20 (1.2%) with pulmonary embolism (PE). The remaining four had portal vein thrombosis, common femoral artery occlusion, femoral artery embolus and superficial femoral artery occlusion. Three patients were diagnosed with both DVT and PE in the same admission. The average duration from time of IBD diagnosis to VTE confirmation was 7.4 years. 5 patients were identified with VTE prior to their IBD diagnosis.
At the time of their diagnosis, 3 (5.3%) patients were treated for malignancy in the previous six months and 4 (7%) had undergone surgery in the previous four weeks. 32 (56%) patients were being treated with 5-aminosalicylic acid (5ASA) drugs, 17 (30%) with azathioprine, 12 (21%) with oral steroids, 4 (7%) with intravenous (IV) steroids, 2 (4%) had infliximab and 1 (2%) had adalimumab. Blood tests at time of diagnosis showed a median CRP of 46 and platelet count of 345. The mortality rate was 10.6%, of which one death was directly related to their VTE. 10.5% underwent surgery, 63% were anticoagulated and 1.8% underwent failed tissue plasminogen activator (TPA) therapy. 3.5% were left with a disability secondary to their VTE disease.
Conclusion: Thromboembolic disease is an increasingly prevalent and preventable complication of IBD. Positive risk factors identified in our cohort were patients that were male, increasing age and diagnosis of ulcerative colitis. Considering almost one third of those diagnosed were receiving oral or IV steroid therapy and had an average raised CRP, this supports the view that a disease flare is an ongoing risk factor for developing VTE and AT.

Introduction: The dysbiosis of enteric microbiota cause host mucosal immune responses that result in gastrointestinal diseases such as enterocolitis.
Aims & Methods: In this study, we investigated the beneficial effect of *Lactobacillus plantarum* (*LP*) 06CC2 in dextran sulfate sodium (DSS)-induced colitis in C57BL6 mice. Heat-killed lyophilized *LP* 06CC2 was suspended in PBS. Two mice groups that had received DSS were orally administered PBS only (control group) or *LP* 06CC2 (LP group) by gavage for 15 consecutive days. We assessed the severity of colitis using a disease activity index, measured the colon length and weight, and colon tissue was examined macroscopically and histopathologically. We also collected colonic lamina propria mononuclear cells (LPMCs). The gene expressions of inflammatory cytokines (IFN-γ, IL-6, IL-12, TNF-α and IL-10) in LPMCs were determined.
Results: The body weight reduction in the LP group was significantly suppressed relative to the control group. The LP group demonstrated significantly lower disease activity index (1.5 ± 0.8 vs. 0.2 ± 0.3, respectively; $p < 0.05$) and pathology score (6.3 ± 1.5 vs. 3.8 ± 1.3, respectively; $p < 0.05$) compared to the control group. The LP strain significantly prevented foreshortening of the large intestine: the average colon length was 80 ± 8 mm in the LP group and 94 ± 7 mm in the control group ($p < 0.01$). IL-10 expression in colonic LPMCs was significantly higher in the LP group than the control group, although there was no significant difference of IFN-γ, IL-6, IL-12 expressions in LPMCs between two groups.
Conclusion: The *LP* 06CC2 strain attenuated colon inflammation by induction of IL-10 production in the colonic LPMCs.

Contact E-mail Address: hang.nguyen@udamail.fr
Introduction: A high prevalence of the adherent-invasive *E. coli* (AIEC) in the intestinal mucosa of Crohn's disease patients has been shown. We previously showed that upon AIEC infection, autophagy is induced in host cells to restrain AIEC intracellular replication. The mechanism underlying such autophagy induction, however, remains largely unknown.
Aims & Methods: Here, we investigated the role of the GCN2/eIF2α/ATF4 pathway in autophagy response to AIEC infection. Autophagic activity was assessed by Western blot and immunofluorescent labelling of LC3. Intracellular bacterial number was determined by bacterial invasion assay and confocal microscopy. Binding of ATF4 to autophagy gene promoters was assessed by Chromatin immunoprecipitation (ChIP) assay. Wild type (WT) and GCN2

knockout (KO) mice were infected with an AIEC reference strain LF82 by gavage.
Results: Infection of human intestinal epithelial T84 cells with the AIEC LF82 strain activated the GCN2/eIF2α/ATF4 pathway as shown by increased phospho-GCN2 and phospho-eIF2α levels, enhanced ATF4 protein expression, and upregulated mRNA expression levels of ATF4 target genes. To explore the role of this pathway in host responses to AIEC infection, we used GCN2-deficient mouse embryonic fibroblasts ($GCN2^{-/-}$ MEF). GCN2 depletion suppressed eIF2α activation and inhibited the increase in ATF4 protein level induced by LF82 infection. mRNA expression levels of the autophagy genes *p62*, *MAP1lc3*, *Beclin1*, *atg3* and *atg7* were significantly increased in WT MEF upon LF82 infection, and this was blocked in $GCN2^{-/-}$ MEF. ChIP assay showed that GCN2 depletion inhibited the LF82-induced binding of ATF4 to the promoters of these autophagy genes. Consequently, autophagy induction upon LF82 infection was suppressed in $GCN2^{-/-}$ MEF, leading to increased LF82 intracellular replication and elevated pro-inflammatory cytokine production, compared to WT MEF. *In vivo* study consistently showed that LF82 infection activated the GCN2/eIF2α/ATF4 pathway in enterocytes from WT mice, but not GCN2 KO mice. In response to AIEC infection, autophagy was induced in WT mouse-derived enterocytes, and this was not observed in KO mice. LF82 persistence in the gut was increased in KO mice, leading to aggravated intestinal inflammation, compared to that in WT mice. Depletion of GCN2 did not affect susceptibility of mice to DSS-induced colitis, indicating that the effects obtained were not a consequence of inflammation and were specific for AIEC infection.
Conclusion: The GCN2/eIF2α/ATF4 pathway is activated in host cells during AIEC infection, which is served as a defense mechanism to induce a functional autophagy to control AIEC intracellular replication.

P0274 EPIGENETIC MECHANISMS OF AIEC-RECEPTOR CEACAM6 REGULATION IN CROHN'S DISEASE: CHROMATIN REMODELLING AND MICRO-RNA SIGNATURES

A. Agus[1], J. Denizot[1], G. Sevrin[1], H. T. Nguyen[1], N. Barnich[1]
[1]*Clermont Université, M2iSH, UMR 1071 INSERM/Université d'Auvergne, Clermont-Ferrand, France Unité Sous Contrat 2018 Institut National de la Recherche Agronomique, Clermont-Ferrand, France*

Introduction: Abnormal expression of CEACAM6 is observed at the apical surface of the ileal epithelium in Crohn's disease (CD) patients. This allows Adherent-Invasive *Escherichia coli* (AIEC) to colonize gut mucosa, leading to development of inflammation. Our aims were to understand the regulation of *CEACAM6* expression in CD ileal mucosa and to investigate epigenetic mechanisms involved in *CEACAM6* overexpression during AIEC infection.
Aims & Methods: HIF-1α and histone H3 Serine 10 phosphorylation (H3S10p) levels were measured in *CEACAM6* promoter region by chromatin immunoprecipitation (ChIP). MicroRNAs (miRNAs) that potentially target CEACAM6 were predicted by in silico algorithms. MiRNA levels in human intestinal epithelial T84 cells were measured using quantitative reverse-transcription polymerase chain reaction (qRT-PCR). Luciferase assays were used to assess binding of predictive miRNAs to the 3'-untranslated region (3'-UTR) of *CEACAM6* mRNA. Effect of transfection of predictive microRNA precursors on *CEACAM6* expression in T84 cells was analyzed by Western blot. Impact of AIEC infection on miRNA levels in T84 cells was analyzed by qRT-PCR.
Results: Higher expression of CEACAM6 was observed in T84 cells compared to Caco-2 cells. This was associated with high binding of HIF-1α on the *CEACAM6* gene promoter in an open chromatin state region characterized by increased H3S10 phosphorylation level. In contrast, Caco-2 cells expressed low levels of CEACAM6 due to a compact chromatin state in *CEACAM6* promoter (low level of H3S10p). AIEC infection led to an increase in CEACAM6 expression related to enhance HIF-1α binding to CEACAM6 promoter. Abnormal H3S10 phosphorylation in *CEACAM6* promoter following AIEC infection enhanced HIF-1α binding and subsequent *CEACAM6* expression. Moreover, *in silico* analysis predicted several miRNAs that are potentially able to regulate *CEACAM6* expression. Luciferase reporter assays showed that among the predictive miRNAs, 11 hsa-miRNAs (in particular 29a-3p, 424-3p and 489-3p) directly bound to the 3'-UTR of *CEACAM6* mRNA. Interestingly, expression of some of these miRNAs was altered after AIEC infection.
Conclusion: This study suggests that AIEC bacteria have the ability to modulate gene expression in the host cell for their own benefit by altering different epigenetic marks as miRNA expression profile and histones post-translational modifications enhancing CEACAM6 abnormal expression. Thus, epigenetic pathways could be new targets to prevent AIEC colonization and AIEC-induced inflammation in CD patients.

Introduction: We have previously shown that anti-TNF treatment of mixed lymphocyte reactions (MLR) results in the induction of macrophages with immunosuppressive and wound healing properties. In patients who respond to IFX treatment, the number of these macrophages increases significantly in the intestine. In contrast, no increase is seen in non-responders, indicating the clinical importance of this cell population. Because Vitamin D has an immunosuppressive effect on immune cells, we wanted to determine the role of vitamin D in anti-TNF induced macrophages. The aim of this study was to determine if the Vitamin D receptor pathway was activated in anti-TNF induced macrophages and if Vitamin D can potentiate immunosuppressive effect of these macrophages.
Aims & Methods: Peripheral blood mononuclear cells (PBMC) were isolated from peripheral blood of healthy donors. MLR were established by co-culturing PBMC of two healthy donors in a 1:1 ratio. Cultures were treated with anti-TNF to induce anti-TNF induced macrophages. IFN- γ induced macrophages were generated by culturing monocytes in the presence of IFN-γ. Gene expression of anti-TNF compared to IFN-γ induced macrophages was determined by microarray or by real-time PCR. Protein expression of the Vitamin D receptor (VDR) was determined by western blot.
To determine the effect of Vitamin D on IFN-γ and anti-TNF induced macrophages cell culture experiments were performed in the presence or absence of 1.25-dihydroxyvitamin D.
Anti-TNF induced macrophages were isolated with CD14 microbeads and co-cultured with activated T-cells from a third donor. Subsequently T-cell proliferation was measured by 3H thymidine incorporation.
Results: Anti-TNF induced macrophages displayed increased expression of a number of components of the vitamin D receptor pathway including the transcripts for VDR, Osteopontin and the Retenoid X receptor. In line with this, anti-TNF induced macrophages showed increased VDR protein expression compared to IFN-γ induced macrophages, confirming the results of the micro array. Furthermore anti-TNF induced macrophages showed increased expression of the VDR response gene cathelicidin antimicrobial peptide after treatment with 1.25-dihydroxyvitamin D. Indicating increased capacity to respond to Vitamin D.
In order to determine if Vitamin D could enhance the immunosuppressive effect of anti-TNF induced macrophages, macrophages were generated in the presence of the active metabolite of vitamin D. Addition of active vitamin D did not alter the number of regulatory macrophages. However anti-TNF induced macrophages generated in the presence of 1.25-dihydroxyvitamin D did show an increased capacity to inhibit of T-cell proliferation.
Conclusion: Anti-TNF induced macrophages show an increased activation of the vitamin D receptor pathway. The immunosuppressive properties of anti-TNF induced macrophages can be potentiated by 1.25-dihydroxyvitamin D.

P0276 THE AUTOPHAGY-RELATED PROTEIN CATHEPSIN S IS ESSENTIAL FOR THE INDUCTION, VIABILITY AND M2 PHENOTYPE OF ANTI-TNF INDUCED MACROPHAGES

A. Levin[1], P. Koelink[1], F. Bloemendaal[1], C. Vos[2], G. D'Haens[3], G. Van den Brink[1,3], M. Wildenberg[1,3]

Contact E-mail Address: a.d.levin@amc.uva.nl
Introduction: We have previously shown in vitro and in vivo that anti-TNFs induce macrophages with immunosuppressive and wound healing properties. These macrophages express the M2 macrophage phenotype marker CD206. Furthermore anti-TNF induced macrophages have increased levels of autophagy and our in vitro studies have shown that the presence of the wild type allele of *ATG16L1* is associated with an increase of anti-TNF induced macrophages. The aim of this study was to further understand the effect of autophagy on anti-TNF induced macrophages.
Aims & Methods: In order to generate anti-TNF induced macrophages mixed lymphocyte reactions (MLR) were performed with peripheral blood mononuclear cells from healthy donors in the presence of anti-TNF. Anti-TNF induced macrophages were isolated by magnetic bead separation using CD14+ microbeads. IFN-γ induced macrophages were generated by culturing human monocytes in the presence of IFN-γ. Expression profile of 84 autophagy related transcripts was determined by real-time PCR array. Protein expression for Cathepsin S was determined by western blot. CD206 expression was determined by flow cytometry and viability was determined by MTS assay.
Results: Anti-TNF-induced macrophages had a different expression profile of autophagy-related transcripts compared to macrophages induced with IFN-γ. Interestingly Cathepsin S was highly upregulated in the anti-TNF-induced macrophages. Because Cathepsin S is a lysosomal protease that has previously been shown to induce M2 polarization in an autophagy dependent manner, we wanted to further study the effect of Cathepsin S on anti-TNF-induced macrophages.
Anti-TNF-induced macrophages showed increased Cathepsin S protein expression compared to IFN-γ-induced macrophages, confirming the results of the RNA array. We then tested the functional role of Cathepsin S in these macrophages. Addition of Cathepsin S inhibitor abrogated the capacity of anti-TNF to induce CD206+ macrophages. Furthermore anti-TNF-induced macrophages isolated from MLR and subsequently cultured in the presence of Cathepsin S inhibitor showed decreased viability and decreased expression of the M2 phenotype marker CD206.

Conclusion: The autophagy-related protein Cathepsin S is highly expressed in anti-TNF-induced macrophages and is essential for the induction, viability and M2 phenotype of anti-TNF-induced macrophages.

Contact E-mail Address: a.disabatino@smatteo.pv.it
Introduction: Inflammatory bowel diseases (IBD), including Crohn's disease (CD) and ulcerative colitis (UC), are chronic inflammatory disorders of the small intestine and colon. Tumor necrosis factor (TNF)-a mediates multiple pro-inflammatory signals and plays a central role in the pathogenesis of IBD. The monoclonal anti-TNF-a antibody infliximab is effective in the induction and maintenance of clinical remission in patients with IBD. Therefore, we studied the *in vitro* effect of infliximab on megakaryocyte development and pro-platelet release in IBD
Aims & Methods: Blood samples were collected from five clinically active IBD patients (two with CD and three with UC; males n = 3; mean age 38.2 yrs, range 24-64). CD45 positive cells were separated by immunomagnetic selection and cultured for two weeks in the presence of 10 ng/mL thrombopoietin together with eitgher 10 mg/mL infliximab or its isotype control (human IgG1). At the end of the culture, CD61 positive megakaryocytes and pro-platelet-forming megakaryocytes were analyzed by flow cytometry. Blood samples were also collected from five IBD (4 males, mean age 38 yrs, min 25 yrs, max 71 yrs) patients before and after 6 weeks of infliximab treatment at the dose of 5 mg/kg administered at week, 0, 2 and 6.
Results: No significant difference in *in vitro* megakaryocyte differentiation was observed in cultures stimulated with either infliximab or IgG1. However, mature megakaryocytes exhibited a significantly ($p < 0.001$) higher capacity in releasing pro-platelets in the presence of infliximab compared to megakaryocytes cultured in the presence of IgG1. Furthermore, hematopoietic progenitor cells derived from the blood of IBD patients after *in vivo* infliximab treatment showed a significantly ($p < 0.05$) higher *in vitro* differentiation in megakaryocytes in comparison to cells collected before the infiximab treatment.
Conclusion: These findings showed that infliximab promotes *in vitro* pro-platelet release in IBD patient-derived megakaryocyte cultures. Further experiments are needed to clarify whether the infliximab-induced development of pro-platelets might have a role in the wound-healing process sustained by the anti-TNF-a treatment.

Introduction: The Geboes Score (GS) is the most commonly used histological score in ulcerative colitis (UC).[1] A Simplified Geboes Score (SGS) that only includes variables linked to active inflammatory disease has been proposed in a previous study.[2] The aim of this study was to compare both scores, and to assess their correlation with the endoscopic findings in patients recently diagnosed with UC and followed up over 5 years.
Aims & Methods: Patients diagnosed with UC between 2005 and 2010, and who had serial endoscopies and biopsies, were retrospectively included. The 5-year histological evolution after diagnosis was recorded. Endoscopic results were recorded based on Mayo Endoscopic Subscore. Histological activity was scored by an experienced pathologist with the GS and the SGS. Conversions were constructed to compare endoscopic/histological scores: 2 conversions from the GS based on the results of a previous study (conversions 3 and 9) and 3 conversions from the GSG were tested, combining grade 1 and 2 (conversion 1), grade 2 and 3 (conversion 2), and grade 3 and 4 (conversion 3) of SGS.[3]
Results: We analysed 339 colonoscopies and their corresponding biopsies obtained from 103 patients with UC (51% women, mean age 40). Twenty-nine (28%) patients had proctitis, 46 (45%) left-sided colitis, and 28 (27%) extensive colitis. Forty (12%) colonoscopies presented Mayo 0, 74 (22%) Mayo 1, 107 (31%) Mayo 2, and 117 (35%) Mayo 3. A comparison of endoscopic and both histological scores of the 339 colonoscopies was performed (see Table). Patients in endoscopic remission (Mayo 0) presented with active microscopic disease (≥ Grade 3.1) in 23% of cases and those with Mayo 1 in 84%. The correlation analysis between endoscopy and both GS and SGS assessed by Kendall rank correlation coefficient (kendall τ, p value) did not show significant differences between the 2 histological scores: GS-conversion 3 (0.51, <0.001), GS-conversion 9 (0.51, <0.001), SGS-conversion 1 (0.48, <0.001), SGS-conversion 2 (0.48, <0.001), and SGS-conversion 3 (0.48, <0.001).

GEBOES S.		Mayo 0	Mayo 1	Mayo 2	Mayo 3	Total
Grade 0	**0.00.10.20,3**	91300	3300	0000	0000	121600
Grade 1	**1.11.21.3**	800	600	200	100	1700
Grade 2	**2.12.22.3**	100	000	100	000	200
Grade 3	**3.13.23.3**	200	100	300	100	700
Grade 4	**4.14.24.3**	000	101	111	000	212
Grade 5	**5.15.25.35.4**	5101	2523101	3334301	21284621	84868624
SIMPLIFIED GEBOES S.		Mayo 0	Mayo 1	Mayo 2	Mayo 3	Total
Grade 0		30	12	2	1	45
Grade 1	1.11.2	00	00	00	00	00
Grade 2	2.12.2	10	00	10	00	20
Grade 3	3.13.2	20	10	30	10	70
Grade 4	4.14.24.34.4	0601	147121	267311	0494621	31698924
Total		40	74	107	118	339

Conclusion: The assessment of histological activity based on the original GS and the SGS in a population of recently diagnosed active UC patients was comparable. Further validation should be performed in order to replace the original Geboes Score with the Simplified Geboes Score for the assessment of histological activity in UC patients' biopsies.

Introduction: Patients with Inflammatory Bowel Disease (IBD) are at increasing risk of developing disorders in bone and mineral metabolism. Osteopenia and osteoporosis are frequent but often underestimated complications in these patients. Several factors could contribute to osteopenia, but the pathogenetic mechanisms are still not completely understood. The aim of this study is to assess the prevalence and the risk factors associated with bone loss in IBD patients.
Aims & Methods: We conducted a retrospective study from January 2007 to June 2012, including all patients with IBD who attended our department. Bone mineral density (BMD) was measured with diphotonic x-ray absorptiometry of the lumbar spine and the neck of the left femur. Results were expressed as T score (osteopenia: -2.5 standard deviation (SD) < T < -1 SD, osteoporosis: T < -2.5 SD) according to the World Health Organization (WHO).
Results: 146 patients with IBD were included, 105 had Crohn's disease (CD) (71.9%), and 41 had ulcerative colitis (UC) (28.1%). The average age at diagnosis was 33.18 years [18-46]. BMD was normal in 61 patients (41.8%) and reduced in 85 patients (58.2%). 57 cases had osteopenia (39%) and 28 patients had osteoporosis (19.2%). In patients with Crohn's disease, 60% of cases (63/105) had reduced BMD (osteopenia in 39 cases and osteoporosis in 24 cases). 53.6% of patients with UC (22/41) had reduced BMD (osteopenia in18 cases and osteoporosis in 4 patients). The univariate analysis showed a statistically significant relationship between bone loss and age over 38 years (0.032), an active tobacco consumption (0.049), low calcium intake ($p = 0.0001$), reduced physical activity ($p = 0.024$), a lower body mass index, particularly below 20 kg / m2 ($p = 0.033$), elevated markers of inflammation ($p = 0.003$), a duration of disease over 12 months (0.049), the extent of disease (0.001), and active disease (0.016), total duration of corticosteroids consumption over 12 months ($p = 0.02$), and a cumulative dose of corticosteroids > 4.5 g of Prednisone ($p = 0.001$). In multivariate analysis, the following factors were independently predictive of bone loss: limited physical activity ($p = 0.013$), body mass index < 20 kg / m2 (0.015), active disease ($p = 0.035$), the extent of the disease ($p = 0.006$), and a cumulative dose of corticosteroid exceeding 4.5g of Prednisone ($p = 0.003$).

Conclusion: Bone loss and osteoporosis are commonly reported in patients with IBD. Bone mineral density screening must be conducted systematically for patients with IBD with greater risk related to reduced physical activity, body mass index < 20 kg / m2, active disease, extensive disease, and a cumulative dose of corticosteroids > 45g.

Contact E-mail Address: cecile_vignal@hotmail.com
Introduction: Inflammatory bowel diseases (IBD) are chronic and relapsing, life-long diseases of the gastrointestinal tract. Environmental factors which have a crucial role in the development of these diseases remain largely unknown. Few studies have described Advanced Glycation End-Products (AGE) as potential contributors of intestinal inflammation, and the role of AGE and their receptor RAGE in the pathophysiology of IBD are not yet fully elucidated.
Aims & Methods: The global aim of our study was to address the link between AGE, RAGE, and IBD which might help to better understand the role of nutrition, as a major source for AGE, in the pathophysiology of IBD.
Three different models of intestinal and colonic inflammation (indomethacin, dextran sodium sulfate (DSS) and trinitro benzene sulfonic acid (TNBS)) were induced in C57BL/6 wild type (WT) and RAGE null mice. In a second set of experiments, mice were orally administered with the food derived ligand for RAGE, carboxymethyllysine-bovine serum albumin (CML-BSA) or control BSA for 30 days; then, intestinal and colonic inflammation were induced. Severity of inflammation was evaluated using macroscopic, histologic and molecular parameters in the small intestine and colon of mice.
Results: Following indomethacin administration, a significant decrease in ulcerations number and area was observed in the duodenum, jejunum and ileum of RAGE null mice compared to WT mice. Consistently, *IL1b* mRNA levels were significantly decreased in the three intestinal segments. RAGE null mice were protected from DSS- and TNBS-induced colitis, with a significant decrease of clinical and macroscopic parameters. Myeloperoxidase (MPO) activity, reflecting the neutrophil infiltration, was also significantly reduced in the colon of TNBS-treated RAGE null mice compared to TNBS- treated WT mice. *IL1b* and *iNOS* mRNA expression were significantly decreased in colitic RAGE null mice compared to colitic WT mice. Chronic BSA-CML administration to mice worsened indomethacin-induced enteritis, as evidenced by a significant increase in ulcerations number and area in the duodenum, jejunum and ileum compared to control BSA-treated mice. Consistently, MPO activity and oxidative stress assessed by anion superoxide dosage were significantly increased in the ileum of CML BSA-treated mice compared to control BSA-treated mice. Chronic CML-BSA administration did not induce any effect on colonic inflammation.
Conclusion: We demonstrated that RAGE signaling pathway is implicated in intestinal and colonic inflammation in mice. We showed that BSA-CML might be a dietary factor involved in intestinal inflammation. The role of RAGE and AGE in IBD now merits further investigations.

P0281 CASP8 INHIBITION IN CD4+ T CELLS BLOCKS CHRONIC INTESTINAL INFLAMMATION

I. Backert[1], M. Leppkes[1], M. F. Neurath[1], **C. Neufert**[1]
[1]*University Hospital Erlangen, First Department of Medicine, Erlangen, Germany*

Contact E-mail Address: clemens.neufert@uk-erlangen.de
Introduction: Caspase 8 (CASP8) is an aspartate-specific cysteine protease that has been recently linked to inflammatory bowel diseases (IBD), and CD4+ T cells are well-known key players influencing the perpetuation of mucosal inflammation in IBD patients. Previous work identified CASP8 as a central regulator of T cell fate decisions which can exert pro– as well as anti-inflammatory effector functions depending on the cellular and molecular context.
Aims & Methods: The T cell-specific role of CASP8 during intestinal inflammation has not been clarified yet. To address that topic, we have analyzed the potency of FACS-sorted naïve CD4+ T cells from several genetically modified mouse strains to induce intestinal inflammation in the adoptive transfer model of chronic colitis. Serial inspections of colonic inflammation were performed in vivo by mini-endoscopy. In addition, histopathological analyses and immunofluorescence studies were done in colon cross-sections, and immunomonitoring was performed by FACS in lamina propria and mesenteric lymph node cells.
Results: Interestingly, CASP8 deficient T cells failed to induce intestinal inflammation, produced decreased levels of pro-inflammatory cytokines and showed diminished accumulation in immunocompromised hosts, despite being highly resistant to Fas induced apoptosis. Co-transfer of congenic wildtype T cells demonstrated that the CASP8-deficient T cell population expanded less efficiently under the same in vivo conditions as wildtype cells. Additional genetic deletion of RIPK3, but not ATG7 fully restored the colitogenicity of CASP8 deficient T cells, indicating that T cell necroptosis represents a key mechanism for the blockade of intestinal inflammation. Moreover, we could show that pro-inflammatory human T cells from IBD patients can be targeted via RIPK3-RIPK1-kinase-dependent necroptosis.
Conclusion: Our study demonstrates a critical role of CASP8 in CD4+ T cells during chronic intestinal inflammation. Thus, the blockade of CASP8 and induction of necroptosis in CD4+ T cells might emerge as a novel therapeutic strategy for IBD patients.

Introduction: Human intestinal dendritic cells (DC) maintain a balance between tolerance to nutrients/commensals and immunogenicity against pathogens. Changes in intestinal DC properties are found in inflammatory bowel diseases including Crohn's disease (CD). Most studies, however, do not consider DC compartmentalization through the human gut. Here we studied whether DC subsets and phenotype change through the human gut in healthy controls (HC) and CD patients.
Aims & Methods: Paired biopsies from human proximal colon and the terminal ileum (TI) were obtained from HC and CD patients. DC were identified following collagenase digestion where DC phenotype were assessed by flow cytometry. Antigen presenting cells ($CD45^+HLA\text{-}DR^{high}$) were identified within single viable cells. Discrimination between DC and Mϕ was subsequently performed based on lineage marker expression (CD3,CD14,CD16,CD19,CD34) and side scatter properties of the cells identifying DC as $CD45^+HLA\text{-}DR^+lineage^-complexity^{low}$. DC were further distinguished from Mϕ as $CD64^-$ with CCR7 up-regulation following overnight culture.
Results: In all samples, intestinal DC were myeloid (mDC, $CD11c^+$) and were further divided into different subsets based on CD103 and SIRPα expression. $CD103^-SIRPa^+$ and $CD103^+SIRPa^+$were type 1 immature mDC ($CD1c^+CD141^-ILT3^+$) while $CD103^+SIRPa^-$ were type 2 mature mDC ($CD1c^-CD141^+ILT3^-$). CCR2 was expressed in all $CD103^-SIRPa^+$ DC, with expression being variable on $CD103^+SIRPa^+$and absent on $CD103^+SIRPa^-$ DC. In HC, total DC numbers were higher in the proximal colon compared with the TI with no differences in the CD103/SIRPα DC subset composition between compartments. However, the TI from HC carried higher numbers of $CCR2^+$DC and $CD11c^{dim}CD1c^-$ DC.
In CD patients compared with healthy controls, DC numbers were higher in both the colon and the TI and displayed a specific reduction of $CD103^+SIRPa^+$ DC in both tissues. CCR2 expression on ileal and colonic DC did not differ between HC and CD. In CD, however, the proportion of ileal $CD11c^{dim}CD1c^-$ DC was lower in CD patients than in HC, an effect that was not seen in the proximal colon. Finally, TLR2 and TLR4 expression were higher in both the colon and TI from CD patients, compared with the healthy matched tissue, due to a specific up-regulation of $CD11c^+CD1c^+$DC.
Conclusion: DC subsets and phenotype change through the length of the human gastrointestinal tract and display different tissue-specific alteration in CD patients. Tissue compartmentalization is, therefore, likely to affect the results of studies addressing the immune system of the human gut, both in health and disease.

[1]*Hospital Therapy, Kazan State Medical University,* [2]*Gastroenterology, Republican Clinical Hospital, Kazan, Russian Federation*

Contact E-mail Address: muhdilyara@gmail.com
Introduction: Disorder of intestinal microbes is thought to play a critical role in the pathogenesis of inflammatory bowel diseases (IBD). Evaluation of bacterial Ig could become a new approach to judge the situation of this disease.
Aims & Methods
Aim: to evaluate IgA, IgM and IgG levels to *Clostridium difficile* infection (CDI) in patients with IBD.
Methods: We prospectively included 147 pts with IBD – 92 pts with ulcerative colitis (UC) (87 in exacerbation and 5 in remission), 55 pts with Crohn's disease (CD) (44 in exacerbation and 11 in remission) and 30 healthy controls. Concentrations of IgA, IgM and IgG to lipopolysaccharide of CDI were evaluated by immunoassay. Mean age in UC was 38.18 ± 1.23 years, CD – 28.04 ± 2.11 and in control group – 30.13 ± 1.53. Severity of UC was assessed by Mayo score: mild – 28 (32.2%), moderate – 43 (49.4%), severe – 16 (18.4%). Severity of CD was assessed CDAI: mild – 15 (34%), moderate – 16 (36.4%), severe – 13 (29.6%).

Results: There was increasing of IgA, IgM and IgG levels to CDI in UC and CD compared to controls (Table 1).

Table 1: IgA, IgM and IgG levels to *Clostridium difficile* infection

	Ig A	Ig M	Ig G
control group	0.009 ± 0.005	2.99 ± 0.4	1.76 ± 0.27
exacerbation of UC	0.017 ± 0.003	5.46 ± 0.41***	6.49 ± 1.13***
remission of UC	0.06 ± 0.05	5.77 ± 2.09	6.05 ± 3.17
exacerbation of CD	0.02 ± 0.003**	6.09 ± 0.79**	8.74 ± 2.0***
remission of CD	0.12 ± 0.002	4.36 ± 1.06	5.83 ± 3.11*

*$p < 0.01$ v. control, **$p < 0.005$, ***$p < 0.001$

Immune response to CDI correlated with clinical parameters of IBD: in CD with IgM increasing faeces were more loose ($r = –0.29$; $p < 0.05$); in UC the increasing of IgA to CDI correlates with defecation rate decreasing ($r = -0.23$; $p < 0.05$), loosing of faeces ($r = -0.27$; $p < 0.05$), less weight loss ($r = -0.26$; $p < 0.05$). There is higher level of IgG to CDI in older patients with UC ($r = 0.24$; $p < 0.05$). In UC the increasing of IgA to CDI correlates with gamma-globulin blood level ($r = 0.31$; $p < 0.05$), alpha 1-globulin level increases with increasing of IgG to CDI ($r = 0.30$; $p < 0.05$).

Conclusion: The majority of pts with active IBD have increased IgM and IgG levels to CDI compared to control. Antibodies changes correlated with IBD clinical features and laboratory data.

Contact E-mail Address: ktriant@med.uoa.gr

Introduction: NLRP3 inflammasome is a multimolecular cytosol complex that when activated contributes to the cleavage of pro-interleukin (IL)-1β to IL-1β via caspase-1 activation[1]. NLRP3 activation can derive from both organic and inorganic substances and has been described to have in a variety of auto-inflammatory disorders. Evidence for a role of systemic NLRP3 activation in inflammatory bowel disease (IBD) is still lacking. Herein, we present the final results of our study on inflammasome activation in IBD; prelimenary results were presented at UEGW 2013[2].

Aims & Methods: Human peripheral blood mononuclear cells (PBMCs) were isolated from 20 Crohn's disease (CD) patients, 21 ulcerative colitis (UC) patients and 17 controls after gradient centrifugation of heparinized whole blood over Ficoll. PBMCs were stimulated at a density of $5x10^6$/ml with 10 and 0.1ng/ml of the TLR4 ligand lipopolysaccharide (LPS) of *Escherichia coli* O55:B5 in the absence or presence of different concentrations of NLRP3 stimulant monosodium urate (MSU). After 24h of incubation at 37^0C at $5\%CO_2$, concentrations of IL-1β, IL-6 and TNFα were measured in cell supernatants by an enzyme immunoassay. In separate experiments, PBMCs were lysed with Trizol for RNA isolation and measurements of *IL-1β* gene transcripts by RT-PCR using *β2*-microglobulin as the housekeeping gene. NLRP3 activation was considered as a more than 30% enhancement of IL-1β production after MSU addition.

Results: NLRP3 activation was found in 12 (75%) patients with CD compared to four (26.7%) controls, ($p = 0.045$) while no significant difference was detected between UC and controls (11/20 or 55% vs. 4/15 or 26.7%, $p = 0.17$), as shown in the table of mean changes of cytokine production and of respective copies. Moreover in CD patients, NLRP3 activation was proportionate to the time since the last intensification of treatment ($r = 0.95$, $p < 0.001$). Among UC patients, NLRP3 activation was found in eight (72.7%) with late (duration >1.5 years) and in nil with early disease ($p = 0.03$), respectively; no similar association was found in CD patients. No difference was detected regarding changes in IL-6 and TNFα levels and IL-1β transcripts numbers among IBD patients and controls (table). There was no association between NLRP3 activation and disease location, activity, current immunosupressive treatment and smoking status in IBD patients.

	Controls	UC	CD
% change of IL-1β	27.7 ± 26.7	258.6 ± 119.4*	$1919.2 \pm 1387.3^{\$}$
% change of IL-6	$2428 \pm 1997^{@}$	$822.3 \pm 701.4^{@}$	$919.3 \pm 599.3^{@}$
% change of TNFα	$203.5 \pm 100.2^{\#}$	$1675.3 \pm 616.6^{\#}$	$779.4 \pm 247^{\#}$
IL-1β transcripts	$206.4 \pm 188.9^{\wedge}$	$55.3 \pm 25.1^{\wedge}$	$528 \pm 510.1^{\wedge}$

*$p = 0.148$ vs. controls, $^{\$}p = 0.032$ vs. controls, $^{@}p > 0.6$ (controls vs. UC & CD), $^{\#}p > 0.082$ (controls vs. UC & CD), $^{\wedge}p > 0.82$ (controls vs. UC & CD)

Conclusion: NLRP3 is activated in CD patients, as compared to controls, and especially in those with long-term intensified treatment. Among UC patients NLRP3 inflammasome activation is detected only in those with long-standing disease.

Introduction: Platelet activation is a consistent feature in inflammatory bowel disease and is thought to contribute to both the proinflammatory and procoagulant states of this disorder. The role of circulating platelet derived microparticles (PDMPs) and the effect of 5-amino salicylate acid (5ASA) and anti-TNF-a agents on their levels has not yet been clarified.

Aims & Methods: The aim of the study is to evaluate the levels of circulating PDMPs, as well as, the effect of 5ASA and anti-TNF-a treatments on these levels in IBD patients. Platelet-rich plasma was isolated from 47 patients with Crohn's disease (CD), 43 patients with ulcerative colitis (UC) and 26 sex and age-matched healthy controls. Clinical disease activity was assessed by Harvey-Bradshaw index for CD, Mayo score for UC and serological activity by measurement of C-reactive protein (CRP). Drug treatment at the time of blood sampling was recorded. Using flow cytometry, PDMPs were measured as the percentage of CD 36+microparticles, as well as, the percentage of CD36+microparticles expressing annexin (a phospholipid binding protein of the platelet surface expressing platelet activation) by total events with appropriate size and scatter; CD36 being a platelet surface marker.

Results: Overall, CD patients have greater percentage of CD36+microparticles ($0.31\% \pm 0.07\%$ vs. $0.14\% \pm 0.04\%$, $p = 0.02$) and of CD36+microparticles expressing annexin ($27\% \pm 2.6\%$ vs. $14.6\% \pm 2.7\%$, $p = 0.002$), in comparison with healthy controls. However, there is no correlation of percentages of both microparticles with Harvey-Bradshaw index and CRP. CD patients not receiving 5ASA have also greater percentage of CD36+microparticles expressing annexin ($25.8\% \pm 2.8\%$ vs. $14.6\% \pm 2.7\%$, $p = 0.005$), in comparison with healthy controls. Moreover, CD patients on 5ASA therapy show lower percentage of CD36+microparticles in comparison with those not receiving 5ASA ($0.30\% \pm 0.07\%$ vs. $0.32\% \pm 0.09\%$, $p = 0.048$). Anti-TNF-a treatment has no effect on both microparticle percentages in CD patients. In contrast to CD, UC patients have similar percentages of CD36+microparticles and of CD36+microparticles expressing annexin, as compared to healthy controls ($p = 0.06$ and $p = 0.2$, respectively), and there is no correlation of percentages of both microparticles and disease activity (Mayo score and CRP). Moreover, 5ASA and anti-TNF-a treatments have no effect on both microparticle percentages in UC patients.

Conclusion: Circulating levels of platelet derived microparticles are increased only in CD but they are not correlated with disease activity. The use of 5ASA is associated with lower levels of CD36+PDMPs only in CD, while anti-TNF treatment does not influence their levels in CD and UC patients.

Introduction: Inflammatory bowel disease (IBD) is a chronic disorder of the gastrointestinal tract characterized by epithelial barrier disfunction and imbalance immune response. Recent pharmacological treatment has significantly improved the course of the disease but there are still a high percentage of patients that do not respond to current therapies.

Aims & Methods: We aim to evaluate the effects of the ethanolic extract of *Hylocerus sp.* (EH) in a murine model of colitis induced by TNBS. Colitis was induced in Balb/c mice by the intrarectal administration of TNBS (3.5mg/20g). Control animals received an intrarectal injection of TNBS-vehicle (EtOH 40%) (day 0). Six hours after TNBS, mice received an i.p. injection of EH (20 mg/20g mice) or its vehicle (DMEM). Changes in body weight were determined daily (results are expressed as percentage vs the weigth at day 0) and mice were sacrificed 2 and 4 days after TNBS administration. Mucosal histology was evaluated according to Wallace Score (1-10). Colons were frozen for RNA and protein isolation. The mRNA expression of *iNOS*, *Arginase I*, *COX-2*,

TNF-α, *IL-1β*, *IL-6* and *IL-10* was analysed by qPCR and protein levels of NF-κB and Iκβ-α were determined by western blot.

Results: Treatment of mice with TNBS induced a loss of body weight that peaked 2 days after treatment. Subsequently, mice began to recover and, four days after treatment, body weight reached similar values to those of control animals. In TNBS-treated mice, the administration of EH significantly ($P < 0.05$) prevented the loss of body weight ($91.97 \pm 1.65\%$) compared with the injection of vehicle ($86.40 \pm 2.05\%$), two days after TNBS. Mice receiving the EH exhibited a significant reduction in histological damage score (3.6 ± 0.6) compared with that detected in mice receiving vehicle (7.0 ± 1.0), four days after treatment. The increase in the expression of pro-inflammatory molecules detected 2 days after TNBS was significantly prevented ($P < 0.05$) by treatment with EH while no significant differences were detected in the expression of the anti-inflammatory molecule IL-10 (Table 1). Iκβ-α degradation and nuclear NF-κβ translocation were detected in the colon of TNBS-treated mice which was significantly prevented in the colon of mice receiving the EH.**Table1:** mRNA expression of different molecules detected in the colon of TNBS-treated mice. Results are expressed as fold induction vs the value obtained in mice that did not receive TNBS.

	iNOS	ArgI	COX-2	TNFα	IL-1β	IL-6	IL-10
Vehicle	5.3 ± 0.2	22.1 ± 4.1	1.7 ± 0.9	8.8 ± 1.9	1.9 ± 0.3	11.8 ± 3.8	1.2 ± 0.2
EH	0.5 ± 0.2	4.1 ± 1.3	0.5 ± 0.1	1 ± 0.2	0.8 ± 0.2	2.0 ± 0.4	1.8 ± 0.3

Conclusion: Systemic administration of the ethanolic extract of *Hylocereus sp* exerts an anti-inflammatory effect and prevents murine colitis induced by TNBS.

Introduction: Endoplasmic reticulum (ER) function and autophagy are necessary to maintain cellular homeostasis. Genetic variants of inflammatory bowel disease (IBD) risk genes like *ATG16L1* or *XBP1* are associated with epithelial ER stress. While *XBP1* plays a beneficial role in resolving ER stress, altered function of *ATG16L1* leads to defective autophagy and subsequent deregulation of ER function. ER stress impairs intestinal immune defense against pathogens and promotes cell death. Interleukin (IL) 22 is known to be a protective cytokine in mucosal regeneration through downstream expression of antimicrobial peptides and epithelial proliferation via STAT3 activation, respectively.

Aims & Methods: In this study, we investigate the impact of IBD risk genes *ATG16L1* and *XBP1* on regenerative function of IL22 in intestinal epithelium. Human colon carcinoma cells (HT-29 and CaCo-2) were treated with recombinant IL22 and ER stress inductors like Tunicamycin and were subjected to wound healing assays, gene expression analysis and immunoblot analysis. Intestinal organoids derived from *Xbp1* ΔIEC and *Atg16l1* ΔIEC mice were generated by culturing small intestinal crypts in collagen matrix. These were treated with recombinant IL22 and subjected to gene expression analysis. Organoids were subjected to RNA sequencing and transcriptome analysis. Secreted cytokines in supernatants from cells and organoids were detected with ELISA.

Results: IL22 induces transient self-limiting ER stress in the intestinal epithelium. Regulation of transient ER stress is dependent on *Xbp1* and *Atg16l1* as IL22 treated intestinal organoids from *Atg16l1* ΔIEC und *Xbp1* ΔIEC mice display a dramatic increase of inducible ER stress and pro-inflammatory gene expression. While IL22 improves wound healing in the absence of ER stress, IL22 leads to impaired wound closure and increased cell death under ER stress conditions. This effect is dependent on STAT3 and autophagy as STAT3 inhibition or autophagy induction through rapamycin completely neutralizes IL22 induced detrimental effect.

Conclusion: These data suggest an unexpected role of the IBD risk genes *ATG16L1* and *XBP1* in coordinating regenerative IL22 function in intestinal epithelium.

P0288 MAGNESIUM IN INFLAMMATORY BOWEL DISEASE: AN UNEXPECTED PLAYER

F. Scaldaferri[1], V. Petito[1], D. Arduini[2], W. Hamersma[2], V. Trapani[2], A. Poscia[3], V. Arena[2], E. Stigliano[2], A. Di Agostini[1], F. I. Wolf[2], A. Gasbarrini[1]

Introduction: Magnesium is an essential mineral that is fundamental in many pathophysiological processes. A mild hypomagnesaemia is a common condition associated to dietary deficiency of magnesium. Hypomagnesaemia is a well-known enhancer of oxidative stress and inflammation. Inflammatory Bowel Disease (IBD) is a collection of chronic inflammatory bowel diseases characterised by a variety of nutritional deficiencies due to reduced absorption and/or increased loss of essential nutrients, which among other conditions, can induce hypomagnesaemia.

Aims & Methods: To investigate the influence of magnesium availability in the diet on the severity of murine dextran sodium sulphate (DSS)-induced acute colitis. Mice were exposed to 2.5% DSS in the drinking water and fed three different diets (low (30mg/kg), normal (1000mg/kg) and high (4000mg/kg) magnesium content). Both acute colitis (5 days exposure to DSS) and recovery after the acute colitis (7 days of recovery without DSS) were studied. The severity of the colitis was scored daily using a four-point Disease Activity Index (DAI) based on the faecal consistency, weight loss and faecal blood loss. Colon, kidney and serum were collected at the sacrifice. Magnesaemia was analysed using atomic absorption spectrometry and severity of the inflammation of the colon was scored on morphological examination of haematoxylin/eosin stained slides.

Results: Dietary magnesium deficiency increased the severity of the DSS-induced colitis as scored with the Disease Activity Index, whereas magnesium supplementation seemed to score more or less like controls. Serum magnesium measurements showed that while magnesium in the diets positively correlated with the magnesaemia, the exposure to DSS reduced magnesaemia in all conditions. However, high magnesium content in the diet compensated for DSS-induced hypomagnesaemia (the colitic mice on the magnesium-enriched diet showed a magnesaemia similar to the control group on the normal magnesium diet). Interestingly, morphological analysis of the colon showed that while the low magnesium diet enhanced mucosal damage and impaired mucosal recovery, magnesium supplementation clearly protected the colonic mucosa against DSS-induced damage (much less crypt destruction and inflammatory infiltrates). And after recovery the colonic mucosa of the mice on the magnesium-enriched diet appeared to be absolutely normal.

Conclusion: Magnesium supplementation protects the colonic mucosa, compensates inflammation-induced hypomagnesaemia and seems to help the colonic mucosa restore after acute colitis. Our data suggest an active role of magnesium in the pathogenesis and in the severity of colon inflammatory diseases. The validation of these results in IBD patients is currently under study.

Introduction: The gut microbiota-innate immunity axis guarantees the development, and the functional integrity of the intestine including the nervous system (ENS) embedded in the gut wall. However, the complexity of animal models is a substantial obstacle to dissect the cellular populations and the molecular pathways involved in this interplay. Since many components of innate immunity, including the sensors for conserved microbial structures such as *Toll* genes and Toll like receptors, are shared between *Drosophila melanogaster* and mammals we aimed to identify the enteric cellular populations generating trophic signals, that secure gut neuronal integrity through the Toll pathways using the *Drosophila* model.

Aims & Methods: We ablated *Toll* genes in adult flies by the expression of siRNA using ubiquitous (actin and beta-tubulin) and cellular specific (smooth muscle cells, neurons and glia) temperature inducible drivers. After 8 days of *Toll* genes silencing we: 1) dissected flies gut (20-30 individuals/measure) to perform quantitative RT-PCR for *Toll*1÷9 and *Elav* (a neuronal marker) gene expression; 2) executed immunohistochemistry on gut whole mount preparations using a neuronal (anti-HRP) marker to quantify neuronal bodies in the flies midgut; 3) exposed flies to an intestinal toxic (5% DSS) and daily recorded survival ($n = 60$-90 individuals/group).

Results: In *Drosophila* lines the expression of specific siRNA under the control of ubiquitous drivers significantly reduced in the gut the mRNA levels of *Toll1* (by 82%), *Toll2* (by 99%), *Toll4* (by 80%), *Toll6* (by 38%), *Toll7* (by 96%), *Toll8* (by 85%), *Toll9* (by 95%), as compared to W^{III8} control ($p < 0.01$). The number of neuronal bodies in the midgut was significantly reduced by the silencing of *Toll2* and *Toll9* ($p < 0.01$) but not by the other *Toll*s. Using the ubiquitous drivers actin and tubulin *Toll2* silencing reduced neurons by 92% and 81%, whereas *Toll9* silencing diminished neurons by 95% and 93% as compared to W^{III8} controls. In agreement to the loss of neurons in the midgut, *Elav* mRNA was reduced by 80% and 85%, respectively, in the gut of flies with ubiquitous *Toll2* or *Toll9* silencing. By using specific drivers to silence *Toll2* in smooth muscle and glial cells, *Toll2* mRNA levels were significantly reduced ($p < 0.01$ vs W^{III8} control) in the gut. Accordingly, the number of neuronal bodies in the midgut and the *Elav* mRNA

levels were reduced by 43% and 50% by using the smooth muscle driver and by 85% and 40%, by using the glial cells driver, respectively.
Ubiquitous *Toll2* or *Toll9* silencing reduced mortality by 32% and 31%, respectively, at the 5th day of DSS administration as compared to W^{1118}. While *Toll2* silencing in smooth muscle cells had a protective effect reducing mortality by 30%, *Toll2* silencing in glial cells exacerbated colitis inducing mortality in 95% of individuals as opposed to 86% of W^{1118} ($p < 0.01$).
Conclusion: Loss of *Toll2*- and *Toll9*-derived signals is associated to significant reduction of neuronal bodies in the *Drosophila* midgut. By using the *Drosophila* model was possible for the first time to observe that *Toll2* silencing has opposite effects in smooth muscle cells and glial cells, supporting specific effects of innate immunity-microbes interplay in specific intestinal cell population.

Introduction: The gut microbiota is involved in many physiological functions. An imbalance in its composition named dysbiosis is associated with several diseases and particularly with inflammatory bowel diseases (IBD). Mucosa associated microbiota, that has been shown to differ from faecal one, could have a key role in induction of host immunity and in inflammatory process. Although the role of fungi has been suggested for a long time in IBD pathogenesis, the fungal microbiota has been poorly explored. The aim of the current study was to analyzed the composition of the mucosa associated microbiota of Crohn's disease (CD) patients and healthy subjects (HS) taking into account both bacterial and fungal fractions.
Aims & Methods: Bacterial and fungal composition of mucosa associated microbiota of 23 CD patients (16 in flare and 7 in remission) and 10 healthy subjects (HS) was determined using 16S (MiSeq) and ITS2 (pyrosequencing) respectively. The obtained sequences were analyzed using the Qiime pipeline to assess composition, alpha and beta diversity. Comparisons between clinical groups were performed using Linear Discriminant Analysis Effect Size (LEFSE). Global fungal load was assessed by real time PCR.
Results: Bacterial microbiota in CD patients was characterized by a restriction in biodiversity, a decrease of *Firmicutes* and *Bacteroidetes* and an increase of *Proteobacteria* and *Fusobacteria*. Global fungi load was significantly increased in CD flare compared to HS ($p < 0.05$). No significant difference in fungi biodiversity was observed between the studied groups. Both in HS and CD, the colonic mucosa-associated fungal microbiota was dominated by *Basidiomycota* and *Ascomycota* phyla. *Dioszegia* genera and *Candida glabrata* species were overrepresented in CD whereas *Leptosphaeria* and *Trichosporon* genera were decreased. *Saccharomyces cerevisiae* and *Filobasidium uniguttulatum* species were associated with non inflamed mucosa whereas Xylariales order was associated with inflamed mucosa.
Conclusion: Our study confirms an alteration of the bacterial microbiota and demonstrates the existence of an altered fungal microbiota in CD patients. These alterations are characterized by an increased fungal load in CD and an abnormal composition suggesting that fungi may play a role in CD pathogenesis.

P0291 ACTIVATION OF AUTOPHAGY BY CROHN'S DISEASE-ASSOCIATED E. COLI IS DEPENDENT OF SIDEROPHORE EXPRESSION

G. Dalmasso[1], H. T. T. Nguyen[1], T. Faïs[1,2], S. Massier[1], J. Delmas[1,2], N. Barnich[1], R. Bonnet[1,2]

Introduction: The intestinal mucosa of Crohn's disease patients are abnormally colonized by *Escherichia coli* able to invade and to replicate inside intestinal epithelial cells. Those pathogenic bacteria have been named adherent-invasive *E. coli* or AIEC. Genomic analysis of the AIEC reference strain LF82 has revealed a pathogenicity island of ~34kb (PAI II, for pathogenicity island II) closely related to the "high pathogenicity island" of pathogenic *Yersinia* sp. that encodes the yersiniabactin siderophore system. Bacteria have developed efficient high affinity iron uptake systems (siderophores) promoting their growth in iron-restricted environments.
Aims & Methods: Here, we aimed at investigating the role of the PAI II during AIEC infection. The entire PAI II was deleted and wild-type or the mutated AIEC LF82 strains were used to infect human intestinal epithelial T84 cells. Morphology of AIEC was observed using electron microscopy. AIEC intracellular survival and proliferation were assessed by counting bacterial numbers on Luria Broth (LB) plates. Activation of the transcription factor HIF-1α was assessed by Western blot and by quantifying mRNA expression levels of VEGF, a target gene of HIF-1α. Autophagy was monitored by Western blot for the conversion of LC3-I to LC3-II and by confocal microscopy.
Results: Deletion of PAI II did not alter either morphological aspects (pili, flagella…) or growth of AIEC LF82 bacteria in LB or in T84 cell culture medium. However, loss of PAI II resulted in increases in AIEC intracellular survival and proliferation in T84 cells. This was associated with inhibition of AIEC-induced HIF-1α expression and activation. HIF-1α has been associated with induction of a functional autophagic response. We observed that autophagy was induced in T84 cells infected with wild-type LF82 but not with the mutated LF82. Furthermore, siRNA-mediated HIF-1α silencing in T84 cells inhibited autophagy response, leading to increased intracellular LF82 number, confirming the key role played by HIF-1α in autophagy induction in response to AIEC infection.
Conclusion: Activation of HIF-1α and subsequently autophagy in AIEC-infected cells requires PAI II expression.

Introduction: Inflammatory bowel diseases (IBD) are associated with differential expression of genes involved in inflammation and tissue remodeling. One mechanism of regulating gene and protein expression is by MicroRNAs (miRs). Recently we performed massive sequencing analysis of ileal biopsies showing that increased expression of multiple miRs occurs in intestinal inflammation, specifically that occurring in ulcerative colitis patients after total proctocolectomy and pouch surgery. miRs expression alterations correlated with disease behavior. Among the miRs with significantly altered expression, miR-424 had a robust increase: 8.4 fold change in Crohn's-like disease of the pouch (CLDP) and 2.6 in normal pouch (NP) compared to the ileum of normal controls (NC). We hypothesized that miRs may have a role in down-regulation of mRNA transcripts in IBD.
Aims & Methods: To define the interaction of candidate miRs with their potential targets and the mechanisms modifying miRs expression in intestinal inflammation. miRs and mRNAs were selected based on our previous microarray studies and *in silico* data. Levels of mature and primary miR-424 as well as its potential target genes: solute carrier family 6 member 4 (*SLC6A4*, neurotransmitter transporter) and solute carrier family 36 member 1 (*SLC36A1*, proton/amino acid symporter) were examined in patients with CLDP and NP as well as in NC and in a human epithelial cell line (HCT-116) incubated with inflammatory cytokines (TNF-α, IL-1β, INF-γ) by quantitative reverse transcription-polymerase chain reaction. Regulation of gene expression by miR-424 was assessed by transfection of specific mimic and miR-424 inhibitor.
Results: miR-424 expression was increased (3.3 fold, $p < 0.001$), while SLC6A4 mRNA expression was decreased (5.8 fold, $p < 0.01$) and SLC36A1 expression was lower in ileal biopsies of CLDP patients compared to NC. Primary to mature miR-424 expression ratios were higher in the NP compared to pouchitis (4 fold increase). Similarly, under inflammatory conditions HCT-116 cells expressed 4 fold more miR-424 ($p < 0.05$) and less SLC6A4 (2.8 fold, $p < 0.05$) and SLC36A1 (1.3 fold, $p < 0.01$) compared to untreated cells. Transfection of miR-424 mimic into HCT-116 cells resulted in a decrease in SLC6A4 and SLC36A1 expression (1.3 fold, $p < 0.05$) whereas transfection of miR-424 inhibitor resulted in an increase in SLC6A4 and SLC36A1 expression (2 fold, $p < 0.01$ and 1.3 fold, $p < 0.05$ respectively).
Conclusion: Mature miR-424 expression is increased and its target genes are decreased in intestinal inflammation suggesting its role in gene expression regulation in IBD. The processing of a primary to mature miR is increased in pouch inflammation. As miRs are robustly increased in IBD, the behavior of miR-424 may serve as a proof of concept for the role of miRs in regulating intestinal inflammation in IBD.

Contact E-mail Address: harry.sokol@aphp.fr
Introduction: The intestinal microbiota plays major roles in human physiology as well as in inflammatory bowel diseases (IBD). It is mostly composed of bacteria, but also contains other microorganisms such as virus and fungi. Although the bacterial part of the gut microbiota is being actively studied, almost no data are available regarding the fungal part. The presence of genes involved in sensing and response to fungi among IBD susceptibility genes and recent results in mouse models suggest a role of the fungal microbiota in IBD pathogenesis. Our aim was to characterize the fungal microbiota in IBD patients.
Aims & Methods: Bacterial and fungal composition of the fecal microbiota of 235 IBD patients and 38 healthy subjects (HS) was determined using 16S (ion torrent) and ITS2 (pyrosequencing) respectively. The obtained sequences were analyzed using the Qiime pipeline to assess composition, alpha and beta

diversity. Bacterial and fungal taxa associated with clinical parameters were identified using Multivariate association with Linear Models (MaAsLin) taking into account the following parameters: IBD status, IBD type, disease activity, ileum involvement, gender, age, smoking and treatment (5 ASA, steroids, anti-TNFa, immunosuppressant). Correlation between bacterial and fungal microbiota was investigated using spearman test.
Results: Among the 235 IBD patients (106 in flare, 129 in remission), 149 had Crohn's disease (CD) and 86 had ulcerative colitis (UC).
The results of the bacterial microbiota analysis were in accordance with published data with notably a decreased biodiversity, a decreased proportion of Firmicutes and an increased proportion of Proteobacteria in IBD patients. Beta diversity analysis showed that samples clustered according to disease activity both for bacterial and fungal microbiota. Fungal microbiota in both IBD patients and HS was dominated by the Basidiomycota and Ascomycota phyla, and by the Saccharomyces, Debaryomyces, Penicillium, and Candida genera. The fungal gut microbiota was found imbalanced in IBD patient with notably an increase Basidiomycota / Ascomycota ratio and a decreased proportion of Saccharomyces and Kluyveromyces compared to HS. The fungal biodiversity was also decreased in IBD patients, particularly in those with colon involvement. Many correlations were observed between bacterial and fungal genera abundance suggesting an inter-kingdom crosstalk. These correlations were stronger in UC patients compared to CD patients and healthy subjects. Global correlation network was homogenous and even in HS, whereas it was unbalanced and uneven in IBD patients and particularly in UC, suggesting unbalanced crosstalk.
Conclusion: The fungal gut microbiota is dominated by the Basidiomycota and Ascomycota phyla. The fungal microbiota is imbalanced in IBD patients with a reduced biodiversity and an increased Basidiomycota / Ascomycota ratio compared to HS. Correlation analyses suggest an unbalanced crosstalk globally within the microbiota and particularly between fungal and bacterial microbiota components in IBD patients.

P0294 ATTENUATION OF DSS-INDUCED COLITIS BY PROBIOTIC ADMINISTRATION IS ASSOCIATED WITH IMMUNOSTIMULATING EFFECTS ON REGULATORY T CELLS

H. Zhang[1], Y. Zhang[1], J. Ma[1], J. Su[1]
[1]*Department of Gastroenterology, The First Affiliated Hospital of Nanjing Medical University, Nanjing, China*

Contact E-mail Address: hjzhang06@163.com
Introduction: The exact etiology of inflammatory bowel disease (IBD) remains unclear, there is much evidence supporting the hypothesis of the involvement of intestinal microbiota in IBD pathogenesis. In recent years, there is increasing interest for using probiotic in IBD. A growing body of evidence suggests that the probiotic bacteria has immune-modulatory ability. So, we investigate the effect of administration of probiotic mixture (bifidobacterium, lactobacillus and enterococcus) on colitis and regulatory T cells in DSS-induced mice.
Aims & Methods: The aim of this study is to investigate the effect of administration of probiotic mixture (bifidobacterium, lactobacillus and enterococcus) on colitis and regulatory T cells in DSS-induced mice.
An acute colitis was induced in BALB/c mice (8-10 week-old) using 3.5% w/v dextrane sulfate sodium (DSS). Mice were randomly divided into five groups: NS group (received saline), DSS group (received DSS), BB group (14-day probiotic mixture without DSS), BD group (received 7-day probiotic mixture prior to DSS administration) and BDB group (14-day probiotic mixture with DSS given at 8th day for 7 days). The Disease Activity Index was monitored daily, colon length and weight were measured and histological scores were evaluated. Regulatory T cells (CD4 + CD25 + Foxp3 + T) in spleen and blood were measured by flow cytometry.
Results: Probiotic mixture administration attenuates the DSS-induced intestinal damage. Compared with DSS group, disease activity Index (DAI) ($P < 0.001$), colonic length ($P < 0.01$), body weight ($P < 0.01$ in BD group; $P = 0.075$ in BDB group) and histological scores ($P < 0.001$) were significantly improved in mice with probiotic mixture administration. The probiotic mixture protection may be associated with a reduction in CD4 + T cells (total CD4 + T cell in BD group was lower than that of DSS group ($P < 0.05$)). Intervention with probitic mixture led to a significant increase of regulatory T cell in blood ($P < 0.05$), but not in spleen.
Conclusion: Administration of probiotic mixture (bifidobacterium, lactobacillus and enterococcus) can reduce intestinal inflammation and damage in DSS-induced colitis.This result was associated with reduction in total CD4 + T cells and increasing regulatory T cells.

P0295 THE ROLE OF MIR-19B TARGETING SOCS3 IN MEDIATING INTESTINAL INFLAMMATION

H. Zhang[1], J. Ma[1], J. Su[1], X. Cheng[1]
[1]*Department of Gastroenterology, the First Affiliated Hospital of Nanjing Medical University, Nanjing, China*

Contact E-mail Address: hjzhang06@163.com
Introduction: The exact etiology of inflammatory bowel disease (IBD) remains unclear. Current evidence suggested that IBD is caused by complex interactions of environmental, genetic, and immuno-regulatory factors. Of these, immune dysregulation is thought to play important roles in the pathogenesis of IBD. Intestinal epithelial cells (IECs) are prominently linked to the pathogenesis of IBD. IECs can attribute to classic inflammatory response. There is accruing evidence that miRNAs play a role in regulating inflammatory processes. Recently, unique miRNA expression profiles have been described in epithelial cells of patients with active IBD. However, the roles of miRNAs in modulating disruption of epithelia during the process of IBD remain incompletely clear.
Aims & Methods: The aim of this study is to investigate whether miR-19b targeting SOCS3 regulate activation of signal transducer and activator of transcription 3 (STAT3) in IECs and mediate intestinal inflammation.
Acute colitis was induced via an intra-rectal injection of TNBS. Levels of SOCS3 and miR-19b in colon tissues from mice were assessed by Western blot (WB) and qRT-PCR. Distribution of miR-19b in intestinal mucosal of CD patients was performed by RNA in situ hybridization (ISH). STAT3 and phosphorylated-STAT3(p-STAT3)in intestinal tissue were determined by immunohistochemical (IHC). CCK8 and flow cytometry were conducted for detection of proliferation ability in HT-29 cells. The expression of cyclinD1 was detected by WB and qRT-PCR after overexpression or knockdown of miR-19b.
Results: Compared with normal control, levels of miR-19b decreased in lesion tissue, while the expressions of SOCS3 protein increased in TNBS-treated mice. The imbalance of miR-19b and SOCS3 in TNBS-induced colitis was similar to that in CD patients. TNBS-induced colitis was improved after intracolonic administration of miR-19b mimic. Using RNA ISH, miR-19b was obviously decreased in intestinal epithelium in CD patients. Expression of p-STAT3 was decreased in CD patients. Overexpression of miR-19b in HT-29 cells downregulated the protein level of SOCS3, but not SOCS3 mRNA. The proportion of cells in phase (S + G2) was increased in HT-29 cells after overexpression of miR-19b. Downregulation of SOCS3 by miR-19b mimic caused phosphorylation of STAT3. Expression of cyclinD1 was induced in cells treated with miR-19b mimic, which was the down stream of STAT3 and associated with cell proliferation and cell cycle.
Conclusion: Intracolonic administration of miR-19b mimic improved colitis in TNBS-induced mice. MiR-19b targeting SOCS3 regulate activation of STAT3 and influence intestinal epetheliul proliferation. This pathway maybe involved in mucosal healing during intestinal inflammatory lesion.

Contact E-mail Address: anders.ronnblom@akademiska.se
Introduction: The aim of the study was to analyse the first five years of a population based cohort consisting of newly diagnosed patients in all age groups with ulcerative colitis, with respect to medication, surgery and mortality.
Aims & Methods: The patients included in the study were recruited 2005-2009 in the Uppsala Health Care Region (population 642,000) and the cohort has previously been described in detail (1). The average incidence during the study period was 20.0/100 000/year. The mean age for the 526 patients was 39.2 years (median 36.0, IQR 23.0-54.0, range 3-88). The gender distribution male/female was 1.24/1. The medical notes were checked, patients that had moved before five years of observation were contacted by mail for supplementary information.
Results: Of the original 526 patients, two individuals were excluded from further analysis because of uncertain diagnose. Thus the cohort consists of 524 individuals, of whom 495 (87%) could be followed up to 5 years. Nineteen patients (3.6%) had died and two of these could be attributed to IBD (one postoperative death and one colonic cancer). The following drugs were used: 5-ASA (91%), steroids (65%), antimetabolites (28%) and anti-TNF (11%). During the 5-year observation period, 27 patients were subjected to colectomy because of ulcerative colitis, representing 5.7% using Kaplan-Meier survival function. Among patients < 17 years at diagnosis (n = 42), two were operated (4.8%) during the observation period. A multivariate analysis demonstrated that severity of symptoms at diagnosis was correlated to risk for colectomy (S2 + S3 vs SR OR = 15.2 (95% CI 1.87-124.03, $p = 0.01$)). The surgical rate varied according to the various geographical areas of the region (3.0% in the area served by the University Hospital and 11.7% in the surrounding counties).
Conclusion: Five years after diagnosis of ulcerative colitis, 5.7% had been subjected to colectomy. The geographic variation of operative treatment was considerable (3.0-11.7%) due to different approaches to severe episodes of colitis. Mortality caused by ulcerative colitis was low (0.44%)

P0297 AFFECTIVE TEMPERAMENT TRAITS IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE ASSESSED BY TEMPERAMENT EVALUATION OF MEMPHIS, PISA, PARIS AND SAN DIEGO AUTOQUESTIONNAIRE AND THEIR IMPACT ON QUALITY OF LIFE

A. Mokrowiecka[1], A. Borkowska[2], E. Malecka-Panas[1]
[1]*Dept of Digestive Tract Diseases, Medical University of Lodz, Lodz,* [2]*Dept of Clinical Neuropsychology, Collegium Medicum, Bydgoszcz, Poland*

Contact E-mail Address: annazlo@wp.pl

Introduction: Affective temperaments can be considered as the subclinical manifestation of affective disorders, which have an impact on the clinical course of chronic diseases as inflammatory bowel disease (IBD). Coping abilities of patients are influenced by their personality. Temperament variations may be useful to identify patients at risk and for further introducing the personalized therapy.

Aims & Methods: To explore the effect of affective temperament traits on disease-specific quality of life in patients with ulcerative colitis (UC) and Crohn's disease (CD).

The study embraces 116 patients with IBD: 61 with UC and 55 – with CD, aged 19-84 years (mean 43 ±7.8), in remission, without serious mental or medical conditions.

The patients completed the Temperament Evaluation of Memphis, Pisa, Paris and San Diego Autoquestionnaire (TEMPS-A), which is the assessment for five dimensions of temperament: depressive (TEMPS-A-D), cyclothymic(C), hyperthymic (H), irritable (I) and anxious (A).

For five temperament traits 0-1 scores were calculated. Higher score indicated the higher intensity of affective temperament. Patients Health-Related Quality of Life (HRQL) was assessed with the Inflammatory Bowel Disease Questionnaire

Results: Overall, more than 70% TEPMS-A scores were higher in IBD patients compared to general Polish population. In 25 patients (22%) we found 3 and more affective temperament traits with scores more than 0.5. In 37 patients (33%) at least one score was more than 0.7. The most common combination of affective traits was: depressive, cyclothymic and anxious and these traits reached the highest scores. Irritable temperament score was significantly higher in CD compared to UC patients ($p < 0.01$).

Mean HRQL in IBD patients were significantly decreased and mean IBDQ scores were 145/ 224. Significant negative correlation was found between HRQL in all IBDQ domains and TEMPS-A traits: D ($p < 0.001$), C ($p < 0.01$), I ($p < 0.05$) and A ($p < 0.001$).

Conclusion: The results confirmed that affective temperament traits have negative impact on quality of life in IBD patients. Personality traits should be taken into account when using IBDQ in studies as well as in management with IBD patients.

Contact E-mail Address: cristina_rdesantos@merck.com

Introduction: ECCO guidelines indicates that psychological factors may have an impact on the course of ulcerative colitis (UC).

Aims & Methods: Here we describe the impact of UC on everyday life and feelings as perceived by patients followed in hospital clinics from Spain.

Methods. Thirty-nine gastroenterologists handed each a survey to 15 consecutive patients aged ≥18 years. Patients completed the survey at home and returned it by mail. The emotional impact was evaluated through questions on impact of UC on everyday life, quality of sleep, and feelings (ranked from "never" to "always").

Results: Response rate was 75% (436/585, mean age 46 years, 53% men). During the past year 51% reported at least one exacerbation and 43% perceived their UC as moderate or severe. For 79% of patients UC prevented them from doing a normal life. The figures were similar regarding age, gender or disease duration. A total of 76% reported UC affected the quality of their sleep, the percentage was higher in women (83% vs 69% in men $p = 0.001$). Those who perceived UC as moderate or severe reported more frequently impact on everyday life and rest than those describing mild disease (92% vs 69%, $p < 0.001$ and 89% vs 65%, $p < 0.001$ respectively). The percentage of patients reporting negative feelings due to UC "frequently" or "most of the time" is shown in the table. No differences were found by age ranges. Anxiety and depression were more frequently rated as "frequently" or "most of the time" by women ($p < 0.001$ and $p = 0.017$ vs men [table]). Those with higher disease burden during past year (with a flare, with perception of moderate/severe UC or with symptoms impacting everyday life), had all the feelings more frequently rated as "frequently" or "most of the time" ($p < 0.05$, table).

Conclusion: Data reported by patients underline the noteworthy impact of UC on emotions, everyday life and rest. Patients with higher burden of disease described more frequently such negative emotions. Following ECCO recommendations checking emotional aspects should be part of regular clinical practice.

Acknowledgments. Funded by Merck Sharp & Dohme of Spain and endorsed by ACCU (Spanish association of Crohn's and ulcerative colitis patients)

P0299 ULCERATIVE COLITIS IN THE ELDERLY: A DESCRIPTIVE ANALYSIS OF DISEASE IN THE UK

C. Alexakis[1], V. Chhaya[2], E. Cecil[3], S. Saxena[3], R. Pollok[2]
[1]*Gastroenterology, St George's,* [2]*Gastroenterology, St George's Hospital,* [3]*Department of Primary Care and Public Health, Imperial College London, London, United Kingdom*

Contact E-mail Address: richard.pollok@nhs.net

Introduction: The presence of an ageing population combined with an increase in the incidence of inflammatory bowel disease (IBD) may mean that the burden of elderly-onset ulcerative colitis (UC) will become more apparent. Relatively limited information is available about the disease process in this group. Recent cohort studies from European IBD populations have shed some light on this issue [1,2], but equivalent data for the British population has not yet been described.

Aims & Methods: We aimed to describe demographics, therapies and outcomes in a cohort of British patients with elderly-onset UC (diagnosis confirmed after 60th birthday). Data was sourced from the Clinical Practice Research Datalink (CPRD). This is one of the largest primary care datasets in the UK and has detailed information on diagnoses, clinical events and prescription data for 8% of the British population. Data on disease parameters, medication prescriptions and surgical procedures were collected on individuals aged greater or equal to 60 years with READ codes indicating a diagnosis of ulcerative colitis, over the study period 1990 to 2012. Patients with co-morbid conditions necessitating regular steroid or immunosuppressant therapy were excluded from the final anaylsis.

Results: Over the study period, 4775 patients (52.5% male) with elderly-onset UC were identified, with a mean follow-up of 3.9 years. Mean age at diagnosis was 71.5 years. The proportion of current, non, and ex-smokers were 10.5%, 53.2% and 36.3% respectively. 58.4% of patients had received at least one prescription of 5-aminosalicylate therapy. 46.0% had received a course of oral steroids during follow up with 34.3% prescribed corticosteroid therapy within the first year after diagnosis. 18.1% of patients were classified as steroid dependent (i.e. receiving steroid course > 3 months, or needing a repeat course of steroids within 3 months of finishing the previous course). 8.7% had a prescription for thiopurine (TP) therapy with 4.6% receiving TPs in the first

(a) $P < 0.05$ vs "Never" ; (b) $P < 0.05$ vs "Sometimes"

year of diagnosis. 3.9% of elderly onset UC patients underwent colectomy during follow up versus 5.1% in patients aged less than 60 (Fisher's exact test $p = 0.009$). Over half of elderly patients requiring colectomy had surgery within the first year of diagnosis. The table demonstrates multivariate logistic regression of risk factors associated with need for colectomy in elderly patients.

	Odds Ratio	95% Confidence Intervals	p value
Smoking	1.27	0.95-1.70	0.1
5-ASA use	1.12	0.73-1.71	0.51
Thiopurine use	3.77	2.42-5.89	< 0.0001
Steroid dependency	2.05	1.35-3.12	0.001

Conclusion: Although colectomy rates appear comparitively lower than in younger populations, suggesting a more benign disease course, there is a concerning level of steroid dependency in this cohort of elderly patients who will be at particular risk from the many side effects of corticosteroid treatment. The low TP use in this group may reflect a less aggressive disease course, but may also indicate cautious prescribing in this age group.

Contact E-mail Address: cristina.rdesantos@merck.com

Introduction: ECCO guidelines point out that psychological disorders contribute to poorer quality of life (QoL) and to increase the number of doctor visits regardless of disease severity.

Aims & Methods: We describe the prevalence of negative feelings and health resources consumption in UC patients followed in Spanish hospitals.

Methods. Thirty-nine gastroenterologists handed a survey to 15 consecutive UC patients aged ≥18 years. Patients completed the survey and returned it by post-mail. The emotional impact of UC was collected by closed questions about feelings (ranked from never to always), and self-confidence. Patients were asked about health resources consumption during the previous year.

Results: Response rate was 75% (436/585, mean age 46 years,53% men). Up to 38% felt that UC reduced their self-confidence. A higher impact of UC on self-confidence was described by older patients ($p = 0.01$), those with longer disease duration ($p < 0.001$) or higher burden of disease [i.e flares during previous year ($p = 0.05$), perception of UC as moderate or severe ($p < 0.001$) and presence of symptoms impacting everyday life ($p < 0.05$)]. The previous year 19%, 31% and 47% respectively reported hospital admissions, emergency room visits or non-scheduled visits. Negative feelings reported by patients are described in the table. Health resources consumption was significantly more frequent among those who scored negative feelings as "sometimes" or "frequently/always" (table).

Conclusion: In this survey, UC patients reported a significant impact on emotional health and self-confidence. Patients with more frequently negative feelings also described more frequency of health resources consumption.

Acknowledgments. Funded by Merck Sharp & Dohme of Spain and endorsed by ACCU (Spanish association of Crohn's and ulcerative colitis patients)

Introduction: Crohn's disease is a chronic relapsing disease affecting men and woman at their prime, influencing both physical and social aspects of life. We hypothesized that surgery can be perceived as a life event that improves disease perception for the patients and those surrounding them. We investigated this issue in a community cohort of adult Crohn's patients.

Aims & Methods: Consecutive adult Crohn's disease patients were recruited from IBD clinics in 5 tertiary hospitals and from our website call, and filled out their demographics, disease status, Harvey-Bradshaw Index (HBI), and the social questionnaires: SF-36 (generic quality of life), and Brief Symptom Inventory (BSI, measures psychological stress). For the analysis parametric and nonparametric statistics were used as required. A logistic multivariate regression model was utilized to examine the associations between surgery as dependent variable with socio-demographic, HBI, BSI and SF-36 variables.

Results: The cohort comprised 518 patients, with mean (±SD) age 40.0 ± 14.8 years. Of these, 156 patients (30.1%) had undergone surgery (CD-S) and 362 (69.9%) not (CD-NS). 38.1% of 189 men underwent surgery versus 25.5% of 329 of women ($p < 0.003$). Duration of illness was greater in CD-S, 15.9 ± 9.7 years, versus CD-NS, 9.2 ± 7.3 years ($p < 0.05$), although there was no statistical difference in age between these groups. Smoking status in CD-S (18.4%) and CD-NS (19.8%) was also similar. CD-S patients had more severe present illness than CD-NS as shown by the HBI scores, with 46.8% having HBI > 7 versus 33.9%, respectively ($p < 0.001$). In the multivariate analysis CD-S was significantly associated with male sex, HBI, and selected components of SF-36 and BSI (Table).

Table: Results of multivariate analysis for Surgery (CD-S) as dependent variable*

	OR	p
Gender (male)	1.592	0.032
HBI	1.144	<0.001
BSI: somatization	0.589	0.025
BSI: global severity index	1.544	0.088
SF-36: bodily pain	1.016	0.005
SF-36: general health	0.972	<0.001
SF-36: vitality	1.026	<0.001

*Adjusted for age, education, and the other components of BSI and SF-36.

Conclusion: Crohn's disease patients who underwent surgery were more likely to be males, had evidence of greater disease activity and more psychological stress. They had reduced quality of life with more bodily pain and poorer general health.

Introduction: A significant proportion of Crohn's disease (CD) patients shows depressive and anxious disorders. Depression may also lead dysfunctional coping strategies, which implement non-adaptive and often counter-productive behaviours.

Aims & Methods: This study assessed the prevalence of anxious or depressive symptoms, and evaluated the coping strategies in CD patients with severe depressive disorders.

One hundred consecutive CD patients in clinical remission, regularly followed in our IBD Unit were included in the study. Patients with diagnosis of psychiatric disorder preceding the diagnosis of CD and patients with history of substance abuse or neoplastic diseases were excluded.

The eligible patients were screened to identify anxiety and/or depression by using Hospital Anxiety and Depression Scale (HADS). Patients with HADS scores ≥8 in the subscale "depression" were further investigated by means of Cognitive Behavioural Assessment 2.0 and Beck Depression Inventory (BDI). Afterwards the coping strategies were assessed through the Brief-COPE questionnaire.

Results: Thirty-seven patients showed psychiatric co-morbidity: 21 patients had anxious symptoms, and 16 had depressive symptoms with (15 patients) or without (1 patient) anxious symptoms. Seven of these patients (43.8%) showed significant depressive symptoms confirmed at Beck Depression Inventory. None of them had ever been treated for depressive disorder.

Compared to patients without psychiatric disorders, these patients showed lower values of "positive reframing" (p:0.017) that refers to the items "I try to see it in a different light, to make it seem more positive" and "I look for something good in what is happening"; lower values in "planning" (p:0.046) that corresponds to the item "I try to come up with a strategy about what to do". Conversely, patients with depression showed higher score in "use of instrumental social support" ($p < 0.001$) corresponding to the items "I talk to someone to find out more about the situation" and "I try to get advice from someone about what to do", in the "denial" scale (p:0.001) that refers to the items "I say to myself this isn't real" and "I pretend that it hasn't really happened", and in the "use of emotional social support" (p:0.003) that includes the item "I try to get emotional support from friends or relatives".

Conclusion: Depressed CD patients have altered coping strategies, meaning that they may not be able to implement functional strategies to manage at best stress related with their disease. These findings confirm that some CD patients may need psychiatric intervention and an interdisciplinary approach between gastroenterologist and psychiatrist.

P0303 CRYPTOGENETIC AND CROHN'S PERIANAL FISTULA: WHAT CHANGE IN PSYCHOLOGY OF PATIENTS

F. Furfaro[1], C. Bezzio[1], S. Carmagnola[1], A. dell'Era[1], A. Cassinotti[1], S. Ardizzone[1], R. de Franchis[1], G. Maconi[1]
[1]*Gastroenterology, AO Luigi Sacco Milano, Milano, Italy*

Contact E-mail Address: federica.furfaro@alice.it

Introduction: Perianal disease has been recognized as a relevant risk factor for anxiety and depression in Crohn's disease. However, its specific impact on mood disorders in patients with cryptogenic fistula has not been reported so far.

Aims & Methods: The aim of our study was to investigate the prevalence and associations of anxiety and depressive symptoms in the subset of Crohn's patients with perianal fistula and in patients with cryptogenic fistula.

Forty-two adult patients with confirmed diagnosis of Crohn's disease, in clinical remission, with perianal fistula and 20 patients with cryptogenetic fistulae were included in the study. Patients were included irrespective to the activity of the fistula, whether actively draining or closed, and clinical history of perianal disease, whether previously operated or not.

All patients were investigated using a standard questionnaire assessing demographic and clinical features of disease, and the presence of psychiatric disorders using standardized questionnaires. The questionnaire assessed the development of psychiatric disorders after the diagnosis of perianal fistula, the use of antidepressant or anti-anxiety therapy and current anxiety or depression by means of the Hospital Anxiety and Depression Scale.

Differences in quantitative data were compared using Chi square and Fisher's exact tests.

Results: Anxiety or depression were reported by 25 (59.5%) patients with Crohn's fistula and by 2 (10%) patients with cryptogenetic fistula ($p < .0001$). Fourteen patients (33.3%) with Crohn's fistulae and 18 (90%) of patients with cryptogenetic fistulae had been operated, whilst actively draining fistula were present in 6 Crohn's patients and in 3 patients with cryptogenetic fistulae.

The prevalence of anxiety with or without depression was not significantly correlated with activity of perianal fistulae, but previous operations for perianal fistulae was significantly correlated with anxiety or depression among Crohn's patients (4.1% vs 12.5%; $p = 0.042$)

Conclusion: Perianal fistula is significantly correlated with anxiety, with or without depression, only in Crohn's disease patients. Further studies are required to assess the impact of perianal disease overall quality of life and to address the need to target interventions.

Contact E-mail Address: felix.brunner@insel.ch

Introduction: Little is known about alcohol drinking behaviour and its influence on gastrointestinal symptoms among patients with inflammatory bowel disease (IBD). In a preliminary analysis of the Swiss IBD cohort data using a screening question on alcohol drinking, we estimated a prevalence of 43% (≥ 1x alcohol consumption per week). Moderate alcohol consumption was associated with a shorter disease extend in ulcerative colitis (UC), whereas a lower risk of flares and hospitalizations was observed in Crohn's disease (CD).

Aims & Methods: We aimed to assess alcohol drinking behaviour and its influence on gastrointestinal symptoms in patients with IBD. Therefore, we sent a questionnaire to patients randomly selected from 3 different groups of patients according to the reported frequency of alcohol consumption at enrolment to the Swiss IBD cohort: Group A (< 1x weekly), B (1-7x weekly) and C (> 1x daily). Data collection was based on demographic variables and disease characteristics from the most recent follow up report available, as well as the average alcohol intake per day (based on standard drinks), type of drinking, the number of days with alcohol consumption per week, influence of alcohol on gastrointestinal symptoms and smoking assessed in a dedicated questionnaire.

Results: We received 383 of 537 (72%) questionnaires from our IBD patients (56% CD and 44%UC): *Group A: 182/243 (75%), B: 175/242 (72%), C: 27/52* (52%). The rate of abstainers was similar to the Swiss population*(12%). Among drinkers, 52% drank up to 1x weekly, 29% on 2-3 and 19% on 4-7 days per week. The amount of alcohol on each occasion was 0-20g in 70% of the patients, 20-40g in 24% and 40-60g in 5% and similar for both diseases. The incidence of binge drinking was similar to the Swiss population[1] with 12% monthly (vs. 11.3%), 3% weekly (3.7%) and 1% more than weekly (6%). Binge drinkers (> 6 drinks on one occasion at least monthly) are younger than the other IBD patients (mean age 39 vs. 49 years) and more often smokers

(42.4% vs. 25.4%) whereas the amount of standard drinks per week increased with age. After IBD was diagnosed 61% of the patients did not change, 29% reduced, 6% quit or 4% increased alcohol consumption. In both, CD and UC, 30% of patients reported worsening of diarrhea and 15% worsening of abdominal pain and bloating after drinking alcohol. The type of preferred beverage did not significantly influence this changes of symptomatology. Patients did not differ significantly regarding age, disease duration, localisation, behaviour, extra-intestinal manifestation and previous surgery in our study population based on alcohol consumption.
Conclusion: Drinking behaviour in Swiss IBD patients is similar to the general population and not influenced by the type of disease. A third of IBD patients reduce or quit drinking after being diagnosed. Worsening of diarrhea, abdominal pain and bloating after drinking alcohol was reported in 15-30% by both UC and CD patients, independently of the type of drinking.

Introduction: Although the polymorphism of *PTPN22* rs2476601 has been reported to be a susceptibility gene for Crohn's disease, results from different studies varies and remain inconclusive. Also, no association has been found between rs2476601 and the risk of ulcerative colitis. The aim of this meta-analysis is to investigate the association between *PTPN22* polymorphism (rs2476601) and the risk of Inflammatory bowel Disease (IBD), Ulcerative Colitis and Crohn's disease.
Aims & Methods: We performed a meta-analysis by two independent reviewers by identifying relevant candidate-gene based studies from EMBASE and PubMed. The Odds ratio (ORs) and 95% confident interval were calculated to estimate the strenght of the associations between rs2476601 and inflammatory bowel disease by using a fixed effect or random effect model meanwhile publication bias was assessed
Results: By pooling the results from 16 different studies, 13 356 controls, 8 182 Crohn's disease, and 8656 Ulcerative Colitis were included. We show that *PTPN22* T > C is not associated significantly with a higher risk of developing ulcerative colitis (OR = 1.06 [0.98-1.14], p = 0.16) but is associated with a decreased risk of developing Crohn's disease (OR = 1.28 [1.17 – 1.40], $p < 0.0001$). T allele in rs2476601 lower the risk of Crohn's disease by 22%.
Conclusion: This study shows that *PTPN22* (rs2476601) is associated with the risk of developing a Crohn's disease significantly but not an ulcerative colitis suggesting different pathways in the pathophysiology of the disease.

Contact E-mail Address: ferdinando.bonfiglio@ki.se
Introduction: Inflammatory bowel disease (IBD) is a chronic inflammation of the digestive tract, which primarily manifests in two forms, ulcerative colitis (UC) and Crohn's disease (CD). Existing therapies are partly effective, and limited understanding of IBD pathogenesis hampers the development of new therapeutic approaches. Recent applications in computational drug repositioning hold the promise for cost effective solutions.
Aims & Methods: We report an in silico pipeline for genotype-driven drug repositioning in IBD using publicly available data from genome-wide association studies (GWAS), expression quantitative trait loci (eQTL) repositories, and drug-induced gene expression profiles from the Connectivity Map (cMap).
GWAS data were retrieved from ibdgenetics.org, and significant SNPs ($p \leq 0.05$) selected at each of the 163 known IBD risk loci. Two expression quantitative trait loci (eQTLs) databases (MuTHER, mRNAbySNP) were screened in order to produce a catalog of IBD genotype-specific eQTLs in different tissues, and to link genetic risk (protection, predisposition) to effect betas (up- or down-regulation). IBD, CD and UC gene expression signatures were then built based on physical distance and consistent cis-effects. These were used for functional annotation with hypergeometric test-based tools (WebGestalt), and as input for cMap drug screening using the embedded algorithm.
Results: We found 900 IBD SNPs associated with eQTLs in 2 databases in 3 different tissues (adipose, skin and/or LCL). After data filtering and quality controls for consistency of eQTL effects across genes, these SNP-eQTL profiles gave rise to IBD- CD- and UC-specific gene expression signatures including 91 annotated genes in total. Gene set enrichment analysis of these signatures highlighted immune response and cytokines production, but also intriguingly blood pressure and sulfur compound metabolism among the involved biological pathways. Similarly, anti-inflammatory compounds were among the top ranking drugs in the cMap screening, but other unexpected high-scoring categories included antipsychotics and antimicrobial. Of note, application of our pipeline to the analysis of available IBD-risk genotypes from individual patients resulted in detectable differences in the output of the corresponding cMap screenings.
Conclusion: We devised a novel computational approach to exploit (risk) genotype and eQTL data for drug repositioning in IBD. While its potential for implementation can greatly increase with the growing number of available tissue-specific eQTL datasets, our study proposes a novel effective translation of genomic information to precision medicine in IBD and other complex diseases.

P0308 GENETIC POLYMORPHISM IN THE TLR4 RELATED GENE CAN BE A PREDICTIVE FACTOR OF LONG-TERM EFFECT OF INFLIXIMAB TREATMENT FOR CROHN'S DISEASE

K. Matsushima[1], H. Isomoto[1], T. Ishida[2], T. Inamine[3], S. Urabe[1], R. Uehara[1], T. Honda[1], H. Minami[1], H. Machida[1], Y. Akazawa[1], C. C. Chen[1], N. Yamaguchi[1], K. Ohnita[1], F. Takeshima[1], H. Hamada[4], K. Nakao[1], K. Tsukamoto[3]

Introduction: Infliximab (IFX) is a chimeric anti-tumor necrosis factor-α (TNF-α) monoclonal antibody exerting therapeutic effects against Crohn's disease (CD). However, some primary failure patients have been unable to achieve remission at the short-term period of 10 weeks. Moreover, the some responders at 10 weeks did get remission at the long-term period of 1 year later. Therefore, identification of biomarkers that might predict IFX therapeutic effects is important.
Aims & Methods: The purpose of this study was to investigate whether polymorphisms of target genes in the TLR4 signaling pathway are associated with the therapeutic effects of IFX for CD patients, and whether such polymorphisms could be used as new genetic biomarkers to identify CD patients having the sensitivity or resistance to IFX for the short- or long-term treatment.
The study subjects were 127 unrelated CD patients treated with IFX in our Hospitals between 2012 and 2013. Patients were classified into two groups, responders and non-responders, based on the presence of IFX effect at 10 weeks and 1 year after IFX administration. We examined a candidate gene-based association of 29 single nucleotide polymorphisms of 8 target genes in the TLR4 signaling pathway with the therapeutic effects of IFX, using the allele, minor allele dominant, and minor allele recessive models.
Results: The genetic analyses indicated that the frequency of a C/T or T/T genotype of rs4251580 in *IRAK4* in the minor allele dominant model were significantly decreased in responders as compared to non-responders for the middle-term treatment of 1 year ($P = 0.014$, odds ratio (OR) = 0.289), implicating ~3.5-fold resistance to IFX. Conversely, a C/C genotype of rs4251580 indicated ~3.5-fold sensitivity to IFX. Likewise, the possession of a T/T genotype of rs7255265 in *TICAM1* indicated ~4-fold resistance to IFX at 1-year treatment period ($P = 0.038$, OR = 0.252). Conversely, a C/C or C/T genotype of rs7255265 showed ~4-fold sensitivity to IFX. Subsequently, we carried out a genetic test with a combination of the two genetic factors (*IRAK4* and *TICAM1* genotypes), indicating that the possession of both the C/C genotype of rs4251580 in *IRAK4* and the C/C or C/T genotype of rs7255265 in *TICAM1* strongly showed responsiveness to IFX ($P = 0.003$, OR = 4.44). The sensitivity and specificity of this genetic test were estimated at 72.2% and 63.2%, respectively.
Conclusion: This is the first report that *IRAK4* and *TICAM1* could be associated with the responsiveness to IFX in CD patients. Combination of the 2 SNPs in rs4251580 and rs7255265 could be a biomarker to predict therapeutic effects at 1 year after IFX administration as well as target molecules for new therapeutic drugs overcoming the resistance to IFX. These results suggested that certain genetic prediction in the TLR4 signaling pathway and its downstream associated molecules might be involved in IFX responsiveness, possibly through altered expression of pro-inflammatory cytokines that would be held in common between the TNF-α and TLR4 signaling and the downstream cascades.

P0309 THE CLINICAL RELEVANCE OF THE IBD-ASSOCIATED VARIATION WITHIN THE RISK GENE LOCUS ENCODING PROTEIN TYROSINE PHOSPHATASE NON-RECEPTOR TYPE 2 IN PATIENTS OF THE SWISS IBD COHORT

M. R. Spalinger[1], M. Vögelin[1], J. Zeitz[1], L. Biedermann[1], J.-B. Rossel[2], M. C. Sulz[1,3], P. Frei[1], S. Scharl[1], S. R. Vavricka[1], M. Fried[1], G. Rogler[1], **M. Scharl**[4], on behalf of Swiss IBD Cohort Study Group
[1]*University Hospital Zürich, Zürich,* [2]*Centre Hospitalier Universitaire Vaudois, Lausanne,* [3]*Kantonsspital St. Gallen, St. Gallen,* [4]*Division of Gastroenterology and Hepatology, University Hospital Zürich, Zürich, Switzerland*

Introduction: The gene locus encoding protein tyrosine phosphatase non-receptor type 2 (PTPTN2) has been associated with an increased risk of developing

inflammatory bowel disease (IBD). We have previously shown that PTPN2 plays a critical role in maintaining intestinal epithelial barrier function, cytokine secretion and autophagy. The single nucleotide polymorphism (SNP) rs1893217 within the PTPN2 gene locus results in a dysfunctional PTPN2 protein and is associated with Crohn's disease (CD). SNP rs1893217 is in perfect linkage disequilibrium with the CD- and ulcerative colitis (UC)-associated PTPN2 SNP rs2542151. Here, we studied the association of PTPN2 SNP rs1893217 and clinical characteristics of the affected IBD patients.

Aims & Methods: 1,073 patients with CD and 770 patients with UC or indeterminate colitis (IC) from the Swiss IBD Cohort Study (SIBDCS) were included. Epidemiologic, disease and treatment characteristics were analysed for an association with the presence of one of the rs1893217 isoforms 'homozygous wild-type' (TT), 'heterozygous' (CT) and 'homozygous variant' (CC).

Results: 2.88% of IBD patients were identified with CC, 26.8% with CT and 70.4% with TT genotype. In univariate logistic regression analysis the CC-genotype was associated with an early age of diagnosis (OR 1.315; 95% CI: 1.068-1.620; $p = 0.010$) and existence of bilestones (OR 4.793; 95% CI: 2.000-11.490; $p < 0.001$) in CD patients as well as with the presence of pancolitis (OR: 4.581; 95% CI: 1.267-16.556; $p = 0.020$) in UC patients. These factors remained significant in the subsequent multiple regression analysis. Presence of the C-allele was associated with the presence of uveitis (OR: 2.020; 95% CI: 1.201-3.398; $p = 0.008$), but protected from aphtous oral ulcers (OR: 0.578; 95% CI: 0.335-0.998; $p = 0.049$) in CD patients. UC/IC patients carrying the C-allele were diagnosed at younger age (OR: 1.122, 95% CI: 1.001-1.257; $p = 0.049$) and required intestinal surgery more frequently (OR: 3.056, 95% CI: 1.011-9.239; $p = 0.048$). Significance was seen both in univariate as well as multiple regression analyses. Both, presence of the CC genotype or the C-allele were associated with a better response to treatment with anti-TNF antibodies in both CD and UC patients (chi-square test, p-value: 0.050).

Conclusion: IBD patients carrying the C-allele of PTPN2 SNP rs1893217 are at greater risk for developing a severe disease course as indicated by younger age at diagnosis, pancolitis and higher frequency of surgeries, but are more likely to respond to treatment with anti-TNF antibodies. These findings indicate a clinical relevance of this PTPN2 risk variant in IBD patients and suggest that PTPN2 may be used as predictive marker for early treatment with anti-TNF antibodies.

P0310 SNP RS6105269, A NEW PROGNOSIS MARKERS FOR CROHN DISEASE

P. Aguilar-Melero[1], J. M. Benitez[1], E. Iglesias[1], R. Medina Medina[1], I. Salgueiro[1], M. L. Garcia[1], V. Garcia-Sánchez[1]

Contact E-mail Address: p.aguilar.melero@gmail.com

Introduction: Crohn disease (CD) is a chronic disease that can have a variable course, from a mild inflammatory effect to a severe disease with the appearance of fistulas, ulcers, abscesses, strictures that can lead to a significant impairment in quality of life. An early identification of these patients, would allow an early intensive treatment for changing the natural history of the disease. For this purpose, is essential to identify prognosis markers. The SNP rs6105269 has been identified as risk factor for CD [1].

Aims & Methods: The aim of the study is to analyze the rs6105269 polymorphism, located in the MACROD2 gene, as a prognosis marker of CD and the effect of the polymorphism in the protein expression of MACROD2. 95 patients have been enrolled and classified according to their genotype of rs6105269 polymorphism (AA, AG and GG). A Chi-square test or Fisher test have been used to study if there are significant differences among the genotypes in clinical characteristics related to a severe CD. We propose a definition of severe/disabling disease based on the development of non reversible tissue lesions as any colectomy or at least two small bowel resections or a unique resection > 50 cm or complex perianal fistulizing disease. Furthermore, plasma levels of MACROD2 protein have been analysed by ELISA assay.

Results: 43% of AA patients has family history of IBD (GG 12%, AG 9%, $p = 0.009$). The AA genotype is link to a stricturing and fistulizing patterns (AA 80% patients, GG 47% and 38% AG, $p = 0.02$) and 73% of patients with AA genotype develops a severe/disabling CD vs AG + GG 44%, ($p = 0.04$). 50% of AA patients suffers from a complex perianal disease vs 12% of GG or 19% of AG ($p = 0.01$). In particular, suprasphincteric, transsphicteric and extrasphicteric fistulas are present in 36% of AA patients vs 10% of AG + GG patients ($p = 0.03$) and 31% of AA patients have required surgical drainage of fistula abscess vs 9% of GG and 2% of AG ($p = 0.01$). Furthermore, the levels of the inflammatory marker CRP were increased in AA patients (AA: 22.5 ng/ml, GG: 3.8 ng/ml, AG: 4.2 ng/ml, $p = 0.02$), while the MACROD2 plasma levels are significantly downregulated in genotype AA (AA: 851 ng/ml, GG: 1372 ng/ml, AG: 907 ng/ml, $p = 0.04$).

Conclusion: Genotype AA of the polymorphism rs6105269 is associated with a more severe CD and the polymorphism can be used as a prognosis marker of the disabling disease. Genotype AA produces a downregulation in protein levels of MACROD2, suggesting that this protein may have a protective role in CD.

Introduction: Despite differences in the information obtained by capsule endoscopy (CE) and magnetic resonance enterography (MRE) regarding mucosal and intestinal wall abnormalities in Crohn's disease patients, one of these modalities may need to be chosen or may suffice when evaluating disease activity. There are no data on patients' preference that would help guide the choice between these two modalities in these instances. Despite differences in the information obtained by capsule endoscopy (CE) and magnetic resonance enterography (MRE) regarding mucosal and intestinal wall abnormalities in Crohn's disease patients, one of these modalities may need to be chosen or may suffice when evaluating disease activity. There are no data on patients' preference that would help guide the choice between these two modalities in these instances.

Aims & Methods

Aim: To compare patients' tolerance to MRE vs CE.

Methods: Patients with known small bowel CD in clinical remission (CDAI < 150) or with mild symptoms (CDAI < 220) were prospectively recruited and underwent video capsule endoscopy after verification of small bowel patency and MRE examination. Patients' were asked to fill a questionnaire addressing specific points regarding inconvenience during preparation, during procedure and post procedure. Side effects and procedure preference were addressed. Degree of severity was graded from 1 (not at all) to 5 (severe). Questionnaires were included for analysis only when more than 95% of the items were addressed.

Results: Out of 62 patients approached 56 fulfilled inclusion criteria. Results are summarized in table 1.

subject	MRE (severity degree± SD)	CE (severity degree± SD)	P value
home preparation	2.38 ± 1.32	1.13 ± 2.68	0.1215
pre-exam discomfort	1.22 ± 2.7	0.99 ± 1.5	< 0.0001
discomfort during the exam	1.22 ± 3.7	1.08 ± 2.0	< 0.0001
nausea	18. 1 ± 2.24	0.53 ± 1.29	< 0.0001
vomiting	1.05 ± 1.5	0.37 ± 1.07	0.009
bloating	1.14 ± 2.01	0.55 ± 1.25	0.0002
Abdominal pain	1.1 ± 2.24	0.63 ± 1.33	< 0.0001
tenesmus	0.87 ± 1.40	0.55 ± 1.14	< 0.0001
claustrophobia	0.7 ± 1.40	0 ± 1	< 0.0001
Time consuming	1.19 ± 3.46	1.23 ± 3.0	0.0594
Difficulty	1.13 ± 3.42	0.98 ± 2.03	< 0.0001
Drinking of contrast material	1.22 ± 3.2	NR	NR

44 patients (78%) preferred to repeat CE.

Conclusion: CE was significantly better tolerated in most parameters and preferred by 78% of patients . The superior tolerability of CE should be considered when choosing between these two modalities for suitable patients.

Abstract number: P0313

Variables	Se, % (95% CI)	Sp, % (95% CI)	PPV, % (95% CI)	NPV, % (95% CI)
Altered US-BP	78.3 (69.3-85.2)	93.3 (86.6-96.9)	75.0 (65.8-82.5)	94.4 (87.9-97.6)
Mesenteric hypertrophy	65.2 (55.6-73.8)	92.2 (85.2-96.2)	68.2 (58.7-76.4)	91.2 (84.0-95.5)
BWT > 3 mm	69.6 (60.1-77.7)	96.7 (90.9-99.0)	84.2 (75.9-90.1)	92.6 (85.6-96.4)
BWT > 3 mm + US-BP + MH	56.5 (46.9-65.7)	100 (95.9-100)	100 (95.9-100)	90.0 (82.6-94.6)
BWT > 3 mm or US-BP or MH	82.6 (74.1-88.9)	86.7 (78.7-92.1)	61.3 (51.6-70.2)	95.1 (88.9-98.1)

Introduction: N-Terminal pro-Brain Natriuretic peptide (NT-proBNP) is currently used as a diagnostic marker in heart failure. Elevated NT-proBNP and significant correlation between NT-proBNP and CRP was recently reported in rheumatoid arthritis (1) and in Crohn's Disease (CD) (2). The purpose of this study was to evaluate NT-proBNPas a marker of inflammatory bowel disease (IBD) activity.
Aims & Methods: In this single-center study, NTproBNP assay was performed in patients with CD or ulcerative colitis (UC), irritable bowel syndrome (IBS) and in healthy controls. Clinical characteristics (Harvey-Bradshaw score (HB), Mayo Clinic score (Mayo)), biological (CRP) and endoscopic (CDEIS, UCEIS) data were collected at the time of NTproBNP dosage. Echocardiography was performed in case of NT-proBNPserum levels > 124pg/ml.
Results: To date, 118 patients with CD, 26 with UC, 20 with IBS and 18 healthy controls were included. The median serum NT-proBNP was 50.5 pg/ml [Q1 = 28-Q3 = 94] in CD group, 72 pg/ml [46-138] in the UC group, 43.5 pg/ml [27-111] in IBS Group and 34.5pg/ml [26-49] in the control group. A significant increase of NT-proBNPlevels was observed in CD patients with HB > 4 ($p = 0.02$) or UC with Mayo > 2 ($p = 0.03$) as compared to inactive patients. There was a significant correlation between NTproBNP and, the HB score ($r = 0.31$, $p = 0.0005$), and the Mayo score ($r = 0.45$, $p = 0.01$) respectively. A significant increase in NT-proBNP was observed in CD ($p < 0.001$) and UC ($p < 0.0016$) patients having CRP > 10 mg/l as compared to patients with CRP£10. There was a significant correlation between NT-proBNP and CRP in both CD ($r = 0.64$, $p < 0.001$) and UC ($r = 0.8$, $p < 0.001$). Among the 34 patients who had a colonoscopy a significant correlation between NT-proBNP and, CDEIS ($r = 0.85$, $p < 0.001$), and UCEIS ($r = 0.78$, $p = 0.007$) was observed respectively. ANTproBNP level of 57pg/ml had a sensitivity (Se) of 70% and a specificity (Sp) of 63% (AUC 0.73, 95%CI [0.63-0.83]) to predict a CRP > 10 mg/l in CD. In UC, a rate of NTproBNP of 75 pg/ml had a Se of 88% and a Sp of 75% (AUC 0.87, 95%CI [0.71-1]) to predict a CRP > 10 mg/l. All echocardiograms performed were normal.
Conclusion: NT-proBNP is correlated to the clinical, biological and endoscopic activity of CD and UC and may be a new biomarker in IBD.

Introduction: Bowel ultrasound (B-US) has been widely recognized as a useful examination in patients with suspected IBD owing to its lack of invasiveness. The relevance of increased bowel wall thickening (BWT) and the additional value of other US parameters (e.g. lymph node enlargement and mesenteric hypertrophy (MH)), in the diagnosis of IBD have not been investigated so far.
Aims & Methods: This study aims at investigating the diagnostic accuracy of several US parameters in detecting IBDs in a pediatric population.
All patients aged 2-18 years referred to the Pediatric Gastroenterology Clinic of our Hospital since 2007 to 2013 for recurrent abdominal pain and/or altered bowel habits were retrospectively considered. Patients presenting with known organic diseases or already investigated with digestive endoscopy were excluded; those with a full US report (including altered US bowel pattern (US-BP), BWT, MH, pathologic lymph nodes, free abdominal fluid, presence of stenosis, abscesses or fistulae) were considered eligible. Ileocolonoscopy, performed in patients with a high index of suspicion of IBD, on the basis of paediatrician's assessment and biochemical test results (e.g. calprotectin, CRP), has been used as reference standard. Children who initially were not selected for endoscopy, were followed for at least one year for the appearance of possible additional symptoms.
Results: 113 patients (mean age 10.8 years [range 2.1- 17.7], 65 male) were enrolled. 23 IBD (20.4%; 8 ulcerative colitis, 12 Crohn's disease and 3 indeterminate colitis) were diagnosed. Among the bowel US variables considered, only US-BP, MH and BWT > 3 mm were found useful to identify IBD on univariate binary logistic analysis. On multivariate analysis, these factors were independent predictors of IBD, even after adjustment for age and sex: US-BP (OR 9.8;95%CI 1.6-59.0); MH (OR 5.2;95%CI 1.1-25.1) and BWT > 3 mm (OR 5.4;95%CI 0.7-40.1). Diagnostic accuracy of single US parameters and their combination, in distinguish between IBD and non IBD patients, is reported in the table.
Conclusion: Among several US parameters suggestive of IBD, only the increased BWT, MH and altered echopattern are independent predictors of IBD and useful in distinguishing IBD from non-IBD patients. Owing to their high specificity and NPV, these parameters can be useful in identifying patients who do not need diagnostic invasive procedures in the short time.

Contact E-mail Address: alessandra.dellera@unimi.it
Introduction: IBD in pediatric age may present with non specific gastrointestinal symptoms overlapping with functional bowel disorders or with extraintestinal manifestations making the diagnosis a challenge.
Aims & Methods: The aim of our study was to assess the accuracy of non invasive parameters including fecal calprotectin (FC), bowel ultrasound wall thickening (BWT) and blood inflammatory indexes (BII) alone or in combination as a diagnostic tool for paediatric inflammatory bowel disease (IBD).
Subjects aged 2-18 years referred to our paediatric gastroenterology clinic from 2007 to 2013 for recurrent abdominal pain and/or altered bowel habits were retrospectively considered. Subjects who underwent laboratory tests (FC, BII: white blood cell count [WBC], C-reactive protein [CRP], erythrocyte sedimentation rate [ESR]) and bowel ultrasound as initial assessment were eligible. Exclusion criteria were: signs or symptoms highly suggestive for IBD (perianal disease or haematochezia), known organic disease, previously performed endoscopy. Eligible patients were followed-up for one year.
Results: Seventy-seven patients (mean age 11.3, 44 males) were retrospectively included. One-year diagnoses were: 23 (29.9%) IBD (8 ulcerative colitis, 12 Crohn's disease 3 indeterminate colitis), 54 (70.1%) non-IBD diseases. Mean values of WBC, CRP, ESR ($p < 0.001$) and at least one BII pathological value were higher in IBD vs non-IBD patients (65.2% v 11.1%, $p < 0.001$). Pathological BWT (> 3 mm) and FC (> 200 μg/g) were more frequent in IBD than in non-IBD patients (69.6% vs 3.7%, $p < 0.001$ and 95.7% vs 27.8%, $p < 0.001$ respectively). Considering 3 (BII + FC + BWT) or 2 parameters together (FC + BWT, FC + BII) IBD patients had more simultaneous pathological results than non IBD-patients (52.2% vs 0%, $p < 0.001$; 69.6% vs 0%, $p < 0.001$; 65.2% vs 3.7%, $p < 0.001$ respectively). Diagnostic accuracy of considered parameters are described in the table.

Variables	Se, % (95% CI)	Sp, % (95% CI)	PPV, % (95% CI)	NPV, % (95% CI)
BII*	65.2 (53.3 – 75.6)	88.5 (78.5 – 94.4)	71.4 (59.7 – 81.0)	85.2 (74.7 – 92.0)
BWT(> 3 mm)	69.6 (57.9 – 79.3)	96.3 (88.5 – 99.1)	88.9 (79.2 – 94.6)	88.1 (78.3 – 94.6)
FC (> 200 μg/g)	95.6 (87.7 – 98.8)	72.2 (60.7 – 81.5)	59.5 (47.7 – 70.3)	97.5 (90.2 – 99.6)
FC + BWT + BII	52.2 (31.8 – 72.6)	52.2 (40.6 – 63.6)	100 (94.1 – 100)	83.1 (72.4 – 90.3)
FC + BWT	69.6 (57.9 – 79.3)	100 (94.1 – 100)	100 (94.1 – 100)	88.5 (78.7 – 94.3)
FC + BII	65.2 (48.5 – 79.1)	88.2 (73.3 – 95.7)	88.2 (73.3 – 95.7)	65.2 (48.5 – 79.1)

Se = sensitivity. Sp = specificity, PPV = positive predictive values, NPV = negative predictive values.* at least one altered

Conclusion: In initial work-up for IBD, FC alone presents highest sensitivity but poor specificity. The combination of FC + BWT presents the highest accuracy in identification of patients needing further invasive procedures in the short term.

P0315 DIFFERENTIAL EXPRESSION OF MICRORNAS IN SERA AND FECES OF PATIENTS WITH INFLAMMATORY BOWEL DISEASE

A. Link[1], K. Schoenauen[1], N. Le[1], U. von Arnim[1], C. Schulz[1], P. Malfertheiner[1]
[1]*Gastroenterology, Hepatology and Infectious Diseases, OTTO-VON-Guericke University Hospital Magdeburg, Magdeburg, Germany*

Contact E-mail Address: alinkmail@gmail.com
Introduction: Assessment of the disease activity in inflammatory bowel disease (IBD) is essential for appropriate treatment management. Symptom-based disease activity scores do not always correlate with endoscopic scores and are not reliable for verification of mucosal healing as a primary treatment goal. New non-invasive molecular biomarkers could substantially simplify the treatment management. MicroRNAs (miRNAs) are functionally active molecules and the

expression pattern is frequently deregulated during inflammation and carcinogenesis.
Aims & Methods: Here, we evaluate the potential of several circulating and fecal miRNAs as diagnostic biomarkers for IBD. In the proof-of-principle trial, we obtained blood or fecal specimens form patients with known or newly diagnosed IBD. From total 61 patients, 41 had histologically confirmed Crohńs Disease (CD) or indeterminate colitis and 18 patients ulcerative colitis (UC). Among them 38 patients had an active disease and 24 were in remission (CDAI < 150 for CD or Mayo-Score ≤ 1 for UC). Total RNA was isolated from sera and fecal specimens and quantitative RT-PCR analyses was performed for miR-16, miR-21, miR-223 and miR-155 using TaqMan Assay.
Results: The sera samples from IBD patients showed an increased expression level of miR-21 ($p < 0.0001$) and miR-223 ($p < 0.0001$), but not miR-155, compared to controls. The expression was higher in patients with clinically active disease compared to those in remission. In subgroup analyses, patients with CD demonstrated highest miRNA expression for both miRNAs compared to controls and UC ($p < 0.0001$, Kruskal-Wallis test). Similarly, miRNAs in feces from IBD patients showed strong increase in expression of all four miRNAs with highest expression of miR-16, miR-223 and miR-155. Opposite to miRNA expression in sera, stool samples from UC showed similarly or even higher miR-16, miR-223 and miR-155 level in feces. Clinical remission in IBD patients was associated with normalization of fecal miRNA expression. Despite the significant correlation with disease activity, only fecal miRNA, but not circulating miRNAs, correlated with surrogate parameters such as fecal calprotectin or C-reactive protein.
Conclusion: Our data provide a novel evidence for differential expression of miRNAs in sera and feces from patients with IBD. The increased expression of miRNAs correlates with disease activity especially in fecal samples. Further studies are needed to optimize this miRNA-based biomarker tool and evaluate the clinical applicability for treatment monitoring in IBD patients.

P0316 UROCORTIN 1 IN COLONIC MUCOSA IN PATIENTS WITH ULCERATIVE COLITIS

A. A. Ghweil[1], **U. A. morsy**[2]
[1]*Tropical Medicine and Gastroenterology, Qena Faculty of Medicine Egypt, Qena,* [2]*internal medicine, sohag faculty of medicine, sohag, Egypt*

Contact E-mail Address: alimena1@yahoo.com
Introduction: Ulcerative colitis (UC) is characterized by a long-standing chronic inflammation of the bowel with intermittent periods of exacerbation and remission. Its acute exacerbation appears to be related to various stresses. Urocortin 1 (Ucn1) may play important roles in integrated local responses to stress. We therefore examined local production of Ucn1 in patients with UC by immunohistochemistry
Aims & Methods: We therefore examined local production of Ucn1 in patients with UC by immunohistochemistry to detect the degree of inflammation. Ucn1 immunoreactivity was predominantly detected in lamina propria plasma cells and enterochromaffin cells. In UC patients without glucocorticoid treatment, Ucn1-positive cells and plasma cells increased in proportion to the severity of inflammation.
Results: Ucn1 immunoreactivity was predominantly detected in lamina propria plasma cells and enterochromaffin cells. In UC patients without glucocorticoid treatment, Ucn1-positive cells and plasma cells increased in proportion to the severity of inflammation ($P < 0.0001$). Ucn1-positive cells significantly increased in UC patients with advanced inflammatory grades, compared with a control group ($P < 0.0001$) and nonspecific colitis group ($P < 0.0001$). In glucocorticoid-treated patients, Ucn1-positive cells were significantly lower in number, compared with the nonglucocorticoid-treated group.
Conclusion: The present study showed that Ucn1-positive cells were correlated with the severity of inflammation in colonic mucosa with UC, and glucocorticoid treatment decreased these cells. Ucn1 therefore may act as a possible local immune-inflammatory mediator in UC.

P0317 USE OF FAECAL CALPROTECTIN PATHWAY IN PRIMARY CARE TO DISTINGUISH IRRITABLE BOWEL SYNDROME FROM INFLAMMATORY BOWEL DISEASE

A. Dhaliwal[1], J. ORourke[1], V. Sagar[1], J. Burdsall[1], R. Ransford[1], A. Milestone[1]
[1]*Gastroenterology, Hereford County Hospital, Hereford, United Kingdom*

Contact E-mail Address: adhaliwal85@gmail.com
Introduction: Faecal Calprotectin (FCP) testing is a simple, non-invasive investigation which can differentiate Inflammatory Bowel Disease (IBD) from Irritable Bowel Syndrome (IBS). It has high negative predictive values which allow utilisation in Primary Care by reducing unnecessary referrals to secondary care & expensive/invasive diagnostic tests eg. Colonoscopy and in turn suggest potential cost-effective benefits. FC is well established in secondary care, but the literature for FC in primary care is extremely limited.
Aims & Methods
Aim: Evaluation of a pilot study of a defined FC pathway in Primary Care.
Method: A primary care referral pathway was devised to guide appropriate use of FC in Primary Care to exclude IBD in appropriate patients, particularly if secondary care referral was being considered.
A pathway proforma with initial screening tests (FBC, LFTs, TTG, CRP, TSH & stool microbiology). Inclusion/Exclusion criteria: 16-45yrs age, IBS-compatible symptoms for ≥6 weeks/recurrent, no red flags. This was based on IBS guidelines (BSG), FC literature & recent NHS Centre for Evidence-Based Purchasing report (2010).
FC results (via Quantum Blue test kits) were classified as normal, intermediate or high. Each result was advised on further appropriate action. Subsequent clinic attendances, investigations, diagnostic outcomes & associated costs were evaluated.
Results: Nineteen GP surgeries (19/22) referred 277 patients via FC pathway over 24 months (Jan 2013-Jan 2015). Forty-five samples rejected as inappropriate.

Table 1: Faecal Calprotectin results (received to date)

FCP Interpretation	FCP result (μg/g)	Patients (n = 232)	Pathway Action
Normal < 50	< 50	62.1% (144/232)	IBD excluded. Retain in primary care
Indeterminate	50-150	22.4% (52/232)	Repeat after 4-6 weeks, if repeat > 50ug/g refer to secondary care
Elevated	> 150	15.5% (36/232)	Refer to secondary care

Diagnosis outcomes were available on 175/232 patients at the time of presented data analysis: Elevated 13.7%(24),Indeterminate 19.4%(34) & Normal 66.8%(117).
In Elevated FC clinic attenders, IBD was detected in 50%(11/22).
Indeterminates were repeated in only 68%: normal repeat 52.2% (12/23), 2 IBD cases detected. After a normal FC, 12.8% were referred to secondary care anyway, but no IBD detected.
In the normal FC group alone, assuming a normal FCP avoided a secondary care referral in 87.2% (102/117), the potential cost savings = £73,468 (assuming new patient clinic + 1 colonoscopy = £741.68).
Conclusion: Preliminary data suggests a structured FC pathway is effective in distinguishing IBD & IBS in Primary Care with significant cost savings. Further refinement is required for age ranges & FC cut-off points. Based on this pilot data & latest NICE Diagnostic Appraisal 11, the local Clinical Commission Group have commissioned a secondary care supervised FC service for primary care.

P0318 ILEAL CROHN'S DISEASE: MAGNETIC RESONANCE ENTEROGRAPHY AS A PREDICTOR OF RELAPSE AFTER ANTI-TNF DISCONTINUATION

J. C. Gallego[1], **A. Echarri**[2], A. Porta[1], S. E. Bencheikh[1], V. Ollero[2], J. Castro[2]

Introduction: Anti-TNF therapy has proven effective in maintaining remission of Crohn's disease (CD), although the optimum duration and strategies for withdrawal in asymptomatic patients remain unclear. The discontinuation of anti-TNF may be considered due to safety and cost issues and decision should be based on clinical, endoscopic, and biological factors. However, in cases of ileal CD, ileocolonoscopy study is limited and biomarkers such as C-reactive protein (CRP) or calprotectin may be less useful in evaluating inflammatory activity.
A multidiscliplinary european expert panel (EPACT-II update) considered imaging techniques to show an "uncertain" suitability for monitoring CD activity, so that there have been few studies about their role in the decision of stopping biologicals.
Aims & Methods: The aim of this study is to evaluate the capability of MR-enterography to predict disease relapse after withdrawal of anti-TNF therapy in patients with ileal CD.
A prospective study was conducted between 2009 and 2014 in our hospital over CD patients with ileal involvement in whom anti-TNF (Infliximab or Adalimumab) was stopped. Withdrawal was only carried out in patients on deep clinical, biochemical, and endoscopic remission, defined as absence of symptoms (Harvey-Bradshaw score ≤ 3), endoscopic mucosal healing (SES-CD < 2), and CRP < 5 mg/L or Calprotectin < 150 μg/g. Follow-up visits were performed every 3 months after cessation of treatment or earlier in cases of suspected relapse.
Patients underwent a Magnetic Resonance Enterography (MRE) before drug withdrawal on a Philips Intera 1.0 scan (median 30 days, range 10-82). The degree of activity of the ileal CD was assessed by an MRE score used in our hospital.
The MRE scores of the patients with and without relapse were compared using the independent samples t-test. Furthermore, a logistic regression analysis of the total MRE score as well as each parameter individually was performed, considering the relapse as the independent variable.
Results: A total of 29 patients (16 females and 13 males) with a mean age of 36.6 years (range 16-64) were included in the study. The median follow-up time since biological withdrawal was 45.2 months (range 15-72). The average time of recurrence was 17.1 months (range 3-57). Relapse rates were 24% at 1 year and 52% at 2 years.
Patients who relapsed had higher MRE score (4.2 vs. 2.5 $p < 0.02$) than those who did not. The relative risk of relapse in patients with an MR score > 3 was 2.21 (1.1-5 $p < 0.05$), significantly higher than in patients with a score of 0-3 in the pre-withdrawal MRE.
Logistic regression analysis showed that MRE score is an independent predictor of relapse (hazard ratio 0.185 $p = 0.02$). In terms of single MR parameters,

only the presence of hyperintensity on T2-weighted sequences, which translates the bowel wall oedema, can be regarded as an independent predictor of relapse (hazard ratio 0.149 $p < 0.04$).
Conclusion: This study demonstrates that, at least in patients with ileal CD, MRE should be taken into consideration when deciding the withdrawal of anti-TNF therapy in patients who are in clinical, biological, and endoscopic remission.
A MRE score > 3 as well as the hyperintensity of the bowel wall on T2-weighted sequences increase the likelihood of relapse.

Introduction: Several studies have shown a correlation between antiTNF trough levels (TL) and clinical or endoscopical remission in luminal Crohńs disease (CD), but there are few data about the role of TL in perianal CD or in radiological response.
Aims & Methods: Our aim was to determine the optimal TL associated with clinical, endoscopical and radiological remission for different phenotypes of CD. We included 32 antiTNF naïve patients with moderate to severe luminal (n = 24) and perianal (n = 8) CD under antiTNF treatment over 24m. Management of patients was based on clinical assessment and investigators were blinded to the TL results.
The TL measurements were performed just before antiTNF injection simultaneously with faecal calprotectin (calprotectin < 250ug/g was defined as normal). The Harvey-Bradshaw and the Perianal Disease Activity Index (PDAI) were reported (HBI-remission < 4; PDAI-remission < 3). Endoscopic evaluation was performed at weeks 0 and 54 (SES-CD remission < 2). In case of ileal location or perianal disease, magnetic resonance enterography (MRE) or pelvic resonance were performed. The activity was assessed with our own validated MRE index (remission < 3) and the Van Assche Index for perianal disease.
Results: At 54w, 84% of patients were in clinical remission. Deep remission (clinical with endoscopical /radiological remission) was observed in 56.2%. Up to 37% of all patients required dose escalation due to a loss of response in the first year (62% of perianal CD vs 21.8% of luminal CD;$p < 0.05$). Intensification was effective in 75% of cases in whom serum TL after escalation was detected above cut-off levels. Patients in clinical remission without endoscopical or radiological remission showed calprotectin > 250 ug/g in 84%.
The optimal IFX /ADA TL cut-off associated with clinical remission in luminal CD was 1.1µg/ml and 2.51µg/ml respectively (sensitivity: 78% and 82%; specificity: 76% and 78%), while IFX /ADA TL cut-off associated with normal calprotectin, endoscopical or radiological remission in luminal disease was 2.7µg/ml and 5.4 µg/ml (sensitivity: 79% and 74%; specificity: 76% and 80%). The optimal IFX /ADA TL cut-off in perianal disease was similar for clinical, endoscopical and radiological remission: 2.7µg/ml and 5.4 µg/ml respectively (sensitivity: 79% and 74%; specificity: 76% and 80%). IFX TL > 2.7 and ADA TL > 5.4 were associated with a decreased risk of treatment failure (RR 0.34; RR 0.38).
Conclusion: 1. Serum anti-TNF TL associated to endoscopical or radiological remission are higher than TL associated to clínical remission in luminal Crohńs disease, but not in perianal disease where cut-off levels are the same in both clinical and radiological remission. Furthermore, perianal CD required dose escalation more frequently than luminal CD.
2. A calprotectin level > 250ug/g was associated with endoscopical or radiological activity in patients on clinical remission and could be useful to decide upon the need of endoscopical /radiological explorations.

P0320 USABILITY STUDY OF A SMARTPHONE-BASED CALPROTECTIN HOME TEST

A. Beyer[1], C. Reinhard[2], J. Weber[2], F. Perretta[2], H. Vogelsang[1]
[1]*AKH - Med. Universität Wien, Vienna, Austria,* [2]*BÜHLMANN Laboratories AG, Schönenbuch, Switzerland*

Contact E-mail Address: cre@buhlmannlabs.ch
Introduction: Inflammatory Bowel Disease (IBD) is a chronic inflammation of the gut presenting with phases of active inflammation, remission and relapses. IBD treatment goals are mucosal healing and persistent remission. Calprotectin measured in patients' stool samples is a well-established biomarker to measure the inflammatory activity in the gut. Periodical assessment of calprotectin levels is important to measure effectiveness of the treatment as well as predicting relapses. Until now this meant that patients send in their stool sample for laboratory analysis, leading to long time spans between sample collection and final test result. To ensure real-time information about the inflammatory activities in the gut for both, the patient and the clinician, we have developed a calprotectin home test called IB*Doc*®. The IB*Doc*® consists of a stool collection and extraction device (CALEX® Valve) and an immunochromatographic calprotectin rapid test, which is measured using a smartphone App (CalApp®) controlling the phone's camera. Once the test is measured the result is sent to a webserver (IB*Doc*® Portal) allowing the treating physician immediate access to the result.
Aims & Methods: The objective of this study was to evaluate the usability of the IB*Doc*® calprotectin home test system with patients in respect of handling both, the physical test components as well as the integrated software.
10 voluntary patients suffering from IBD and naïve to the IB*Doc*® system were trained to perform the test by their IBD nurse. The patients were then asked to perform a calprotectin stool test every two weeks over a period of two months by themselves at home using the IB*Doc*® system. The patients were asked to fill in a questionnaire after the first and the last test performed. The questionnaires were based on 5-point Likert scale questions concerning all steps of the test in respect of usability aspects. It also contained free commentary sections and system usability scale (SUS) score question. The SUS is commonly used for measuring and comparing the usability of software and integrated software systems.
Results: All patients were able to able to perform home test using the IB*Doc*® system during the course of the test period. All patients (100%) felt well instructed and the instructions for the test were well understood (4.7 on a 5-point Likert Scale). When asked how easy it was to measure the test cassette with the smartphone, the patients judged this question with an average score of 4.8 on a 5-point Likert scale. The test result was displayed by the smartphone app in a clear way with a traffic light interpretation and quantitative results within the measuring range of 30-1000 µg/g of calprotectin. The test result was easy to understand for all patients (100%). All patients would use the IB*Doc*® system in the future (100%). 87% of the patients felt that the home test helps them in their disease management. The IB*Doc*® system reached a mean SUS score of 88 on a scale from 0 to 100. This SUS is well above the software industry's average score of 68.
Conclusion: This study shows that calprotectin home testing using a smartphone as measuring system was well accepted among IBD Patients. The complexity of the application is low, the entire IB*Doc*® system can be considered very user-friendly and is easy to handle by lay users without prior knowledge or experience of immunochromatographic rapid tests.

P0321 SELECTING IBD PATIENTS WHO WILL BENEFIT FROM THROMBOPROPHYLAXIS THROUGH A RISK ASSESSMENT THAT INCLUDES CLOT LYSIS PARAMETERS AND CLINICAL ASSESSMENT

L. Bollen[1], N. Vande Casteele[1], W. Van Moerkercke[2], G. Van Assche[2], M. Ferrante[2], S. Vermeire[2], **A. Gils**[1]

Contact E-mail Address: ann.gils@pharm.kuleuven.be
Introduction: Patients with inflammatory bowel disease (IBD) have a higher risk of developing thromboembolic events (TE) compared to the healthy population. TE has a substantial impact on mortality in IBD and TE prevention requires improved awareness and management.
Aims & Methods: The aim of the study is to describe the clinical characteristics of IBD patients with a history of TE and to compare markers of clot lysis between (1) IBD patients and healthy controls (HC) and (2) IBD patients with (IBD + TE) and without a history of TE (IBD-TE).
In this study, 84 IBD patients in whom a TE occurred (between January 1987 and March 2014) after the diagnosis of IBD, seen at an academic referral center between February 2009 and May 2012 were included. During the same period, 118 IBD patients without a history of TE and 113 healthy controls were selected as control groups in this case-control study. Three clot lysis parameters (area under the curve (AUC); 50% clot lysis time (CLT) and amplitude) were determined.
Results: Of the 84 IBD + TE patients (63% Crohn's disease, 44% males), 70/84 (83%) developed a venous TE and 25/84 (30%) patients were identified with recurrent TE. At time of TE, 60/84 (71%) patients had active disease and 36% received steroids. Within a 6-month period preceding the TE, 31/84 (37%) had been operated of whom only 17% received thromboprophylaxis at hospital discharge. Both the 50% CLT and AUC were significantly associated with the presence of IBD as compared to controls. Moreover, AUC (31 (24-49) vs. 22 (13-31), $p < 0.05$), 50% CLT (110 (64-132) vs. 95 (70-126) minutes, $p < 0.05$) and amplitude (0.295 (0.222-0.436) vs. 0.241 (0.168-0.308), $p < 0.05$) were significantly higher in IBD + TE vs. IBD-TE and remained higher after adjustment for age, gender, C-reactive protein, type of disease, presence of comorbidities and disease activity.
Conclusion: This study reveals that IBD patients have an altered clot lysis profile compared to healthy controls. In addition, the clot lysis parameters differ significantly between IBD patients with and without a history of TE. Of the IBD patients with a history of TE, 36% received steroids at time of TE and 37% underwent recent surgery of whom only a minority received thromboprophylaxis at hospital discharge. To date, IBD patients with a high risk for TE are given thromboprophylaxis. However, for the patients with low to moderate risk for TE it is less clear who will benefit from prophylactic therapy. Therefore, we propose to perform a risk assessment in which clot lysis parameters and IBD specific risk factors for TE are combined to identify the patients who can benefit from prophylactic therapy with low molecular weight heparins.

P0322 VITAMIN D STATUS IN IBD PATIENTS: A COMPARISON OF THREE DIFFERENT ASSAYS

A. Krajcovicova[1], T. Hlavaty[1], Z. Leskova[1], Z. Kubinova[1], M. Huorka[1], J. Payer[1]
[1]*5th Internal Medicine Department, Faculty of Medicine Comenius University and University Hospital Bratislava, Slovakia, Bratislava, Slovakia*

Contact E-mail Address: krajann@hotmail.com

Introduction: Vitamin D (VD) is a fat soluble secosterol that is produced in the skin after the sun exposure. Epidemiological studies show significant associations of VD deficiency and immune mediated diseases. The plasma 25-OH vitamin D3 concentration is a reliable biomarker for VD status but assays' variability makes adequate monitoring of VD difficult.

Aims & Methods: The aim of this study was to compare three different assays for measurement of 25(OH)D and to evaluate the impact of 25(OH)D assessment on clinical decision making.

Blood samples from 50 IBD patients were evaluated in a blinded way in three different laboratories using diverse assays of 25 (OH) vitamin D monitoring such as high-performance liquid chromatography (HPLC), IDS automated immunoassay (IDS) and competitive binding assay (CBP). We correlated the VD levels of different assays using Pearson correlation coefficient. To quantify the agreement between total 25(OH)D serum levels from all three assays, the interclass correlation coefficient (ICC) was calculated. We evaluated the clinical accuracy of each assay by examining the agreement of assays in sorting patients into distinct categories according to difference of VD levels using the cutoffs (< 5ng/ml) for acceptable agreement, (5-10ng/ml) significantly different and (> 10ng/ml) insufficient.

Results: The median serum 25(OH)D level measured by CBP was 17.9ng/ml (range 3.0 to 39.3ng/ml), by HPLC 27.3ng/ml (range 4.6 to 53.2ng/ml) and by IDS 24.4ng/ml (range 9.0 to 48.0ng/ml). The linear correlation between different assays was Pearson r = 0.69 for HPLC and RIA, 0.69 for HPLC and CBP, 0.63 for RIA and CBP. Comparing 25(OH)D assay HPLC with CBP gave the best agreement with an ICC 0.23 (95% CI -0.06, 0.481; p = 0.058). We saw total disagreement between assays IDS and CBP with an ICC = 0.02 (95% CI -0.258, 0.299; p = 0.439). To a lesser extent, we saw a disagreement between IDS and HPLC with an ICC = -0.22 (95% CI -0.476, 0.067; p = 0.063). By sorting individual patients samples into distinct categories according to the difference of 25(OH)D levels, we have seen the best agreement between the HPLC and IDS (64%, 29/48). Total discordance in 24% (12/50) patients was found comparing CBP and IDS. When applying the cut-off 30ng/ml for defining optimal level of 25(OH)D, the HPLC and IDS classifies 31.25% (15/48) and 26% (13/50) of patients as normal, respectively. CBP with 16% (8/50) underestimates the number of individuals having 25(OH)D concentrations above 30ng/ml.

Conclusion: The linear correlation between different assays was 0.63-0.69. We have seen a clinically significant difference between measured 25(OH)D values in 18.8-24% samples.

Contact E-mail Address: annatesta82@virgilio.it

Introduction: Anaemia (AN) is frequently associated with inflammatory bowel diseases (IBD) with a prevalence varying from 17% to 68%. In recent years, the management of AN in IBD has became a major issue as it negatively affects both the underlying disease and the quality of life of affected patients.

Aims & Methods:

Aim: To evaluate the prevalence and causes of AN in patients with IBD living in a region of Southern Italy.

Methods: We prospectively performed a one-year multicentre study in Campania (Italy) including all consecutive IBD cases attending 5 Units. AN was defined in presence of haemoglobin values Hb < 13 g/dl for males and Hb < 12 g/dl for females; severe AN was defined in case of Hb < 10 g/dl. To explore the causes of AN, all anaemic patients underwent a second-line haematological assessment including ferritin, transferrin, vitamin B12, folic acid and homocysteine levels and screening for celiac disease (total IgA and anti-transglutaminase antibodies). Furthermore, in all IBD cases CRP and ESR were evaluated. Iron deficiency AN (IDA) was diagnosed in case of ferritin < 30 ng/ml and transferrin saturation (TSAT) < 16%. AN of chronic disease (ACD) was diagnosed when elevated CRP/ESR values coexisted with TSAT < 16% and ferritin > 100 ng/ml; mixed type AN was considered in case of TSAT < 16% and 30 ng/ml < ferritin < 100 ng/ml.

Results: The study population included 965 IBD patients (582 CD; 383 UC) of whom 142 in- and 823 out-patients. AN was diagnosed in 134 out 965 IBD patients (14%). No significant difference was seen between CD and UC groups (81 CD vs 53 UC; 13.9% vs 13.8%; p = n.s.). The prevalence of AN was more frequent in the admitted IBD group (26% in- vs 11.7% out-patients; p < 0.01; O.R. 2.2) and in patients with active disease (CD: 34% active vs 16% in remission; p < 0.01; OR 2.1 – UC: 26% active vs 19% in remission; p = 0.03; O.R. 1.3). Furthermore, AN appeared to be more frequent in patients with ileocolic CD and in those with extensive UC (p < 0.01). Regarding the causes of AN, IDA was present in 72 patients (53.7%), ACD in 12 patients (8.2%), 11 patients (8.2%) had mixed type AN, 9 had thalassemia (6.7%), 8 (5.9%) had macrocytic AN, while in 18 patients (13.4%) the causes remained unclassifiable. Vitamin B12 deficiency was observed in 7.4% of CD patients and in no case of UC. Folic acid deficiency was detected in 6.1% of CD and in none of the patients with UC. There was no evidence of celiac disease.

Conclusion: AN is common among patients with IBD in Southern Italy and is more frequent in IBD patients with active and extensive disease and in whom needing hospitalization. Iron deficiency still remains the major cause of AN in IBD population.

Contact E-mail Address: a_buisson@hotmail.fr

Introduction: Emergence of mucosal healing as therapeutic goal in Crohn's disease (CD) has highlighted the need for endoscopic scores. Although other scores are available, the CD Endoscopic Index of Severity (CDEIS) [1] remains, to date, the most validated score to assess the severity of CD endoscopic lesions. Clarifying the definition of the endoscopic lesions composing this score appeared as a keypoint to optimize the CDEIS use.

Aims & Methods: This expert consensus was performed according to a Delphi-like method (12 experts) to define aphtoid erosions (AE), superficial ulcerations (SU), deep ulcerations (DU), stenosis and fistulas. These consensual definitions were then submitted to 30 other IBD physicians from the GETAID to determine an independent acceptance rate (AR). For the intra and inter-observer variation studies, 100 short films were selected (study leader), focusing on AE, SU, DU or a sham lesion (≈25% for each lesion). Overall 15 GETAID members (not the study leader) read independently the 100 films, indicating the recognized lesion. A re-reading of the same 100 films in a randomized order by the same readers was organized one month later using the same methodology. For the intra-observer variation study, the standard κ-coefficient was used from repeated readings of each observer to measure the agreement level on defining endoscopic lesions. For the inter-observer variation study, the κ-coefficient was estimated as described by Fleiss for nominal agreement among many observers.

Results: AE was defined as an ulceration with a white center whose diameter is < 5 mm with red halo (AR = 29/30). **DU** was defined as a frank depression compared to the surrounding mucosa OR striated bottom of the ulceration OR mucosal detachments OR well-like ulcerations (AR = 24/29). **SU** was defined as an ulceration whose features fit neither with that of AE nor with that of DU, as previously defined (AR = 24/29). **Stenosis** was defined as a narrowing of the intestinal lumen making impossible or difficult to pass with an adult colonoscope (AR = 25/29). **Fistula** was defined as a deep and well-limited hole whose bottom cannot be seen, with leaking faecal or purulent material OR with a suspected communication with another organ (AR = 27/29).

Intra and inter-observer agreements (κ-values)

	AE	SU	DU	sham lesions
Intraobserver estimate range	0.419-0.843	0.572-0.891	0.502-0.934	0.289-0.805
Interobserver estimate ± sd	0.554 ± 0.03	0.548 ± 0.04	0.693 ± 0.04	0.569 ± 0.03

IBD experience duration, mean endoscopies number for IBD for the last 3 years and the participation to the definition process, did not influence intra-observer agreement.

Conclusion: The definitions of CD endoscopic lesions retrieved from this GETAID expert panel, showing substantial reproducibility, should improve the standardization and the use of the CDEIS in the era of mucosal healing.

Contact E-mail Address: a_buisson@hotmail.fr

Introduction: Magnetic resonance entero-colonography (MREC) enables accurate assessment of ileocolonic Crohn's disease, but the need for bowel cleansing and rectal enema limits considerably its use in daily practice. Diffusion-weighted MREC (DW-MREC), with no bowel cleansing and no rectal enema, is highly accurate in assessing inflammation in ileal CD using the Clermont score ($=1.646 \times$ bowel thickness $-1.321 \times$ ADC $+5.613 \times$ edema $+8.306 \times$ ulceration $+5.039$) as it is highly correlated to the Magnetic Resonance Index of Activity (MaRIA) and the simplified endoscopic score for CD (SES-CD)[1-3]. DW-MREC highly assess CD colonic inflammation using apparent diffusion coefficient (ADC), the quantitative parameter of DW-MREC, compared to the MaRIA [3]. However the ADC performances in colonic CD compared to endoscopy remain unknown.

Aims & Methods: We evaluated DW-MREC accuracy to assess endoscopic activity. Overall, 44 CD patients underwent prospectively and consecutively DW-MREC and colonoscopy within 4 weeks (mean interval $=17 \pm 11$ days). Apparent diffusion coefficient (ADC) and Clermont score were calculated from DW-MREC. The colonoscopies were scored using CDEIS and SES-CD. Radiologists were blinded from endoscopic findings and endoscopists were blinded from radiologic findings.

Results: Mean ADC was moderately correlated with total CDEIS ($r\hat{h}o = -0.40$; $p = 0.0067$) and total SES-CD ($r\hat{h}o = -0.33$; $p = 0.032$).

Considering the 194 segments, ADC was moderately correlated with segmental CDEIS ($r\hat{h}o = -0.48$; $p < 0.001$) and segmental SES-CD ($r\hat{h}o = -0.44$; $p < 0.001$). ADC values were lower in segments with deep ulcers (1.30 ± 0.23) or superficial ulcerations (1.75 ± 0.64) than in non-ulcerated segments (2.15 ± 0.5)($p = 0.001$). Using a receiver operating curve, we determined that segmental ADC < 1.42 detected endoscopic deep ulcerations with sensitivity (se) $= 0.91$ and specificity (spe) $= 0.83$ (AUC $= 0.84$; $p < 0.001$). Segmental ADC < 1.88 detected endoscopic superficial ulcerations with se $= 0.64$ and spe $= 0.75$. The segmental ADC values decreased when the ulcerations size increased($p < 0.001$).

Considering ileal segments ($n = 36$), Clermont score was correlated with ileal CDEIS ($r\hat{h}o = 0.63$;$p < 0.05$) and ileal SES-CD ($r\hat{h}o = 0.58$;$p < 0.05$). Clermont score was higher in ulcerated segments (23.3 ± 8.4) than in non-ulcerated segments (12.4 ± 10.0)($p = 0.006$) and increased with ulceration size ($p = 0.012$). Clermont score > 18.9 detected ulcerations with se $= 0.79$ and spe $= 0.73$.

Among the 44 CD patients, while 10 (22.7%) were in endoscopic remission (no ulceration and no endoscopic stenosis), 8 (18.2%) were in DW-MRI remission (no segmental ADC < 1.88 AND no Clermont score ≥ 18.9 AND no MRI stenosis). The DW-MRI remission detected endoscopic remission with high Spe and NPV (90.9% and 85.7%, respectively).

Conclusion: DW-MREC using ADC and Clermont score is effective to indirectly detect endoscopic ulcerations in ileocolonic Crohn's disease.

P0326 ENDOSCOPIC FACTORS INFLUENCING FECAL CALPROTECTIN VALUE IN CROHN'S DISEASE

F. Goutorbe[1], M. Goutte[1,2], R. Minet-Quinard[3], A.-L. Boucher[1], B. Pereira[4], G. Bommelaer[1], **A. Buisson**[1,2]

Contact E-mail Address: a_buisson@hotmail.fr

Introduction: Fecal calprotectin is usually an accurate biomarker of Crohn's disease (CD) endoscopic activity. Identifying the endoscopic situations in which fecal calprotectin is less reliable remains unexplored. We aimed to determine the endoscopic factors influencing fecal calprotectin level in CD.

Aims & Methods: Overall, 53 CD patients underwent consecutively and prospectively colonoscopy, with CD Endoscopic Index of Severity (CDEIS) calculation and stool collection. Fecal calprotectin was measured using quantitative immunochromatographic test. To calculate the overall affected or ulcerated surfaces, we considered that each segment (according to CDEIS) represented 20% of the overall surface. Correlation analysis was done with Pearson statistics. In multivariate situation, linear regression was performed according to univariate results and clinical relevance.

Results: Fifty-three CD patients were included (57% female), with a median age of 31 [21–44] years and a median CD duration of 3.5 [1.0-9.0] years at the inclusion time. Thirteen patients (24.5%) had pure ileal disease (L1 according to Montreal classification), 12 (22.7%) had colonic disease (L2), and 28 (52.8%) had ileocolonic CD (L3). The median CDAI and CRP were 198.5 [101-258] and 11.40 [4.20-33.70] mg/L, respectively. Median CDEIS was 3.6 [2.66 – 6.4]. Endoscopic ulcerations were reported in 40 patients (75.5%).

Fecal calprotectin level was correlated with CDEIS (0.66, $p < 0.001$). In univariate analysis, fecal calprotectin was correlated with the affected surface (0.65, $p < 0.001$) and the ulcerated surface (0.47, $p < 0.001$). Fecal calprotectin was significantly associated with ulcerations depth, with median fecal calprotectin values of 867.5µg/g, 1251.0µg/g and 1800.0µg/g, for non-ulcerated lesions, superficial ulcerations and deep ulcerations, respectively. Lesions locations (ulcerated or not) did not influence fecal calprotectin level.

In multivariate analysis, fecal calprotectin level was associated with affected surface ($p = 0.04$) and the presence of CD lesions. Moreover, fecal calprotectin increased with the ulcerations depth ($p = 0.03$). However, ulcerated surface and CD location did not impact fecal calprotectin.

Using a ROC curve, we showed that fecal calprotectin ≥ 400µg/g was the best compromise between sensitivity (0.76) and specificity (0.77) (AUC (95% CI) $= 0.795$, (0.624-0.966)) to detect CD superficial or deep ulcerations. A cut off value of 200 µg/g detected superficial or deep ulcerations with sensitivity, specificity, positive predictive value and negative predictive value of 0.86, 0.70, 0.86 and 0.70, respectively.

Conclusion: Fecal calprotectin is a very reliable biomarker to detect endoscopic ulcerations in CD. We suggest to repeat measurement for intermediary results (200-400µg/g) in daily practice. Fecal calprotectin level is not related to CD location but is mostly influenced by the affected surface and the presence of CD lesions (even non-ulcerated), with high impact of deep ulcerations.

P0327 POSTOPERATIVE RECURRENCE IN CROHN'S DISEASE: NATURAL HISTORY, RISK FACTORS AND MANAGEMENT STRATEGIES IN A RETROSPECTIVE COHORT (1986-2015)

A. Buisson[1,2], A.-L. Boucher[1], M. Goutte[1,2], F. Goutorbe[1], S. Decousus[3], A. Dubois[4], P. Dechelotte[3], B. Pereira[5], G. Bommelaer[1]

Contact E-mail Address: a_buisson@hotmail.fr

Introduction: As surgical resection is not curative, postoperative recurrence (POR) remains a crucial issue in Crohn's disease (CD). Several factors have been considered as POR predictors, but their true impact remains debated. Recently, the POCER trial[1] suggested that an early endoscopic-based management (EBM) decreased the risk of endoscopic POR at 18 months. However the long-term impact of EBM remains unknown.

Aims & Methods: We aimed to describe the natural history, the risk factors, and the optimal prevention strategy of POR in CD.

From the pathology department database, we retrieved the data of all the patients who underwent intestinal resection for CD in our centre between 1986 and 2015. Surgical POR was defined as re-operation for CD. Clinical POR was defined as symptoms recurrence leading to hospitalization or therapeutic modifications. Endoscopic POR was defined as a Rutgeerts' score $\geq$ i2. Patients were classified as Endoscopic-based management (EBM) if they underwent a systematic colonoscopy with no clinical POR. Considering the censored data, multivariate analyses were performed according to univariate results (log rank tests) and clinical relevance.

Results: Among the 161 CD patients, 59% were females, 33% active smokers, 33% had previous intestinal resection and 47% had previous perineal lesions (37% with abscess/fistula). Mean age at surgery was 37 ± 13.5 years.

The rates of POR were:

	1 year	5years	10 years	15 years	20 years
Surgical POR (%)	1.3	19.0	38.9	57.7	64.7
Clinical POR (%)	21.5	61.4	75.9	88.7	92.5
Endoscopic POR (%)	31.7	67.6	79.7	91.1	95.5

In multivariate analysis, fistulizing CD (B3 according to Montreal classification) (Hazard ratio: HR 1.78 [1.04-3.04], $p = 0.003$) and previous intestinal resection (HR 1.7 [1.00-2.72]; $p = 0.05$) were predictive of surgical POR. Previous intestinal resection (HR 1.65 [1.10-2.48]; $p = 0.02$) and previous perineal abscess or fistula (HR 1.48 [1.01-2.19] ; $p = 0.048$) were predictive of clinical POR. Fistulizing CD (HR 1.78 [1.04-3 .04] ; $p = 0.03$) and previous intestinal resection (HR 1.7 [1.00-2.92]; $p = 0.05$) were predictive of endoscopic POR. In our cohort, no other factor, including smoking and resection length, were POR predictors. Neither anti-TNF agents nor thiopurines therapies decreased the risk of POR.

The median interval between surgery and endoscopy was 9.5 [5.6-54.2] months) in the EBM group ($n = 49/161$). An EBM decreased the risks of clinical (HR 0.4 [0.25-0.66]; $p < 0.001$) and surgical POR (HR 0.31 [0.13-0.73]; $p = 0.007$).

Conclusion: POR remains common in CD. The identification of risk factors may enable targeted strategies to reduce this recurrence rate. EBM should be recommended in all CD patients within the first year after surgery as it highly decreased the long-term risk of POR.

Introduction: The capsule endoscopy is the most powerful exam to detect small bowel (SB) mucosal lesions in patients with Crohn's disease (CD) but the disease severity remains difficult to evaluate. The aim of this study was to develop prospectively a new index of severity devoted to the small bowel using the Pilcam® SB capsule

Aims & Methods: Patients with CD were prospectively enrolled between June 2007 and May 2013. Inclusions were stratified according to the SB disease location in a ratio 1/1/2/2 (none, ulcer at endoscopy only, non severe and severe at radiology whatever endoscopy) crossed with clinical activity in a ratio 3/1 (active or not) to ensure a wide range of severity of the SB lesions. The SB was divided into 3 tertiles from the duodenum to the caecum or to the end of the record. When possible, the terminal ileum (TI) was defined as the last 15 cm above the caecal valve. All lesions i.e. erythema, oedema, villous denudation, nodularity, lymphangiectasia, pseudo-polyp, aphtous lesions, ulcerations in relation to size, depth and shape were described, fistulas and stenosis were quantified according to predefined frequency. The extension in length of oedema, in length and circumference of ulcerations were quantified according to predefined proportions. The surface and length of lesions and ulcerations were quantified on linear analog scales. The severity physician global assessment (PGA) for each segment and for the whole SB, was assessed on a linear analog scale. Multiple linear mixed model was used to construct the new severity index in two ways as a linear combination of lesions, lengths and surfaces highly correlated either to the whole SB or to the segmental severity PGAs. Random factors were used to take into account the dependency of estimates performed in different segments of the same patient or by the same investigator on different patients.

Results: 118 patients (33 yrs [25-44]) were enrolled, 23, 21, 41 and 33 according to disease lesion strata, 76 and 42 according to clinical activity strata. Seven films were unusable for the construction of the index because of missing data or a prolonged stay in the stomach. The colon was identified in 80 patients (71%). The extension of oedema, the presence of >8 ulcerations ($>$ 10mm or superficial), the presence of deep or circular ulcerations, the extension of ulcerations in length or circumference, the lesion surface and ulceration length, and the presence of stenosis were highly related to severity, whereas the presence of villous denudation, lymphangiectasia, pseudo-polyp or aphtous lesions was clearly not

Conclusion: The preliminary results of this prospective study highlights the importance of oedema, deep and circular ulcerations and the extension of the disease in evaluating the severity of SB lesions to build this new index

P0329 RECEIVING CORTICOSTEROIDS THERAPY IS ASSOCIATED WITH A POOR OUTCOME IN PATIENTS WITH ELDERLY-ONSET ULCERATIVE COLITIS: A POPULATION-BASED STUDY

B. Pariente[1], M. fumery[2], H. Sarter[1], L. Armengol-Debeir[3], L. Dauchet[1], E. Laberenne[4], H. Coevoet[5], L. Peyrin-Biroulet[6], C. Gower-Rousseau[1], G. Savoye[3]

Introduction

Background: In elderly-onset ulcerative colitis (UC) patients, clinical course has been reported to be mild, with a rare disease extension and a majority of patients never exposed to any immunosuppressant (IS) or anti-TNF-therapy, nor operated. Nevertheless, some patients have poor clinical outcome with early resort to surgery. Along this, the impact of receiving corticosteroids (CS) therapy on the evolution of elderly-onset UC has not been evaluated.

Aims & Methods

Methods: In a French population-based cohort we identified from 1988 to 2006 473 UC patients >60 years of age at diagnosis with a median follow-up of 6.3 years [Q1 = 2.3-Q3 = 10.3]. Clinical outcome of patients undergoing CS (CS group) was compared with patients who never received CS (control group) after adjustment on receiving or not IS and/or biothérapies (as clinical surrogate marker), and on colonic location and disease duration.

Results: Among the 473 UC patients, 157 (33%) received at least one time CS therapy (prednisone or prednisolone in 97% of cases). The cumulative probabilities of receiving CS was 21% (95% CI: 17-25) at 1 year, 39% (34-45) at 5 years, and 45% (38-52) at 10 years. Gender, median age and presence of extra-intestinal manifestations at diagnosis were not different in CS and control groups. In CS group, proctitis (21%) was less frequent and pancolitis (36%) more frequent compared to control group (32% and 21% respectively, $p < 10^{-2}$). At maximal follow-up, 7% and 49% of patients in CS group had proctitis and pancolitis respectively, compared to 22% and 26% in control group respectively ($p < 10^{-4}$). Colectomy rate was higher in CS group (13%) than in control group (4%, $p = 10^{-3}$). Total number of flares and hospitalizations per year but also time spent in hospital were significantly higher in CS group compared to control group ($p < 10^{-4}$). The median duration of CS exposure was 4.6 months (2.4–9.0). Thirty-two (20%) patients were CS-dependent, 14 (9%) CS-resistant, and 15 (10%) became intolerant to CS (in which almost 30% of patients developed insulin-dependent diabetes). The cumulative probabilities of developing intolerance to CS was 1.3% (0.0 ; 4.0), 6.7% (2.6 ; 16.4) et 17.3% (8.1 ; 34.6) at 1, 5, and 10 years respectively. Four patient stopped CS because of intolerance.

Conclusion: In elderly-onset UC, receiving CS therapy is associated with a more pejorative evolution of the disease, with higher rate of surgery, flares and hospitalization. Moreover a significant proportion of patients become intolerant to CS with more than one third who developed diabetes. Unlike the majority of cases in elderly-onset UC, IS or anti-TNF treatments should be early considered in patients receiving CS.

Contact E-mail Address: bernd.bokemeyer@t.online.de

Introduction: From the genetic point of view ulcerative colitis (UC) and Crohn's Disease (CD) are not strictly separated in genome-wide association studies (GWAS). This was the reason to investigate UC-patients with a Small Bowel Capsule Endoscopy (SBCE). The nationwide BioColitis Registry (*Bio*logical Registry with Ulcerative *Colitis* Patients in Germany) of the German Competence-Network IBD is a five-year prospective registry of about 1.000 patients with ulcerative colitis (UC) in Germany. The CapColitis Study is a sub-study of the BioColitis Registry reporting the results of a SBCE in these UC-patients.

Aims & Methods: The primary study objective was to describe the type and frequency of small bowel lesions detected by SBCE in UC-patients and secondary to evaluate the prognostic impact of SBCE in new TNF-therapies. Within the framework of this non-interventional prospective online documentation, data in respect to the results of the SBCE and the course of disease, psychosocial burden, health economics and the genetic profile were analyzed. Until April 2015 about 500 UC-patients have been included in the BioColitis Study, the recruitment is ongoing. End of 2014 the recruitment of the CapColitis study was stopped having analyzed the data of 127 UC-patients with a SBCE in early disease UC-patients (disease duration < 2 years) and in UC-patients ($n = 57$) starting with an anti TNF-alpha antibody therapy (TNF) included by 11 gastroenterology practices and hospitals with IBD-experience. All patients will have a prospective 5 year follow-up period. The data of the baseline and the 6-months visit will be analyzed.

Results: 127 UC-patients have been examined with SBCE and 125 SBCE (incomplete small bowel examination ($n = 2$); no capsule retention) could be analyzed (average age: 40 years; female: 47%; disease duration: 4.5 years; pancolitis: 42%, NSAIDs 0%). Small bowel lesions/inflammation have been found in 16/125 UC patients (13%). These 16 patients with small bowel lesions/inflammation could be divided in different categories: only single-non-relevant small bowel lesions ($n = 7$) (PE-induced-lesions ($n = 3$); single-non-relevant lesions ($n = 4$)) and pathologic findings in 9 UC-patients (backwash ileitis in active pancolitis ($n = 4$); switch to Crohn's Disease ($n = 5$; 4%) after discussing all findings with the study centers). The findings in the 57 UC-patients starting a TNF-therapy have not been significantly different compared with the early disease group.

Conclusion: In this real life setting SBCE showed small bowel lesions/inflammation in 13% in these NSAIDs free UC-patients with relevant findings in 9/125 (7%), perhaps indicating an overlapping phenotyp between UC and CD as shown earlier in the partial genetic association of UC and CD in the entirety of inflammatory bowel diseases (IBD). In 5/125 UC-patients (4%) the diagnosis

have been switched following the SBCE-findings to CD. In accordance with the UC-guidelines a small bowel diagnostic is required at the point of UC-diagnosis and in this case SBCE seems to be a sensitive procedure, possibly better suited than small-bowel MRT.

P0331 NETWORKING AND IMPLEMENTATION OF EVIDENCE-BASED PATHWAYS FOR PATIENTS WITH INFLAMMATORY BOWEL DISEASES (IBD)

B. Bokemeyer[1,2], J. Langbrandtner[3], P. Jessen[4], H. Raspe[3], A. Hüppe[3]
[1]*Clinic of General Internal Medicine I, University Hospital Schleswig-Holstein, Campus Kiel, Kiel,* [2]*Gastroenterology Practice Minden, Minden,* [3]*Institute of Social Medicine and Epidemiology, University of Luebeck, Luebeck,* [4]*Gastroenterology Practice, Altenholz, Germany*

Introduction: IBD-patients experience various somatic and psychosocial impairments. They need a comprehensive, interdisciplinary and problem-oriented health care. To improve their quality of health care IBD-pathways recommend a systematic assessment of health-related problems and focus on a multidisciplinary, patient-centered care. In a prospective controlled cohort study German gastroenterologists tried to optimize their quality of care by network activities. The impact on patient reported outcomes was evaluated.
Aims & Methods: In a region of North Germany 15 gastroenterologists recruited outpatients with IBD (IG: intervention group), outside this region 18 gastroenterologists included nationwide IBD-patients in a control group (CG). At baseline (t0), 6 (t1) and 12 months (t2) patients completed a questionnaire assessing 22 somatic and psychosocial problems. Medical data on the course of disease were gathered by the gastroenterologists. IG-patients received written feedback of their problem-profile together with individualized recommendations for appropriate treatment. Further IG-interventions were the implementation of interdisciplinary IBD-case conferences and the offer of a patient training in small groups. Main outcomes were health related quality of life (HRQoL: EQ-VAS, score: 0-100) and social participation restrictions (IMET, score: 0-10); self-management skills (heiQ) and work productivity (WPAI) were among the secondary outcomes.
Results: 282 of 349 IBD-patients (80.8%; IG: 142 of 189; CG: 140 of 160) participated in both follow-up visits. Baseline characteristics were broadly similar (age: 43 years; 61% female; 50% with Crohn's Disease; 66% in remission; 68% in full- or part time employment). Only minor differences between IG and CG for age, school education and medication could be found. Covariance analyses were used to adjust for baseline differences. No significant differences between IG and CG were seen at follow-up with respect to the primary outcomes, the entire group showed small improvements from t0 to t2 (EQ-VAS: 72.5 to 76.2, $p = 0.002$; IMET: 2.1 to 1.9; $p = 0.025$). After 12-months only the IG reported increased self-management skills, the CG remained nearly unchanged (treatment x time interaction: $p = 0.002$). Work productivity of both groups was unimproved. In contrast, the feedback of the physicians in the IG were more favourable at the 6-months follow-up. 67% of the physicians participated in IBD-case conferences, the benefit of networking has been ranked with 7 on a scale from 0 (no benefit) - 10 (best benefit).
Conclusion: Our complex intervention could not be proved as effective and beneficial in the primary outcomes. Both groups showed slight positive effects over the 12 months. In a secondary outcome (self-management skills) we found an advantage for the intervention-group. The missing differences between IG and CG could be partially explained by (i) a positive side effect in the CG caused by the systematic medical documentation during the study and (ii) by the fact, that not all network activities in the IG could have been realised in the aimed frequency. Further (sub group) analysis will promote the discussion.

P0332 NON-INVASIVE TESTING IS DIAGNOSTIC AND PROGNOSTIC IN INTESTINAL GRAFT VERSUS HOST DISEASE

B. H. Hayee[1], P. Pavlidis[1], L. Floro[2], K. Raj[2], D. McLornan[2], H. de Lavallade[2], T. Pagliuca[2], V. Potter[2], G. Mufti[2]
[1]*Gastroenterology,* [2]*Haematology, King's College Hospital, London, United Kingdom*

Contact E-mail Address: b.hayee@nhs.net
Introduction: Intestinal graft versus host disease (iGVHD) is a debilitating and sometimes fatal consequence of bone marrow transplantation[1]. Malnutrition and profuse diarrhoea are common. The diagnosis is often based on clinical criteria alone and intestinal biopsies are frequently negative[1,2]. Even after successful treatment, iGVHD can relapse and reliable disease monitoring is unavailable.
Aims & Methods: We conducted this prospective study to evaluate the diagnostic accuracy of the xylose/rhamnose/lactulose small bowel permeability test (SBPT) and faecal calprotectin (FC) in the work-up of patients with suspected iGVHD. Prospective data was collected on all patients referred for endoscopic investigation of suspected iGVHD at KCH, from Jan-Dec 2014. All patients underwent OGD and colonoscopy to at least the caecum, with serial intestinal biopsies taken. Samples were collected for SBPT and FC. Infection and other pathologies were excluded with extensive testing. SBPT and FC results were compared to biopsy results and the site of positive biopsies was noted.
Results: 15 patients had positive intestinal biopsies (PB) with 9 negative (NB). SBPT was unavailable in 2, and FC in 1 patient in each group. SBPT was abnormal in 1/7 NB and in 11/13 PB. The sensitivity (Sn) and specificity (Sp) for SBPT in the diagnosis of iGVHD was 84.6% and 85.7% respectively; PPV 91.7%. FC was high in 2/8 NB and 9/14 PB, returning Sn 64.2% and Sp 75%. Addition of the two tests reduced sensitivity and specificity further. Mortality was high in the PB group (6/14, 43% - exclusively from gram-negative sepsis +/− multi-organ failure). FC was elevated > 300mcg/g in 5/6 deaths and 2/8 survivors. Intestinal biopsies were positive in all but one case from the right hemicolon, 3/6 ileum and only 2/15 from duodenum. At present, no significant patterns have emerged with regard to conditioning regimen or other aspects of the transplant protocol.
Conclusion: SBPT appears to be a highly sensitive and specific marker of iGVHD. A high FC does not appear to be related to iGVHD itself, but may predict severe disease and mortality. Biopsies were most often positive at full colonoscopy in our cohort. These non-invasive tests are simple and cheap and may serve to assist clinicians in the investigation and management of this debilitating condition.

P0333 ULTRASOUND SHEAR WAVE ELASTOGRAPHY IDENTIFIES MUSCLE WALL HYPERTROPHY AND IS A NOVEL SURROGATE FOR INFLAMMATION IN CROHN'S DISEASE

C. Lu[1], X. Gui[2], W. Chen[2], S. Ghosh[1], K. Novak[1], S. Wilson[3]
[1]*Gastroenterology,* [2]*Pathology and Laboratory Medicine,* [3]*Diagnostic Imaging, University of Calgary, Calgary, Canada*

Contact E-mail Address: clu@ualberta.ca
Introduction: Crohn's Disease (CD) is an inflammatory bowel disease mainly affecting the terminal ileum. Inflammation, fibrosis, and muscular hypertrophy lead to thickened and narrowed bowel detected on ultrasound (US). US shear wave elastography (SWE) assesses elastic properties of tissue through an acoustic US force providing a quantitative measurement of tissue stiffness. SWE has been described to differentiate inflammation from fibrosis in ex vivo CD bowel specimens[1]. As confirmed on histology, neo-angiogenesis is an important component of CD bowel wall inflammation. Quantification of bowel wall vascular perfusion can be uniquely detected by contrast enhanced ultrasound (CEUS).
Aims & Methods: We aim to prospectively correlate SWE of ileal CD in-vivo to CEUS peak enhancement as a measurement of inflammation, and to pathology grades of inflammation, fibrosis, and muscular hypertrophy of resected small bowel. We predict patients with a higher SWE score will have greater bowel stiffness attributable to fibrosis and muscular hypertrophy, and concurrent chronic inflammation as measured by lower CEUS peak enhancement. All consecutive CD patients (March to October 2014) attending outpatient US appointments received greyscale US. In patients with ileal CD and bowel wall thickness (BWT) > 3mm, SWE was measured at a point of maximal BWT and CEUS peak enhancement using microbubble (Definity®) contrast was performed ($n = 95$). An average of ten SWE readings were collected using Virtual Touch Quantification; Acuson S3000, Siemens Medical Solutions USA, Inc or with Philips Epiq 5, (Bothell, WA). Receiver operating characteristic (ROC) curve analysis was performed. Differences in low and high inflammation, fibrosis, and muscular hypertrophy of bowel specimens were compared using the student t-test. Of these 95 patients, fifteen had ileal resections within an average of 47 days (SD 90.4 days) from the time of CEUS. A gastrointestinal pathologist scored these specimens for inflammation, fibrosis, and muscular hypertrophy for comparison to SWE measurements of the corresponding regions.
Results: Of fifteen ileal specimens, chronic inflammatory histological change ($p < 0.001$) with lower corresponding CEUS peak enhancement ($p = 0.04$) exceeded acute inflammatory changes. Mean in-vivo SWE measurements for all patients who had and did not have surgery were 2.82 ± 0.68 m/s and 2.17 ± 0.79m/s ($p < 0.01$), respectively. Of the operated patients with a SWE > 3m/s, there was an inverse relationship with inflammation matching to lower CEUS peak enhancement ($p = 0.04$), and more smooth muscle hypertrophy ($p = 0.03$). There was no significant difference in SWE and fibrosis scores ($p > 0.05$).
Conclusion: SWE measurements of in vivo small bowel CD increases when there is smooth muscle hypertrophy. Overall, CD patients with lower CEUS peak enhancement parameters have more chronic bowel inflammation as confirmed on histology. A novel observation; higher SWE is related to bowel smooth muscle hypertrophy, and is inversely related to both chronic inflammation and CEUS peak enhancement. In vivo SWE and CEUS differentiates between acute

and chronic bowel wall inflammation and thickening, improving selection between medical therapy and surgery.

P0334 PERFORMANCE TESTING OF A SMARTPHONE-BASED PATIENT MONITORING SYSTEM MEASURING CALPROTECTIN AS IBD THERAPY FOLLOW-UP MARKER BY LAY USERS VERSUS LABORATORY PROFESSIONALS

J. Weber[1], P. Spies[2], M.-E. Ueberschlag[1], **C. Reinhard**[1], S. Kräuchi[1], T. Jermann[1]
[1]*BÜHLMANN Laboratories AG, Schoenenbuch,* [2]*University of Applied Life Sciences, Muttenz, Switzerland*

Contact E-mail Address: jw@buhlmannlabs.ch

Introduction: Inflammatory Bowel Disease (IBD) is a chronic inflammation of the gut comprising active inflammation, remission and flares. The disease course can be followed by biomarkers such as calprotectin which is measured in patients' stool samples. Most studies have shown that a threshold around 250 µg/g correlates well with mucosal healing. Hence, one of the therapy goals is to achieve calprotectin values below 250 µg/g and to keep them below this level. Therefore, we have developed a system, called IB*Doc*®, which allows the patient to perform calprotectin tests at home in order to regularly test that this low level is under control. The IB*Doc*® consists of a stool extraction device (CALEX® Valve) and an immunochromatographic rapid test, which is measured by a smartphone App (CalApp®) controlling the phone's camera. Results are automatically sent to and administered on a webserver (IB*Doc*® Portal) for the consulting physician or IBD nurse.

Aims & Methods: The objective of this study was to validate the IB*Doc*® home testing system by lay users vs. professional laboratory personnel and to compare its quantitative performance with routine laboratory-based methods.

Stool samples containing various levels of calprotectin (18-2582 µg/g), kindly provided by a local routine clinical laboratory, were extracted with the CALEX® Valve device by 31 lay users and two laboratory professionals. The stool extracts were then either loaded by the lay users onto immunochromatograhic test cassettes (TCs) or analyzed with a commercial ELISA test by the professional users. The lay users read the TCs via the CalApp® installed on 11 different models of iPhones and Android phones, whereas the professional users measured the TCs with the Quantum Blue® (QB) lateral flow reader. Agreement between lay users and professional users as well as quantitative performance of IB*Doc*® versus routine laboratory methods were assessed by Analyze-it for Microsoft® Excel.

Results: The IB*Doc*® test system produces a quantitative test result between 30 and 1000 µg of calprotectin/g of stool which covers the clinically relevant range of this biomarker. The total agreement (TA; based on a traffic-light system) of performing IB*Doc*® between lay users and laboratory professionals was 96.8% with 0% false positive and 0% false negative rates. The TA between measuring the TCs with 11 different smartphone models and the QB reader was 90.3%, whereas the TA of CALEX® Valve extractions performed by lay vs. professional users was 80.6%. The IB*Doc*® home test performed by 31 lay users correlated well with a state-of-the-art laboratory-based fCAL® ELISA method showing a slope of 1.03, a bias of 40 µg/g and R^2 of 0.941. The TA of these 31 single test results was 87.1%, and no false positive (red instead of green traffic-light) or false negative result (green instead of red traffic-light) was reported.

Conclusion: IB*Doc*® is the first complete and validated test system which allows the IBD patient to monitor and follow his inflammatory status by measuring the IBD biomarker, fecal calprotectin, using his/her own smartphone. The performance of the IB*Doc*® home testing system is comparable to professional, laboratory-based methods. IB*Doc*® is the first CE-marked self testing home device of its kind.

Introduction: Many patients with penetrating Crohn's disease (CD) undergo surgery for perianal disease of presumed cryptoglandular etiology before diagnosis of IBD is established.

Aims & Methods: This study aimed for the first time (1) to determine the frequency of postoperative IBD diagnosis (Dx-POP) among patients undergoing surgery for perianal abscess or fistula, and (2) to identify predictive factors for Dx-POP.

Patients who underwent surgery for perianal abscess or fistula at two major surgical departments in the city of Graz, Styria, between 1997 and 2007 were searched electronically. Dx-POP patients were identified by a registry containing all patients who received a first diagnosis of IBD between 1997 and 2007 and were residents of Styria. Dx-POP patients were compared with sex- and age-matched non-IBD controls (CO) (ratio 1:3).

Results: Among 975 patients included (73% male; age 46 ± 14 y) 58 had a pre-existing diagnosis of IBD (52 CD, 6 UC). Twenty-two patients received a first diagnosis of IBD (18 CD, 4 UC) 0.1-70 months (median; CD 9, UC 24) after surgery. Age at surgery of patients with and without a first diagnosis of CD during follow-up was 28 ± 9 and 47 ± 14 years, respectively ($p < 0.001$). According to life-table analysis, the cumulative risk of non-IBD patients to receive a diagnosis of IBD within 11 years after surgery was 2.9% (CD 2.5%, UC 0.4%). Clinical and laboratory results of Dx-POP vs. CO are compared in the Table.

	Dx-POP	CO	p
N	22	66	
Median age (y)	28	28	
Male (%)	63.6	63.6	
Number of patients with fistula/abscess/both	4/8/10	20/36/10	0.013
Fistula simple/komplex (%)	64/36	90/10	0.039
Abscess type P/I/IR/S/H* (%)	44/17/22/6/11	85/11/4/0/0	0.004
Mean (±SD) hemoglobin (g/dL)	13.4 ± 1.5	14.8 ± 1.6	0.002
Median (IQR) platelets (10^3/µL)	321 (265-428)	249 (213-291)	0.001
Mean (±SD) ESR after 2h (mm)	57 ± 30	29 ± 28	0.026
Median (IQR) length of hospital stay (d)	5 (4-6)	4 (3-5)	0.007

*P, perianal; I, interspincteric; IR, ischiorectal; S, suprasphincteric; H, horseshoe

Conclusion: A small but important fraction of patients operated for perianal abscess or fistula will receive a diagnosis of IBD during follow-up. Young age, more complex perianal disease, low hemoglobin, and high platelets at surgery predict future diagnosis of IBD. Surgeons need to be aware of undiagnosed IBD when operating perianal lesions.

Contact E-mail Address: cristina.bezzio@unimi.it

Introduction: Crohn's disease (CD) is frequently complicated by intestinal strictures, fistulae and abscesses. The natural course of intestinal fistulae, in particular early enteromesenteric lesions like fissuring-type ulcers originating from penetrating ulcers, is not well known.

To date, the possibility to accurately detect these lesions (IUS) by means of intestinal ultrasound, as hypoechoic irregularities of the outer margins of the intestinal wall, allows us to obtain information regarding their natural history in relation to treatment and clinical features of the disease.

Aims & Methods: The aim of this study was to evaluate the clinical features and outcome, of a cohort of patients with Crohn's disease complicated by intestinal fissuring-type ulcers.

We retrospectively identified 40 CD patients (male 23; mean age, 48 years) regularly followed in our Unit, in whom an intestinal ultrasound has detected intestinal fissuring ulcers, in absence of any other intestinal complications. All these patients had a regular clinical and sonographic follow up. The features of these patients and their clinical outcome, namely the need of surgery, biological or immunosuppressive therapy, as well as the sonographic behaviour of the lesions over time, including their disappearance or worsening into a evident intestinal fistula or abscess, have been evaluated.

Results: Eleven patients were active smokers, 22 had an ileal, 16 an ileocolic and 2 a colic CD. Four patients had a concomitant perianal disease. In 14 patients (35%) intestinal fissuring ulcers worsened, becoming an intrabdominal abscess (2 pt) or an evident internal fistula (12 pts) in a mean follow up of 2 years. Four of these patients had been treated immunosuppressive therapy, 2 also with biological therapy. Ten patients (25%) underwent surgery within 2 years, 6 of them despite the treatment with immunosuppressive therapy (2 pt) or biologics (4 pt). Fourteen patients (35%) showed the complete disappearance of the fissuring ulcers, 10 of them (71.4%) had been treated with azathioprine plus biologics (8 patients) or azathioprine alone (2 patient). Two patients (5%) under treatment with mesalamine showed the persistence of fissuring ulcer after 2 years.

Conclusion: This preliminary report showed that intestinal fissuring-type ulcers complicating CD seem to have progression into evident internal fistulae and a poor clinical outcome and in most patients. These lesions seem to disappear in less than one-third of patients and in most of these cases this is correlated with immunosuppressive and biological therapy.

P0337 INFLAMMATORY BOWEL DISEASE ACTIVITY AND VITAMIN D DEFICIENCY: AN ASSOCIATION?

C. Teixeira[1], D. Trabulo[1], S. Ribeiro[1], C. Martins[1], I. Cremers[1], A. L. Alves[1], A. P. Oliveira[1]
[1]*Gastrenterology, Centro Hospitalar de Setubal, Setubal, Portugal*

Contact E-mail Address: ac.corda.teixeira@gmail.com
Introduction: Vitamin D deficiency is commonly diagnosed among patients with inflammatory bowel disease (IBD). Recent studies suggest that vitamin D may have a role in clinical disease activity in ulcerative colitis (UC) and Crohn's disease (CD).
Aims & Methods: This study aims to assess an association between vitamin D levels and clinical disease activity in patients with IBD.
Prospective study with 1 year recruitment in a Southern European Center. Demographic and clinical data of patients with IBD were collected. C-reactive protein (CRP) and vitamin D levels within 30 days of their clinic visit were measured. Seasonality of the data was also considered. Patients under vitamin D replacement were excluded. Clinical activity was defined using Truelove-Witts score in UC patients and Harvey-Bradshaw score in CD patients. Vitamin D levels were defined as: normal > 30 ng/ml; insufficient 20–29 ng/ml; deficient < 20 ng/ml. Statistical analysis was performed using SPSS 21, considering statistical significance $p < 0.05$.
Results: One hundred and twenty patients; 57 females; mean age 45.8 years. 60 patients with UC and 60 patients with CD. Mean years of disease 9.69 (0-42). Seventy-seven patients presented deficient vitamin D levels and 40 patients had active disease. There was a statistically significant association between vitamin D deficiency and clinical disease activity in CD ($P = 0.005$) and in UC ($p = 0.038$). There was also a significant association between clinical disease activity and increased CRP levels in both diseases ($P = 0$), but there was no association between increased CRP and vitamin D deficiency in any type of IBD. Despite a higher percentage of vitamin D deficiency in active disease, we found that a significant percentage of patients of patients with inactive disease had insufficient or even deficient vitamin D levels. There was not season variability.
Conclusion: In our series, vitamin D deficiency is related to clinical activity of IBD, especially in CD. Vitamin D supplementation may have a potential role as a treatment for patients with active IBD.
Disclosure of Interest: None declared

P0338 ARE CLINICAL INDICES OF INFLAMMATORY BOWEL DISEASE ACTIVITY SUPERIOR TO PATIENT OPINION AT PREDICTING ACTIVITY AS DEFINED BY FAECAL CALPROTECTIN?

D. J. Gracie[1,2], C. Williams[2], R. Sood[1,2], S. Mumtaz[2], H. Bholah[2], P. J. Hamlin[1,2], A. C. Ford[1,2]

Introduction: The Harvey-Bradshaw Index (HBI) and Simple Clinical Colitis Activity Index (SCCAI) are clinical scoring systems used to estimate Crohn's disease (CD), and ulcerative colitis (UC) activity respectively. However, their performance compared with patient opinion at predicting disease activity defined by faecal biomarkers of IBD activity is unclear. We conducted a cross-sectional survey of IBD activity to assess these issues.
Aims & Methods: Demographic data and patient opinion regarding whether they were, or were not having a flare of disease was assessed by standardised questionnaire. IBD activity was assessed by HBI for CD and SCCAI for UC, with active disease defined by a score of ≥5 for each. Stool was collected for faecal calprotectin (FC) analysis by enzyme linked immunosorbent assay (ELISA) (Biohit, Finland). Patients were dichotomised into those with or without active disease using a FC of ≥200μg/g of stool to define active disease. Mean FC was compared between those with and without active disease by patient opinion and clinical indices of IBD activity by independent samples t-test. The sensitivity, specificity, positive predictive value, negative predictive value and overall accuracy of patient opinion and clinical activity indices at predicting active disease define by FC was also calculated. ROC curve for HBI and SCCAI against active disease defined by FC was used to calculate the AUC for each clinical assessment index.
Results: There was no difference in mean age, sex, education level, marital status, smoking or alcohol usage for CD or UC patients dichotomised in those with and without active disease defined by FC. In CD mean FC was lower in patients with active disease defined by HBI than those without (381 vs. 472; $P = 0.368$). Mean FC was higher in patients with active disease defined by patient opinion than those without but this failed to reach statistical significance (474 vs. 425; $P = 0.711$). In contrast, mean FC was significantly higher in UC patients with active disease defined by both patient opinion and SCCAI (919 vs. 381; $P < 0.001$ and 949 vs. 311; $P < 0.001$ respectively). The sensitivity, specificity, positive predictive value, negative predictive value, overall test accuracy and AUC for each test when used to predict disease activity defined by FC is illustrated in table 1.**Table 1:** performance of individuals IBD assessment tools

(continued)

Table 1 Continued

	Crohn's disease		ulcerative colitis	
patient opinion	HBI	patient opinion	SCCAI	
	Crohn's disease		ulcerative colitis	
patient opinion	HBI	patient opinion	SCCAI	
sensitivity	0.17	0.37	0.45	0.54
specificity	0.84	0.64	0.78	0.73
PPV	0.45	0.44	0.62	0.62
NPV	0.57	0.57	0.64	0.65
Accuracy	0.55	0.53	0.63	0.64
ROC AUC	-	0.49	-	0.66

Conclusion: The performance of clinical disease activity indices at predicting IBD activity is modest in UC and poor in CD when compared to faecal biomarkers of intestinal inflammation. Neither HBI nor SCCAI appear to outperform patient opinion. Faecal biomarker point of care testing may aid clinical decision making.
Disclosure of Interest: None declared

P0339 PREVALENCE AND IMPACT OF IRRITABLE BOWEL TYPE-SYMPTOMS IN QUIESCENT INFLAMMATORY BOWEL DISEASE

D. J. Gracie[1,2], C. Williams[2], R. Sood[1,2], S. Mumtaz[2], H. Bholah[2], P. J. Hamlin[1,2], A. C. Ford[1,2]

Contact E-mail Address: djgracie1982@doctors.org.uk
Introduction: The prevalence of symptoms compatible with irritable bowel syndrome (IBS) in inflammatory bowel disease (IBD) has been previously described. However, the association between the presence of these symptoms and occult disease activity is less well known, as is the effect of these symptoms on psychological health. We conducted a cross-sectional survey examining these issues.
Aims & Methods: Demographic and gastrointestinal symptom data were collected from 439 adult patients via the Rome III questionnaire. IBD activity was assessed via clinical scoring systems and faecal calprotectin (FC) in a subset of patients. Mood was assessed using the hospital anxiety and depression scale, whilst somatisation and quality of life data were collected using the patient health questionnaire-12 (PHQ-12) and SF-36 questionnaire respectively. Mean FC, as well as anxiety, depression and somatisation severity and quality of life were compared between CD and UC patients meeting Rome III criteria for IBS and those who did not.
Results: More patients with CD met criteria for IBS than UC (97 (42.4%) of 229 vs. 63 (30.9%) of 204 respectively, $P = 0.01$). In CD, there was no difference in anxiety ($P = 0.106$), depression ($P = 0.156$) or somatisation severity ($P = 0.104$) when patients with IBS-type symptoms were compared to those without. Mean quality of life scores for pain ($P = 0.003$) and general health ($P = 0.009$) were significantly lower in CD patients with IBS-type symptoms. In contrast, in UC anxiety severity was higher in those with IBS-type symptoms ($P = 0.001$), and there was a trend towards greater depression and somatisation severity in patients with IBS-type symptoms ($P = 0.035$ and $P = 0.011$ respectively). UC patients with IBS-type symptoms had significantly lower mean quality of life scores for role limitations due to physical health ($P = 0.004$), energy/fatigue ($P = 0.003$), emotional wellbeing ($P = 0.002$), social functioning ($P = 0.006$), pain ($P < 0.001$) and general health ($P = 0.003$). For CD, mean FC levels were higher in those with IBS-type symptoms than those without (543.3 vs. 444.9; $P = 0.529$) and the same trend was observed in UC (423.5 vs. 282.8; $P = 0.368$). There was no difference in the proportion of individuals with a normal FC in CD patients fulfilling criteria for IBS (12 (63.2%) of 19) than those not (31 (56.4%) of 55) ($P = 0.605$). The same was true in UC (7 (50%) of 14 vs. 38 (69.1%) of 55 ($P = 0.181$).
Conclusion: The prevalence of IBS-type symptoms is higher in CD than in UC. IBS-type symptoms are associated with more severe anxiety in UC patients and lower quality of life scores in both CD and UC. Whether such symptoms arise from occult disease activity, or true coexistence of IBS, remains unclear.
Disclosure of Interest: None declared

P0340 THE FECAL NEUTROPHIL GELATINASE-ASSOCIATED LIPOCALIN (NGAL) AS NOVEL SURROGATE BIOMARKER OF INFLAMMATION IN THE DIAGNOSIS OF INFLAMMATORY BOWEL DISEASES

D. Mukhametova[1], **D. Abdulganieva**[1], O. D. Zinkevich[2], N. A. Saphina[2], M. Koporulina[2], A. Odintsova[3]

Contact E-mail Address: muhdilyara@gmail.com
Introduction: Today there is active search of non-invasive surrogate biomarkers of intestinal inflammation in inflammatory bowel diseases (IBD). Fecal neutrophil gelatinase-associated lipocalin (NGAL) secreted by neutrophils and epithelial cells during inflammation and possibly can be used as a biomarker of inflammation.
Aims & Methods: To evaluate the fecal concentration of NGAL in different courses of inflammatory bowel disease (IBD).

We prospectively included 96 patients with IBD exacerbation [29 pts with Crohn's disease (CD) and 67 pts with ulcerative colitis (UC)] and 15 healthy controls. Fecal NGAL was determined by ELISA in fecal specimens. We used a set of Human Lipocalin-2 / NGAL ELISA, production BioVendor, Czech Republic. The average age of patients with CD was 36 ± 2 years, UC - 37 ± 1 years, in the control group - 31 ± 2 years. Severity of CD was assessed by CDAI: mild CD was seen in 7 (24%), moderate – 13 (45%), severe – 9 (31%), in UC by Mayo score: mild – 22 (33%), moderate – 28 (42%), severe – 17 (25%).

Results: Fecal NGAL level was increased in active IBD – 4122 [861; 6850] ng/ml ($p < 0.05$) compared with healthy controls – 181 [169; 720] ng/ml. Level of NGAL in UC was higher – 4668 [1298; 7792] ng/ml ($p < 0.05$) than that in CD – 2688 [200; 5710] ng/ml. In severe CD NGAL was higher – 5908 [2860; 12920] ng/ml than in moderate CD – 2236 [172; 4236] ng/ml ($p < 0.05$) and mild CD 896 [200; 3828] ng/ml ($p < 0.05$). In severe UC fecal NGAL was higher – 6044 [4605; 9632] ng/ml than in moderate UC – 4963 [2198; 7780] ng/ml ($p > 0.05$) and mild CD – 2194 [786; 4668] ng/ml($p < 0.05$).

Fecal NGAL correlated with clinical parameters of IBD: in CD with the severity of fever ($r = 0.40$; $p < 0.05$), in UC with the stool consistency ($r = 0.25$; $p < 0.05$) and the weight loss ($r = 0.27$; $p < 0.05$). Also in CD NGAL levels had a significant correlation with the C-reactive protein ($r = 0.70$; $p < 0.05$), in UC – with the erythrocyte sedimentation rate ($r = 0.44$; $p < 0.05$).

ROC-analysis defined the threshold of fecal NGAL as a marker for determining an active phase of inflammation in IBD - 1144 ng/ml, to which were empirically determined sensitivity of 72%, specificity of 100%, and AUC – 0.88. Thus, the findings suggest that studied indicator have high resolution in identifying IBD.

Conclusion: The fecal level of NGAL significantly increased during flare of IBD with a high sensitivity, specificity and AUC. The concentration of NGAL in UC was higher than that in CD. NGAL correlated with the severity and activity of CD.

Disclosure of Interest: None declared

P0341 HETEROGENEITY IN THE ENDOSCOPIC MANAGEMENT OF CROHN'S DISEASE ASSOCIATED STRICTURES: RESULTS FROM AN INTERNATIONAL INFLAMMATORY BOWEL DISEASE SPECIALIST SURVEY

D. Bettenworth[1], R. Lopez[2], P. Hindryckx[3], B. G. Levesque[4], F. Rieder[5,6]

Introduction: Crohn's disease (CD) is frequently complicated by a stricturing phenotype, leading to intestinal obstruction. Endoscopic balloon dilation (EBD) represents a widely used approach for the management of intestinal strictures in CD. Available evidence in this area, however, is limited. Aim of this study was to depict heterogeneity of endoscopic management of CD associated strictures among international CD specialists to identify common treatment standards.

Aims & Methods: A questionnaire was developed by the gastroenterology faculties of the Cleveland Clinic and the University Hospital Muenster and placed on an online platform. Participants were asked about their endoscopic experience, practice setting and number of EBD annually. Two case scenarios as well as technical practice parameters were investigated. The questionnaire was distributed through the IOIBD, ECCO, PROVIT and national IBD networks. Statistical analysis was performed using appropriate tests.

Results: 126 subjects from 15 countries (11.1% colorectal surgeons; 40.5% subspecialized in interventional endoscopy; endoscopy experience 15.2 ± 8.2 years) completed the survey. The maximal length of dilated stricture was 4.5 ± 1.7 cm. The most commonly used balloon size was graded 15-18 mm with a dilation time of 1.7 ± 1.2 minutes. While 87.2% of participants favored the use of EBD for anastomotic strictures, only 58.6% did so in case of naïve strictures. Only 35.7% of physicians dilated actively inflamed strictures. Concomitant therapies employed were injection of steroids (11.2%) or infliximab (1.7%), cutting techniques (5.2%), and stent placement (0.9%). 89.7% used serial dilations in the same patient over time.

Heterogeneity in practice existed among the participants: Interventional endoscopists were more likely to dilate only clinically symptomatic strictures ($p = 0.046$). Surgeons favored surgical treatment of *de novo* ileocaecal strictures ($p = 0.026$ compared to gastroenterologists) and reported a shorter stricture length being amendable to EBD ($p = 0.045$). They more frequently used concomitant therapies ($p = 0.001$). Traversal of the colonoscope after dilation was more frequent in academic hospitals followed by community hospitals and then private practice ($p = 0.013$). Balloon inflation time was longest in Europe and shortest in North America ($p = 0.041$). Operator experience increased the likelihood of EBD in actively inflamed strictures ($p = 0.002$), maximum length of stricture and maximum balloon size ($p = 0.001$).

Conclusion: EBD is a widely used treatment approach for stricturing CD. However, individual selection of strictures appropriate for EBD and the technical approach differ widely based on individual background of the operator, experience level and practice setting. Therefore, evidence-based consensus guidelines for the practical management of EBD are highly desirable.

Introduction: Endothelial dysfunction plays a pivotal role in the development of inflammatory bowel diseases (IBD). Activity of endothelial cells can be determined by the use of both physical and biochemical methods as well. One of the recently discovered plasma biomarkers are microparticles derived form the endothelium. They can play an important role in interactions with circulating cells and the vascular wall.

Aims & Methods: The study aimed to assess level of circulating microparticles in IBD patients as well their correlation with clinical status.

Sixty IBD patients aged 18-65 (32 Crohns's disease (CD), 28 ulcerative colitis (UC)) and 60 sex- and age-matched healthy controls were included into the study. Levels of circulating endothelial microparticles were measured and related to disease phenotype, clinical and biochemical activity.

Results: In UC group (14F and 14M) mean microparticles level was 122 +/- 70/ul of plasma and in CD group (17F and 15M) - 144 +/- 40/ul of plasma. We found statistical differences between active and inactive UC group (140 +/- 60/ul vs 96 +/- 64/ul, $p < 0.05$) as well between active and inactive CD group (176 +/- 66/ul vs 102 +/- 56/ul, $p < 0.01$). There were no differences between inactive disease and healthy controls ($p > 0.05$) Microparticles level correlated weekly positively with CD activity ($r = 0.35$) but not with UC activity ($r = 0.12$).

Conclusion: Elevated level of circulating endothelial microparticles confirms the role of endothelial dysfunction in IBD patients. It is also an indicator of the disease activity, however this relationship is more pronounced in CD patients.

Introduction: As Crohn's disease (CD) is characterized by its unpredictable clinical course, the ideal approach for the assessment of disease activity would be real-time monitoring of patient's symptoms.

Aims & Methods: The aim of this study was to identify discordance of patients' symptoms between on routine clinic visits and at home using a web-based self-reporting Crohn's disease symptom diary (CDSD) and to evaluate its impact on clinical outcomes. CDSD consisted of 5 clinical parameters based on the Harvey-Bradshaw Index, which could easily be recorded online, by using CDSD website (www.cdsd.or.kr). Between February 2012 and October 2014 patients with CD were invited to record their symptoms at home at least once a week and on the routine outpatient clinic visit as well. We identified the patients who showed disparity of disease activity between on the regular hospital visits and at home and evaluated clinical outcomes of these patients such as biologic use, abdominal surgery, and unscheduled visits with Kaplan-Meier analysis. Risk factors related with unscheduled visits were also assessed.

Results: Among 280 patients with CD invited, 155 (male 109, age 26.17 ± 8.19 years) who recorded their symptoms weekly basis at least for consecutive 3 months were included in the study. Fifty four patients (34.8%) showed different disease activities between at home and on the hospital. Cumulative risk of abdominal surgery ($P = 0.046$) and unscheduled visits ($P < 0.001$) was significantly higher in this disparity group than concordance group. Disparity in symptoms (HR 3.61, 95% CI 1.68-7.77, $P = 0.001$), steroid exposure (HR 2.71 95% CI 1.02-7.24, $P = 0.046$) and use of biologics (HR 3.92, 95% CI 1.81-8.49, $P = 0.001$) were independent risk factors associated with unscheduled visits to the hospital.

Conclusion: Disparity in disease activity is considerable in patients with CD and is related with the negative clinical outcome. More attention should be paid to identifying patients with this unstable activity using a real-time monitoring tool.

Introduction: Fecal calprotectin (fcal) has been reported as an important biomarker of endoscopic healing in ulcerative colitis (UC).
Aims & Methods: We assessed accuracy of fcal – evaluated by 2 assays, Quantum Blue (QB) and automated fluoroimmunoassay (EliA) – and fecal Neutrophil gelatinase-associated lipocalin (NGAL), aiming to predict the histological activity in UC patients without clinical activity according to partial Mayo score. Histological evaluation was performed by 3 independent pathologists.
Results: 369 UC patients were recruited, left side colitis (57%) or pancolitis (43%). The Geboes scoring system was used to evaluate the histological activity, and 22% of UC patients were scored as $\geq$3.1. In 29% of the cases there was endoscopic activity (Mayo 1, 2 or 3). In 20% of the patients, basal plasmocytosis was observed, diffuse in 5% of the cases. Histological activity was observed in patients with Mayo score 0 (11%) and Mayo scores 1 and 2 (43% and 86%, respectively). In asymptomatic UC patients, high fcal was observed in 25% evaluated by QB ($>$250 ug/g), 20% evaluated by EliA ($>$150 ug/g), and in 31% of the cases there was a high level of NGAL($>$12 ug/g). The median values of fcal and NGAL in patients with histological remission were: QB-81.5 ug/g (IQ: 30-224); EliA- 29 ug/g (IQ: 6.8-99.5); NGAL-8.5 ug/g (IQ: 4.7-15.1). The negative predictive value (VPN) and accuracy for histological activity (Geboes $\geq$ 3.1) was the following for different assays: QB ($>$250 ug/g): VPN-83%, accuracy-70%; EliA ($>$150 ug/g): VPN-84%, accuracy-73%; for NGAL ($>$12 ug/g), the VPN-83% and accuracy 63%, respectively. The predictability of histological remission evaluated by the area under curve was: QB: 0.72 (CI:0.66-0.78); EliA 0.71 (CI:0.65-0.76); NGAL 0.66 (CI:0.58-0.74).
Conclusion: Approximately 30% of asymptomatic UC patients had high biomarkers levels and histological or endoscopic activity. Calprotectin and NGAL are reliable and accurate biomarkers to detect persistent histological inflammation in asymptomatic UC patients.

Introduction: Anti-TNF alfa adalimumab (ADA) is a well-established treatment in inflammatory bowel disease (IBD). The drug is administered subcutaneously in an uniform dose regardless of body weight. Monitoring ADA trough levels may be recommended in the future to optimize and personalize therapy and to improve efficacy. Our aim was to explore whether body composition parameters influence ADA trough levels and its variability.
Aims & Methods: Eighteen IBD patients initiating ADA treatment were included in our study. Induction therapy was started with ADA 160/80mg at weeks 0/2, then 40mg every other week as a maintenance. ADA trough levels were measured at week 6 and 12. Bioelectrical impedance analysis (BIA) was carried out and body composition was measured by InBody 720 body analyser device right before starting biological therapy. Body composition indexes were derived from the computed values (fat-free mass index [FFMI], skeletal muscle index [SMI] and body fat mass index [BFMI]) of BIA. Body surface area was calculated by using DuBois-DuBois formula.
Results: According to our findings ADA trough levels had not differ significantly at week 6 and 12 (8.00 ± 2.9µg/mL vs. 7.73 ± 3.14µg/mL). Three of the patients (6.7%) had suboptimal ADA trough levels, only one of them were detected to have antibodies, he was excluded from further investigations. The changes of adalimumab trough levels correlated with body surface area ($r = -0.682$; $p = 0.002$). We also found moderate correlation between the variability of trough levels and muscle parameters (FFMI: $r = -0.494$, $p = 0.045$, SMI: $r = -0.508$, $p = 0.038$). However the changes of ADA trough levels did not correlate with BIA fat parameters nor the proportion of extracellular and intracellular fluid (BFMI: $r = -0.099$ and extracellular/intracellular water $r = 0.089$)
Conclusion: The results of our pilot study suggest that body surface area and body muscle parameters may influence the constancy of ADA trough levels. The findings arise the question whether adalimumab dosage offerd to be adjusted to body surface area or body compostion in the future. To confirm this suspicion larger patients population and their ADA trough levels should be investigated.

Introduction: Crohn's disease (CD) patients treated with tumor necrosis factor antagonists (anti-TNFs) may require therapy changes over time, which may be considered as indicators of suboptimal therapy.
Aims & Methods: A multinational, multicentre, retrospective, chart review study was conducted to assess the indicators of suboptimal therapy among adult CD patients receiving their first anti-TNF [infliximab (IFX) or adalimumab (ADA)] between June 2009 and June 2011 (index therapy). The indicators of suboptimal therapy during 2-year follow up were: anti-TNF dose-escalation (assessed $>$4 months after index to allow for initial dose adjustments), augmentation with a non-biologic drug, discontinuation of first anti-TNF, switching to another anti-TNF and CD-related surgery. Percentages of patients with each indicator type and $\geq$1 indicator by country for each anti-TNF drug are summarized descriptively.
Results: The study included 657 CD patients with mean age (SD) of 39.2 (13.2) years, 51% females, 51% with moderate to severe CD at index, 44% and 56% on ADA and IFX respectively, and 71% on combination therapy with a non-biologic drug. Overall, 56% of CD patients had $\geq$1 indicator of suboptimal therapy, 20% of patients had dose escalation, 18% needed augmentation with a non-biologic, 29% discontinued first anti-TNF, and 17% underwent a CD-related surgery. Of those who discontinued ($N = 183$), 70% switched to another anti-TNF. Patients with indicators of suboptimal therapy for each country by the anti-TNF are shown in the Table.
Conclusion: In this large multinational cohort, over half of the CD patients had $\geq$1 indicator of suboptimal anti-TNF therapy. Predominant indicators included dose escalation, discontinuation and switching to another anti-TNF.

Contact E-mail Address: fmocciaro@gmail.com
Introduction: Adalimumab (ADA) is effective in the induction and maintenance of steroid-free remission in patients (pts) with steroid-dependent Crohn's disease (CD). We have already reported data on efficacy and prognostic factors of response of ADA (80/40 or 160/80 mg every other week followed by 40 mg every other week) in 110 steroid-dependent pts. At week 6, 91% of pts have had a clinical benefit (remission: 45.5%, response: 45.5%). At the end of the follow-up (mean 14.6 months), 80.9% of responders have maintained the clinical benefit (remission: 64.5%, response: 16.4%). Only higher induction regimen was related to remission at week 6. At the end of the follow-up, none of the variables were associated with remission. Up to now no data are available on long term efficacy of ADA in the setting of steroid dependent pts.

Abstract number: P0346

Table: Indicators of suboptimal anti-TNF therapy among CD patients during 2-year follow up

Indicator of suboptimal anti-TNF therapy	Canada IFXN = 40	France		Germany		Italy		Spain		UK		Overall	
		ADAN = 24	IFXN = 50	ADAN = 26	IFXN = 43	ADAN = 66	IFXN = 75	ADAN = 69	IFXN = 66	ADAN = 78	IFXN = 91	ADAN = 29	IFXN = 365	ADAN = 292
						%								
≥1 of the following Indicators	75.0	50.0	74.0	65.4	34.9	62.1	60.0	44.9	42.4	41.0	64.8	62.1	58.6	51.71
Anti-TNF Dose escalation	40.0	41.7	32.0	23.1	9.3	18.2	18.7	14.5	9.1	11.5	17.6	31.0	19.7	19.2
Augmentation with a non-biologic drug[1]	20.0	12.5	32.0	15.4	11.6	22.7	24.0	13.0	7.6	10.3	17.6	34.5	18.6	16.8
Discontinuation of first anti-TNF[2]	27.5	16.7	36.0	30.8	20.9	31.8	34.7	21.7	25.8	17.9	38.5	13.8	31.8	22.6
Switching to another anti-TNF[3]	15.0	12.5	30.0	19.2	11.6	22.7	22.7	18.8	18.2	12.8	28.6	3.4	22.2	16.1
CD-related Surgery	20.0	16.7	24.0	15.4	7.0	16.7	21.3	18.8	13.6	15.4	16.5	13.8	17.3	16.4

[1] Augmentation defined as any new additions or increase in dose/frequency of the concurrent non-biological therapy with anti-TNF therapy. [2]Discontinuation as reported in patients' medical charts and by excluding patients that reported discontinuing first anti-TNF because it was effective. [3]Switch defined as a subset of discontinuation patients who initiated another anti-TNF therapy over the course of the follow-up period.

Aims & Methods: All the 110 pts treated in the previous study were followed up until April 2015 and the following variables were evaluated at the end of the follow up: maintenance of clinical benefit, ADA discontinuation, dose exalation, switch to another biologic, surgical treatment and side effects.
Results: At the end of the follow up (mean 74.16 ± 10.3 months) only 5 pts resulted lost during the follow-up. Concerning the remaining 105 pts, 42 pts (40%) obtained the clinical benefit: 1) 37/42 (88%) were still in maintaining treatment with ADA at the dosage of 40 mg sc (of these pts 13/37 [35%] received a weekly maintaining treatment); 2) 5/37 (12%) discontinued ADA due to mucosal healing. Sixty-three pts (60%) discontinued ADA: 1) 50/63 (79%) for lost of clinical benefit (20 of these 50 pts were operated on [40%]); 2) 6/63 (10%) for side effects; 3) 5/63 (8%) for severe endoscopic activity despite clinical response; 4) 2/63 (3%) died for reason not related to ADA treatment. Among pts who discontinued ADA 24/63 (38%) were then effectively switched to another biologic (infliximab or golimumab). At univariable analysis we did not find variables related to the treatment outcomes. ADA was well tolerated. Only one pts developed an acute leukaemia after 2 years of ADA discontinuation.
Conclusion: This long-term "real-life" prospective study showed that ADA is a good maintaining treatment in steroid dependent CD but 1/3 of them needed dose escalation to maintain clinical benefit. The rate of long term side effects that needed treatment discontinuation is quite low. In pts intolerant to or with lost of response to ADA a switch to another biologic is an effective opportunity.

P0348 THE COMBINATION OF MESENCHYMAL STROMAL CELLS AND INFLIXIMAB INCREASES THE ANTI-INFLAMMATORY EFFECT OF THE TREATMENT OF ULCERATIVE COLITIS

O. Knyazev[1], **A. Kagramanova**[1]
[1]*Department of Inflammatory Bowel Disease, Moscow Clinical Research Center, Moscow, Russian Federation*

Contact E-mail Address: oleg7@bk.ru
Introduction: Mesenchymal stromal cells (MSCs) have a high immunosuppressive potential. Concentration of azathioprine, methotrexate, 6-mercaptopurine, infliximab (IFX) no effect on the viability, differentiation, phenotype MSC and ability to suppress proliferation of peripheral blood mononuclear cells. These results are important for the clinical application of MSCs in combination with immunomodulators and anti-TNF-α therapy. However, little is known about the effectiveness of the combined use of MSC and immunomodulatory drugs in the treatment of IBD. Aim. Assess the clinical and endoscopic efficacy of combination therapy of ulcerative colitis (UC) with concurrent use MSC and IFX.
Aims & Methods: 1st group patients (n = 28) who were administered MSCs twice a month at intervals of 1 week + after 6 months from the date the first administration of MSCs. 2nd group patients with UC (n = 26) received IFX. 3rd group of patients with UC (n = 10) received MSC and IFX. Follow-up was 24 months. To assess the clinical activity of ulcerative colitis, we used the index Rachmilevitz, to assess the endoscopic activity. Analysis of the effectiveness of different biologic therapy of patients with UC after 2, 6 and 12 months of therapy. Initial level clinical activity index before treatment was in group 18.98 ± 0.38 points in the 2nd - 9.1 ± 0.4, and 3rd, respectively, - 9.1 ± 0.6, the level of endoscopic activity index before treatment was in the 1st group 7.46 ± 0.2 points, in the 2nd - 7.62 ± 0.16, in the 3rd - 7.6 ± 0.4 ($p > 0.05$).
Results: After 2 months of clinical activity index decreased significantly from baseline in 1st group to 1.53 ± 0.24 points in the 2nd - to 1.27 ± 0.12, in the 3rd to 1.1 ± 0.17 points ($p > 0.05$ between groups). After 6 months of clinical activity index was in group 11.64 ± 0.24 points in the 2nd - 1.35 ± 0.14 points, 3rd - 0.7 ± 0.15 points, which was significantly lower than in the 1st and 2nd groups ($p < 0.05$). After 12 months of clinical activity index was in group 11.68 ± 0.8 points in the 2nd - 1.62 ± 0.16 points, 3rd - 0.5 ± 0.16 points, which was significantly lower than in the 1st and 2nd groups ($p < 0.05$). Index Mayo after 2 months decreased significantly from baseline in the 1st, 2nd and 3rd groups of up to 1.57 ± 0.24, 1.65 ± 0.25, 1.22 ± 0.2 scores ($p < 0.05$), respectively. After 6 months the index Mayo in 1st group was 1.6 ± 0.24 points, in the 2nd - 1.65 ± 0.19, in the 3rd - 1.1 ± 0.2 points. After 12 months, the index of the Mayo patients 3rd group was 0.8 ± 0.2 points, which was significantly lower ($p < 0.05$) than in 1st group - 1.46 ± 0.22 points and 2nd - 1.43 ± 0.1, groups of patients with UC.
Conclusion: Combined biological therapy of inflammatory bowel disease contributes to more stable clinical and endoscopic remission compared to monotherapy with biological agents after 1 years.

P0349 COMPARATIVE ASSESSMENT OF THE SAFETY OF STEM CELLS AND STANDARD ANTI-INFLAMMATORY THERAPY OF CROHN'S DISEASE

O. Knyazev[1], **A. Kagramanova**[1], A. Parfenov[1]
[1]*Department of Inflammatory Bowel Disease, Moscow Clinical Research Center, Moscow, Russian Federation*

Contact E-mail Address: kagramanova@me.com
Introduction: Mesenchymal stromal cells (MSCs) are now widely used in clinical studies with various diseases, providing a positive effect due to the immunomodulatory and paracrine mechanisms. However, the safety profile of these cells remains unproved.
Objective: To compare the safety of treatment of the patients with Crohn's disease (CD), receiving comprehensive anti-inflammatory therapy with the application of MSCs standard therapy with 5-aminosalicylic acid (5-ASA), glucocorticosteroids (GSCs) and immunosuppressive agents (IS).
Materials and methods.
Aims & Methods: Within the period from 2008 to 2014 the system transplantation of allogenic MSCs was carried out in 64 patients with CD. 47 patients were included in the first group, the average monitoring time averaged 62 ± 4 months. 19 of them (40.4%) were men and 28 (59.26%) women. The average age was 30.4 ± 1.2 years. 124 patients with CD, who received standard anti-inflammatory therapy with 5-ASA and GCSs, were included in the second, control group. Out of them 56 (45.2%) were men and 68 (54.8%) women. The average age was 36.8 ± 1.5 years. The patients, who received anti-cytokine therapy, were not included in this group. The safety of the used therapy was assessed by the presence of complications, arising during the observation, infectious complications, exacerbation of chronic inflammatory diseases, serious infectious complications, a malignant transformation, a lethal outcome.
Results: In the first group of patients with CD the development of non-severe infectious complications or exacerbation of chronic inflammatory diseases were registered in 7 patients out of 56, that totaled 12.5%, in the second in 14 (16.7%) patients out of 84. When comparing the two groups, no differences were found in the risk of the development of infectious complications and exacerbation of chronic inflammatory diseases on the background of the standard anti-inflammatory CD therapy or with the introduction of the MSCs (RR-0.75, 95% Cl 1.5-23.58; x^2-0.16; p = 0.66). Severe infectious complications (pneumonia, pleurisy, activation of latent TB) in the first group were detected in 1 patient (1.8%) out of 56, and in the second group in 5 (5.9%) out of 84. When comparing the two groups no differences in the risk of this type of complications were also found (RR-0.3; 95% Cl 0.04-2.5; x^2-0.59; p = 0.44). Colorectal cancer was registered only in one she-patient from the first group (1.8%). The time between the introduction of the MSCs and diagnosed colon cancer was 10 days. In the second group of patients over the 5 years of follow-up, malignant transformation was observed in 4 (4.8%) patients out of 84 (RR-0.5, 95% Cl 0.05-4.96; x^2-0.01; p = 0.97). Within 5 years of follow-up in the first and second groups of patients, fatal outcomes were registered on one occasion in each group, 1.8% and 1.2% respectively (RR-1.5, 95% Cl 0.1-23.49; x^2-0.19, p = 0.66).
Conclusion: The analysis did not reveal any differences in the development of severe infectious complications, exacerbation of chronic inflammatory diseases, serious infectious complications of malignant transformations and deaths in patients with CD, who received the MSCs and the standard anti-inflammatory therapy.

P0350 FINAL THIOPURINE METABOLITE LEVELS AND SHUNTER STATUS CAN BE PREDICTED AFTER SIX WEEKS OF THIOPURINE THERAPY–BIOCHEMICAL OUTCOMES FROM THE EATME STUDY

A. B. Friedman[1], J. D. Brookes[1], M. G. Ward[1], H. Belinda[1], L. N. Nihill[1], J. Reynolds[1]

Introduction: Dosing of thiopurines [azathioprine (AZA) and mercaptopurine (MP)] in the management of IBD has been based upon patient weight. However, it appears unreliable in predicting final levels of thiopurine metabolites. This leads to suboptimal clinical outcomes because of under- and over-dosing, and 'shunting' in 15% where toxic 6-methylmercaptopurine (6MMP) is preferentially produced over the efficacious 6-thioguianine nucleotides (6TGN), with 6MMP:6TGN ratio $\geq$20.
Aims & Methods
Aims: 1. To determine prospectively the clinical value of timing of measurement of thiopurine metabolites during dose-escalating regimen of thiopurine initiation in a consecutive cohort of IBD patients being initiated on a thiopurine. 2. To determine if the 6MMP:6TGN ratio changes during thiopurine dose escalation.
Methods: In this single-centre, prospective, open label study patients were commenced on either a daily dose of 50 mg AZA or 25 mg MP (physician discretion). Doses increased fortnightly by 50 mg for AZA or 25 mg for MP until target was achieved, aiming for 2–2.5 mg/kg for AZA and 1–1.5 mg/kg for MP. Hematology, CRP and liver function tests were performed fortnightly to monitor toxicity, and thiopurine metabolites were measured fortnightly until steady-state was achieved, but these results were not used for dosing decisions. Clinical and biochemical outcomes were recorded. Landmark analyses of shunter status used logistic regression models. Metabolite levels were analysed using linear regression models.
Results: 64 patients (52 Crohn's, 11 ulcerative colitis and 1 IBD-U) were enrolled. Final metabolite outcomes were: 11 (17%) patients were shunters, 27 (42%) were underdosed (6TGN level of $<$260 pmol/8X10^8 RBCs), 5 (8%) patients' levels were supratherapeutic (6TGN $>$450) and only 21 (33%) were therapeutic. 6MMP:6TGN ratios escalated over time in shunters, but not in others. After 2 weeks of therapy, a 6MMP:6TGN ratio above 9 ($p=0.058$) was suggestive of shunting, while after 6 weeks, a ratio $\geq$12 (95% CI 7–28, $p=0.01$) was predictive of shunting. 6TGN levels at week 2 (median 106, range 0–328) predicted final 6TGN outcomes (median 282, range 50–746, $r=0.681$, $p<.001$) and 6MMP levels at week 2 (median 236, range 0-2163) predicted final 6MMP outcomes (median 1301, range 62–14600, $r=0.835$, $p<.001$). 23% of MP and 14% of AZA patients were shunters ($p=0.395$). At no time point did levels predict an adverse event to thiopurines. No correlation was detected between the weight-based dose of thiopurines and final ratios ($r=-0.277$), 6TGN ($r=0.044$) and 6MMP ($r=-0.193$) levels (all p values $>.10$).
Conclusion: 6MMP:6TGN ratios increase during dose escalation in shunters only. Patients with a 6MMP:6TGN ratio 12 or above after 6 weeks should be considered for optimisation with allopurinol rather than waiting until 12 weeks of therapy. Weight-based dosing of thiopurines should no longer be used in standard practice.

Introduction: Biosimilar infliximab CT-P13 received EMA approval in June 2013 for all indications of the originator product. We aimed to prospectively evaluate the immunogenicity of the biosimilar infliximab in IBD in a nationwide, multicentre cohort.
Aims & Methods: Demographic data were collected and a harmonized monitoring strategy was applied. Clinical and biochemical activity were evaluated at week 14. Trough level (TL) and anti-drug antibody (ADA) concentration were measured by ELISA (LT-005, Theradiag, France) at baseline and before each anti-TNF administration during the induction treatment.
Results: 141 consecutive IBD patients (90 CD patients and 51 UC patients) were included in the present cohort. 29% (26 and 3%) of CD patients and 22% (16 and 6%) of UC patients had received previous anti-TNF (infliximab and adalimumab) therapy. None of the patients had received infliximab within 12 months prior to initiation of the biosimilar infliximab. 62/61% of CD/UC patients received concomitant immunosuppressives at baseline. Mean TLs were 0, 19.2, 9.1. and 3.4μg/ml at weeks 0, 2, 6 and 14. There was a tendency towards lower TLs at week 2 and 6, but not at week 14 in patients with previous infliximab exposure compared to infliximab naive patients. This was coupled with higher ADA positivity. There was no significant difference in the remission and response rates between patients with or without previous anti-TNF exposure. 6 patients had allergic reactions during induction treatment, of which 4 patients had received previous infliximab treatment.
Conclusion: Patients with previous exposure to the originator infliximab had a tendency towards lower early TL coupled with ADA positivity. Although there were no significant difference in efficacy, patients with previous infliximab exposure were more likely to develop allergic reactions.

Introduction: Patient reported outcome (PRO) components of the Crohn's disease (CD) Activity Index (CDAI) are being explored as clinical remission (CR) endpoints,[1] as are composite measures of endoscopic remission (ER) plus CR as outcome measures in CD trials.
Aims & Methods: To explore the use of different definitions of CR, based on CDAI stool frequency (SF) and abdominal pain (AP) components, and composite endpoints on efficacy estimations in the mucosal healing study EXTEND.[2] Three CR definitions were explored in patients (pts) from EXTEND: 1) CDAI $<$150, 2) sum of 7 day weighted SF/AP PRO components of CDAI $<$69 (PRO2 $<$69), and 3) average (avg) daily SF $\leq$1.5 and avg daily AP score $\leq$1.0, both not worse than baseline (BL) (SF $\leq$1.5 and AP $\leq$1.0). Pooled data from 4 CD adalimumab (ADA) trials were used to identify the threshold for PRO2 which correlated best with CDAI $<$150 in pts with elevated BL avg daily SF $\geq$2.5 or AP score $\geq$2.0, and the combined SF/AP definition was based on a recent report.[1] In EXTEND, adults with moderate to severe CD received induction ADA 160/80 mg at weeks (wks) 0/2. At wk 4, pts were randomized to ADA 40 mg every other wk or placebo (PBO) to wk 52. Pts (N = 104) with BL avg daily SF $\geq$2.5 or AP score $\geq$2.0 and Simple Endoscopic Score for CD (SES-CD) $\geq$6 (or $\geq$4 for pts with isolated ileal disease) by central read were analyzed at wks 12 and 52. Endpoints assessed were the 3 CR definitions, ER (SES-CD $\leq$4 and at least 2 point reduction from BL, by central read), and composite ER and CR for each remission definition.
Results: ER was achieved by 37.3% and 15.1% of ADA- and PBO-treated pts, respectively, at wk 12 (Δ22.2%, $p=0.01$); wk 52 values were 27.5% and 1.9% (Δ25.6%, $p<0.001$), respectively. Compared with ER, composite endpoints generally showed diminished effect sizes for ADA vs PBO at wks 12 and 52 (Table). Overall, composite endpoint effect sizes were similar to or slightly less than CR effect sizes. At wk 52, the SF/AP definition was associated with the lowest rates of remission in both PBO and ADA groups, and the lowest effect size of all CR definitions.
Table. Effect size for various definitions of remission (NRI)
Conclusion: Use of a composite endpoint (endoscopic plus symptomatic remission) led to diminished effect sizes compared to the endoscopic definition alone. Use of new endpoints should consider the ability of the endpoint to distinguish drug effect from PBO.

P0353 THE LONG-TERM EFFECT OF ANTI-TNF ALPHA THERAPY ON SERUM LIPID PROFILE AND ATHEROGENIC INDEX IN PATIENTS WITH INFLAMMATORY BOWEL DISEASES

C. Kalkan[1], F. Karakaya[1], E. A. Kalkan[1], A. E. Tüzün[1], Z. B. Gençtürk[2], M. Törüner[1], H. Çetinkaya[1], I. Soykan[1]
[1]*Gastroenterology,* [2]*Biostatistics, Ankara University, Ankara, Turkey*

Contact E-mail Address: isoykan@medicine.ankara.edu.tr

Introduction: Cardiovascular morbidity appears to be increased in inflammatory bowel diseases (IBD). Tumor necrosis factor (TNF) is a pivotal proinflammatory cytokine in inflammatory diseases and causes deterioration of the lipid profile in inflammatory conditions. It is postulated that in patients with IBD, proinflammatory cytokine TNFα can alter lipid profile causing dyslipidemia that promotes atherogenesis. However, previous reports investigating the effect of anti-TNFα blockers on lipid profile in IBD patients showed conflicting results.

Aims & Methods: Therefore, the aim of this study was to identify long-term effect of anti-TNFα therapy on lipid profile and atherogenic index (AI) in patients with IBD followed-up to 36 months (mos). A total of 56 patients diagnosed as having IBD [44 Crohn's disease (CD) and 12 colitis ulcerosa (CU)] and treated with anti-TNFα agents (33 received adalilumab, 23 received remicade) were evaluated by means of serum lipid profile and serum total cholesterol, triglyceride, LDL-c and HDL-c were measured within 1 month before the first dose of anti-TNFα agent and then after six-month periods. AI was also calculated by dividing total cholesterol to HDL-c before biologic agent and then every six-month periods. Patients followed-up less then 12 mos, with diabetes, receiving antilipidemic agents were not included into the study.

Results: The median follow-up period was 26.1 months. With anti-TNFα treatment, serum cholesterol level was found to be increased compared to baseline (163.1 vs 179 mg/dL, p = 0.01), triglyceride level increased at 24th mos compared to baseline (118 vs 152.1 mg/dL, p < 0.001), LDL level increased at 36th mos compared to baseline (92 vs 110.71 mg/dL, p = 0.022), and HDL level did not show any significant change during follow-up period. As for AI, AI significantly increased at 36th mos compared to baseline (3.84 vs 4.09, p < 0.001). There were no significant differences by means of lipid profile and AI between patients with CD vs UC and patients receiving adalilumab vs remicade.

Conclusion: Significant changes were observed in cholesterol and LDL levels of patients with IBD on anti-TNFα after 36 mos of treatment. A significant increase in AI was also observed in this study. Therefore, anti-TNFα treatment might affect lipid profile and AI which may contribute to cardiovascular morbidity. AI can contribute significantly in the prediction of coronary artery disease risk especially when lipid profile is not markedly deranged.

P0354 VALPROIC ACID REGULATES MUCOSAL CYTOKINE PRODUCTION, APOPTOSIS PATHWAYS AND HISTONE ACETYLATION IN PATIENTS WITH INFLAMMATORY BOWEL DISEASES

C. Felice[1,2], A. Lewis[1], R. Jeffery[1], T. Kumagai[1], A. Nijhuis[1], H. Thompson[1], A. Armuzzi[2], J. O. Lindsay[1], A. Silver[1]

Contact E-mail Address: c.felice@qmul.ac.uk

Introduction: Novel therapeutic strategies are required for inflammatory bowel diseases (IBD), as significant numbers of patients do not respond to current treatments. Oral administration of valproic acid (VPA) has been shown to reduce acute and chronic intestinal inflammation in animal models of colitis.[1] VPA inhibits histone deacetylase (HDAC) enzymes[2] involved in the epigenetic regulation of apoptosis, cell differentiation and cytokine production. No data are available about the effect of VPA on human intestinal inflammation.

Aims & Methods: The aim of this study was to determine whether VPA induces histone hyperacetylation, influences mucosal cytokine production and impacts on apoptosis pathways in patients with IBD. Intestinal biopsies from IBD patients undergoing routine colonoscopy at the Royal London Hospital were collected and cultured with VPA (0.05 mM, 0.5 mM and 5 mM) or control media for 24 hours. Total RNA was extracted and the mRNA levels of cytokines and markers of apoptosis assessed by qPCR. The cytokine protein levels in culture supernatant were quantified using Luminex assays (IFNγ, IL-1b, IL-23, IL-6, TNFα and IL-10) and ELISA (IL-6). To confirm the proposed mechanism of action, the effect of VPA on histone-3-acetylation levels was assessed using immunofluorescence microscopy. SPSS version 22 was used for statistical analysis.

Results: Intestinal biopsies from 17 IBD patients (7 Crohn's disease, 10 ulcerative colitis) were collected and cultured with or without VPA. Relative to control, culturing with the highest concentration of VPA (5 mM) was associated to a significant reduction in IL-6, IL-22 and IL-10 mRNA expression (p = 0.001, p = 0.01 and p = 0.001, respectively, Wilcoxon test). VPA did not affect TNFα and IFNγ mRNA expression. Culture with VPA 5mM reduced IL-6, TNFα and IL-10 protein levels in biopsy culture supernatants (p = 0.005, p = 0.002 and p = 0.002, respectively, Wilcoxon test). No differences were found in the level of IFNγ, IL-1b and IL-23 protein. IL-6 concentration in the culture supernatant was confirmed to be significantly reduced by VPA 5 mM using ELISA (p = 0.02, Wilcoxon test). The reduction in cytokine expression was associated with a significant reduction in Bcl-3 mRNA expression (p = 0.008) and an increase in Caspase-9 gene expression (p = 0.001, Wilcoxon test), demonstrating a stimulation of pro-apoptotic pathways. The percentage of H3-acetylated positive cells was significantly higher in biopsies treated with VPA 5 mM compared with untreated (n = 4; p = 0.002, t test).

Conclusion: VPA, a broad-acting HDAC inhibitor, regulates cytokine production, increases the activity of pro-apoptotic pathways and induces histone-3 hyperacetylation in intestinal mucosa of IBD patients. These results encourage further investigation of the therapeutic role of HDAC inhibition in patients with IBD.

P0355 FISTULIZING PERIANAL CROHN'S DISEASE TREATMENT WITH INFLIXIMAB ALONE OR COMBINED WITH SURGERY - RESULTS OF ONE YEAR FOLLOW-UP

C. Bernardes[1], D. Carvalho[1], P. Russo[1], J. Saiote[1], J. Ramos[1]
[1]*Hospital de Sto António dos Capuchos, Lisbon, Portugal, Lisbon, Portugal*

Contact E-mail Address: carlosfbernardes@gmail.com
Introduction: Infliximab (IFX) is effective in the treatment of Fistulizing Perianal Crohn's Disease (FPCD); however, data regarding its long-term efficacy is still limited. Combined biological and surgical treatment may offer some advantages in selected patients.
Aims & Methods: The aim of this study was to assess IFX's efficacy, alone or combined with surgery, in patients with FPCD. We conducted an analysis of prospective and systematic clinical registries of patients in whom FPCD was the indication for IFX therapy, either alone or following surgery. Examination under anesthesia was executed prior to the initiation of treatment. Clinical registries were performed at weeks (wk) 0, 2, 6, 14, 30 and 54 of IFX therapy and included evaluation of Perianal Disease Activity Index (PDAI) and Fistula Drainage Assessment (FDA). Partial response (PR) was defined as at least 50% reduction in the PDAI value and at least 50% reduction in the number of draining fistulas or at least 50% healing of the perianal post-surgical wound in those who underwent surgery. Complete response (CR) was defined as a PDAI score ≤ 4 and closure of all draining fistulas or complete healing of the perianal post-surgical wound. Loss of response (LR) was defined by any increase in PDAI, by the recrudescence of draining fistulas, by the occurrence of any other perianal complication or the need for additional therapy.
Results: Thirty-six patients (19 males; average age 34 ± 14 years, range 16-75 years) with FPCD initiated IFX therapy. Seventeen (47%) patients underwent previous surgical procedure: abscess drainage (n = 9), abscess drainage and fistulotomy (n = 6) or fistulotomy/fistulectomy (n = 2); seton placement was performed in 7. At baseline (wk0), median PDAI value was 12. At wk14, 83% of patients achieved response (PR 30%, CR 53%), with an average decrease of 8.3 in PDAI score from baseline. At wk54 response was 75% (PR 19%, CR 56%); LR occurred in 7 patients (19%), all of them maintaining lower PDAI score than at baseline (average decrease of 5.6 from wk0). Biological therapy was suspended in 2 patients because of serious adverse reaction; there were no cases of perianal abscess development during follow-up.
Conclusion: Therapy with IFX, combined with surgery when appropriated, achieved early clinical response and healing in FPCD, maintaining response in 75% (partial response 19%, complete response in 56%) of patients at the 52nd week.

Introduction: The impact of anti-TNF exposure on the outcomes of adalimumab (ADA) therapy in ulcerative colitis (UC) patients is not well known. The aim of this study was to compare the long-term outcomes of ADA in UC patients according to previous anti-TNF use.
Aims & Methods: This was a retrospective multicentre cohort study evaluating UC patients who were primary responders to ADA induction therapy and who advanced to a maintenance regimen. We compared the outcomes of the cohorts of anti-TNF-naïve patients versus anti-TNF-experienced patients. The primary endpoints were the cumulative probabilities of ADA failure-free survival and colectomy-free survival. ADA failure was defined as withdrawal of the drug due to intolerance or complete loss of response. We also assessed the need for ADA dose escalation during follow up. Predictors of event-free survival were estimated using Cox proportional hazard regression analysis.
Results: Of the 184 UC primary ADA responders included, 116 (63%) had previous anti-TNF use. During a median follow-up of 16 months (interquartile range [IQR] 7-39), 69 patients (37%) had ADA failure. Anti-TNF-naïve patients had a significantly lower adjusted rate of ADA failure compared to anti-TNF-experienced patients (hazard ratio [HR] 0.65; 95% CI: 0.52-0.80; $p < 0.001$). After a median follow-up of 21 months (IQR 12-47), 22 patients (12%) needed colectomy. Median time to colectomy was 10 months (IQR 4-18). Anti-TNF-naïve patients had a significant 74% reduction in the need for colectomy (HR 0.26; 95% CI: 0.10-0.65; p = 0.004). Seventy-six patients (41%) required escalation to weekly ADA dosing. The median time to escalation was 4 months (IQR 2-9). Anti-TNF-naïve patients had a significantly lower adjusted rate of the need for escalation (HR 0.38; 95% CI: 0.21-0.69; p = 0.002). Patients who needed escalation had a significantly higher adjusted rate of ADA failure (HR 1.78; 95% CI: 1.08-2.94; p = 0.02) and need for colectomy (HR 3.13; 95% CI: 1.22-8.03; p = 0.02).
Conclusion: In this real–life cohort of primary ADA responders with UC, 63% of patients maintained sustained clinical benefit and 88% of patients avoided colectomy. Anti-TNF-naïve patients had better outcomes in the long-term, with a significant reduction in the rates of ADA dose escalation, ADA failure and colectomy.

P0357 LONG-TERM TREATMENT WITH FERRIC MALTOL IS EFFECTIVE AND WELL TOLERATED IN CORRECTING IRON DEFICIENCY ANEMIA IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE: RESULTS FROM A PHASE-3 OPEN-LABEL STUDY

C. Schmidt[1], T. Ahmad[2], Z. Tulassay[3], D. C. Baumgart[4], B. Bokemeyer[5], S. Howaldt[6], A. Stallmach[1], C. Büning[7], on behalf of AEGIS Study Group

Introduction: Iron deficiency anemia (IDA) is frequently seen in inflammatory bowel disease (IBD). Oral iron supplementation with ferrous products (OFP) is linked to possible gastrointestinal side effects and disease exacerbation in some IBD-patients. Recently, ferric maltol provided rapid and clinically meaningful improvement in Hb and showed a favorable safety profile during a pivotal 12 week study [1]. The following multicenter phase-3 open-label extension study evaluated the long-term efficacy and safety of ferric maltol.
Aims & Methods: Initially, adult patients with quiescent or mild-to-moderate ulcerative colitis or Crohn's disease, mild-to-moderate IDA, and failure on previous OFP received oral ferric maltol capsules (30 mg twice a day) or placebo for 12 weeks. Following the randomised, double-blind phase of the study, patients were eligible to receive open-label ferric maltol for up to an additional 52 weeks.
Results: In total, 111 subjects received ferric maltol for up to 64 weeks. Hb continued to rise in those previously treated with ferric maltol (mean from baseline 3.07 (SD 1.46) g/dL at week 64, n = 36). Increases were also observed in former placebo-treated subjects (mean 1.87 (SD 1.20) g/dL by week 24 (12 weeks of treatment; n = 53), and 2.19 (SD 1.61) g/dL by week 64 (52 weeks of treatment; n = 36). The proportion of subjects with normal Hb concentration continued to rise for those treated with ferric maltol initially (week 12: 71%, week 64: 86.1%;) and for those switching to ferric maltol (week 12: 15.1% and 83.3% at week 64). Ferritin rose from 8.4 ug/L at baseline (n = 128) to 24.9 ug/L at 12 weeks (n = 112) and 68.9 ug/L at 64 weeks (n = 36). In total, 80% of subjects reported at least one AE, however, only 24% of subjects reported an AE considered to be treatment related. 18 subjects (16%) discontinued due to adverse events, but only 8 (7%) of these were evaluated as treatment related AEs. The most common AEs were abdominal pain (16%), diarrhoea (14%), nasopharyngitis (18%), flatulence (8%), and arthralgia (8%). No worsening of IBD scores (SCCAI, CDAI) was observed during the entire study.
Conclusion: Long-term treatment with ferric maltol resulted in a continuous rise of mean Hb, with Hb normalisation in more than 80% of patients. Ferritin levels increased when treatment was continued past 12 weeks. The adverse event profile in the open label phase confirmed the benign safety profile of oral ferric maltol and the feasibility of long-term treatment.

Introduction: Haemopoietic stem cell transplantation (HSCT) leads to complete regression of endoscopic signs of Crohn's disease in about one third of patients, implying an alteration in the natural history of Crohn's disease. We investigated whether these substantial changes were also seen histologically.

Aims & Methods: Patients with impaired quality-of-life from active Crohn's disease not amenable to surgery despite treatment with at least 3 immunosuppressive agents all underwent stem cell mobilisation before randomisation to immuno-ablation followed by unselected cyclophosphamide-based conditioning and HSCT after one month (Early HSCT) or one-year (Delayed HSCT). They underwent full ileocolonoscopy at baseline and after one and two years. Endoscopic involvement and activity were assessed using the Simple Endoscopic Score of Crohn's disease (SES CD) in which a value of zero means no evidence of active or inactive Crohn's disease in any examined segment of the ileum or colon. In 17 patients segments were biopsied systematically for blinded histological assessment, using ECCO-approved scales for intensity and diffuseness of acute and chronic inflammation, granulomas, ulceration, distortion and metaplasia.
Results: There was a strong correlation between endoscopic findings and histology (Table).

% Normal Histology	Endoscopy: Normal	Involved	p
Ileum	78%	25%	0.001
Right Colon	90%	36%	<0.0001
Transverse Colon	83%	38%	0.003
Left Colon	93%	24%	<0.0001
Rectum	73%	27%	0.001

The % of colonic biopsy samples that were histologically normal rose from 39% (baseline) to 50% at 1 year and 78% at 2 years after Early HSCT ($p = 0.039$). In patients undergoing Delayed HSCT values were 52% (baseline), 50% 1 year after mobilisation only and 75% after a further year following delayed HSCT ($p = 0.329$). Improvements were mainly due to reduction or regression of acute and chronic inflammatory changes.
Conclusion: Blinded histological assessments fortify the evidence that HSCT can have a profound objective benefit in Crohn's disease.

Introduction: Azathioprine (AZA) and thiopurine are widely used for induction and maintenance of remission in patients steroid-dependent with inflammatory bowel disease (IBD). The treatment must be withdrawn in 5-30% of patients due to the occurrence of adverse events.
Aims & Methods: Aim of this study has been to investigate its efficacy and safety in maintaining steroid-free remission in steroid dependent IBD patients four year after the institution of treatment. Data from consecutive IBD outpatients referred in our Institution, between 1985-2013, were reviewed and all patients treated with AZA were included in this retrospective study. AZA was administered at the recommended dose of 2–2.5 mg/kg. Blood chemistry was analysed before administration of the drug, every 10-15 days for the first 3 months and then every 1-2 months following the institution of treatment.
Results: Out of 2556 consecutive IBD outpatients visited in the index period, AZA was prescribed to 376 patients, 198 (52.7%) were affected by Crohn's disease (CD) and 178 (47.3%) by ulcerative colitis (UC). One hundred and four patients with a follow-up <48 months were excluded from the study. Two hundred and seventy-two patients were evaluated, 146 (53.7%) with CD and 126 (46.3%) with UC. One hundred and forty-nine (54.8%) were male and 123 (45.2%) female (average age of 33.56 ± 14.34 SD years, range 14-74 y.). Four year after the institution of treatment, 149 (54.8%) patients still were in steroid-free remission (89 CD vs 60 UC, 61% and 47.6%, respectively, $p = 0.0288$), 71 (26.1%) had a relapse requiring retreatment with steroids (42 UC vs 29 CD, 33.4% and 19.8%, respectively, $p = 0.0130$), 52 (19.1%) discontinued the treatment due to side effects (28 CD vs 24 UC, 19.2% and 19%, respectively). Loss of response from 1st to 4th year of follow-up was low, about 17%.
Conclusion: Four years after the onset of treatment 55% of patients did not require further steroid courses. After the first year loss of response was low in three subsequent years. In the present series the maintenance of steroid-free remission was significantly higher in CD than in UC patients. The occurrence of side effects leading to the withdrawal of AZA treatment has been low.

Contact E-mail Address: clifford.kiat@gmail.com
Introduction: It has been well established that patients with inflammatory bowel disease (IBD), both ulcerative colitis (UC) and Crohn's disease (CD), are at increased risk of osteoporosis. Prior studies have shown that both Adalimumab and Infliximab have beneficial effects on bone metabolism in patients with CD in the short term. However, no data is available on the longer term effect of maintenance anti-TNF on bone mineral density (BMD) in patients with IBD
Aims & Methods: We aim to evaluate the medium to long-term impact of maintenance anti-TNF therapy on BMD in patients with IBD. The study was a retrospective observational cohort study of patients with IBD who were commenced on anti-TNF therapy (either Infliximab or Adalimumab). All patients underwent BMD measurement (DEXA scan) prior to commencement of anti-TNF therapy. BMD was then measured at variable intervals following commencement of therapy, with a minimum of one year prior to repeat BMD. A detailed chart review of patients' demographics, disease phenotypes and concomitant treatments was performed. This review is on- going and to date data for 30 patients has been analysed. A paired t-test was performed to evaluate the changes in BMD in patients on Adalimumab or Infliximab.
Results: To date, data for 30 patients has been analysed. There were 18 female patients and the mean age for the cohort was 45 years (SD +/- 12.8). 28 patients have CD and 2 have UC. 16 patients were on maintenance Infliximab and 12 on Adalimumab. Mean T score prior to commencement of biologic therapy was -1.68 (SD +/- 1.10). The mean T-score at follow up DEXA was -1.41 (SD +/- 1.15). The mean interval between BMD measurements was 2.9 years (SD +/- 1.5). There was a significant improvement in T score between initial and follow up BMD, $P = 0.039$ (CI:-0.531,-0.014)
Conclusion: In this study, we show a significant improvement in T scores of IBD patients following commencement of maintenance anti-TNF therapy.

Introduction: To report the results of an interferon-γ release assay (IGRA) versus standard tuberculin skin test (TST) as a screening tool for latent TB infection in patients with ulcerative colitis (UC) in PURSUIT.
Aims & Methods: UC patients with moderately to severely active UC were screened for latent TB using the standard TST and the IGRA to assess eligibility for entry into the induction studies of golimumab (PURSUIT-SC [C0524T17]and PURSUIT-IV [C0524T1]Any patient with a newly identified positive finding for TB on a diagnostic test in whom there was no evidence of active TB was permitted to enter provided appropriate treatment for latent TB was initiated before or at the time of the first dose of study agent. TST was performed according to the Mantoux method, using 5 tuberculin units (TU) of purified protein derivative (PPD) standard or 2 TU of PPD RT-23. The TST was deemed positive for latent TB infection according to the local country guidelines for defining an immunosuppressed host or, in the absence of local guidelines, according to the presence of induration $\geq$5mm. The IGRA used to screen for latent TB was the QuantiFERON-TB Gold In-Tube test. Overall IGRA and TST results were assessed. The impact of prior BCG vaccination and concomitant medication (ie corticosteroids and/or immunomodulators) on outcome was also assessed.
Results: In this analysis, 1283 patients had both IGRA and TST screening prior to GLM treatment. Among these patients, 8.7% had at least one test yielding positive findings for latent TB, including 6.2% with positive results only by TST, 3.7% with positive results only by IGRA, and 1.2% with positive results on both tests. The rate of indeterminate results for TB on IGRA was 7.7%. Agreement between the TST and IGRA results, measured by the kappa coefficient, was 0.135 (95% confidence interval [95% CI] 0.050-0.220; $p = 0.028$). Among patients with positive IGRA findings, 31.3% had positive TST results. Among patients with positive TST findings, 19.0% had positive IGRA results. Overall, 501 (40.5%) of 1283 patients had previously received BCG vaccine; among this vaccinated group, the rate of positivity for latent TB by TST was 10.4% vs 5.0% for IGRA positivity. Among patients who had not received BCG vaccine, the rate of positivity by TST was 1.9% vs 2.8% for IGRA positivity. When IGRA was repeated in patients whose results were initially indeterminant, the majority of patients (67.0%) were IGRA negative on repeat whereas the number of patients whose results were positive was 5.3%; IGRA remained indeterminate for 27.7%. Overall, 2.1% tested indeterminate on first and repeat screening. Concomitant corticosteroid and/or immunomodulator use did not appear to have an impact on results.
Conclusion: Results of this comparison of IGRA and TST in a large cohort of patients with UC suggest that the IGRA provides greater specificity and possibly greater sensitivity than the TST in patients with moderate to severe UC.

P0362 THE EXPENSES OF ACADEMIC INPATIENT CARE OF INFLAMMATORY BOWEL DISEASE PATIENTS ARE ALMOST DOUBLE COMPARED WITH AVERAGE ACADEMIC GASTROENTEROLOGY AND HEPATOLOGY CASES AND NOT FULLY RECOVERED BY DIAGNOSIS-RELATED GROUP (DRG) PROCEEDS

D. C. Baumgart[1], M. le Claire[2]
[1]*Department of Medicine, Division of Gastroenterology and Hepatology,* [2]*Enterprise Controlling, Charité Medical Center - Medical School of the Humboldt-University of Berlin, Berlin, Germany*

Contact E-mail Address: daniel.baumgart@charite.de
Introduction: Crohn's disease (CD) and ulcerative colitis (UC) challenge economies worldwide. Detailed diagnosis-related group (DRG) data of academic inpatient care for inflammatory bowel disease (IBD) patients in Europe is unavailable.
Aims & Methods: IBD was identified through ICD-10 K50 and K51 code groups. We took an actual costing approach, compared expenditures to G-DRG and non-DRG proceeds and performed detailed cost center and type accounting to identify coverage determinants.
Results: Of all 3093 hospitalized cases at our department 164 were CD and 157 UC inpatients in 2012. On average, they were 44.1 (CD 44.9 UC 43.3 all 58) years old, stayed 10.1 (CD 11.8 UC 8.4 vs. all 8) days, carried 5.8 (CD 6.4 UC 5.2 vs. all 6.8) secondary diagnoses, received 7.4 (CD 7.7 UC 7 vs. all 6.2) procedures, had a higher cost weight (CD 2.8 UC 2.4 vs. all 1.6) and required more intense nursing. Their care was more costly (means: total cost IBD 8477€CD 9051€UC 7903€vs. all 5078€). However, expenditures were not fully recovered by DRG proceeds (means: IBD 7413€, CD 8441€, UC 6384€vs all 4758€). Here, we discovered substantial disease-specific mismatches in cost centers and types and identified the medical ward personnel and materials budgets to be most imbalanced. Non-DRG proceeds were almost double (IBD 16.1% vs. all 8.2%), but did not balance deficits at total coverage analysis, that found medications (antimicrobials, biologics and blood products), medical materials (mostly endoscopy items) and in CD also non-medical intrastructure costs to contribute most to the deficit.
Conclusion: DRGs threaten sophisticated, academic care for the neediest of all IBD patients.
Disclosure of Interest: None declared

P0363 LONG-TERM OUTCOMES OF ULCERATIVE COLITIS PATIENTS ON MONOTHERAPY MAINTENANCE TREATMENT WITH THIOPURINES: PRELIMINARY DATA

Contact E-mail Address: danipug@libero.it
Introduction: Thiopurines have been used for the treatment of inflammatory bowel disease from several years. However there are few evidence-based data to support their efficacy in ulcerative colitis (UC).
Aims & Methods: The aim of our study was to assess the long-term outcome of UC patients receiving thiopurines monotherapy and to identify possible predictors of efficacy in a large cohort of patients.We retrospectively collected data on all UC patients who started monotherapy thiopurines at three tertiary IBD centers from February 1995 to April 2015. Associations between clinical and epidemiological characteristics and treatment efficacy were analyzed with survival regression models clustered for IBD center and adjusted for age, sex and calendar period and expressed as hazard ratios (HRs) and 95% confidence intervals (CIs). Models incorporated treatment failure, intolerance and adverse events as competing risks. Treatment efficacy was defined as either sustained clinical remission on thiopurines treatment or withdrawal of thiopurines for remission.
Results: A total of 234 UC patients started thiopurines during the interval. The mean (SD) age at diagnosis was 39 (15) years and the median duration of disease was 4 years (range 0-32 years). One-hundred and forty-four patients (62%) had pancolitis and 90 (38%) extensive colitis. One-hundred and thirty-two patients (61%) had endoscopic moderate activity and 85 (39%) severe colitis. The main indication for treatment was steroid-dependence for 137 patients (59%). Azathioprine was prescribed to 90% of patients and mercaptopurine to 10%. Participants contributed a total of 760 person-years of follow-up (median follow-up 28 months, range 0.2-207 months). Eighty-eight of 234 patients (38%) maintained clinical remission and were still on thiopurines therapy and 37 of 234 (16%) withdrew thipurines because of sustained remission without clinical relapse. Thiopurines were discontinued in 71 patients (30%) for failure and 35 of these patients (49%) started biologics. Twenty-seven patients (12%) experienced intolerance, in particular: medullary aplasia (n = 10, 37%), hepatitis (n = 6, 22%), pancreatitis (n = 5, 19%), arthromyalgia (n = 1, 37%) and other (n = 5, 19%). Eleven patients (5%) stopped thiopurines for other reasons. Duration of disease (HR 1.02, 95% CI 0.97, 1.07), disease extension (HR for pancolitis vs extensive colitis 1.01, 95% CI 0.55, 1.85), endoscopic activity at baseline (HR for severe vs moderate colitis 0.83, 95% CI 0.59, 1.18), smoking status (HR for smoking vs non smoking 1.18, 95% CI 0.79, 1.76) and indication for treatment (HR for 5-amynosalicilates refractoriness vs steroid-dependence 1.12, 95% CI 0.72, 1.75 and HR for severe acute attack vs steroid-dependence 1.44, 95% CI 0.98, 2.10) were not significantly associated with treatment effectiveness.
Conclusion: Thiopurines monotherapy was effective in large proportion of UC patients. We could not identify any independent predictors of treatment efficacy in our sample.

P0364 HEALTH-RELATED QUALITY OF LIFE VARIES AS A FUNCTION OF REMISSION STATUS IN PATIENTS WITH MILD-TO-MODERATE ULCERATIVE COLITIS RECEIVING SHORT-TERM AND LONG-TERM DAILY THERAPY WITH MULTIMATRIX MESALAZINE

A. Yarlas[1], G. D'Haens[2], **D. Willshire**[3], M. Teynor[4]
[1]*Optum, Lincoln, RI, United States,* [2]*Academic Medical Center, Amsterdam, Netherlands,* [3]*Shire, North Ryde, Australia,* [4]*Shire, Lexington, MA, United States*

Contact E-mail Address: mteynor@shire.com
Introduction: Studies have shown an inverse relationship between disease activity and health-related quality of life (HRQL) for patients (pts) with ulcerative colitis (UC), such that decreases in disease activity predict better HRQL. Consistent with this are findings that pts with UC in complete (clinical and endoscopic) remission (CR) exhibit better HRQL than pts not in remission (NR). What has not been established is whether HRQL for UC pts in partial remission (PR) is more similar to pts in CR or NR.
Aims & Methods: Data were from a multinational, open-label, prospective trial of multimatrix mesalazine (NCT01124149). During induction treatment, pts with active mild-to-moderate UC received 4.8 g multimatrix mesalazine once daily (QD) for up to 8 weeks. Pts in CR or PR at Week 8 were eligible to receive 12 months of maintenance treatment with 2.4 g multimatrix mesalazine QD. Remission status at Week 8 or early withdrawal (EW) visit during the induction phase (induction endpoint) and at Month 12 or EW visit of the maintenance phase (maintenance endpoint) was determined using a modified UC-Disease Activity Index (UC-DAI). CR was defined as UC-DAI $\leq$1 with scores of 0 for both rectal bleeding (RB) and stool frequency (SF) components and $\geq$1-point reduction from baseline for the endoscopy component. PR was defined as UC-DAI $\leq$3, RB + SF $\leq$1, and not in complete remission. All EW pts were classified as NR. Pts completed measures of generic HRQL (12-item Short-Form survey [SF-12v2]) and disease-specific HRQL (Shortened Inflammatory Bowel Disease Questionnaire [SIBDQ]) at baseline and at the end of induction and maintenance treatment. Analysis of variance models tested if HRQL scores at both endpoints differed as a function of pts' remission status. Repeated-measures mixed-effects models (RMMM) tested if changes in HRQL over time varied by maintenance endpoint remission status. All tests used Bonferroni-adjusted P values to control for multiplicity.
Results: The numbers of pts in CR, PR, and NR (including EW pts) were, respectively, 186 (26.6%), 282 (40.3%) and 231 (33.0%) at Week 8, and 159 (39.7%), 103 (25.7%) and 139 (34.7%) at the end of maintenance (Month 12). At both time points, pts in CR and PR scored significantly better on all 8 SF-12v2 and all 4 SIBDQ domains than NR pts (all $P < 0.0001$). Including EW pts in all analyses, there were no statistical differences between scores of CR and PR pts on 7 of 8 SF-12v2 domains (all but bodily pain, $P = 0.013$) or any SIBDQ domains at Week 8, while at Month 12, there were no statistical differences between CR and PR pts on any SF-12v2 or SIBDQ domains (all $P \geq 0.251$). Estimated parameters and means from RMMM indicated that pts in CR or PR showed similarly larger improvements and better maintenance of HRQL over time than did NR pts.
Conclusion: HRQL was similar for pts whose UC was in CR or PR following both short-term and long-term daily treatment with mesalazine. Furthermore, at both endpoints, CR and PR pts exhibited better HRQL than NR pts. These results indicate that improvement and maintenance of HRQL for pts with UC in PR was comparable with those in CR.

Introduction: Studies have shown that increased disease activity for patients with ulcerative colitis (UC) predicts impairment in work-related outcomes (WRO),

such as decreased productivity and increased absenteeism. In addition, patients whose UC is in complete (clinical and endoscopic) remission (CR) demonstrate less impairment in WRO than patients whose UC is not in remission (NR). The objective of the current study was to examine WRO of UC patients in partial remission (PR) relative to WRO of patients in CR or NR.

Aims & Methods: Data were from a multinational, open-label, prospective trial of multimatrix mesalazine (NCT01124149). In the induction phase, patients with active mild-to-moderate UC received 4.8 g of multimatrix mesalazine once daily (QD) for 8 weeks. Patients in CR or PR after induction were enrolled in the maintenance phase, during which they received 2.4 g of multimatrix mesalazine QD for 12 months. Remission status at induction endpoint (Week 8 or early withdrawal [EW] visit) and at maintenance endpoint (Month 12 or EW visit) was determined by a patient's score on a modified UC-Disease Activity Index (UC-DAI). CR was defined as UC-DAI $\leq$1 with scores of 0 for both rectal bleeding (RB) and stool frequency (SF) components, and $\geq$1-point reduction from baseline for the endoscopy component. PR was defined as UC-DAI $\leq$3, RB + SF $\leq$1, and not in complete remission. Patients who did not complete the full course of treatment were classified as NR.

A UC-specific version of the Work Productivity and Activity Impairment (WPAI:UC) questionnaire measured the impact of UC on 4 WRO domains – absenteeism, presenteeism, overall work impairment (OWI), and activity impairment – at baseline, Week 8, and Month 12 (including EW patients at all time points). Analysis of variance models compared WPAI:UC scores at these time points among CR, PR, and NR patient groups. Changes in OWI scores over time as a function of remission status was examined using a repeated-measures mixed-effects model (RMMM). All tests used Bonferroni-adjusted *P* values to control for multiplicity.

Results: The numbers of patients in CR, PR, and NR (including EW patients) were, respectively, 186 (26.6%), 282 (40.3%) and 231 (33.0%) at Week 8, and 159 (39.7%), 103 (25.7%) and 139 (34.7%) at Month 12. Patients in CR and PR had significantly lower (better) scores on all WPAI:UC domains than did NR patients at both time points ($P < 0.05$ and $P < 0.001$, respectively). Further, at both induction and maintenance endpoints, WPAI:UC domain scores did not statistically differ between CR and PR patients (all $P \geq 0.415$). Estimated parameters and means from the RMMM indicated that patients in CR or PR showed similarly larger improvements and better maintenance of improvements in OWI over time than did NR patients.

Conclusion: Patients whose UC was in CR or PR following both short-term and long-term daily treatment with multimatrix mesalazine exhibited better WRO than NR patients. Furthermore, WRO was equivalent for patients in CR and PR groups, indicating that improvement and maintenance of WRO for patients who achieved PR was just as good as for those in CR.

P0366 MILD TO MODERATELY ACTIVE ULCERATIVE PROCTITIS: ORAL MESALAZINE MMX PLUS RECTAL MESALAZINE VS RECTAL MESALAZINE ALONE

D. Sgambato[1], M. V. D'Auria[2], A. Miranda[1], C. Cardone[3], G. Vicinanza[2], D. F. Sergio[2], V. Gallo[2], **M. Romano**[1], A. Cuomo[2]

Introduction: Mesalazine (MSZ) 1 g suppository once daily is the preferred initial therapy for the treatment of mild to moderately active ulcerative proctitis (UP). Whether the use of oral mesalazine MMX (MMX) together with rectal MSZ improves the clinical outcome of UP is not known.

Aims & Methods: The aim is to evaluate the efficacy of combination therapy with MSZ suppository plus MMX vs rectal MSZ alone in inducing remission of UP. Secondary endpoint was to assess whether combined therapy had any effect on the extension of the inflammation at 6 months follow-up compared with rectal MSZ alone.

We retrospectively studied 156 consecutive patients (pts) (81males, 75 females) with mild to moderately active UP admitted to our IBD Units, from 2010 to 2014. Forty pts (26%) were excluded from the analysis because they had been treated with oral MSZ other than MMX. Therefore 55 (35%) pts treated with MMX 1200 mg/die plus MSZ suppositories 1g/die and 61 (39%) pts treated with MSZ 1 g suppositories/die alone were included in the study. Patients on combined therapy, stopped daily MSZ suppository after two months and continued MMX 1200 mg/die plus MSZ suppository every other day up to 6 months. Patients treated with MSZ suppository alone, stopped daily rectal MSZ after 2 months and continued with MSZ suppository every other day up to 6 months. After 2 months pts were clinically evaluated according to the partial Mayo score. After 6 months follow-up, pts underwent control endoscopy. Significance of differences was assessed by X_2 test.

Results: After two months follow-up, 46 pts (84%) on combined therapy and 49 pts (80%) on rectal MSZ alone reached clinical remission. At 6 months follow-up, proximal extension of the inflammation both at the endoscopy and histology level was observed in 8/55 (14%) pts on combined therapy and in 18/61(29%) pts on rectal MSZ alone ($p < 0.05$).

Conclusion: 1) Combined therapy with oral MMX plus rectal MSZ or rectal MSZ alone are equally effective in inducing clinical remission in pts with UP, however, 2) combined oral MMX plus rectal MSZ is associated with a significant reduction in the proximal extension of the disease compared with rectal MSZ alone.

Introduction: Intestinal strictures are a frequent complication of Crohn's disease (CD), leading to intestinal obstruction. Endoscopic balloon dilation (EBD) represents a widely used approach for the management of intestinal stenosis in CD patients. Available evidence in this area, however, is limited. We therefore performed a combined efficacy and safety analysis based on all studies of endoscopic balloon dilation available in the literature.

Aims & Methods: A systematic literature search regarding EBD in CD was performed. Available technical and clinical variables were extracted from studies with > 15 patients for a descriptive pooled data analysis. Weighted efficacy averages were calculated for sub-groups. Study authors were contacted to provide individual patient data. Frailty models were used with study as a random effect for heterogeneity between studies. An automated stepwise variable selection method was used to choose variables in the multivariable models. In addition, generalized linear mixed models were used to assess associations. Binomial distribution with log link was used for all the other outcomes.

Results: 34 studies with a total of 1500 CD patients and 3252 performed dilation procedures were included. 82.7% of intestinal strictures were located in the ileum and 66.4% were anastomotic strictures (33.6% *de novo*, respectively). Technical success rate was 89.9% of all patients, resulting in clinical efficacy in 79.5% of patients. Major complications, defined as perforation, bleeding or dilation-related surgery, occurred in 2.6% of all procedures. During a mean follow-up period of 39.8 months, 48.6% of patients reported symptomatic recurrence, while 30.2% of all patients had to undergo surgical intervention. Concomitant therapy with steroid injection and cutting techniques post dilation was associated with a poorer dilation efficacy (all $p < 0.001$).

Multivariate analysis of 676 individual patients from 12 studies identified a 50% higher hazard of re-dilation in CD with *de novo* strictures as compared to anastomotic strictures ($p = 0.014$). Additionally, concomitant therapy with steroid injection doubled the hazard of need for re-dilation ($p = 0.029$). A greater maximum dilation diameter (per 1 mm increase) was found to be associated with a higher likelihood of both, technical success ($p = 0.004$) and scope passing ($p = 0.001$). Finally, every 1 cm increase of stricture length increased the hazard of need for surgery by 8% ($p = 0.008$).

Conclusion: EBD has a high rate of short-term technical and clinical success with substantial long-term efficacy and acceptable complication rates. Main predictors of successful EBD are a greater maximum caliber of dilation and anastomotic stricture. Steroid injection and an increased length of stricture reduced time to surgical intervention. EBD is a valuable alternative to surgery in patients with CD associated strictures.

Introduction: Inflammatory bowel disease (IBD) is a chronic inflammatory disorder in which tissue damage and inflammation lead to long-term, often irreversible, impairment of the structure and function of the gastrointestinal tract. Chemokine Receptor 9 (CCR9) is expressed on lymphocytes in the circulation, and is the key chemokine receptor that enables these cells to home to

the small intestine due to the localised expression of its ligand, Chemokine (C-C) Ligand 25 (CCL25). It has been suggested that CCR9 antagonism represents a means to prevent the aberrant immune response in IBD. NR11/1943 has been identified as a promising, small-molecule candidate by a medicinal chemistry programme, aimed at producing an orally-available CCR9 antagonist with a superior pharmacokinetic (PK) profile to vercirnon, a first generation compound of this class.

Aims & Methods: In this study we describe the *in vitro* and *in vivo* properties of a new, orally-available CCR9 antagonist molecule using various calcium-flux and chemotaxis based assays and *in vivo* procedures and models commonly used in the early discovery and development phases of new IBD therapies.

Results: In a number of experiments, studying the interaction between the CCR9 receptor and NR11/1943, inhibitory constants (Ki) were obtained ranging from 6nM to 24nM showing the compound to be a potent antagonist of the receptor. PK data demonstrated that the molecule has an excellent profile, being highly bio-available and with a long half-life in all the species studied. Following BID oral dosing, the molecule also demonstrated efficacy in three different models of colitis in mice (3 mg/kg to 100mg/kg) and rats (30 mg/kg and 120 mg/kg), showing significant protection against DSS- and TNBS-induced weight loss and other adverse effects, especially with respect to faecal consistency and intestinal bleeding.

Conclusion: NR11/1943 is an orally available CCR9 antagonist with a superior pre-clinical PK profile to vercirnon and with suitable pharmacological properties, both *in vitro* and *in vivo*, to allow it to progress towards the clinic.

P0369 CROSS-SPECIES TRANSLATABILITY OF NONCLINICAL SAFETY ASSESSMENTS OF A HUMAN INTERLEUKIN-22FC, AN IG FUSION PROTEIN FOR THE POTENTIAL TREATMENT OF INFECTIOUS OR INFLAMMATORY DISEASES

D. W. Lee[1], S. Zhong[2], R. Pai[3], E. Doudement[4], E. Stefanich[2], J. Rae[2], J. Gutierrez[2], J. Lutman[2], X. Wang[2], A. Lekkerkerker[2], J. Qiu[2], K. Loyet[2], A. Herman[2], W. Ouyang[2], M. Keir[2], D. Danilenko[2]

Contact E-mail Address: lee.donnaw@gene.com

Introduction: Interleukin 22 (IL22) belongs to the IL10 cytokine family (Ouyang et al. 2011) and binds specifically to the IL22 receptor (IL-22R) heterodimer, expressed on a variety of epithelial tissues (Gurney 2004). Due to its ability to modulate innate immunity via activation of the transcription factor, STAT3, and subsequent regenerative and protective properties (Wolk et al. 2004), IL-22 is thought to have therapeutic potential in treating tissue injury or chronic tissue damage.

Aims & Methods: To assess the pharmacological activity of IL-22 recombinant fusion protein (IL-22Fc) that links the human cytokine IL-22 with the Fc portion of a human immunoglobulin, STAT3 activation was evaluated in primary hepatocytes isolated from human, cynomolgus monkey, minipig, rat, and mouse after incubation with IL-22Fc. The nonclinical safety profile of IL-22Fc was evaluated to establish a safe clinical starting dose for humans in Phase I trials and support clinical intravenous (IV) and/or subcutaneous (SC) treatment regimen. Studies included pilot systemic toxicity studies in mice, rats, and cynomolgus monkeys; and repeat-dose GLP systemic toxicity studies, one in rats and one in cynomolgus monkeys. In addition, a pilot single-dose SC local toxicity study was performed in minipigs; and a tissue cross-reactivity study was conducted ex vivo using human and cynomolgus monkey tissues.

Results: Results demonstrated that all species achieved similar levels of STAT3 phosphorylation but higher concentrations of IL-22Fc and longer incubation times were required to achieve equivalent levels of STAT3 phosphorylation in rat hepatocytes when compared to hepatocytes from other species. Taken together, these results confirmed that the cynomolgus monkey, minipig, rat, and mouse were all appropriate nonclinical species for toxicology studies, and that the rat was not as sensitive to the effects of IL-22Fc as the cynomolgus monkey. Systemically administered IL-22Fc was well tolerated in both cynomolgus monkeys and rats up to highest doses tested. In monkeys, skin reddening with microscopic findings of dose-dependent epidermal hyperplasia or acanthosis, sometimes accompanied by variable increased vascularity in the superficial dermis was observed. In addition, cynomolgus monkeys exhibited transient and dose-dependent increases in acute phase reactants (Sonnenberg et al. 2011), without a concomitant increase in any proinflammatory cytokines or chemokines. Epidermal hyperplasia was also observed in mice, rats and minipigs.

Conclusion: Results from these nonclinical studies demonstrate the cross-species translatability of the biological response in activating the IL-22 pathway as well as the translatability of findings from *in vitro* to *in vivo* systems. The predicted safety risks for IL-22Fc are exaggerated pharmacologic effects of epidermal hyperplasia and a transient increase in acute phase proteins, both of which are considered predictable, manageable, monitorable, and reversible in the clinic.

P0370 FIRST OBSERVATIONS OF THE USE OF BIOSIMILAR INFLIXIMAB FOR TREATMENT OF ULCERATIVE COLITIS AND CROHN DISEASE IN PAEDIATRIC POPULATION

D. Jarzebicka[1], J. Sieczkowska[1], M. Dadalski[1], J. Kierkuś[1]
[1]*Department of Gastroenterology, Hepatology, Feeding Disorders and Pediatrics, The Children's Memorial Health Institute, Warsaw, Poland*

Contact E-mail Address: dorota.jarzebicka@wp.pl

Introduction: Biosimilar infliximab (Remisma/Inflectra) was introduced into therapy in European Union and also in Poland at the beginning of 2014. Biosimilar infliximab (BI) was authorised based on preclinical and clinical studies and is considered therapeutically equivalent in terms of safety and efficacy to the reference infliximab.

Aims & Methods: The aim of the study was to present first, to our knowledge, observation on the safety and efficacy of BI in children with ulcerative colitis and Crohn disease. From the beginning of 2014 we start treatment with biosimilar infliximab Remsima (5mg/kg) patient with ulcerative colitis (9 patients) and Crohn disease (16 patients). Patients received BI at weeks 0, 2 and 6. Disease activity (PUCAI/PCDAI) and laboratory values (CRP, ESR, platelet count) were assessed at qualification for the biological treatment and after induction treatment at week 10. Mean and range of clinical values is reported.

Results: Median age of 9 patients with UC was 15 years (range 4.5-17.5). Mean PUCAI before infliximab initiation was 48 (range 5-85). Mean (range) CRP, ESR and platelet count before initiation were 1.95 mg/dL (0.03-8.05), 31 mm (25-38) and $451x10^9$/L ($259-786x10^9$). For 2 patients it was the second course of biological treatment. For 2 from 9 patients treatment was discontinued, in 1 due to lack of response after first dose (disease flare), in second due to allergy reaction during dose 3 infusion. As of April 2014, 6 patients received 3 doses and were evaluated at week 10. After 3 doses of biosimilar infliximab mean PUCAI values decreased to 30 (range 0-65). CRP, ESR and platelet count were 0.6 mg/dL (0.02-1.77), 29 mm (18-65) and $510x10^9$ (236-706), respectively. In the group of patients with Crohn disease (16 patients) median age was 17.7 years (range 3-18). At BI start mean PCDAI was 45 (range 15-65); CRP, ESR, platelet count values were 2.05 mg/dL (0.14-6.92), 30 mm (3-93), $362x10^9$/L ($235-573x10^9$), respectively. Eight out of 16 patients were previously treated with a biologics (7 with reference infliximab, 1 with adalimumab). Time of previous treatment was mean 20 months (6-59) with biologic-free interval of 23 months (10-72). Actual treatment was discontinued in 2 from 16 patients, after first BI dose due to lack of response, accompanied by adverse event in one patient and withdrawal of consent in second patient. As of April 2014, 10 out of 14 patients received all 3 induction doses. For those patients, median initial PCDAI was 47 (15-62.5) and decreased to 6.75 (0-27.5) . Before treatment and at week 10 CRP, ESR and platelet count were 2.8 (0.15-6.92), 35.4 (3-93), $375x10^9$ (235-573) and 0.53 (0.03-2.62), 18 (6-52), $285x10^9$ (228-340), respectively. Adverse events during infusion were observed in 2/16 patients: one allergic reaction leading to treatment discontinuation and one blood pressure rise that resolved after infusion rate lowering.

Conclusion: In this preliminary report BI appears to be safe and efficacious in inducing remission in ulcerative colitis and Crohn disease paediatric patients. No unexpected safety and product quality issues were identified. Further studies with larger patient groups are required.

Disclosure of Interest: None declared

P0371 CORTICOSTEROID DOSE REDUCTION WITH VEDOLIZUMAB TREATMENT OF CROHN'S DISEASE

E. V. Loftus Jr[1], C. A. Siegel[2], R. Panaccione[3], W. J. Sandborn[4], M. Smyth[5], A. Green[5], J. Xu[6], B. Abhyankar[5]
[1]*Mayo Clinic, Rochester,* [2]*Dartmouth-Hitchcock Medical Center, Hanover, United States,* [3]*University of Calgary, Calgary, Canada,* [4]*University of California San Diego, La Jolla, United States,* [5]*Takeda Development Centre Europe Ltd, London, United Kingdom,* [6]*Takeda Pharmaceuticals International Co, Cambridge, United States*

Introduction: Corticosteroids (CS) can effectively induce remission of Crohn's disease (CD), but serious side effects prohibit long-term use. Vedolizumab (VDZ) maintenance therapy resulted in a greater percentage of patients (pts) with CS-free remission at week (wk) 52 versus placebo (PBO) in the phase 3 GEMINI 2 study of moderately to severely active CD.[1]

Aims & Methods: In GEMINI 2, pts who responded to VDZ induction therapy at wk 6 were re-randomised to PBO or VDZ for 46 wks. From wk 6 onward, pts with clinical response discontinued CS use. With exploratory and post hoc analyses, we characterised CS dose reductions following VDZ therapy in pts on stable CS doses (≤30 mg/day prednisone or equivalent) at wk 0. Median CS dose over time, change from baseline CS dose, and CS-free status at wk 52 were summarised overall and by anti-tumour necrosis factor (anti-TNF) treatment (naïve or failure) history. Median-based analyses were used since the data were not normally distributed.

Results: At wk 52, numerically similar percentages of VDZ- and PBO-treated pts had reductions from baseline CS dose (**Table**). The median CS dose in either treatment group (VDZ or PBO) at wk 52 was 5 mg/day. Higher percentages of pts (overall and anti-TNF-naïve) had doses ≤7.5 mg/day with VDZ versus PBO (**Table**). In anti-TNF-naïve pts, the median CS dose at wk 52 was 2.7 mg/day with VDZ (vs 5.0 mg/day with PBO). Higher percentages of VDZ-treated pts were CS-free for 90 and 180 days at wk 52 than PBO-treated pts (**Table**).

Conclusion: VDZ therapy was associated with a numerically higher percentage of CS-free pts and a longer duration of being CS-free than PBO. Interpretation of these post hoc analyses, including the degree of dose reduction, is limited by CS discontinuation on study and small sample sizes.

Introduction: Corticosteroids (CS) are effective for the short-term treatment of patients (pts) with ulcerative colitis (UC), but serious side effects prohibit long-term use. In the GEMINI 1 study, a higher percentage of pts with moderately to severely active UC were in CS-free remission at week (wk) 52 with vedolizumab (VDZ) treatment than with placebo (PBO).[1]
Aims & Methods: In GEMINI 1, pts who responded to VDZ induction therapy at wk 6 were re-randomised to PBO or VDZ for 46 wks. From wk 6 onward, pts with clinical response discontinued CS use. We characterised CS dose reductions achieved with VDZ therapy in exploratory and post hoc analyses of pts with baseline (wk 0) CS use (≤30 mg/day prednisone or equivalent). Median CS dose over time, change from baseline CS dose, and CS-free status at wk 52 were summarised overall and by anti-tumour necrosis factor (anti-TNF) treatment (naïve or failure) history.
Results: Of pts with baseline CS use, 74% decreased their CS dose with VDZ treatment (vs 57% with PBO) (**Table**). At wk 52, 56% of VDZ-treated pts were on ≤7.5 mg/day of CS (**Table**), and the median CS dose was 2.5 mg/day for VDZ-treated pts and 10.0 mg/day for PBO. Numerically higher percentages of VDZ-treated pts were CS-free for 90 and 180 days at wk 52 than PBO-treated pts (**Table**). Similar trends were observed in the anti-TNF-naïve and anti-TNF-failure populations.
Conclusion: At wk 52, numerically greater reductions in CS use were achieved with VDZ compared with PBO. VDZ therapy was associated with a numerically higher percentage of CS-free pts and a longer duration of being CS-free than PBO. Interpretation of these post hoc analyses, including the degree of dose reduction, is limited by CS discontinuation on study and small sample sizes.

Introduction: The ideal length of treatment with thiopurines in ulcerative colitis (UC) patients in sustained remission remains unknown. It is widely accepted that the withdrawal of these drugs is associated with a worse outcome of the disease.

Aims & Methods: The aim of this study is to analyze the clinical outcome after this withdrawal and to identify possible predictors of clinically significant relapse (CSR).

A multicenter, observational and retrospective study was designed. 102 patients with UC who discontinued thiopurines in a situation of sustained free-steroid clinical remission were included. All the patients were followed up until last revision or until CSR (understood as the occurrence of signs and symptoms of UC that required a rescue treatment).

Results: The mean duration of the disease in all patients was 13 +/- 0.61 years, the median time from diagnosis to the start of thiopurines was 48.14 +/- 5.51 months and the mean duration of total treatment with thiopurines was 60.87 +/- 4.89 months. After thiopurines withdrawal, overall CSR was recorded in 32.35% of the patients. The cumulative percentage was 18.88% in the first year, 36.48% in the third year and 43.04% in the fifth year after withdrawal. On multivariate analysis, predictors of relapse were the time from diagnosis of UC until the starting of thiopurines (HR 1.01; 95% CI, 1.01-1.02; $p = 0.039$), the duration of treatment with thiopurines (HR 0.15; 95% CI, 0.03-0.66; $p = 0.013$), the situation of biological remission at withdrawal (HR 0.004; 95% CI, 0.0001-0.14; $p = 0.0021$), the number of relapses before the withdrawal (HR 1.3; 95% CI, 1.01-1.66; $p = 0.029$) and pancolitis (HR 5.01; 95% CI, 1.95-26.43; $p = 0.0277$).

Conclusion: The withdrawal of thiopurines in patients with UC, although in sustained remission, is related to a high relapse rate. Clinical variables such as the extent of the disease, the total duration of treatment or time from diagnosis to the start of thiopurines should be considered before stopping these drugs. Further controlled, randomized and prospective studies with long follow-up periods are required to clarify this issue.

Introduction: The broader and prolonged use of anti-tumor necrosis factor (TNF) agents in inflammatory bowel disease (IBD) could expose patients to an increased risk of adverse reactions, including dermatological complications.

Aims & Methods: We assessed the cumulative incidence of anti-TNF-induced cutaneous adverse reactions in IBD patients, their risk factors, their dermatological management and their outcome in a large cohort of IBD patients.

In a single-center observational retrospective study including all consecutive adult IBD patients treated with anti-TNF agent between 2001 and 2014, all patients with dermatological complications under anti-TNF therapy were identified in a well-defined cohort of IBD patients. We conducted a survival analysis to determine the cumulative incidence of dermatological complications and risk factors for developing any dermatological complications, cutaneous infections and psoriasiform lesions. Survival curves were estimated by the Kaplan-Meier method, and we used a Cox proportional hazards model to test the association between parameters and time to each event: any dermatological complication, cutaneous infections, and psoriasis lesions.

Results: Among 583 IBD patients, 176 dermatological complications occurred, involving 20.5% of patients. Median duration of follow-up was 38.2 months (Range: 1-179). Psoriasiform lesions (10.1%; 59/583) and cutaneous infections (11.6%, 68/583) were the most frequently observed, with a cumulative incidence of respectively 28.9% and 17.6% at 10 years. They led to anti-TNF discontinuation respectively in 18.6% and 2.9% of patients. In case of switching to another anti-TNF agent for psoriasiform lesions, recurrence occurred in 57% of patients. Ulcerative colitis was associated with a lower risk of developing cutaneous infections than Crohn's disease (HR 0.25; 95% CI, 0.09-0.68; $p = 0.007$). Higher dosing of infliximab, longer duration of treatment, and maintenance regimen were associated with a higher risk of developing cutaneous infections (respectively $p = 0.01$, $p < 0.001$, and $p = 0.04$). A younger age at time of anti-TNF initiation was associated with a risk of psoriasiform lesions (HR 5.11; 95% CI, 2.43-11.16; $p < 0.001$).

Conclusion: Dermatological complications involve one of 5 patients treated with anti-TNF therapy after a 14-year follow-up. Association of cutaneous infections with higher infliximab dosing, shorter intervals between infliximab infusions, and maintenance regimen suggests a dose-dependent effect. Discontinuation of anti-TNF therapy due to dermatological complications is required in one out of 5 patients with psoriasiform lesions, but specific dermatological treatment allows to continue anti-TNF therapy in half of them.

Introduction: Monitoring of patients on immunomodulators increases the workload of consultants in gastroenterology outpatient clinics. This study evaluates how a clinical pharmacist can improve drug monitoring outcomes, safety and quality of service for patients taking thiopurines for IBD and AIH[1,2]

Aims & Methods: The number of patients seen at the pharmacist-led IBD clinic for the research period of three months was 81. Patients were seen initially once face to face then follow-up by telephone consultation. Three different quantitative forms were designed and validated for the evaluation of the study. The first one evaluated the quality of the service, the second evaluated each blood test

requested in clinic and the third evaluated the overall patient's clinical performance for the research period. The satisfaction questionnaires were posted to them, advising them to return it anonymously.
Results: The number of patients in the study were 81 [(45 Female); median age 46 years; range age [18-74]]. Indications were IBD (n = 75), AIH (n = 6). The questionnaires were posted to each patient (n = 81), 51.8% (n = 42) were returned anonymously with responses. A vast majority found the telephone follow up clinic to be conventient 92.9% (n = 39) and 95.2% (n = 48) were satisfied with the clinic service.
The therapeutic target was not achieved in 39.5% (n = 32) of the patients due to drug intolerance. Consequently, 29.6% (n = 24) of the patients needed a check of the level of thioguanine nucleotides (TGN) for better dose adjustment.[3] The results showed sub-therapeutic TGN levels in 13.6% (n = 11), a high TGN level in 14.8% (n = 12) and 1.2% (n = 1) shows non-adherence to therapy.
The total number of blood tests monitored were 304; 85.5% (n = 260) were scheduled as expected, 12.8% (n = 39) were rescheduled by the pharmacist and 1.6% (n = 2) did not attend so therapy was discontinued. The number of blood tests identified in clinic with white cell counts and neutrophils below lower limit is 6.9% (n = 21) but only 2.5% (n = 2) of the blood tests led the pharmacist to stop therapy and refer back to gastroenterologist.
Conclusion: In conclusion, the pharmacist-led clinic is a safe alternative to traditional clinical monitoring of patients initiated on immunomodulators. It reduces the number of patients who had to discontinue treatment due to myelosuppression, optimises dosage by TGN level, and increases adherence to blood monitoring. It reduces the number of doctor visits due to monitoring and thereby proves to be a cost-effective strategy.

Introduction: Fecal microbiota therapy (FMT) has been successful in treating *Clostridium difficile* (CDI) colitis, while its possible application in the management of inflammatory bowel disease (IBD) remain unclear.
Aims & Methods: We report preliminary results of an open label feasibility trial on fecal microbiota transplantation in mild to moderate ulcerative colitis. Outpatients affected by active ulcerative colitis (UC) (partial Mayo score ≥4 with an endoscopic Mayo score ≥ 1 with no upper limit on Mayo score), negative for *C. difficile* toxin were enrolled. Concomitant medications were admitted if stable 2 weeks before and thought the trial. Enrolled patients underwent to colonoscopy and received three administration of FMT using 200 cc of fecal slurry from an healthy donor proposed by the patient, negative for active infections. Primary outcome was feasibility and safety of FMT in UC. Secondary end points were: clinical remission defined as partial Mayo score ≤ 2 with no subscore ≥ 1 and clinical response, defined as reduction of Mayo score of at least 2 points at week 2, 6, 12; endoscopic remission defined as Mayo score = 0 at week 6. Consecutive patients with similar clinical features, candidates to anti-TNF-a or immunosuppressant, acted as a "real life" controls (standard therapy, ST).
Results: We enrolled 8 patients for FMT group and 7 patients for ST. Baseline characteristics were similar between FMT (6M, 2 F; mean age 37 ± 7 yo) and ST group (5M, 2 F, mean age 37 ± 10 yo): Pancolitis in 47%, left-side colitis in 33%; 80% were on steroids and 5-ASA, 40% on immunemodulators. In FMT group we observed: 1 SAE (kidney stone) and 2 drop out for disease worsening, while in ST group: 1 SAE (cerebral arterial thrombosis), 2 drop out for disease worsening, 1 infusion reaction. Clinical remission and clinical response for FMT and ST group were respectively: 37.5%/50% and 28.6%/28.6% at week 12, 25%/25% and 14.3%/57.1% at week 2, 25%/50% and 42.8%/42.8% at week 6. Endoscopic remission was observed in 33.3% of FMT group of patients while it was not evaluated in ST group.
Conclusion: The proposed protocol for FMT seems to be safe and well-accepted by UC patients. This FMT protocol have a good potential in inducing clinical response in real life mild-moderate UC patients. Further studies are mandatory.

Introduction: Response to infliximab (IFX) depends on use of immune suppressants and BMI/body fat content. Few informations however exist on how these factors interact with pharmacokinetics of IFX.
Aims & Methods: Assess a possible correlation between BMI, body fat and use of immunosuppressants with serum IFX, TNF-α and ATI before and after drug administration (trough levels, post-infusion levels). Assess a possible correlation between the serum concentrations of IFX, TNF-α and ATI before and after drug administration (trough levels, post-infusion levels) with the prospective and retrospective clinical response. We enrolled 12 Crohn's disease (CD) patients and 12 ulcerative colitis (UC) patients, in maintenance treatment with IFX, for at least 14 weeks. Blood samples were collected from each patient before infusion of the drug (trough levels) and half hour after the end of the infusion (post-infusion levels). Clinical data were registered 2 months before the infusion (for retrospective analisis) and also 2 months following the infusion (prospective analysis). Trough levels and post-infusion levels of infliximab, TNF-α and anti-infliximab (ATI) were measured by ELISA (Immunodiagnostik). Body fat levels were measured by DEXA.
Results: As expected, higher BMI and body fat levels were associated to reduced response to IFX. Higher IFX trough levels correlated to retrospective response to IFX. ATI associated to lower IFX trough levels and also post-infusion levels. BMI and body fat levels correlated to IFX postinfusion levels, suggesting that IFX does not distribute in the adipose tissue. Patients under immunosuppressant display higher IFX post-infusion levels and reduced ATI levels. The ration between IFX trough levels/TNF-α trough levels predicted the response to IFX at 2 months following IFX infusion.
Conclusion: Patients lacking response to IFX have higher values of body fat and BMI, which directly influence IFX post infusion levels, suggesting that the drug does not distribut in adipose tissue. Immunosuppressants also associate to higher IFX post infusion levels but with lower ATI levels. Finally, for the first time, our study showed that the ratio between IFXtrough-levels and TNF-αtrough-levels in serum, predict clinical response to the drug at 2 months. If confirmed in wider population, the last is a good parameter in order to promote a personalized therapy, based on the study of a specific pathogenic pathway.

P0378 INFLIXIMAB TROUGH LEVELS AND ANTI-DRUG ANTIBODIES AFTER INDUCTION PREDICT LONG TERM CLINICAL REMISSION IN INFLIXIMAB-TREATED PATIENTS WITH INFLAMMATORY BOWEL DISEASE

G. Bodini[1], L. Del Nero[1], E. Giannini[1], V. Savarino[1], C. De Maria[1], I. Baldissarro[1], J. Anjali[2], E. Savarino[3]
[1]*Internal Medicine, IRCCS San Martino, Genoa, Italy,* [2]*Research and Development, Prometheus Laboratories, San Diego, United States,* [3]*Suregery, Oncology Gastroenterology, University of Padua, Padua, Italy*

Introduction: The treatment paradigm of Inflammatory Bowel Disease is dramatically changed in the past decades, thanks to the development of biological drugs. However, approximately 40% of primary responder patients to anti-TNF therapy experience a loss of response (LOR) during the first year of treatment. Recently, drugs trough levels (TL) and anti-drug antibodies (ADA) presence were proposed as useful tools in the management of patients who have a LOR. Currently, one of the most important issue in IBD patients on biological therapy is to timely identify patients at risk of anti-TNF therapy failure.
Aims & Methods: The aim of our prospective study was to evaluate TL and ADA presence after Infliximab (IFX) induction and their correlation with clinical activity in a series of patients with Inflammatory Bowel Disease (IBD) followed-up for at least 48 weeks. We included 32 consecutive Inflammatory Bowel Disease patients [20 Crohn's Disease (CD) and 12 Ulcerative Colitis (UC); 17 males, median age 42 years, range 18-69] who underwent IFX therapy and achieved clinical remission after induction (schedule: 5 mg/kg at week 0, 2 and 6). Blood samples were drawn at standardized time points (i.e., 0, 2, 6, and 14 week) before IFX infusion. TL and IFX ADA were measured using an homogenous mobility shift assay (HMSA; Prometheus Lab, San Diego, United States). Disease activity was assessed both at week 14 and week 48 by the Harvey-Bradshaw Index (HBI, remission defined by HBI < 5) in CD patients and by the Mayo score for UC patients (remission defined by Mayo score <2). Also, protein-C reactive and erythrocyte sedimentation rate (ESR) were measured.
Results: During 48 weeks follow-up, 14 patients (43.8%) experienced LOR. We found significantly lower IFX TL after induction in patients who experienced LOR as compared to patients who maintained clinical remission during the follow-up period (0.78 mcg/ml, range 0-14.97 mcg/ml *versus* 10.01 mcg/ml, range 0.00-42.83 mcg/ml; $P = 0.0018$). Moreover, IFX TL were significantly lower in ADA positive patients as compared to ADA negative ones (0 mcg/ml, range 0-9.66 mcg/ml *versus* 11.91 mcg/ml, range 2.00-42.83 mcg/ml;

$P < 0.0001$). Lastly, ADA concentration after induction was significantly higher in relapsers as compared to patients in remission (3.13 U/ml, range 0-30.52 U/ml *versus* 0 U/ml, range 0-16.83 U/ml; $P = 0.02$).
Conclusion: Patients who experienced LOR to IFX mono-therapy during long-term follow-up (48 weeks) had significantly lower IFX TL and higher ADA serum concentrations after IFX induction (i.e., 14 weeks). Therefore, assessment of IFX TL and of ADA serum concentrations after IFX induction can be used as a predictive tool for estimating the long-term clinical response to biological therapy.

Introduction: Plasmapheresis is used in immune-mediated disease in order to remove humoral factors and, in addition, to modulate cellular immunity. It has been shown that during aphaeretic centrifugation, whole and/or re-folded soluble HLA class I molecules (sHLA-I) bind to the circuit surfaces. Similarly, neutrophils can bind sHLA-I molecules with immunoglobulin-like transcript (ILT) membrane receptors, becoming hereafter sensitive to the immunomodulation of sHLA-I such as transcriptional and post-transcriptional transforming growth factor (TGF)-β_1 modulation. On the other hand, TGFβ signaling plays a major role in the pathogenesis of inflammatory bowel diseases and it is known to directly induce Foxp3 expression. Besides, Foxp3 expression has been reported increased in patients who responded to granulocytes apheresis with remission of clinical symptoms.
Aims & Methods: The aim of this prospective study was to evaluate a possible sHLA-I mediated immunomodulation in granulocytes and monocytes apheresis in ulcerative colitis patients who responded to therapy. We prospectively enrolled a total of 10 patients (4M/6F; mean age 49, range 27-73) who achieved clinical remission with GMA. The GMA sessions (5 cycle/session) were performed using Adacolumn device. Instantly before each single apheresis and immediately after each procedure, neutrophils were analyzed for a possible *in vivo* aftermath of sHLA-I binding with corresponding ligands Ig-like-transcripts. The concentrations of sFasL molecules were determined by double-determinant immunoassay (DDIA) and the concentrations of $TGFb_1$ were determined by double-determinant immunoassays utilizing a commercially available kits.
Results: Between every GMA cycle a significant upregulation of intracytoplasmic $TGF\beta_1$ molecule or $TGF\beta_1$-mRNA was observed in neutrophils and $CD8^+$ T lymphocytes drawn along the apheretic therapeutic treatments. In particular, the greatest mean increase was found after the first and the forth GMA cycles (from +1% to +30%). A significant up-regulation of sFasL and TGFβ1 concentrations in plasma was observed along the procedures. Similarly, the mean difference increases in comparison with previous samples were constantly found raising during scheduled blood sampling for both molecules. In $CD4^+$ T lymphocytes, unable to bind sHLA-I, the aphaeretic procedures never induced $TGF\beta_1$ modulation
Conclusion: Our findings suggest that the immunosuppressive effects following therapeutic apheresis might at least in part depend on activated leukocyte sensitivity to sHLA-I molecule bioactivity.

Contact E-mail Address: armandoafp5@gmail.com
Introduction: Ischemic colitis is the most common form of intestinal ischemia with a wide spectrum of severity, with possible risk of death.
Aims & Methods: Evaluate predictive factors of in-hospital and short-term mortality, in a cohort of patients with ischemic colitis. Retrospective analysis of ischemic colitis cases diagnosed between 2008 and 2013 in a single center, with assessment of factors at diagnosis associated with in-hospital mortality and at 3 months.
Results: Of the 203 patients included (132 women), 47 (23%) died during the follow-up (median: 16 months). 21 (45%) died during hospitalization and at three months there were 30 deaths (64% of total). In the univariate analysis, higher values of LDH ($p = 0.004$), urea ($p < 0.001$), creatinine ($p = 0.001$) and leukocytes, more days of hospitalization ($p = 0.006$), male gender ($p = 0.006$), atrial fibrillation (AF) ($p = 0.03$), intestinal occlusion ($p < 0.001$), recent intravascular intervention ($p = 0.001$), endoscopic severity ($p = 0.02$) need for surgery ($p < 0.001$) or vasopressor support ($p < 0.001$), parenteral nutrition ($p < 0.001$) or antibiotic use ($p = 0.013$), prophylactic anticoagulation ($p = 0.02$) and hospitalization in intermediate/intensive care (ICU) ($p < 0.001$) were associated with in-hospital mortality. In the multivariate analysis, AF, vasopressor support and ICU admission for in-hospital mortality. These factors have been used for the creation of a risk score that showed high acuity with an area under the curve (ROC) of 0.89 (S = 89%; E = 78% - mortality 32%). At 3 months, the presence of chronic renal failure ($p = 0.002$) and lower values for hemoglobin ($p = 0.006$) at admission were also independently associated with mortality.
Conclusion: Multiple clinical and analytical factors at admission were associated with in-hospital mortality, and the presence of AF, vasopressor support or admission in ICU proved to be independent factors (risk score probability of 32%). The mortality rate at 3 months presented similar risk factors.

Introduction: Ischemic colitis is the main form of intestinal ischemia, especially in the elderly population, it is essential to have an early diagnosis with subsequent treatment.
Aims & Methods: Evaluate the demographics, etiology, clinical manifestations and prognosis of ischemic colitis in a referral tertiary center. Retrospective analysis of patients with ischemic colitis histologically confirmed between 2008 and 2013.
Results: 205 patients included (64% women), mean age of 75 years. Median follow-up time of 16 months, with an overall mortality rate of 22%. The majority of patients was admitted in the emergency department (88%) and presented with rectal bleeding and/or abdominal pain (87%). The main medical problems were HTA (65%), diabetes mellitus (24%), cerebrovascular disease (21%), heart failure (18%), coronary artery disease (17%), renal failure (15%) and atrial fibrillation (10%). The most prevalent medications were antihypertensives, diuretics and aspirin/NSAID. At admission, the majority presented with leukocytosis and renal dysfunction, without anemia. The diagnosis was established by colonoscopy in the majority of cases (87%), with a correlation of 94% with the histology. Urgent surgery was necessary in 11% of cases (due to peritonitis in half of them) and 12% of patients required blood transfusions. The main complication reported was acute kidney injury (10%). 80% underwent antibiotic therapy. The median length of hospital stay was 8 days, with need for intermediate/intensive care in 19% of cases. The in-hospital mortality rate, at 30 days and at 3 months was 9%, 10% and 14%, respectively. The recurrence rate was 6.5%.
Conclusion: We observed a high incidence of ischemic colitis in the elderly females, especially in the presence of cardiovascular risk factors. Colonoscopy was the preferred method of diagnosis. The vast majority recovered after medical support. The in-hospital mortality represents approximately half of the overall mortality.

P0382 ENDOSCOPIC BAND LIGATION (EBL) IS SUPERIOR TO ENDOSCOPIC CLIPPING FOR THE TREATMENT OF COLONIC DIVERTICULAR HEMORRHAGE

A. Yamauchi[1], K. Watanabe[1], S. Yazumi[1]
[1]*Division of Gastroenterology and Hepatology, Digestive Disease Center, Kitano Hospital, Osaka, Japan*

Contact E-mail Address: atsushi7200@gmail.com
Introduction: Colonic diverticular hemorrhage is a common cause of lower gastrointestinal bleedings. However, low detection rate of a responsible diverticulum for bleeding, less than 20%, and high early re-bleeding rate, more than 30%, are clinical problems. Recently, there were several reports of high successful rate of endoscopic band ligation (EBL) for colonic diverticular hemorrhage. Therefore, we retrospectively compared the efficacy of hemostasis for colonic diverticular hemorrhage in our hospital.
Aims & Methods: From April 2012 to March 2015, total 149 cases of 90 patients in whom colonic diverticular hemorrhage was diagnosed or clinically suspected (mean age 73.5 years (41-95 years); male: 66, female: 24) were retrospectively enrolled. Urgent colonoscopy was performed within 24 hours from arrival to our hospital by colonoscopy with a water-jet function. To better identify a responsible diverticulum, a transparent soft hood (Olympus Optical Co, Ltd, Tokyo, Japan) was attached to the tip of the scope. Diverticular hemorrhage was definitely diagnosed when active bleeding from a diverticulum, a visible non-bleeding vessel within a diverticulum, or a densely adherent clot despite vigorous irrigation, was recognized. After identifying a responsible diverticulum a marker clip was placed near the diverticulum. Hemostasis was selected from following three methods; closing an orifice of the responsible diverticulum with clipping device (closing method); clipping a vessel within a diverticulum (clipping method); EBL (Sumitomo Bakelite Co Ltd, Tokyo, Japan) method. Early re-bleeding rates within a week were evaluated.
Results: Colonic diverticular hemorrhage was diagnosed in 55 of 149 cases (36.9%); active bleeding in 46, non-bleeding visible vessels in 4, and a densely adherent clot in 5 cases. Hemostatic treatments were done in 53 of 55 cases; closing method in 20, clipping method in 27, and EBL method in 6. Residual 2 cases could not received hemostatic treatment because of inappropriate cases for endoscopic hemostasis. Respective re-bleeding rates within a week were 11 (55%), 10 (37%), and 0 (0%). There was a significant difference of re-bleeding rate between closing and EBL methods ($p = 0.02$), although no significant difference was found between clipping and EBL methods ($p = 0.145$). There was no significant adverse event related to endoscopic hemostasis. One case refractory to closing method required surgery.
Conclusion: EBL would be safe, effective, and superior to hemoclips for the treatment of colonic diverticular hemorrhage. The hood method is useful to identify the responsible diverticular hemorrhage.

Introduction: Limited data exist for clinically significant (that requires transfusion or hospitalization) post-polypectomy bleeding (PPB) risk factors and the role of thienopyridines (ticlopidin, clopidogrel, prasugrel, ticagrelor).

Aims & Methods: To determine factors associated with PPB and if thienopyridines use prior to colonoscopy increases the risk of clinically significant PPB. A case-control study of patients with clinically significant PPB was performed at our Hospital. Information collected included age, gender, uninterrupted assumption (within five days of colonoscopy) of thienopiridines, aspirin, low weight molecular eparine (LWMH), comorbidities, polyp characteristics, and polypectomy technique. The control group consisted of patients matched with the controls for the same characteristics

Results: During the study period (from 2007 to 2014), 15,946 patients underwent colonoscopy with polypectomy at our institutions and 84 patients presented with clinically significant PPB. Three patients were excluded from analysis because of lack of informations about the patient. The remaining 81 patients with removal of 130 polyps (32 immediated bleeding and 49 delayed bleeding) were well matched to 443 patients who had undergone colonoscopy with 855 polypectomies without complications. Uninterrupted thienopyridine use prior to polypectomy was 5% in the bleeding group and 7% in the control group. Mean ± standard deviation dimensions of polyps wiht PPB and in the control group was 18.4 mm ± 15 mm and 7.7 ± 7.9 mm respectively. Median size of polyps removed during thienopyridine assumption was 7.5 mm. According to a multivariate logistic regression analysis that included significant factors from the univariate logistic regression and known risk factors for bleeding, polyps superior than 10 mm (OR 3.6; 95% CI 2.1-6.2; $P < 0.0001$), polyps located in the right colon (OR 2.13; 95% CI 1.3-3.4; $P = 0.003$) aspirin use (OR 7.7; 95% CI 3.2-18.7; $P < 0.0001$) and LWMH use (OR 10.8; 95% CI 5.6-20.7; $P < 0.0001$) were significantly associated with the development of PPB. Polypectomies under thienopyridine showed a positive association without significance (OR 1.4; 95% CI 0.3-7.0; $P = 0.6$) possibly for minor dimensions of the polyps removed. Preventive measures for bleeding were found to be protective for only immediate PPB (OR 3.7; 95% CI 1.4-9.3; $P = 0.005$).

Conclusion: Polypectomies under thienopyridines are safe for polyps less than 10 mm. Polyp ≥10mm, located in the right colon, aspirin or LWMH is associated to PPB while prophylactic clip are protective only for immediate bleeding.

Introduction: Diseases causing hematochezia in children are diverse and range from benign to potentially life-threatening. Systematic pediatric data on the causes of hematochezia are scarce. We aimed at elucidating the range of disorders causing hematochezia in children. A second aim was to investigate antibiotic-associated colitis (AAC) presenting with hematochezia, focusing on antibiotic-associated hemorrhagic colitis (AAHC), a recently described entity caused by *Klebsiella* (*K.*) *oxytoca*.

Aims & Methods: Infants, children and adolescents with visible bloody stool were recruited at 5 Austrian pediatric hospitals. Patients were grouped in infants (<1 year), young children (1-5 years), children (6-13 years) and adolescents (≥14 years). As an addition to routine diagnostics a stool culture for *K. oxytoca* was done (API 20E test). Further clinical investigations or therapy were not influenced by the study. We collected data on history, laboratory findings, infectiological investigations, imaging, final diagnosis and clinical course.

Results: We included 221 patients (female n = 102, 46%): 57 infants, 64 young children, 46 children and 54 adolescents. 17 (7.7%) had a positive stool culture for *K. oxytoca*. In 129 (58%) hematochezia was caused by infectious diseases. In 51 (23%) no final diagnosis could be made and hematochezia resolved spontaneously. Thirty (14%) patients underwent endoscopy, which led to a definite diagnosis in 17/30 (57%). 21 (9.5%) were diagnosed with diseases occurring only once or twice within this study. The most common diagnoses in regard to age groups were: Food protein-induced proctocolitis in infants (n = 19, 33%), bacterial enterocolitis (*Campylobacter*/*Salmonella*; n = 34, 53%) in young children and inflammatory bowel disease in children (n = 10, 22%) and adolescents (n = 11, 20%). AAC was diagnosed in 12 (5%) patients: 2 infants with AAHC, 2 young children with *C. difficile*; in the remaining 8/12 (67%) with the clinical diagnosis of AAC no known pathogen was identified.

Conclusion: Hematochezia was caused by infections in the majority of patients. In most patients invasive diagnostic procedures were not necessary. Thus, in children with hematochezia indication for endoscopy should be restrictive, especially in infants and young children. AAC presenting with hematochezia might be caused by pathogens other than *C. difficile* and *K. oxytoca*. AAHC, caused by *K. oxytoca*, was a rare diagnosis in our pediatric cohort.

Introduction: Ischemic colitis (IC) is one of the most frequent causes of sudden bloody bowel discharge, melena. It is generally accepted in Japan to perform emergency colonoscopy (E-CS) for detection of causative lesion of melena, and as necessary, endoscopic treatment for the bleeding from such lesions as diverticulum, tumor etc. However, for IC, such as endoscopic intervention is rarely needed because the bleeding quite often spontaneously ceases. Thus, less invasive modality than CS which is useful only for diagnosis would be much beneficial for IC patients with melena. Edematous swelling of colon wall on CT has been widely accepted as a target sign of IC.

Aims & Methods: In the present study, its diagnostic value for IC was elucidated. 249 patients with a complaint of melena were enrolled and target sign in 177 patients who underwent both CT and CS were analyzed. The Toshiba Aquilion64 (64DAS) CT scanner was used for CT. Scans were acquired with use of 130kVp, 0.5 s/rot and 0.5mmx64 HP53, respectively. Images were retrospectively reconstructed by using a 0.5 mm section index.

Results: Of 177 patients, 94 showed typical sign of IC on CS. Of these 94 patients, 80 were demonstrated to have a target sign on CT (85.1% sensitivity). Of 83 patients who were negative for CS sign, 72 patients were target sign free (86.7%specificity). When the analysis was carried out on only those patients who received CS within 48hrs, sensitivity increased to 92.9%(75/83).

Conclusion: CT at an early stage after the episode of melena showed similar sensitivity and specificity as E-CS for detection of IC. Thus this less invasive modality can be used, replacing E-CS for patients with IC.

P0386 THE HISTORY OF COLONIC DIVERTICULAR HEMORRHAGE AND COLONOSCOPIC HEMOSTASIS ARE INDEPENDENT PREDICTORS FOR RECURRENT HEMORRHAGE

M. Wada[1], M. Kato[1], E. Sakaguchi[1], Y. Ishibashi[1], S. Banno[1], K. Abe[1], Y. Takada[1], T. Hirata[1], Y. Takatori[1], S. Kinoshita[1], K. Takabayashi[1], M. Kikuchi[1], M. Kikuchi[1], Y. Fujiyama[1], M. Suzuki[1], T. Uraoka[1]
[1]*Department of Gastroenterology, National Hospital Organization Tokyo Medical Centre, Tokyo, Japan*

Contact E-mail Address: michikosato@ntmc.hosp.go.jp

Introduction: Colonic diverticular hemorrhage (CDH) is a common health care problem, and it is reported to occupy 40% of lower gastrointestinal hemorrhage. Although it is often self-limited and eventually ceases spontaneously in up to 70-90% of cases, recurrence of CDH is not so rare and it occurs in about 30%. It has also been reported that once hemostasis was obtained for CDH endoscopically, recurrent hemorrhage significantly decreases (*Jensen* et al. *N Engl J Med 2000*). However, it is not easy to perform colonoscopy urgently, and therefore, narrowing down candidates is necessary who would be more benefited by colonoscopy from the viewpoint of long-term outcome.

Aims & Methods: The aim of this study was to clarify risk factors of recurrent CDH.This was a retrospective cohort study from a tertiary hospital. A total of 265 patients who were diagnosed as CDH from March 2004 to October 2014 were enrolled. CDH was defined as apparent hematochezia in patients with known colonic diverticulum diagnosed by computed tomography, colonoscopy, and/ or barium enema examination without any other causes. We analyzed the association between patients' characteristics (age, gender, history of CDH, arteriosclerotic disease, antiplatelet use, anticoagulant use, to be obtained hemostasis by colonoscopy) and recurrence of CDH using Cox proportional hazards model. The cumulative recurrent curve was plotted using Kaplan-Meier methods.

Results: Of 265 patients, 170 were men and 95 were women, and median age was 75 [IQR 63-83]. The median observation period was 276 [IQR 29-1047]

days. A total of 227 patients underwent colonoscopy while hospitalized, and 22 patients (10%) obtained colonoscopic hemostasis. One patient obtained hemostasis by interventional radiology. The other patients eventually obtained spontaneous hemostasis. Recurrent CDH was seen in 54 patients (20%). Univariate analysis showed significant association of history of CDH and colonoscopic hemostasis with recurrent CDH. Multivariate analysis showed that history of CDH is an independent risk factor for recurrent CDH (OR 2.26 [95%CI 1.15-4.16], p = 0.0192), and obtained colonoscopic hemostasis independently reduces recurrent CDH (OR 0.30 [95%CI 0.05-1.0], p = 0.0492). One year cumulative recurrent hemorrhage rate was 35% in those with history of CDH, whereas 15% in those without (log rank test, p = 0.0047).

Conclusion: History of CDH and colonoscopic hemostasis were independent predictors for recurrent CDH. Although the identification rate of bleeding point remained only 10%, colonoscopic hemostasis could reduce 70% of recurrent hemorrhage. Therefore, patients with past history of CDH should be aggressively considered to undergo urgent colonoscopy, since they are at high risk for recurrent CDH.

Introduction: Diverticular bleeding of the colon occurs in 2-4% of colonic diverticula diseases and it has been reported to be the most common cause of lower gastrointestinal bleedings. In general, the treatment strategy for diverticular bleeding of the colon is endoscopic hemostasis or interventional radiology (IVR) in cases of the colonic diverticula in which bleeding points are able to be detected. However, it is difficult to precisely detect the bleeding point in most of diverticular bleedings by colonoscopy or enhanced computed tomography. There have been few reports regarding the recurrence of diverticular bleeding, and the rate of recurrence of diverticular bleedings was reported from 10.8 to 43.4%. However, the risk factors of recurrent bleedings of colonic diverticula are still unknown. Thus, we assessed the risk factors of recurrent bleedings to estimate the prognosis of the patients with bleeding colonic diverticula.

Aims & Methods: We aimed to investigate the risk factors of diverticular re-bleeding in the colon. Ninety-three patients who were referred to our hospital due to lower gastrointestinal bleeding and were diagnosed as colonic diverticular bleeding between January 2008 and December 2014 were analyzed. The patients with melena or hematochezia who had no other bleeding lesions except for colonic diverticula were diagnosed as diverticular bleeding by colonoscopy. Ninety-three patients were divided into two groups; 38 patients without repeated diverticular bleeding, non-recurrence group; 55 patients requiring more than two hospitalizations due to diverticular bleeding, recurrence group). Patients' backgrounds such as sex, age, comorbidities and use of medicines were compared between the two groups.

Results: Thirty-eight patients (40.9%) (24 men and 14 women; median age, 70.4 ± 11.0 years old) were included in the recurrence group. Antiplatelet or anticoagulant drugs were administered in 14 patients (38.8%), and NSAIDs were administered in 4 patients (10.5%). Ten patients (26.3%) had diabetes mellitus, 3 patients (7.9%) had ischemic heart diseases. On the other hand 55 patients (59.1%) (33 men and 22 women; median age, 73.7 ± 10.5 years old) were included in the non-recurrence group. Antiplatelet or anticoagulant drugs were administered in 17 patients (30.9%), NSAIDs were administered in 3 patients (5.4%). Five patients (9.1%) had diabetes mellitus, 7 patients (12.7%) had ischemic heart diseases. Univariate analysis revealed that the patients with diabetes mellitus significantly harbored higher frequency of diverticular re-bleeding than those without diabetes mellitus ($p = 0.043$). However, there were no significant differences in other factors between the two groups. Multivariate analysis showed that diabetes mellitus was an independent and significant predictor for diverticular re-bleeding of the colon (odds ratio, 3.60; 95% confidence interval, 1.1-11.8; $p = 0.035$).

Conclusion: Patients with diabetes mellitus harbored about a 4-fold higher risk of diverticular re-bleeding compared with patients with other comorbidities. Patients with diabetes mellitus suggested to be carefully observed after initially diverticular bleeding.

Introduction: It is still controversial whether antithrombotic agents, i.e., antiplatelets and anticoagulants, increase post-polypectomy bleeding (PPB).

Aims & Methods: The aim of this study was to elucidate risk factors for PPB including antithrombotic agents.This was a case-control study based on medical records of single center. PPB was defined as bleeding that occurred 6 hours to 10 days after colonoscopic polypectomy and required endoscopic hemostasis. All colonoscopic polypectomies performed between January 2011 and December 2014 were reviewed.

Results: PPB occurred in 29 (3.7%) of 788 polypectomies performed during the period. Four PPB cases required transfusion and no PPB cases required surgery. Any antiplatelets or anticoagulants were prescribed to 210 (26.6%) patients; antiplatelets to 155, anticoagulants to 83 and both to 28 patients. All anticoagulants and antiplatelets except for aspirin or cilostazol in 19 cases were ceased before polypectomy. Anticoagulants were significantly associated with PPB ($P < 0.0001$) while antiplatelets were not. Bridging therapy using intravenous unfractionated heparin was adopted to 73 patients and also significantly correlated with PPB ($P < 0.0001$). None of the followings correlated with PPB; age, gender, polyp location, size, shape (flat vs. sessile vs. pedunculated), histology, number of polyps resected, prophylactic clipping, resection method (polypectomy vs. endoscopic mucosal resection vs. endoscopic submucosal dissection). Thromboembolic event occurred in one patient taking anticoagulant after cessation.

Conclusion: Patients taking anticoagulants have increased risk of PPB, even if anticoagulants are interrupted before polypectomy. Heparin-bridge therapy might be responsible for the increased PPB in patients taking anticoagulants.

Introduction: Lynch syndrome (LS) is the most common hereditary cause of colorectal cancer (CRC). Identifying LS carriers among CRC patients is of great importance, since surveillance programs for their affected relatives can reduce CRC morbidity and mortality by 56-70%. However, many LS carriers are still not identified. The aim of this study was to assess the cost-effectiveness of routine molecular screening for LS in CRC patients up to 70 years of age.

Aims & Methods: A population-based series of CRC patients aged ≤70 years was routinely screened for LS by analysis of microsatellite instability, immunohistochemistry and *MLH1* hypermethylation, followed by germline mutation analysis in indicated cases. Effectiveness of screening was expressed in life years gained (LYG), based on the number of LS carriers detected among CRC patients and their relatives. Total costs consisted of LS diagnostics and surveillance, including gynaecological surveillance and prophylactic surgery for female LS carriers. We calculated incremental cost-effectiveness ratios (ICERs) comparing different age cut-offs and comparing age-targeted screening with the revised Bethesda guidelines. One-way sensitivity analyses were performed to test the robustness of ICERs.

Results: Screening among 1117 CRC patients identified 23 LS carriers, of whom 7 were ≤50, 7 were 51-60 and 9 were 61-70 years of age. Additionally, 70 LS carriers were identified among relatives (14, 42 and 14 per age category respectively). Overall, screening amounted to 68.1 LYG or 14.4, 39.1 and 14.6 LYG per age category. Total costs for LS screening and surveillance increased from €232,395 (€11,066 per LS carrier detected) for LS screening among CRC patients ≤50 years of age to €1,056,191 (€11,357 per LS carrier detected) for screening CRC patients ≤70 years of age. ICERs were €12,941/LYG for LS screening in CRC patients ≤60 years compared with ≤50 years and €21,728/LYG for screening CRC patients ≤70 years compared with ≤60 years. The revised Bethesda guidelines identified 17/23 (74%) LS carriers among CRC patients and 53/70 (76%) LS carriers among relatives. The ICER for LS screening in CRC patients ≤70 years of age was €22,485/LYG compared with LS screening according to the revised Bethesda guidelines. The ICERs were most sensitive to the assumed LYG by relatives. All ICERs remained < €30,000/LYG in sensitivity analyses.

Conclusion: Routine LS screening by analysis of microsatellite instability, immunohistochemistry, and *MLH1* hypermethylation in CRC patients up to 70 years of age is a cost-effective strategy according to currently accepted standards, with important clinical benefits for LS carriers among CRC patients and their relatives.

P0390 CEA AND CYFRA21-1 IMPROVE THE SPECIFICITY OF A 29-GENE BLOOD-BASED TEST FOR EARLY DETECTION OF COLORECTAL CANCER

C. Nichita[1], S. Hosseinian[2], S. Monnier-Benoit[2], L. Ciarloni[2], G. Dorta[1], on behalf of DGNP-COL-0310 study group

Contact E-mail Address: laura.ciarloni@novigenix.com

Introduction: An effective and convenient test for colorectal cancer (CRC) screening is needed in order to increase compliance and reduce mortality from CRC. Recent studies[1,2] demonstrate that an effective blood test could be an attractive alternative to increase participation rate to CRC screening. Previously[3] we validated a novel blood test for the detection of CRC and large adenomas based on a 29-gene panel in peripheral blood mononuclear cells.

Aims & Methods: The aim of this study was to investigate how addition of CEA, CYFRA21-1, CA125 and CA19-9, circulating protein tumor biomarkers used in the management of different cancers, could improve accuracy of the 29-gene test.

Subject enrolled in the DGNP-COL-0310 study, a multi-center case-control study previously described[3], were older than 50 years and referred for screening/diagnostic colonoscopy or scheduled for surgical removal of CRC. 371 plasma samples from the Swiss participants, including 118 samples from CRC patients, 103 from patients with adenomas $\geq$1cm and 150 from subjects without colorectal lesions (controls), were used to measure protein concentration on the Architect platform (Abbott Diagnostics). Subjects were assigned to training, validation, and test set, using the same design used to develop the 29-gene classifier. Training and validation set were used to select the most relevant circulating protein tumor markers and to determine a new predictive algorithm combining the protein biomarkers with the existing 29-gene classifier. The test set was used to validate the predictive algorithm on the independent data set.

Results: Among the 4 tested proteins, CEA and CYFRA21-1, alone or in combination, showed the highest predictive accuracy for CRC discrimination and were included in the final predictive algorithm. When validated on an independent test set, including 73 CRC, 42 adenomas and 74 controls, the algorithm showed a specificity of 92% and a sensitivity of 78% for CRC and of 52% for adenoma detection.

Conclusion: The addition of the tumor biomarkers CEA and CYFRA21-1 improved the specificity of our 29-gene algorithm, which increased from 88% to 92%. Sensitivity for CRC and large adenomas increased only slightly. Thus, we confirmed that this blood test could be an effective complement to colonoscopy to increase compliance to CRC screening. The test has now been launched on the Swiss market under the trade name Colox®.

P0391 NEW HORIZONS IN T1 CANCERS: DIFFERENT METASTATIC RISK PARAMETERS ARE PROBABLY NEEDED FOR CRC SCREENING POPULATIONS

E. Rosa-Rizzotto[1], E. Guido[1], D. Caroli[1], M. Lo Mele[2], R. Cappellesso[2], M. Rugge[2], E. Tessari[3], A. Frasson[3], P. Pilati[3], F. De Lazzari[1]

Contact E-mail Address: erik.rosarizzotto@gmail.com

Introduction: Actually we don't know how long does it takes for a preneoplastic lesion to become a cancer invading the submucosal layer (pT1). We don't know, also, how long a pT1 lesion rest in the submucosal layer before going deeper to reach the muscolaris propria becoming pT2. At present, in these neoplasic lesions hystological parameters alone determine wether a low (7%) or high (35%) risk of metastasis exists[1,2].

Aims & Methods: The aim of this study was to assess the metastatical risk in pT1 lesions diagnosed during routine colonoscopies (RC) in comparison with those found during CRC screening colonoscopies (SC). We retrospectively reviewed the files of 17587 colonscopies (8343 RC and 9244 SC) performed in our Endoscopy Unit from july 2009 to january 2015 and extracted all the pT1 CRC. pT1 patients gone for a strict follow-up: first visit in 6 months, then a visit every year. The schedule was: physiscal examination, CEA marker and colonscopy every year, CT scan and liver Ultrasonograpy every other year.

Results: In 67 months 144 pT1 (80M, 55F) tumors were detected, 115(79.9%) during SC and 29(20.1%) during RC. The median follow-up was 39 months. Overall pT1 prevalence was 115/9244(1.2%) in SC and 29/8343(0.3%) in RC (Pearson $\chi^2 = 43.4$, $p < .0001$). 71(49%) patients undergone for surgery because considered at high metastatic risk, 3 refused. During the follow-up only 5 patients (5/144, 3.4%) presented limphnode metastasis. In high-risk group 2/7 (28%) in RC and 3/61 (4.7%) in SC presented metastatsis (Pearson χ^2, $p = 0.019$). No patient 0/73 with low metastatic risk presented metastsis during follow-up. Population mean age was higher in RC 72 vs 62 ($p < 0.00001$). High risk pT1 were more frequent in SC (53% vs 24%, $p < 0.01$). No differences were found in the two populations for: dimension, tumor grading, deep/extent of invasion, vascular invasion, budding, polypectomy resection margin ($p = ns$). Presence of tumor budding was higher in male (21% 16/77 vs 5% 3/61, $p = 0.006$). Survival curves for metastatic risk shows a non significative difference between SC and RC (Breslow test $\chi^2 = 1.528$, $p = 0.216$; Long Rank Mantel-Cox $\chi^2 = 1.137$, $p = 0.286$).

Conclusion: CRC pT1 are 4 times more frequent in SC than in RC. However, only in the RC group the real risk of limph node metastsis justfy the surgical resection. In the SC one, the present series highlighted a remarkable overtreatment and the pressing need to identify new parameters more strongly associated to limph node metastasis in this kind of patients.

Introduction: Colorectal cancer (CRC) screening programs are implemented worldwide. Many are based on biennial fecal occult blood testing (FOBT). Despite well-known differences between men and women in incidence of CRC and its precursors, screening programs invariably use the same strategy for both genders. In recent years fecal immunochemical tests (FITs) replace guaiac FOBTs. The quantitative nature of FIT allows tailored screening by using different cutoffs. We aimed to evaluate whether different cutoffs should be used in men and women.

Aims & Methods: Participants (50-75 years) in an invitational primary colonoscopy screening program were asked to complete one sample FIT (OC-sensor, Eiken, Japan) before colonoscopy. We determined FIT positivity rates, sensitivity, specificity, detection rate and false-positivity rate in detecting advanced neoplasia (AN) for cutoff levels of 10 (FIT10), 20 (FIT20), 30 (FIT30) and 40 (FIT40) µg Hb/g feces in both men and women, corresponding to 25, 50, 75 and 100 ng Hb/ml feces. A receiver-operating-characteristic (ROC) curve was calculated for both men and women at multiple cutoffs to calculate the highest predictive ability.

Results: In total 1,256 invitees underwent FIT and colonoscopy, 638 men and 618 women, with a median age of 61 years (IQR 56-66) and 60 years (IQR 55-65). The prevalence of AN was 10.6% in men and 8.3% in women. At all FIT cut-offs, men had higher positivity rates than women. These ranged from 10.8% (95% CI 8.6-13.5%) to 3.8% (95% CI 2.5-5.6%) in men, and 8.4% (95% CI 6.5-10.9) to 3.2 (95% CI 2.1-5.0) in women. Sensitivity in men ranged from 40% (95% CI 29-52%) for FIT10 to 25% (95% CI 16-37%) for FIT40, and in women from 35% (95% CI 24-49%) for FIT10 to 22% (95%CI 12-35%) for FIT40. The highest predictive ability was similar for men and women with a maximum AUROC of 0.72, at different thresholds of 30 µg Hb/ml and 20 µg Hb/ml respectively. More advanced neoplasia was found and missed in absolute numbers in men for all cutoffs.

Conclusion: FIT-based CRC screening has a lower sensitivity and specificity for advanced neoplasia in women than in men. However, in absolute numbers more advanced neoplasia was both detected and missed in men compared to women at all cut-offs. When implementing a FIT-based CRC screening program these gender differences should be taken into account when aiming for optimal use of colonoscopy capacity.

Contact E-mail Address: estanigomez@yahoo.com.ar

Introduction: Serrated polyposis syndrome (SPS) is characterized by the presence of multiple serrated polyps (SP) in the colon and may represent a risk for colorectal cancer (CRC). The SPS remains to be mostly unrecognized and not-well understood among other colorectal polyposis. The CRC prevalence and clinicopathological features of SPS are not well established.

Aims & Methods

Aim: To describe clinicopathological features of patients who meet WHO SPS diagnostic criteria and to determine prevalence and predictors of CRC.

Methods: We retrieved records from two teaching Hospitals to detect individuals with high diagnostic suspicion of SPS, between February 2002 and October 2014. Patients who met 2010 WHO SPS diagnostic criteria were included. Clinical and demographic data concerning age, gender, personal and familiar history of CRC, smoking status and surgical history were collected and analyzed. Continuous and categorical variables were reported as median with interquartile ranges (IQR), and percentages, respectively. Univariate analysis determining CRC predictors was performed. A P value < 0.05 was considered to be statistically significant.
Results: In all, 64 patients met WHO diagnostic criteria for SPS;: 33 (51%) fulfilled criteria 1, 29 (45%) criteria 2 and criteria 3 was observed in only 2 (3%) patients. Median age at diagnosis was 57.9 years (IQR, 25-80) and 42 (65%) were female. Nineteen (29.7%) had familiar history of CRC in first-degree relatives. Twenty nine (45%) had smoking history. A total of 220 colonoscopies were performed; an average of two per patient was necessary to confirm SPS diagnosis. Average endoscopic follow-up was 43.7 months. At index colonoscopy, 8 patients (12.5%) had between 5-10 polyps, 19 (29.7%) between 10-20 polyps, 25 (39%) between 20-30 polyps and 12 (18.7%) more than 30 polyps. A total of 659 SP were diagnosed by pathology reports; 193 (29.3%) were sessile serrated adenomas, 372 (56.5%) microvesicular hyperplastic polyps; 85 (12.8%) caliciform or unclassified hyperplastic polyps and 9 (1.4%) were traditional serrated adenomas. Forty-one patients (64%) had at least one conventional adenoma, 19 (29.7%) had at least one advanced adenoma and 32 (50%) had at least one advanced SP. CRC was found at diagnosis or during surveillance in 9 patients (14%). No clinicopathological predictors for CRC were identified in the univariate analysis. Surgery was performed in 12 (18.5%) patients due to polyposis (n = 6), CRC (n = 4) and impossibility of SP endoscopic resection (n = 2).
Conclusion: In this two-center retrospective cohort study we found a high prevalence of CRC in SPS patients. However, we did not find clinical, endoscopic or pathological predictors for CRC. Our data suggests the need for a better detection and surveillance for CRC in SPS patients.

Contact E-mail Address: cheerea@gmail.com
Introduction: Liver transplant patients are at high risk of malignancy because of the prolonged immunosuppression for avoiding rejections. The aim of this study was to determine whether the prevalence of advanced colorectal neoplasms increases in liver transplant recipients and to define the appropriate duration for surveillance colonoscopy after liver transplantation.
Aims & Methods: Our study consisted of 348 liver transplant patients who underwent a colonoscopy at Seoul National University Hospital from 1991 to 2012. For each patient, two or more age-and sex-matched controls were identified from a population of asymptomatic individuals.
Results: Eighteen (5.2%) patients had advanced colonic neoplasms, including colorectal cancers (10 patients, 2.9%), after liver transplantation. A case-control study showed that the odds of advanced colonic neoplasms occurring in transplant patients were 3.8 times greater than in the matched healthy controls. Transplant patients 50 years of age or older had a 4.1-fold higher risk of developing advanced neoplasm than did the matched subjects (OR 4.127; 95% CI 1.818-9.369; P = 0.000).
Conclusion: Liver transplant patients are at an increasing risk of developing advanced colorectal neoplasms. Colonoscopy is recommended for patients before and after liver TPL, especially 50 years of age or older.

P0395 IMPACT OF SUBSEQUENT SCREENING EPISODES ON THE POSITIVE PREDICTIVE VALUE FOR ADVANCED NEOPLASIA AND ON THE DISTRIBUTION OF ANATOMIC SUBSITES OF COLORECTAL CANCER: A POPULATION-BASED STUDY ON BEHALF OF THE FRENCH COLORECTAL CANCER SCREENING PROGRAM

F. G. Assogba[1], D. Jezewski-Serra[1], D. Lastier[1], C. Quintin[1], B. Denis[2], N. Duport[1], N. Beltzer[1]
[1]*Department of Chronic Diseases and Injuries, French Institute for Public Health Surveillance, Saint-Maurice,* [2]*Association for Colorectal Cancer Screening, Colmar, France*

Contact E-mail Address: f.assogba@invs.sante.fr
Introduction: The anatomic distribution of advanced colorectal neoplasia is increasingly important for choosing screening strategies and treatment options. We sought to evaluate the impact of repeated screening on the positive predictive value (PPV) for advanced colorectal neoplasia (advanced adenoma, AA, and colorectal cancer, CRC) and their distribution according to anatomic subsite distribution in average-risk adults.
Aims & Methods: The study included 98,031 men and women aged 50-74 who had a positive g-FOBT in 2010 and 2011 and underwent total colonoscopy. The PPV for detection of AA and CRC and the relative risks were determined with log-binomial models, and the distribution of anatomic subsites was estimated according to screening history.
Results: The median age was 61 years (62 years for participants with AA and 64 for those with CCR). The PPV for detection of advanced neoplasia was 24.5%, substantially higher in men than women (30.7% vs 17.7%), and it increased with age. It also fell at all screening episodes after the first. Subsequent screening episodes were associated with an increased RR for proximal AA (RR 1.13, 95%CI 1.16-1.20). Advancing age (RR 1.28, 95%CI 1.19-1.39 for every 10-year increase in age), female gender (RR 1.31, 95%CI 1.19-1.44), and subsequent screening (RR 1.15, 95%CI 1.04-1.27) were significantly and independently associated with detection of proximal adenocarcinoma. The latter was also detected at an advanced stage more often (RR, 1.24, 95%CI: 1.09-1.42). Early invasive adenocarcinoma (stages I and II) was more likely to be detected in a subsequent than an initial screening (RR 1.07, 95%CI 1.01- 1.13).
Conclusion: This study found that subsequent screening episodes using g-FOBT were associated with an increase in the detection rate of proximal AA and CCR, especially among women. The more frequent detection of CCR at an advanced stage in later screenings suggests that some of these tumors were present in earlier screenings. This potential for missed diagnoses on initial screening, together with the more modest increase in the rate of detection of invasive adenocarcinoma at early (and more curable) stages from the first to subsequent screenings, underlines the need to reinforce the population's awareness of the importance of regular consistent screening, even after negative results.

P0396 CHARACTERIZING THE INTERPLAY BETWEEN THE WNT SIGNALING PATHWAY AND CD24 IN INTESTINAL TUMORIGENESIS

A. Fokra[1], S. Shapira[1], D. Kazanov[1], S. Kraus[1], N. Arber[1]
[1]*Integrated Cancer Prevention Center, Tel Aviv Sourasky Medical Center, Tel Aviv, Israel*

Contact E-mail Address: afokra@gmail.com
Introduction: CD24 is a glycosylphosphatidylinositol-linked protein that functions as an adhesion molecule and is overexpressed at an early stage of CRC (Sagiv et al., 2006). The Wnt/b-catenin signaling pathway plays an important role in CRC carcinogenesis process. A previous publication from our lab indicated that CD24 could affect the tumorigenesis process in Apc^{Min} mice (Naumov et al., 2014); Apc^{Min} mice usually develop anemia (polyp bleeding) and splenomegaly (extra-medulary hematopoiesis).
Aims & Methods: CD24's role might be, partly, through direct interaction/s with components of the Wnt pathway. Apc^{Min} and *CD24* knockout (KO) mice, both on a C57BL/6J genetic background, were crossed to generate double KO transgenic mice. Genotypes were routinely verified by analysis of DNA extracted from tail biopsies. Small and large bowel polyps were counted macroscopically following methylene blue staining and histology was verified microscopically. Colonic polyps were measured and counted using mice colonoscopy. CD24-inducible 293T-Rex cells previously developed in our lab (Shapira et al., 2011) and SW480 CRC cells stably transfected with CD24 (Naumov et al., 2014) were used to study this interaction *in vitro*.
Results: *In vitro* Western blotting analyses showed that expression of CD24 in 293T-Rex cells induced the activation of β-catenin, while down-regulation of CD24 in SW480 cells caused a decrease in the levels of active β-catenin. Depletion of *CD24* alleles in Apc^{Min} mice led to a significant reduction in the number of polyps in the small and large intestine. C57BL6/J mice carrying the Apc^{Min} mutation develop $\sim 24.3 \pm 3.7$ adenomas and several carcinomas in the small intestine by the age of 16 weeks. The $Apc^{Min}/CD24^{+/-}$ mice developed 8 ± 1.4 polyps and $Apc^{Min}/CD24^{-/-}$ (double KO) mice developed $\sim 7 \pm 1.7$ polyps ($p = 0.006$). Colonoscopy shows a significant reduction in the number and size of polyps upon depletion of *CD24* alleles. In the current study the Apc^{Min} displayed severe splenomegaly (355 ± 68 mg) compared to (205 ± 51 mg) in $Apc^{Min}/CD24^{+/-}$ mice and (141 ± 49 mg) in double KO mice similar to WT mice ($p = 0.006$). Hb level was 3.8 ± 2.5 in the Apc^{Min} significantly lower in the double KO mice (8.2 ± 0.9) and the WT ($p = 0.0009$)
Conclusion: CD24 plays a major role in intestinal tumorigenesis. Knocking down even one copy of CD24 almost completely abolished formation in vivo, and prevent anemia and splenomegaly the whole mark of intestinal blood loss seeing in the Apc^{Min}. CD24 interacts with the Wnt pathway by activating β-catenin. 4. Down regulation of CD24 maybe an important aim in the therapy of CRC.

P0397 IDENTIFICATION OF LONG NON-CODING RNAS (LNCRNA) WITH ALTERED EXPRESSION LEVELS IN COLORECTAL ADENOMA AND CARCINOMA

A. Kalmár[1], Z. B. Nagy[1], O. Galamb[1,2], B. Wichmann[1,2], B. K. Barták[1], K. Tóth[1], P. Miheller[1], Z. Tulassay[1,2], B. Molnár[1,2]

Contact E-mail Address: alexandra.kalmar@gmail.com
Introduction: Among several functions long non-coding RNAs (lncRNA) are known to act as crucial epigenetic regulators of cell proliferation. Their expression level alterations can lead to cancer formation. Identification of lncRNA expression profiles in colorectal adenoma and cancer (CRC) would be beneficial to expand our knowledge of CRC development.
Aims & Methods: This study aimed to identify differentially expressed long non-coding RNAs (lncRNA) in colorectal adenoma and CRC cases. Total RNA was isolated from 94 human colonic biopsy samples (27 CRCs, 29 colonic adenomas, 38 normal donors without evidence of disease) with RNeasy Mini Kit (Qiagen). Expression levels of lncRNAs were analyzed with HGU133Plus2.0 microarrays (Affymetrix). Affymetric probe sets of 2090 lncRNAs already represented on this array type were extracted with non-coding (‚NR'') Refseq IDs. Furthermore, total RNA including miRNAs was isolated from 36 independent biopsy samples (20 CRCs, 9 colonic adenomas, 7 normal donors without evidence of disease) with High Pure miRNA Isolation Kit (Roche) and expression levels of 40.914 non-protein coding transcripts were analyzed by using Human Transcriptome Array 2.0 (Affymetrix). Data were analysed using Expression Console and Transcriptome Analysis Console softwares (Affymetrix).
Results: According to HGU133Plus2.0 microarray results 3 significantly upregulated lncRNAs were identified in adenomas and 4 in CRCs, while 10 significantly downregulated lncRNAs were found in adenomas and 12 in CRC compared to the healthy controls ($p < 0.05$; $-1 \geq \log Fc \geq 1$). On the basis of the Human Transcriptome array results -analyzing broader range of non-coding RNAs- 76 upregulated lncRNAs were detected in adenomas and 154 in CRC, while 65 downregulated lncRNAs were found in adenomas and 122 in CRC compared to the healthy controls ($p < 0.05$; $-2 \geq \log Fc \geq 2$). 100% of the lncRNAs showing significant gene expression alteration on HGU133Plus2.0 arrays showed similar expression alteration tendency on Human Transcriptome arrays in the adenoma vs. normal and 94% in the CRC vs. normal comparisons. Interestingly, on HGU133Plus2.0 arrays 69% and on Human Transcriptome Arrays 73% of lncRNAs upregulated in CRC samples showed significantly elevated expression ($p < 0.05$) already in adenoma samples (e.g. upregulated CRNDE, linc-FAM75A7-18, linc-FAM135A, lincDUSP26-1 and downregulated linc-DCLK3-2, linc-AMN1, linc-SOD3-2, lincFAM55D compared to healthy controls) containing lncRNAs already associated with CRC or other types of cancer.
Conclusion: The identified lncRNAs with significantly altered expression levels can play a central role in the regulation of transcription during colorectal adenoma-carcinoma sequence. Common up- or downregulated lncRNAs in colorectal adenoma and in CRC samples can be the basis of further investigations in order to enhance early detection of the colorectal cancer development.
This study was supported by the National Research, Development and Innovation Office (KMR-12-1-2012-0216 grant).

Contact E-mail Address: asimoes@ff.ulisboa.pt
Introduction: The discovery of the deregulation of microRNA (miRNA) expression in cancer, particularly in colon cancer has demonstrated the potential therapeutic use of miRNAs. However, the biggest obstacle relies in the low miRNA delivery efficiency *in vivo*.
Aims & Methods: In this study, we aimed to develop an efficient strategy for the delivery of miRNAs to colon cancer cells. Cetuximab was used as a delivery and targeting agent.
Cetuximab was FITC-labeled using FluoReporter® FITC Protein Labeling Kit, providing a labeling ratio of ~ 11 (FITC:Cetuximab). Subsequently, we linked anti-FITC-Protamine single chain Fv (scFv) antibody conjugate to the FITC-labeled Cetuximab. Further, miRNAs were loaded onto Protamine moieties, which display high affinity for nucleic acids and have already been demonstrated effective in *in vitro* and *in vivo* delivery of siRNAs to cancer cells. We have tested the effectiveness and specificity of our delivery complex through *in vitro* evaluation of increased levels of miRNA payload in target cells.
Results: Immunofluorescence and flow cytometry results showed that Cetuximab-FITC efficiently binds to HCT116 cells, but not SW620 cells that do not express EGFR. For Cetuximab-FITC above 0.5 nM, all HCT116 cells were FITC-positive, whereas all SW620 cells were FITC-negative, as evaluated by FACS ($p < 0.05$). Further, for Cetuximab-FITC up to 50 nM, only 3% of SW620 cells were FITC-positive, demonstrating the specificity of EGFR targeting by Cetuximab-FITC. Subsequently, we confirmed by ELISA the specific binding of anti-FITC-protamine to Cetuximab-FITC ($p < 0.01$). The concentration of 3 nM Cetuximab-FITC was selected to evaluate the delivery of anti-FITC-protamine scFv at 10:1 ratio (scFV:cetuximab-FITC), and the results show specific delivery to HCT116 cells as evaluated by Western blot. Finally, we confirmed by flow cytometry and RT-PCR the increase and specific delivery of miRNAs into colon cancer cells with the developed delivery tool consisting of cetuximab-FITC:scFV:miRNA ($p < 0.05$).
Conclusion: The great enthusiastic advantage of the development of this delivery tool arises from the combination of the therapeutic agent Cetuximab already in use for colon cancer treatment together with RNA interference technology. The results obtained thus far illustrate the high potential for efficient and specific delivery of miRNAs to cancer cells, and may provide additional and novel therapeutic tools to expand current options in colon cancer management.
(Supported by PTDC/SAU-ORG/119842/2010, and SFRH/BD/79356/2011 from FCT).

P0399 GUT MUCOSAL MICROBIOME ACROSS STAGES OF COLORECTAL CARCINOGENESIS

G. Nakatsu[1], X. Li[1], H. Zhou[2], S. H. Wong[1], W. K. Wu[1], S. C. Ng[1], H. Tsoi[1], Y. Dong[1], J. J. Sung[1], J. Yu[1]

Introduction: Sustained gut microbial dysbiosis is a potential risk factor for exacerbating colorectal lesions toward carcinogenesis. However, it remains unclear whether specific members or a consortium of the gut microbes has the potential to explicate observations about tumor progression.
Aims & Methods: To catalogue the taxonomic landscape of microbial communities in colorectal carcinogenesis, we performed 16S rRNA gene sequencing on mucosal biopsies from 61 lesion-free individuals, and on paired biopsies from 47 and 52 individuals with histology-proven adenomas and carcinomas, respectively. Using the DMM models, we partitioned the relative abundance profiles into microbial community types to design tumor-stage analysis of the changes in community types and marker taxa between paired samples. The taxon abundances were also subjected to sparsity-corrected correlation analyses of occurrence relationships using the SparCC algorithm. Finally, we imputed the metagenomic content of mucosal community types associated with the disease-states using the PICRUSt algorithm and HUMAnN pipeline.
Results: We detected five robust community types, which were strongly associated with phenotypes of the colorectal mucosae ($P = 0.00007$). A community type predominated by the potentially pathogenic members of oral microbiome was primarily associated with carcinomas, whereas adenomas were assigned to a community type with high intra-cluster variabilities. Normal control mucosae were more likely to be represented by a community type enriched with members of Clostridia. We confirmed the consistent enrichments of representative taxa by real-time PCR amplification on an independent cohort of comparable size. Disease-stage analysis revealed significant patterns of change in community types at cancerous but not adenomatous sites relative to their adjacent normals. The fold changes of marker taxa were most significant in early-stage CRC. Colorectal niches of cancer- and cancer-adjacents were characterized by a markedly increased number of parasitic relationships. Adenoma-adjacents harboured co-excluding partners underlying early signs of mucosal dysbiosis. By contrast, microbial partners in normal mucosae showed strong mutualistic relationships. Furthermore, both pathological phenotypes of mucosa and the community types strongly distinguished the predicted metabolic potentials of mucosal communities.
Conclusion: Pathogenesis of CRC can be linked to the appearances of pathobiont-like microbial consortia in which protagonists interact with one another. Such polymicrobial signature predicts the statuses of colorectal lesion, the progression of which may be dependent on the processes of microbial community assembly at the mucosal interface. By interrogating the mucosal community ecology across disease-states, we gain deeper understanding of etiological factors in colorectal carcinogenesis by considering complex bacterial driver-passenger interactions.

Contact E-mail Address: julieveziant@gmail.com
Introduction: Colorectal carcinoma (CRC) is a complex association of non neoplastic and tumoral cells and a large amount of microorganisms. *E. coli* is a consistent commensal of the human gut microbiota but some pathogenic strains have acquired the ability to produce toxins as cyclomodulins that can interfere with eukaryotic cell cycle or directly induce DNA damages. It was observed that cyclomudulin-producing-*E. coli* are more frequently detected on CRC patients and exhibit procarcinogenic properties on murine models (HCT116 xenograft, AOM/DSS; APCmin/+).
Aims & Methods: Aim of this study was to investigate some molecular or cellular mechanisms related to the infection of epithelial mucosa by cyclomudulin-producing-*E. coli* using optical in vivo imaging (IVIS spectrum; Perkin Elmer). In vivo imaging is an innovative tool for noninvasive, spatiotemporal and quantitative monitoring of carcinogenesis process in mice models. We

choose to evaluate the tumor metabolic activity using a FDG analogue as 2-DG-750 fluorescent probes and inflammation measuring myeloperoxidase (MPO) activity with a bioluminescent inflammation probe. This detection is dependent on reactive oxygen species (ROS) production. Detection and quantitation of these two signals were validated on a xenograft model of human colon adenocarcinoma epithelial cells (HCT-116) in nude mice infected with a cyclomudulin-producing-*E. coli* (11G5) and then tested on the murine CRC susceptibility model, $APC^{min/+}$.

Results: Using the 2-DG-750 probe, we observed a high and specific HCT-116 tumor uptake in correlation with tumoral volume (Pearson correlation factor: 0.9181 $p < 0.05$). Using inflammation probe, we detected a rapid systemic elimination and a strong signal in the HCT116 tumor of the 11G5 infected group 10 minutes post-probe-injection. Quantitation showed a significant increase (+1288%) of luminescent signal in the tumors of the infected group ($p < 0.05$). We confirmed this by enzyme-linked immunosorbent assay (ELISA) on tumor specimens. MPO levels (ng/ml) was significantly higher (1556 ± 313.6 vs 234.6 ± 121.6 $p = 0.001$) in xenograft infected with pathogenic *E.coli*-11G5 strain. Moreover histological examination of tumor samples confirmed the massive infiltration of HCT116-11G5 infected xenograft by neutrophils as compared to uninfected group. These data validated used of inflammation probe and showed that *E.coli* strain infection induced inflammation and ROS production in the tumor. Study of intra-digestive signal on the murine $APC^{min/+}$ models is in progress. Strong signals were co-localized with polyps.

Conclusion: Novel imaging techniques like optical imaging could be a powerful tool in translational cancer research. Bioluminescent approach can be applied to digestive tumor and seems sensitive to noninvasively monitor longitudinal tumor inflammation and oxidative stress using a commercial probe. Here we showed that *E.coli* infection induce inflammation and oxidative stress which could participate on carcinogenesis process. In vivo imaging could be an effective technology to better understood host-pathogen interactions on tumoral development.

Contact E-mail Address: kengliang_wu@yahoo.com.tw

Introduction: Our previous study showed galectin-3 enhanced the migration of DLD-1 cells through K-Ras-Raf-Erk1/2 pathway, but extracellular galectin-3 on the migration of cancer cells and interaction with epithelial growth factor receptor (EGFR) remained unknown.

Aims & Methods: To clarify the effect of extracellular galectin-3 on the migration and invasion of colon cancer cells and relation with EGFR. Western blotting was used to analysis the secretion of galectin-3, short hairpin ribonucleic acid to stably knockdown the expression of galectin-3, wound healing and trans-well assays to evaluate the migration and invasion of colon cancer cells and immunoprecipitation /immunoblotting and proximity ligation assays for analyzing the interaction between galectin-3 and EGFR.

Results: Caco2 cells secreted more galectin-3 and migrated faster than DLD-1. The migration was inhibited by lactose and neutralizing anti-galectin-3 antibody. DLD-1 cells with knockdown of galectin-3 decreased the migration but restored by recombinant galectin-3. Blocking EGFR by EGFR antibody caused decrease of migration. DLD-1 cells with knockdown of galectin-3 decreased the invasion but recombinant galectin-3 reversed the decrease. An interaction between EGFR and galectin-3 was proven by immunoprecipitation and proximity ligation assays. Addition of recombinant galectin-3 induced an increase in phosphorylated EGFR expression within minutes, and recombinant galectin-3 enhanced entrance of EGFR from cell membrane to cytoplasma, especially under EGF stimulation. Extracellular galectin-3 increased the migration and invasion of colon cancer cells and that was correlated to its interaction with EGFR and internalization of EGFR from cell membrane to cytoplasm.

Conclusion: Targeting galectin-3 might have a synergistic effect on the EGFR targeting therapy.

Introduction: The French colorectal cancer (CCR) screening program was generalized in 2008 and is based on a biennial fecal occult blood testing (FOBT) proposed to everyone with an average risk for colorectal cancer and aged 50-74 years. Subjects from this population who undergo a normal colonoscopy are invited 5 years later for a biennial FOBT. Our data base contains information about FOBTs performed five years after colonoscopy as well as about several rounds of FOBTs. The test in use till 2015 was guaiac FOBT (gFOBT), Hemoccult II®.

Aims & Methods: Our primary aim was to compare CCR and advanced adenoma (AA) detection rates following gFOBT 5-6 years after normal colonoscopy with those observed on third and fourth rounds of screening with gFOBT. We evaluated data from 46 French districts. The study population was those aged 55-74 years and eligible for screening who had performed a gFOBT from 2008 to 2013 and qualified for one of three groups: subjects with gFOBT preceded by normal colonoscopy (COLO), subjects with gFOBT preceded by two negative gFOBTs (R3) and subjects with gFOBT preceded by three negative gFOBTs (R4). The last group had data from only 11 districts where screening existed for long enough. In R3 and R4, the intervals between all consecutive tests had to be 18-36 months. The interval between colonoscopy and gFOBT had to be 5-6 years.

Results: In total, 38 587 men and 56 957 women were included in the COLO group, 370 975 men and 469 082 women in R3 and 101 994 men and 115 090 women in R4. CCR detection rates for men were 0.7‰ in COLO, 2.0‰ in R3 and 1.6‰ in R4; it was 0.4‰, 0.9‰ and 0.8‰ respectively for women. Among men, AA detection rates were 3.2‰ in COLO, 5.9‰ in R3 and 5.8‰ in R4; it was 1.7‰, 2.6‰ and 2.3‰ respectively for women. Among men, the relative risk (RR) to detect CCR in COLO compared to R3 was 0.36 (95% Confidence Interval (95%CI) 0.25-0.52); it was 0.44 (95%CI 0.30-0.66) compared to R4. Among women, the COLO to R3 RR was 0.40 (95%CI 0.26-0.61) and the COLO to R4 RR was 0.45 (95%CI 0.28-0.72). Among men, the RR to detect AA in COLO compared to R3 was 0.55 (95%CI 0.49-0.66); it was 0.56 (95%CI 0.46-0.68) compared to R4. Among women, the COLO to R3 RR was 0.65 (95%CI 0.53-0.79) and the COLO to R4 RR was 0.74 (95%CI 0.59-0.93).

Conclusion: The risks to discover CCR or AA were lower within the group of the subjects who performed gFOBT five-six years after normal colonoscopy in comparison to those who performed a gFOBT after two or three negative gFOBTs. The observed difference was larger for CCR than AA. While French colorectal cancer screening program is changing with replacement of the guaiac based test by more sensitive fecal immunochemical test (FIT), these results support this evolution. Further analysis would be of great benefit to evaluate how several rounds of screening with high-sensitivity FIT compares to single colonoscopy and what is the number of screening rounds needed to equal colonoscopy. In France the five-year period to reintegrate into screening program subjects with a normal colonoscopy could be discussed and compared to a 10-year interval.

Contact E-mail Address: alessandro.lugli@pathology.unibe.ch

Introduction: Tumor budding in colorectal cancer (CRC) is a strong, reproducible and independent prognostic factor. Whereas intra-tumoral budding (ITB) is defined as single tumor cells or a small cluster of up to 5 cells found in the tumor center, peri-tumoral budding (PTB) can be detected at the invasion front of CRC. Until now, a comparison of the clinicopathological impact of ITB and PTB by tumor region has not been performed.

Aims & Methods: The aim of the study was to validate the performance of tumor budding as a marker of tumor progression in all CRC stages independently of the cancer region.

Postoperative resections of 156 surgically treated and well-characterized stage I-IV CRC patients were systematically reviewed according to the latest UICC/AJCC classification. Collected information included patient age, gender, tumor location, TNM stage, L and V stage, tumor grade, histological subtype, perineuronal infiltration, tumor border configuration, mismatch repair status, R classification and information on adjuvant therapy. Tumor budding was optimally visualized by immunohistochemistry using pancytokeratin, a well-established marker in daily diagnostics. ITB was scored using the 1 high-power field (HPF) method to simulate the clinical scenarios in pre-operative biopsies and malignant polyps. A cut-off score of 5 buds/HPF based on Receiver Operating Characteristic (ROC) curves was used to distinguish between high and low-grade budding. Next, PTB was assessed using the 10 HPF method and the ROC based cutoff of 100 buds was identified for categorizing high and low-grade budding in postoperative CRC resections.

Results: ITB (1 HPF) and PTB (10 HPF) were strongly correlated ($r = 0.82$, $p < 0.0001$). PTB was associated with T stage ($p = 0.02$), N stage ($p = 0.04$), TNM stage ($p = 0.04$) and tumor grade ($p = 0.02$), whereas ITB significantly correlated with higher T stage ($p < 0.01$), N stage ($p = 0.03$), distant metastases ($p = 0.02$), L stage ($p < 0.01$), V stage ($p = 0.03$) and tumor border configuration ($p < 0.01$). Combined ITB and PTB scores independently correlated with poor survival outcome (HR (95%CI): 1.02, CI: 1.0002-1.04, $p = 0.03$) when adjusted for TNM-stage and adjuvant therapy.

Conclusion: Tumor budding is a strong adverse prognostic parameter independent of the cancer region (center vs front). The 10HPF/1HPF tumor budding scoring method can be applied in all CRC stages, which may be applicable to clinical scenarios including preoperative biopsies, malignant polyps and stage II CRC.

P0405 SERRATED ADENOMA MODEL OF THE COLON

M. Y. Byakhov[1], D. L. Rotin[1], **A. E. Lychkova**[2]
[1]*Moscow Clinical Scientific Center, Moscow, Russian Federation,* [2]*patent department, Moscow Clinical Scientific Center, Moscow, Russian Federation*

Contact E-mail Address: lychkova@mail.ru
Introduction: Serrated adenoma is a distinct type of lesion of the colon, with potential to evolve into colorectal cancer through a different molecular pathway than the traditional adenoma-carcinoma sequence.
Aims & Methods: Establish a possibility of creating a model of colon serrated adenoma.
Proposed a novel rat model for SA caused by picrilsulfonic acid administration. 6 Wistar rats weighing 220-250 g received picrilsulfonic acid administrated into the lumen of the common bile duct in a dose of 0.03-0.05 ml, and readministrated 5-10 days after in the same dose. The control group consisted of 5 rats. A sample of colon after 3-4 months under anesthesia was taken. Histopathological examination of the tissues stained with hematoxylin and eosin was carried out.
Results: Histologically the cecum contain polypoid formations extending out of the mucous surface; dilated crypts were presented, glands with irregular outlines parallel to a broad base of muscularis mucosa were located. Crypts were lined by epithelial cells with small nuclei and light eosinophilic cytoplasm, sometimes with mild dysplasia; crypts not contained endocrine cells. The combination aserrated crypts and surface epithelial dysplasia revealed the presence of serrated adenoma.
Conclusion: Proposed model explicitly includes morphological signs of a serrated adenoma and may be used in potential screening strategies for colorectal cancer.
Disclosure of Interest: None declared

P0406 CLINICAL IMPLICATION OF AXIN-2 EXPRESSION IN COLORECTAL CANCER

Contact E-mail Address: apopapp300@yahoo.com
Introduction: The Wnt pathway regulates cellular homeostasis and deregulation of this pathway has been implicated in the pathogenesis of many diseases including colorectal (CRC) cancer. The Axin-2 protein plays an important role in the regulation of the stability of the Wnt signaling pathway. Although initially described as a tumor suppressor, recent findings support the presence of a pro-tumorigenic role.
Aims & Methods: The aim of this study is to investigate the association of Axin-2 mRNA and protein expression with clinicopathological parameters and survival in CRC. Fifty seven patients who were diagnosed with adenocarcinoma of the colon and rectum and underwent resection at our surgical department were included in this study. Expression of Axin-2 was investigated using quantitative PCR and immunohistochemical staining.
Results: In most cases Axin-2 immunolocalization was detectable in the cytoplasm as opposed to only one case where it was shown to be expressed in the nucleous. The positive expression rates of Axin-2 mRNA and protein were 51% (29/57) and 33% (19/57), respectively. Statistical analysis showed no association between Axin-2 mRNA/protein expression and patients' clinicopathological parameters and survival.
Conclusion: In the present study Axin-2 mRNA and protein expression failed to provide with significant prognostic information in CRC patients. These findings may reflect the complex tumorigenic role of this marker in CRC. Further studies are required to verify our results.
Disclosure of Interest: None declared

P0407 CLINICAL SIGNIFICANCE OF E-CADHERIN IN COLORECTAL ADENOCARCINOMAS

A. Pappas[1], G. Veloudis[2], C. Liatsos[3], S. Gourgiotis[2], D. Keramidaris[2], E. Pikoulis[4], J. Bramis[4], E. Bastounis[4]

Contact E-mail Address: apopapp300@yahoo.com
Introduction: The epithelial–mesenchymal transition (EMT) represents a fundamentally important process during the embryonic development, but it is also recognized as a critical event in the progression and metastases of many epithelial tumors. E-cadherin is the best-characterized molecular marker of EMT and loss of expression has been linked to poorer prognosis in several cancers. To date, in patients with colorectal cancer (CRC), the correlation between E-cadherin and patient prognosis remains controversial.
Aims & Methods: The aim of this study was to investigate E-cadherin mRNA/protein expression in a series of 57 CRC patients and relate these findings with the patients' clinicopathological features and prognosis. Quantitative PCR and immunohistochemistry analyses were performed to characterize the expression of E-cadherin in CRC tissues.
Results: The positive expression rates of E-cadherin mRNA and protein were 53% (30/57) and 42% (24/57), respectively. E-cadherin immunostaining showed no correlation with the patients' clinicopathological features. There was a trend towards higher mRNA expression levels in patients with well compared to poorly differentiated tumors ($p = 0.09$). Kaplan-Meier survival curves demonstrated that patients with negative E-cadherin mRNA and protein expression, presented a significantly and marginally significantly unfavorable disease-free survival (DFS) time ($p < 0.001$ and $p = 0.05$, respectively). Patients with negative E-cadherin mRNA expression presented also a significantly unfavorable overall survival (OS) time ($p = 0.02$). Multivariable COX regression analysis adjusted for age, gender, tumor location, TNM stage and grade of differentiation, showed that E-cadherin mRNA expression is an independent prognostic factor for OS.
Conclusion: E-cadherin downregulation is an important component of disease progression in CRC patients. Gene expression levels are a strong predictor of OS and DFS.

Contact E-mail Address: apopapp300@yahoo.com
Introduction: Aberrant activation of the Wnt signaling pathway has been implicated as a key regulator of colorectal (CRC) tumorigenesis. β-catenin plays a key role in the signaling output of the Wnt cascade. There are many reports about the significance of β-catenin in CRC, yet correlations with prognosis remain highly variable and contradictory.
Aims & Methods: The aim of this study was to investigate β-catenin expression and its relationship to clinicopathological parameters and prognosis in CRC. Immunohistochemistry analyses were performed to characterize the expression of β-catenin in CRC tissues.
Results: The study included 29 female and 28 male patients with a mean age of 67 ± 10.4 years. Cytoplasmic and focal nuclear accumulation of β-catenin was observed in 88% (50/57) and 25% (14/57) of patients respectively. There was no significant association between β-catenin overexpression in the cytoplasm and the patients' clinicopathological parameters. β-catenin overexpression in the nucleus was associated with advanced N stage ($p = 0.04$). Kaplan-Meier survival curves demonstrated that patients with β-catenin overexpression in the nucleus presented a significantly unfavorable overall survival (OS) time ($p = 0.04$). Multivariable COX regression analysis adjusted for age, gender, tumor location, TNM stage and grade of differentiation, showed that β-catenin overexpression in the nucleus is an independent prognostic factor for OS. There was no significant association between β-catenin overexpression in the cytoplasm and OS.
Conclusion: The protein expression level of nucleus, rather than cytoplasmic β-catenin predicts CRC patients with worse prognosis.
Disclosure of Interest: None declared

P0409 WHICH CRITERIA TO USE TO DIFFERENTIATE BETWEEN SESSILE SERRATED ADENOMA (SSA) FROM MICROVESICULAR HYPERPLASTIC POLYPS – A 5-YEAR RETROSPECTIVE HISTOPATHOLOGICAL STUDY

C. Sumánszki[1], R. Horváth[1], T. Micsik[2], Z. Tulassay[1], **A. V. Patai**[1]
[1]*2nd Department of Internal Medicine,* [2]*1st Department of Pathology and Experimental Cancer Research, Semmelweis University, Budapest, Hungary*

Contact E-mail Address: arpad.patai@gmail.com
Introduction: During the past two decades sessile serrated adenomas (SSA) received considerable attention due to their increased risk of leading to colorectal carcinoma (CRC). CRCs arising from SSA have frequently been associated with interval cancers (those arising after negative colonoscopy). Diagnosis of these lesions can be challenging, as both macroscopic and microscopic features show similarities to microvesicular hyperplastic polyps (MVHP). Since in contrast to SSA, there is almost no malignant potential of MVHP, therefore it is critical to distinguish them from SSA in order to determine the appropriate follow up and prevent interval cancers.
Aims & Methods: The aims of our study were to compare the published histopathological classification criteria currently available in the literature for the diagnosis of SSAs and to use these criteria to examine the reclassification rate of MVHP to SSA. Colorectal polyps diagnosed between 2010 and 2014 at the 1st Department of Pathology and Experimental Cancer Research were searched for samples with descriptions matching serrated lesions. For the diagnosis of SSAs the criteria recommended by Rex et al. were used. The remaining serrated lesions were classified using the WHO 2010 criteria. These lesions were then reanalysed using seven major histopathological classification studies (Aust 2010, Chung 2008, Higuchi 2005, Mohammadi 2011, Rex 2012, WHO 2010, Yao 2011) and reassessed whether they met the diagnostic criteria for the diagnosis of SSA.
Results: A total of 347 serrated colonic polyps were found that included 50 (14.4%) SSAs, 143 (41.2%) MVHPs, 148 (42.7%) goblet cell rich hyperplastic polyps (GCHP) and 6 (1.7%) traditional serrated adenomas (TSAs). A significant difference for SSA diagnosis was noted between the classification studies, with results varying from 100% (Rex 2012, Higuchi 2005, Mohammadi 2011) to 20% (Chung 2008). This difference was also observed in the reclassification

rate of MVHP to SSA: ranging from 15 (10.5%) (Rex 2012) to 2 (1.4%) (Chung 2008) of all MVHPs.
Conclusion: In conclusion, we would like to emphasize the significant difference among studies differentiating colorectal serrated lesions. It seems to be clear that a universal diagnostic criteria based on prospective clinicopathological studies is needed to avoid the underdiagnosis that can result in inadequate surveillance and increased risk of CRC.
Disclosure of Interest: None declared

P0410 WHICH CRITERIA TO USE TO DIAGNOSE TRADITIONAL SERRATED ADENOMA (TSA) AND DIFFERENTIATE FROM CONVENTIONAL ADENOMA – RESULTS FROM A 3-YEAR RETROSPECTIVE HISTOPATHOLOGICAL STUDY

R. Horváth[1], C. Sumánszki[1], T. Micsik[2], L. Vass[3], I. Horváth[3], E. Román[3], B. Nagy[4], Z. Tulassay[1], **A. V. Patai**[1]

Contact E-mail Address: arpad.patai@gmail.com
Introduction: Among the recently described colorectal serrated lesions traditional serrated adenoma (TSA) is the rarest subtype. The morphologic distinction between TSA and conventional adenoma, especially villous/tubulovillous adenoma (VA/TVA), may be difficult, because there is a significant histological overlap between these lesions. According to the literature, there are three characteristic features usually present in TSAs: ectopic crypt foci (ECF), luminal serration and typical cytology with columnar epithelial cells with eosinophilic cytoplasm and elongated, centrally placed nuclei. Currently, TSA diagnosis needs at least two of the three features above with at least one present in 50% of the polyp.
Aims & Methods: The aim of our study was to evaluate the presence of these morphological features in TSAs and TVAs, and define which features are most helpful in distinguishing TSA from TVA. Colorectal polyps diagnosed as TSA ot TVA between 2012 and 2014 at the Flór Ferenc Hospital were retrieved and histologically reassessed by two pathologists.
Results: A total of 115 polyps diagnosed as TSA or TVA were reviewed and 11 polyps were selected and classified as TSA on the basis of the current diagnostic criteria. As a control group, we studied 104 TVAs and determined the same features. Both ECF and typical cytology were seen in 10 of the 11 TSAs (91%), luminal serration was present in 73%. To the extent of more than 50% of the polyp, typical cytology was noted in 7 cases (64%), ECF and luminal serration was seen in 3 TSAs (27%). Of the 104 TVAs, typical cytology was present in 35 cases (34%), ECF was found in 9% and luminal serration was noted in 20%. Typical cytological features were seen only in 3 TVAs (3%) to the extent of more than 50% of the adenoma. Luminal serration in more than half of the specimen was seen only in one TVA. The presence of all three morphological features simultaneously was observed in 6 of the 11 TSAs (55%), and only in 3 of the 104 TVAs (3%). Two TVAs showed typical TSA-like patterns to a considerable degree.
Conclusion: In conclusion, ECF proved to be the most helpful morphological feature regarding the diagnosis of TSA, although it is not specific to TSA and is not seen in every case of TSA. Luminal serration and TSA-like cytology are frequently present in TVAs, but they are only visible in extreme cases in more than 50% of the adenoma. Some polyps show a mixed morphology, with TSA-like and conventional adenoma-like areas. These cases may be regarded as mixed polyps.

P0411 1H HR NMR SPECTROSCOPY OF FECAL EXTRACTS ENABLES DETECTION OF ADVANCED COLORECTAL NEOPLASIA

A. Amiot[1,2], A. Dona[1], A. Wijeyesekera[1], C. Tournigand[3], Y. Lebaleur[2], I. Sobhani[2], E. Holmes[1]
[1]*Section of Biomolecular Medicine, Computational and Systems Medicine, Department of Surgery and Cancer, Faculty of Medicine, Imperial College London, London, United Kingdom,* [2]*Department of Gastroenterology,* [3]*Deartment of Oncology, CHU Henri Mondor, EC2M3, APHP, UPEC, Creteil, France*

Contact E-mail Address: aurelien.amiot@hmn.aphp.fr
Introduction: Colorectal cancer (CRC) is a growing cause of mortality in developing countries warranting investigation into its etiopathogenesis and earlier diagnosis. Here, we assessed the value of fecal metabolic phenotype of patients with advanced colorectal neoplasia and controls using ^{1}H-nuclear magnetic resonance (NMR) spectroscopy.
Aims & Methods: Fecal extract samples from 55 patients with advanced colorectal neoplasia and control patients, were evaluated using ^{1}H-nuclear magnetic resonance (NMR) spectroscopy. Unsupervised (principal component analysis) and supervised (orthogonal partial least-squares discriminant analysis OPLS-DA) multivariate analyses were applied to discriminate between samples using MATLAB (v.2013a) and SIMCA-P+ (v.13.0.1) softwares. The 7-fold cross validation, a 1000 permutation testing and determination of the area under the receiver operator characteristics curves (AUROC) were applied for internal validation. Wif-1 methylation levels in stools, serum and urine and seven dominant and subdominant bacterial populations in stools were quantified and correlated to metabolic profile of each patients.
Results: The predictability of the model was 0.507 (Q2Y) and the explained variance was 0.755 (R2Y). The goodness of fit and predictive capability (Q^2) of the ^{1}H-NMR OPLS-DA model remained higher than those of the 1000 permutated models indicating that the model was statistically robust. Patients with advanced colorectal neoplasia disclosed increased signals of four short-chain fatty acids (valerate, acetate, propionate and butyrate) and decreased signals of β-Glucose, glutamine and glutamate. The predictive accuracy of the ^{1}H-NMR OPLS-DA model for predicting advanced colorectal neoplasia (AUROC = 0.94, IC95% [0.84-0.99]) was higher than FOBT (0.71, IC95% [0.56-0.83], p = 0.0001) and the serum and/or urine Wif-1 methylation test (0.81, IC95% [0.68-0.91], p = 0.03). Correlation analysis of the microbiome and metabolome data revealed strong associations between *Faecalibacterium prausnitzii* and *Clostridium leptum* species and butyrate and valerate concentration and inverse correlation between *Faecalibacterium prausnitzii* and glucose.
Conclusion: ^{1}H-NMR spectroscopy of fecal extract samples identified a specific metabolic signature that clearly distinguish patients with advanced colorectal neoplasia from the controls. These preliminary results suggest that urinary metabolomics may have a future potential role in non-invasive colorectal screening program.

P0412 IRON DEFICIENCY ANAEMIA; APPROPRIATE SEQUENCE OF ENDOSCOPIC INVESTIGATIONS

A. Rehman[1], B. Natarajan[1], **B. Javaid**[1]
[1]*Bedford Hospital, Bedford, United Kingdom*

Contact E-mail Address: amerrehman964@yahoo.co.uk
Introduction: Iron deficiency anaemia (IDA) is present in 2-5% of men and postmenopausal women and is a common reason for gastroenterology referral (1, 2). British society of gastroenterology recommends an upper and lower gastrointestinal (GI) endoscopy to rule out pathology including malignant disease (2). Traditionally an oesophago-gastro-duodenoscopy (OGD) is performed first followed by colonoscopy. This retrospective study evaluates the usefulness of this strategy.
Aims & Methods: We analysed our endoscopy database to look for patients who underwent both an OGD and colonoscopy to investigate IDA over a period of one year to 31 December 2014. Further data was collected from the clinical letters and hospital pathology database. Results were evaluated using Microsoft excel.
Results: A total of 204 patients were investigated including 113 (55%) female and 91 (45%) male patients. Among these 20 (10%) patients had upper GI symptoms, 48 (23%) had lower GI symptoms and 6 (3%) had both upper and lower GI symptoms. Remaining 136 (67%) patients were asymptomatic. In the studied group, 93 (46%) had haemoglobin less than 100g/L, 54 (26%) had Haemoglobin 100-109 g/L, 31 (15%) had haemoglobin 110-120 g/L and 26 (13%) had haemoglobin more than 120g/L. Ferritin levels were less than the lab cut off in 158 (78%), less than 50 but above the lab cut off in 26 (13%), between 50 and 100 in 11 (5%) and >100 in 8 (4%). OGD was normal in 108(53%) patients. Gastritis was found in 29 (14%), Large hiatus hernia in 22 (11%), oesophagitis in 14 (7%), gastric polyp in 12 (6%) and other findings were found in 19 (9%) including 1 gastric malignancy. Duodenal biopsies were normal in 178 (87%) and not taken in 22 (11%). Coeliac was diagnosed in 1 (<1%). Colonoscopy results showed normal findings in 81 (40%), diverticulosis in 42 (21%), polyps in 33 (16%), Haemorrhoids in 31 (15%), Malignancy in 17 (8%) and others in 15 (7%). Among those with polyps adenomatous polyps were confirmed on histology in 20 (10%) and hyperplastic in 13 (6%). Caecal intubation rate was an acceptable being 91% (186) with 18 (9%) patients having completion Virtual colonogrpahy (Computerised tomography). Coeliac serology was not checked for 150 (74%). It was negative in 53 (26%) and was positive in 1 (<1%). Importantly the only one patient with gastric malignancy did not have any upper or lower GI symptoms. Among patients with colonic malignancy 3 (18%) patients had lower GI but no upper GI symptoms.
Conclusion: This study showed that 17 (8%) patients had colonic malignancy while only 1 (<1%) had upper GI malignancy. Hence we would recommend colonoscopy as the initial endoscopy procedure instead of an OGD when investigating iron deficiency anaemia both in asymptomatic patents and those who present with lower GI symptoms

P0413 "SCORE SYSTEM" FOR CARDIOVASCULAR RISK: A TOOL TO SELECT PATIENTS AT HIGH RISK FOR COLORECTAL NEOPLASIA

C. J. Gargallo[1], P. Carrera[2], C. Scarpignato[3], A. Lanas[4]
[1]*Gastroenterology, University Hospital " Lozano Blesa", [2]Ciberehd, zaragoza, Spain,* [3]*Pharmacology, University of Parma, Parma, Italy,* [4]*gastroenterology, University Hospital Lozano Blesa, zaragoza, Spain*

Contact E-mail Address: carlajerusalen@hotmail.com
Introduction: Cardiovascular (CV) disease and colorectal cancer (CRC) are important health problems worldwide and share several risk factors. Little is known about the risk of colorectal neoplasia (adenomas or CRC) among individuals at different risk for CV disease. European Guidelines on CV disease prevention recommend the SCORE system to assess the total CV risk in apparently healthy persons.
Aims & Methods: To evaluate: 1) the prevalence of colorectal neoplasia in an average CRC risk population according to the individual CV risk, 2) the

relationship between the CV risk and type of colorectal neoplasia (non advanced adenoma, advanced adenoma [AA] and CRC).
Results: 605 patients were included in this study. The mean age was 59.7 ± 11.6 years, and there were 311 men (51.4%). 9.8% of patients were diabetic and 23.8% were smokers. 223 patients (36.9%) had 1 or more colorectal neoplasias. The prevalence of colorectal neoplasia in patients with low CV risk, intermediate CV risk and high/very high CV risk was 8.3% (9/109), 41.6% (126/303) and 45.6% (88/193), respectively ($p < 0.001$). The prevalence of advanced colorectal neoplasia (AA or CRC) was 4.6% (5/109), 24.1% (73/303) and 34.7% (67/193), respectively ($p < 0.001$). In multivariate analyses, the moderate risk group and the high/very high risk group had a significantly increased risk of colorectal neoplasia compared with the low risk group, [Odds Ratio (OR) 5.69 (95% confidence interval (CI), 2.41-13.42)] and [OR 5.62 (95% CI, 1.99-15.89)], respectively, ($p = 0.001$). The moderate risk group and the high/very high risk group had also a significantly increased risk of advanced colorectal neoplasia compared with the low risk group [OR 5.43 (95% CI, 1.86-15.88)] and [OR 8.56 (95% CI, 2.46-29.79)], respectively, ($p = 0.001$). The high/very high risk group had a non-significantly increased risk of advanced colorectal neoplasia compared with the moderate risk group [OR 1.58 (95% CI, 0. 96- 2.60), $p = 0.075$].
Conclusion: The prevalence and risk of overall and advanced colorectal neoplasia increase in parallel with the risk of death due to CV disease. The SCORE system may be used as a predictive risk model of colorectal neoplasia. Hence, patients at increased CV risk may benefit from CRC screening.

P0414 IS THE INFORMATION PROVIDED ON HISTOPATHOLOGY REQUEST FORMS FOR COLORECTAL CANCER ADEQUATE?

C. Ntala[1], A. Gumber[1], G. Kaur[1]
[1]*Surgery, Scunthorpe General Hospital, Scunthorpe, United Kingdom*

Contact E-mail Address: gkaur@email.com
Introduction: Surgical pathology depends heavily on the input of clinicians and surgeons. The pathologist's need for adequate clinical information before diagnosis can be made has been highlighted in the past. According to the Royal College of Pathologists' UK guidelines for reporting colorectal cancer, histopathology requests need (1) a diagram of the surgical procedure, (2) if the cancer has been detected as part of the bowel cancer screening programme, (3) the histological type of tumor if known, (4) a history of inflammatory bowel disease/ familial cancer, (5) the pre-operative stage of tumor, (6) any pre-operative therapy has been given, when it finished and its nature, (7) if open, laparoscopic or robotic surgery has been performed, the type and dissection plane of the operation.
Aims & Methods: We aimed to audit the quality of clinical information provided in colorectal cancer resection histology requests for the past 5 years in our hospital.
Data was collected for 500 patients with large bowel cancer resections between 2/12/2009 and 18/11/2014
Results: Of 498 histology request forms, only two had a diagram present (0.4%) and three (0.6%) reported that the tumor was detected in the bowel cancer screening programme. The histological type was reported in 72 out of 496 samples (14.52%) and the presence of IBD or familial cancer was reported in 2 out of 497 (0.4%). The pre-operative stage of tumor was recorded in 27 out of 496 reports (5.4%) and the pre-operative therapy given in 56 out of 496 (11.3%). Finally, the type of surgery and dissection were adequately documented in 221 out of 497 reports (44.5%).
Conclusion: Overall, the quality of reporting of clinical information in histology reports remains suboptimal. This audit identified important areas in which reporting quality needs to be improved.

P0415 PREDICTIVE FACTORS OF PARTICIPATION IN SURVEILLANCE PATIENTS WITH HIGH-RISK ADENOMAS

A. Fernandez[1], D. Zaffalon[1], A. Garcia[1], L. Marquez[1], L. Carot[1], C. Alvarez[1], X. Bessa[1], M. Andreu[1], F. Macia[2]
[1]*Gastroenterology,* [2]*Epidemiology, Hospital Del Mar, Barcelona, Spain*

Contact E-mail Address: agnesfc07@gmail.com
Introduction: A good adherence to surveillance programs of people with high-risk adenomas (AAR) is essential to reduce the incidence of colorectal cancer. Identifying predictors of participation could improve the efficiency of this program, through the implementation of improvement measures.
Aims & Methods
Objective: To evaluate the possible predictors of participation and non-participation in a program of colonoscopy surveillance of individuals with AAR, and to assess the impact of reminder measures.
Methods: Analysis of 627 cases from the population screening program of CCR from Ciutat Vella Sant Martí, who had been recommended to colonoscopy surveillance after 3 years because of having high-risk adenomas (advanced adenoma and / or multiplicity) in baseline colonoscopy performed at the Hospital del mar during the years 2010-2011. Individuals who did not participate received a phone call reminder.
Results: We identified a total of 627 cases, 418 men (66%) with average age 63.6± 5.2 years. After 3 years a colonoscopy surveillance was done in 407 cases (64.9%) and it was completed in 387 cases (95%). The causes of non-performing colonoscopy in 220 cases were: to be performed (scheduled or requested) in 131 (59%) cases, ignorance of the need of control in 26 (11.7%) cases, individual negative in 11 (5%) cases, contraindicated in 3 (1.4%) cases, in 3 cases (1.4%) changed place of living and deaths in 10 (4.5%) cases.
There were no significant differences in participation because of age, sex, toxic habits, place of birth or social status. The use of statins and regular exercise were independently associated with a greater involvement ($p = 0.035$ and $p = 0.007$). With regard to comorbidity, the presence of renal failure and dyslipidemia showed a trend towards greater participation, but not significant ($p = 0.089$ and $p = 0.09$). A phone call was performed in 114 cases, contacted in 86 patients who had not made the follow up colonoscopy (39.1%). This call led to a change of attitude in 45 cases (59.2%), mostly associated with the group that did not made because of ignorance (66%), compared to other reasons ($p = 0.001$). In the group of non-participation because of individual negative it made a change of attitude in 17% of cases.
Conclusion: The most frequent reason for non-participation in colonoscopy surveillance program in individuals with high-risk adenomas is ignorance. A phone call reminder produces a significant impact on their attitude.

Contact E-mail Address: naribo_maro@yahoo.co.jp
Introduction: After endoscopic stenting with self-expandable metallic stent (SEMS) was covered by government medical insurance in Jan. 2012, this procedure is widely adapted in Japan. With an approval of a new flexible SEMS by insurance in July 2013, we conducted a prospective feasibility study of this SMES.
Aims & Methods: Our objectives were to estimate safety and feasibility of a new SEMS placement for malignant colorectal obstruction in general clinical practice in Japan. We conducted a prospective, observational, single-arm and multicenter clinical trial from Oct. 2013 to May. 2014. This study was registered with UMIN Clinical Trial Registry (UMIN000011304). Thirty two facilities consisted of 7 academic and 25 community hospitals participated this study. Ahead of this study, we launched a website (http://colon-stent.com/) and pronounced the standard methods based on previous published data to standardize the maneuver of SEMS placement. Each patient was treated with a Niti-S Enteral Colonic Uncovered Stent, D-type. SEMSs were deployed under fluoroscopy and endoscopy. Technical success was defined as placement of the stent across the entire length of the stricture on the first attempt. Clinical success was defined as a resolution of symptoms and radiological relief of the obstruction within 24h. Patients undergoing the stenting as a bridge to surgery (BTS) were followed until surgery, and incurable patients undergoing palliative treatment (PAL) were followed until death or 12 months, whichever came first. The following conditions were considered to be complications: stent occlusion, insufficient expansion of stent, obstruction of the other gastrointestinal site, stent migration, perforation, tenesmus, abdominal pain, pneumonia and bacteremia. Complications were categorized as early (within 7 days) or late (after 7 days). In this analysis, we estimate the early complications.
Results: We registered 205 patients. Six patients were excluded for analysis, because of loose stenosis with passed by colonoscope (2), benign stricture (1), inability to visualize the tumor (1), fistula (1), and deterioration of respiratory condition during the procedure (1). We enrolled 199 patients for a BTS (112) and PAL (87) indication for a per-protocol analysis (PPA). In PPA, technical and clinical success was 98% (BTS : 99.1%, PAL : 97.7%) and 97% (BTS : 98.2%, PAL : 95.4%). Within 7 days after SEMS placement, the overall complication rate was 4.0% (3.6% BTS, 4.6% PAL), including abdominal pain (1.5%), insufficient expansion (1.5%), stent occlusion (1.0%), obstruction of the other gastrointestinal site (1.0%), stent migration (0.5%), death (0.5%) and pneumonia (0.5%). There was no perforation.
Conclusion: This study demonstrates the feasibility of a new flexible SEMS placement for malignant colorectal obstruction. Within 7days after SEMS placement, the incidence of complications was relatively low as well as no perforation.

P0417 TUMOR DIAMETER IS AN EASY AND USEFUL PREDICTOR OF RECURRENCE IN STAGE II COLORECTAL CANCER

C. Maeda[1], E. Hidaka[1], Y. Mori[1], S. Mukai[1], H. Miyachi[1], N. Sawada[1], F. Ishida[1], S.-E. Kudo[1]
[1]*Digestive Disease Center, Showa University Northern Yokohama Hospital, Yokohama, Japan*

Contact E-mail Address: maechiyo@hotmail.co.jp
Introduction: Adjuvant chemotherapy for stage II colorectal cancer can generally be administered to high-risk subgroups. The ASCO and ESMO have stated 9 risk factors associated with recurrence of stage II colorectal cancer. The risk factors are defined as patients with ≤ 12 sampled lymph nodes, a T4 lesion, perforation, poorly differentiated histology, vascular invasion, lymphatic vessel invasion, perineural invasion, obstruction, or a high carcinoembrionic antige level. To better identify these patients, we aimed to assess factors that affect recurrence.
Aims & Methods: In our hospital, 432 colon and 96 rectal stage II cancer patients who underwent surgical resection between 2001 and 2011 were divided into recurrence and non-recurrence groups. Age, sex, lymphatic vessel invasion, venous invasion, tumor diameter, tumor depth, histological type, preoperative carcinoembryonic antigen level, number of sampled nodes, adjuvant chemotherapy, morphology, surgical approach, anastomotic leakage, preoperative bowel obstruction, and preoperative perforation were retrospectively compared between the groups.
Results: For colon cancer, multivariate analysis revealed a significant association between tumor diameter ≥ 40 mm and recurrence ($p = 0.039$). For rectal cancer, multivariate analysis revealed that tumor diameter ≥ 50 mm ($p = 0.001$) and ≤ 12 sampled nodes ($p = 0.021$) were associated with recurrence. Tumor diameter in rectal cancer was associated with worse disease-free survival ($p = 0.026$).
Conclusion: Tumor diameter is a significant predictor of recurrence in stage II colorectal cancer. This is an important finding because tumor diameter is easy to evaluate clinically and might help to identify candidates for adjuvant chemotherapy.
Disclosure of Interest: None declared

Contact E-mail Address: drodrigueza@salud.madrid.org
Introduction: Due to the increased colorectal cancer (CRC) risk in patients with Serrated Polyposis Syndrome (SPS), annual surveillance colonoscopy with polyp removal is currently advised. However, incidence of neoplastic lesions under endoscopic surveillance remains poorly studied and current recommendations are based on low-quality evidence.
Aims & Methods: We aim at describing colorectal neoplasia incidence in SPS under endoscopic surveillance. From March 2013 through April 2015, SPS patients were retrospectively recruited at eighteen Spanish centers. Data were collected from medical, endoscopy and histopathology reports. We included those patients who, after a successful clearing colonoscopy, underwent endoscopic surveillance with an interval up to 3 years. Patients with total colectomy were excluded. Cumulative incidence of neoplasia [CRC, advanced adenomas, serrated polyps (SP) with high-grade dysplasia (HGD), SP ≥10mm, proximal SP and proximal sessile serrated adenomas (SSP)] was calculated by Kaplan-Meier survival analysis. Advanced SP was defined as ≥10 mm and/or SP with HGD and/or proximal SP.
Results: In 158 SPS patients with a median follow-up time of 25.6 months (range: 6.4-129.1) a total of 321 surveillance colonoscopies were performed (median: 2, range: 1-7). Mean age at SPS diagnosis was 55.5 years (SD: 10.0) and 71 (44.9%) were female. Median time between procedures was 13.7 months (range: 6.0-35.8). Four invasive CRC were detected during surveillance (3-year cumulative risk: 3.0%). Three-year cumulative incidence of colorectal polyps was as follows: advanced adenomas, 12.4%; SP with HGD, 0.9%; SP ≥10mm, 32.5%; proximal SP, 72.8%; proximal SSP, 30.8%. The cumulative risk of advanced SP under surveillance was 74.3% and 87.9% at 3 and 5 years, respectively. During follow-up, 10 (6.3%) patients were referred for surgery due to an invasive CRC (n = 4, 2.5%) or severe polyposis (n = 6, 3.8%).
Conclusion: Whereas SPS patients under endoscopic surveillance show a considerable risk of polyp recurrence, the majority of them can be managed endoscopically. Cumulative risk of CRC under close endoscopic surveillance seems to be low. Further studies are needed to define high-risk patients in order to tailor surveillance strategy.
Disclosure of Interest: None declared

P0419 ENDOSCOPIC TREATMENT ALONE OR COMPLEMENTARY SURGERY FOR T1 COLORECTAL CANCER – IS THERE STILL ROOM FOR OPTIMIZING CURATIVE RESSECTION CRITERIA?

D. Branquinho[1], N. Almeida[1], P. Monsanto[1], M. A. Cipriano[2], P. Amaro[1], F. Portela[1], L. Prado[2], C. Sofia[1]
[1]*Gastroenterology,* [2]*Pathology, Coimbra University Hospital (CHUC), Coimbra, Portugal*

Contact E-mail Address: diogofbranquinho@yahoo.com
Introduction: Up to 9% of colorectal polyps may conceal an adenocarcinoma with submucosal involvement (Malignant Polyp). Careful surveillance or complementary surgery after endoscopic are accepted treatment strategies. Identifying high-risk patients remains challenging, as oncologic results are a priority while unnecessary surgery should be avoided
Aims & Methods: Our objective was to evaluate oncologic results of endoscopic excision of T1 colorectal with or without complementary surgery.
A total of 121 patients were included between 2003-2007 and 2010-2014 (male patients – 74.4%; average age – 68.5 ± 10.6 years; follow-up: 30 ± 20 months). Clinical, endoscopic and histological features were analyzed. Unfavorable outcome was defined as residual lesion after endoscopic excision, regional or distant metastasis, recurrence or disease-related deaths.
Results: All 121 identified lesions were subject to endoscopic treatment. About 43.4% (53/121) of those were submitted to surgery as well. The most relevant criteria for surgical referral were the presence of lymphatic/vascular invasion ($p = 0.001$), involved margins ($p = 0.014$) and being under 65 years-old ($p = 0.02$). Residual cancer cells were identified in only 12.2% of surgical specimens (7/53) and 10.7% of patients had an unfavorable outcome. Univariate analysis revealed that incomplete or piecemeal endoscopic excision ($p = 0.046$), free margin < 1 mm ($p = 0.028$) and the need for surgical treatment ($p = 0.012$) are associated with an unfavorable prognosis.
There was no significant difference in procedure-related complications between the two groups (surgery *vs* endoscopy alone), with one death due to perforation during an endoscopic procedure.
Conclusion: Overall, we can affirm that the treatment of these lesions is safe and efficacious. However, the presence of incomplete endoscopic excision, positive margins and the need of complementary surgery is associated with worse prognosis. The large majority of surgical specimens had no residual cancerous lesion, suggesting that criteria for referral should be improved in order to avoid unnecessary surgery.

Giuseppe, Albano L., Rome, Italy,* [2]*Endoscopy Division, National Cancer Center Hospital,* [3]*Department of Gastroenterology & Hepatology, Tokyo Medical University, Tokyo, Japan,* [4]*Surgical Digestive Endoscopy, Catholic University, Rome,* [5]*Anesthesiology Unit, Ospedale S. Giuseppe, Albano L., Rome, Italy*

Contact E-mail Address: federico.iacopini@yahoo.it
Introduction: Endoscopic submucosal dissection (ESD) achieves significantly higher en bloc and R0 resection rates than endoscopic mucosal resection (EMR) and represents the best technique to achieve the curative resection of gastrointestinal superficial neoplasms. Although a level of competence can be achieved in the Western world through a stepwise training, it is unclear if it is sufficient to safely adopt ESD for colorectal lesions.
Aims & Methods: Aim was to identify pre-operative patient and lesion features prognostic of successful ESD. A prospective single center study conducted by an endoscopist who achieved an initial level of competence in colorectal ESD. Inclusion criteria were: colorectal neoplasms either ≥15 or ≥20 mm associated or not to a scar, respectively; no features of SM-deep invasion (pit pattern V associated with a demarcation area). ESD was performed by the standard technique without expert supervision. The multivariate analysis was used to identify prognostic variables of successful ESD (en bloc resection). The following variables were evaluated: patient age and sex; location in different colorectal segments; location on fold; morphology; size (cm2); nodularity (>20 mm); scar of a previous resection; endoscopist experience.
Results: From March 2010 to July 2014, ESD was attempted in 106 patients (mean age 66; females 43%) for 114 lesions (median size 10 cm^2, range 1-85). Lesions were 85 (75%) in the colon, 29 (25%) in the rectum; LST-G 70 (61%), LST-NG 35 (31%), Is 9 (8%); with scar 11 (10%) and a nodule in 27 (24%).
En bloc, R0, and curative resection rates were achieved in: 92 (81%), 90 (79%), 86 (75%). SM invasion was diagnosed in 13 (11%). Perforation occurred in 5

Abstract number: P0423
Comparison between EMR-C and conventional EMR, EMR-C and ESD for all rectal neuroendocrine tumors.

Number of lesions	EMR-C (n = 34)	EMR (n = 56)	*p*-value(EMR-C Vs. EMR)	ESD(n = 32)	*p*-value(EMR-C Vs. ESD)
Lesion size, mean ± S.D. (range), mm	5.3 ± 1.6 (2–8)	5.0 ± 1.8 (2–13)	0.354	9.1 ± 2.2 (6–14)	< 0.001
En bloc resection, n (%)	34 (100)	56 (100)	NA	32 (100)	NA
Procedure time, mean ± S.D., minutes	4.2 ± 2.0	2.1 ± 1.2	0.002	19.8 ± 11.3	0.002
Histologic complete resection, n (%)	32 (94.1)	43 (76.8)	0.032	30 (93.8)	> 0.999
Intraprocedural bleeding, n (%)	3 (8.8)	0	0.051	4 (12.5)	0.705
Postprocedural bleeding, n (%)	1 (2.9)	1 (1.8)	> 0.999	1 (3.1)	> 0.999
Perforation, n (%)	0	0	NA	0	NA

(4%) without precluding a successful ESD in 3. Prognostic variables of successful ESD in colon at the multivariate analysis are reported in the Table; no significant variables were identified for rectal ESD.

	OR (95% CI)	P =
Age	1.11 (1.01-1.23)	0.037
Location in fixed looping segments	0.14 (0.02-0.78)	0.025
Size diameter > 40 mm	0.08 (0.01-0.46)	0.005
Scar presence	0.02 (0.01-0.33)	0.007

Conclusion: A level of competence in colorectal ESD is not sufficient for a widespread adoption of ESD in the colon. Superficial neoplasms at a very high level of difficulty for ESD are colonic either located in the cecum or flexures, larger than 40 mm, and associated with a scar. Western endoscopists without expert supervision should avoid ESD of very difficult lesions until an expertise level has been achieved.

P0421 THE THERAPEUTIC EFFECT OF IRREVERSIBLE ELECTROPORATION ABLATION IN MOUSE MODEL OF COLORECTAL CANCER

H. S. Choi[1], H. J. Chun[1], I. K. Yoo[1], J. M. Lee[1], S. H. Kim[1], E. S. Kim[1], B. Keum[1], Y. T. Jeen[1], H. S. Lee[2], C. D. Kim[2], J. Y. Kim[3]
[1]*Internal Medicine, Institute of Gastrointestinal Medical Instrument Research, Korea University College of Medicine,* [2]*Internal Medicine,* [3]*Pathology, Korea University College of Medicine, Seoul, Republic of Korea*

Introduction: Irreversible electroporation (IRE) is a promising novel technique for the ablation of tumors. IRE has an advantage over other ablation techniques in its mechanism to remove undesired cells by affecting the cell membrane without thermally destructing blood vessels, nerves and the surrounding tissues. Studies regarding the clinical application of IRE have been performed in humans, as well as in animals, for organs such as the liver, kidney, prostate, etc. and IRE is now accepted as a novel anti-cancer ablation modality.
Aims & Methods: The aim of this study was to evaluate the therapeutic effect of IRE in mouse model of colorectal cancer for the first time. The Caco2 cells (ATCC) were cultured in petri-dishes. Male nude mice (Immunodeficient (CAnN.Cg-Foxn1 nu/CrljBgi) 6 weeks old, Orient inc., Korea) were introduced. Caco2 cells were each visually injected at 1.0 x 10^7 cells/ml into both flakes (one for control, the other for IRE). We performed in vivo IRE procedures in the tumors of nude mouse model. Electrical pulses were applied to the tumor of nude mouse using a DC generator at 1∼2kV/cm amplitude, 20∼50 pulses, 100 < length, with 1mm separation between two needle type electrodes. We analyzed the tissues with H&E staining and TUNEL assay immediately afterwards, and then 10 hours, 24 hours.
Results: All mice were preserved during the experiment without significant complications. There was complete cell death within the IRE lesions without intervening live cells. Variable nucleic changes-pyknosis and karyohexis, and vacuolar degeneration were observed only within the IRE lesions. The framework of extracellular matrix and blood vessels were not affected by IRE. The apoptotic area and signals were increased in IRE groups comparing control groups in tunnel assay.
Conclusion: The present study demonstrated that IRE ablated colon cancer tissue very effectively through the induction of cellular apoptosis. This study suggests that IRE is the potential use of IRE in gastrointestinal cancer patients.

Introduction: Statin has been ascribed not only to their cholesterol lowering effect but also to their pleiotropic actions including anti-inflammatory and anti-oxidant effects as well as anti-neoplastic effect. Nrf2 (NF-E2-related factor 2) is a transcription factor that control the transcriptional response of cells to oxidative stress. There are little known how statins affect activation of Nrf2 and Nrf2 signaling pathway in colon cancer cells.
Aims & Methods: We investigated the effect of simvastatin on expression of Nrf2 and nuclear translocation of Nrf2 in two colon cancer cell lines, HT-29 and HCT 116 by cell proliferation assay, western blotting and immunocytochemical analysis. We also investigated which signal cascade such as ERK or PI3K pathway control nrf2 activation and whether simvastatin affects induction of antioxidant enzymes (heme oxygenase-1 (HO-1), NAD(P)H: quinine oxidoreductase 1 (NQO1), γ-glutamate-cysteine ligase catalytic subunit (GCLC)).
Results: We demonstrated simvastatin induced dose-dependent upregulation of Nrf2 expression and anti-oxidant enzymes (HO-1, NQO1, and GCLC) in HT-29 and HCT 116 cells. We demonstrated that simvastatin stimulated Nrf2 nuclear translocation. In addition, PI3K/Akt inhibitor (LY294002) and ERK inhibitor (PD98059) blocked simvastatin induced Nrf2 and HO-1 expression in both HT-29 and HCT 116 cells.
Conclusion: In this study, we show that simvastatin induces Nrf2 activation and nuclear translocation of Nrf2 and expression of anti-oxidant enzymes via ERK and PI3K/Akt pathway in colon cancer cells.

Introduction: The incidence of rectal neuroendocrine tumors (NETs) is increasing, and most rectal neuroendocrine tumors with a size < 15 mm can be treated endoscopically. Given that almost all rectal NETs involve the submucosal layer or deeper layers of the rectal wall, conventional endoscopic mucosal resection (EMR) may not be suitable for achieving high en bloc and histologic complete resection. Cap-assisted endoscopic mucosal resection (EMR-C) was suggested as an effective treatment for rectal NETs in a few studies.
Aims & Methods: We aimed to compare the outcomes of conventional endoscopic mucosal resection (EMR), EMR-C resection, and endoscopic submucosal dissection (ESD) for the treatment of rectal NETs. A total of 138 rectal NETs < 15mm in diameter were treated endoscopically by a single endoscopist at Asan Medical Center from 2009 to 2014. We retrospectively analyzed 122 rectal NETs that had been removed using EMR (n = 56), EMR-C (n = 34), or ESD (n = 32) methods.
Results: The mean size of the rectal NETs was larger in the ESD group (9.1 ± 2.2 mm; range, 6–14 mm) than in the EMR group (5.0 ± 1.8 mm; range, 2–13 mm) and the EMR-C (5.3 ± 1.6 mm; range, 2–8 mm) group ($P < 0.001$). Six (4.9%) of one hundred and twenty-two lesions were larger than 10 mm in size (five in the ESD group and one in the EMR group). The histologic complete resection rate was higher in the EMR-C group than in the EMR group (94.1% vs. 76.8%, $P = 0.032$). Intraprocedural bleeding tended to be more frequent in the EMR-C group than in the EMR group (8.8% vs. 0, $P = 0.051$). All intraprocedural bleeding was controlled easily during the endoscopic procedure. No differences in the rates of adverse events or histologic complete resections were observed between the EMR-C group and the ESD group for 6–8 mm sized NETs; however, the procedure time was significantly shorter in the EMR-C group (3.9 ± 1.1 mm) than in the ESD group (19.0 ± 12.1 minutes) ($P < 0.001$). Meanwhile, the role of EMR-C in the treatment of rectal NETs larger than 8 mm could not be clearly assessed in this study. No recurrence occurred in any of the three groups.

Conclusion: EMR-C is the most advisable technique for endoscopic resection of rectal NETs with sizes equal to or smaller than 8 mm.

Introduction: The usefulness of postoperative carcinoembryonic antigen (CEA) monitoring and improvements in imaging techniques have renewed enthusiasm for second-look operation (SLO) as the most effective treatment for recurrent colorectal cancer by reresection following early detection. The aim of our study is to evaluate the role of CEA and imaging techniques-directed SLO.
Aims & Methods: Seven hundred fifty-six patients with Dukes stages B and C, who had undergone curative resection, were monitored postoperatively using CEA and imaging techniques. An SLO was performed on any potentially resectable recurrence, and in addition, an SLO was done when a persistently rising CEA value was detected.
Results: Recurrence developed in 18.8% (142/756) of patients, and 90.8% (129/142) of the recurrences were detected within the first 3 years following curative resection. When comparing carcinomas of the colon with that of the rectum, the former were associated with significantly more hepatic and intraabdominal recurrences, whereas the latter had significantly more locoregional and pulmonary recurrences. Seventy-two patients underwent SLO. Of these patients, 54.2% (39/72) had all of their disease resected, and 1.4% (1/72) had no detectable disease at the SLO. Among the142 patients with recurrence, 71 (50%) patients underwent SLO. The resectable group at SLO carried a significantly better survival than the unresectable recurrence group (41.3 vs. 5.2%; $P < 0.01$).
Conclusion: Complete removal of colorectal cancer recurrences by SLO, on the basis of postoperative, follow-up CEA and imaging technique findings, results in improved survival.

Introduction: The colorectal endoscopic submucosal dissection (CR-ESD) procedure is very technically demanding because of the inherent histological and anatomical features of the human colorectum. Clinically, endoscopists should learn to perform CR-ESD on the rectum because of the lower risk of perforation and less difficulty. Training using an animal model is generally recommended before performing a CR-ESD in human. We reported the similarities of histological characteristics between the bovine rectum (B/R) and the human rectum. In light of those findings, we created a novel animal training model using B/R, which reproduces the colorectal shape and elasticity of the human colorectum. This model was made using a sponge and a B/R of appropriate length fitted in a model. The maneuverability and feeling of the ESD procedure in this model were extremely similar to that in human CR-ESD. In addition, the anatomical features of the human colorectum, including the thinner wall, the narrow lumen, the presence of angulations, and haustra folds were reproduced in this model.
Aims & Methods: Aim: To assess the utility of a new animal training model for CR-ESD.
Methods: Study1: Two endoscopists (E1, E2) without experience performing CR-ESD but with some experience in gastric ESD performed the ESD of 3-cm artificial lesions in 28 consecutive sessions using this colorectal ESD training model. The speed of the ESD procedure (s/cm^2), the injury score of the muscularis propria layer (MP) (scoring 1–4: 1, no damage; 2, injury to the surface of the MP; 3, laceration of the MP; 4, perforation), the injury score of the resected specimen (1, no damage; 2, injury to marking spot; 3, cut into the resected specimen), and the rate of perforation were recorded. We evaluated the effects of this training model by comparing the results of the first 14 sessions (former period; FP) with those of the last 14 sessions (latter period: LP). Study2: A follow-up survey was performed for the clinical outcomes of the first 5 cases of colorectal ESD carried out by those two endoscopists (E1, E2). For evaluating the technical aspects of the ESD procedure, size of the lesions, procedure time, en bloc resection rate, R0 resection rate and complications were evaluated.
Results: Study1: The speed of the ESD procedure were significantly faster in the LP compared to the FP in all endoscopists: mean procedure speed (FP/LP) (s/cm^2): E1, 397/195 ($p = 0.044$); E2, 421/302 ($p = 0.02$). The MP injury scores were significantly lower in the LP than the FP in both endoscopists ($p = 0.046$, $p = 0.0071$). The injury score of resected specimen were also significantly lower in the LP than the FP in both endoscopists ($p = 0.046$, $p = 0.0062$, respectively). Study2: The median size of the lesions were 32 (20-40) mm for E1 and 22 (12-34) mm for E2. The median procedure times were 51 (10-115) min for E1 and 57 (32-74) min for E2. En bloc resection rate were 100% (5/5) for both endoscopists, R0 resection rate were 100% (5/5) for E1 and 80% (4/5) for E2. There were no complications.
Conclusion: The utility of the novel ex vivo animal training model using B/R was demonstrated. This model has the potential to simulate CR-ESD with great similarity to that performed in humans and contribute to a safe induction of clinical colorectal ESD.

Introduction: The involvement of peroxisome proliferator-activated receptors (PPARs) in the cancer cell apoptosis is a generally accepted fact. However, some reports indicate that the activation of PPARγ might be directly responsible for carcinogenesis. It is well known that the high level of heat shock proteins (HSPs) in cancer cells is associated with metastasis, poor prognosis and the resistance to radio as well as chemotherapy. HSP70 as a part of the most important systems for maintaining the viability of the cell, is known to counteract against the apoptosis. Here we report the involvement of HSP70 in anti-apoptotic action of activated PPARγ in γ-irradiated human colon cancer cells.
Aims & Methods: We have employed undifferentiated Caco-2 cells cultures as an experimental model of human colon adenocarcinoma. In this system PPAR-γ agonists (ciglitazone 1x10-6M and retinoic acid RA, 1x10-6M) induced nuclear translocation of PPAR-γ as well as HSF-1. This translocation was followed by the increase of HSP70 mRNA and protein expression. As it had been previously shown by us, cell cultures subjected to γ-radiation (photons) using the therapeutic dose of 2.5 Gy, manifested typical for apoptosis PARP degradation pattern, presenting both the native 112 KD and digested 85 KD forms. It suggests activation of caspases 3 or 6.
Results: Stimulation of the cultures with PPARγ agonists prior to the irradiation eliminated PPAR-γ nuclear translocation and PARP degradation altogether. PPARγ was found to be sequestered in the complexes with AKT-1 in cytoplasmic as well as in nuclear pool. However γ-radiation did not affect PPAR-γ agonists stimulated HSF-1 translocation and subsequent HSP70 expression. Based on the obtained results, we would like to propose a plausible molecular mechanism of chemo- and radio- resistance of colon cancer cells. In γ-irradiated cells, nuclear translocation of PPARγ is abolished and PPARγ-AKT-1 complexes are conserved in which PPARγ remains insensitive for its agonists treatment. Most likely, at the same time PPARγ agonists directly activate HSF-1 nuclear translocation and subsequent HSP70 expression. The process seems to be undisturbed by the γ-irradiation what renders the colon cancer cells resistance to apoptosis under combined chemo- and radiotherapy treatment.
Conclusion: Our results provide evidences for the anti-apoptotic action of PPARγ agonists used simultaneously with the γ-radiation due to the formation of stable complexes of PPARγ with AKT-1 in which PPARγ was restrained in inactive form. Moreover, the up-regulated HSP70, in response to PPARγ agonists in γ-irradiated cultures promotes cell survival.

Introduction: Diet, health and disease is one of the most frequent and less comfortable questions gastroenterologists are asked about. The role of diet in physiopathology and treatment of IBS is still under-evaluated. A predominantly vegetable diet is commonly associated with bloating and flatulence. Vegetarianism may affect gut microbiota, intestinal peristalsis and inflammation. A balanced vegetarian diet may have some health benefits, but which is its influence on IBS?
Aims & Methods: We use a case-control design; patients with IBS were selected by purposive sampling; vegetarians were recruited from gastroenterologist offices, vegetarian and health food sites, the Vegetarian Society, and from friends and relatives of participants; the control sample was randomly selected from the general population. A questionnaire was delivered to all subjects to reveal recent gastrointestinal symptoms (using GSRS), to diagnose IBS (using Rome III criteria) and to evaluate eating habits (a food frequency questionnaire based on a validated European Prospective Investigation of Cancer protocol). We conducted descriptive, bivariate, and multivariate analysis to examine the associations between food habits and IBS.
Results: We compared 47 cases of IBS patients with a control group ($n = 104$) from the same community. Among IBS patients, only 8.5% were vegetarians and

among vegetarians only 8.8% were diagnosed with IBS (OR = 0.14, 0.04-0.42, CI 95%, $p < 0.001$), since the prevalence of IBS in general population was 15.8%. Among potential risk factors in the study, age, past history of digestive disease, canned food, processed meat, whole cereals and pulses were statistically significant predictors of IBS.
Conclusion: Although some vegetable foodstuffs can exacerbate digestive symptoms, a well-balanced and customized vegetarian diet can be a protective factor for IBS.

P0429 EXCESS MEDICAL DIAGNOSES IN FAMILIES OF PATIENTS WITH IRRITABLE BOWEL SYNDROME (IBS)

O. S. Palsson[1], M. van Tilburg[1], W. Whitehead[1]
[1]*Medicine, University of North Carolina, Chapel Hill, United States*

Contact E-mail Address: opalsson@med.unc.edu

Introduction: Previous studies have shown that IBS patients as a group have an excess of co-morbid chronic medical conditions. Past work has also indicated intergenerational transmission of illness and evidence if illness modeling and/or reinforcement in IBS. However, the general amount of chronic illness in IBS families of origin has not been well documented to date.
Aims & Methods: We aimed to test whether the frequency of chronic medical problems in IBS families of origin is elevated and whether it is related to amount of IBS co-morbidities, associated with IBS morbidity and poorer current disease coping, and whether there is evidence of illness modeling. 530 IBS patients (Rome II or III criteria+ physician diagnosis; 79.4% females; mean age = 35.8 years) and a sample of 337 demographically similar control subjects without gastrointestinal problems (78.7% females; mean age = 34.7 years) reported whether they themselves, their mother, father or siblings had ever been diagnosed with 12 chronic medical conditions (in addition to IBS and psychiatric conditions) on the validated Comorbid Medical Conditions Questionnaire – CMCQ. Subjects also completed the IBS Severity Scale Score (IBS-SSS), the IBS-QOL, the Visceral Sensitivity Index (VSI) and the Catastrophizing subscale of the Coping Strategies Inventory.
Results: IBS patients reported more medical conditions in their families than healthy subjects (Means: 2.86 vs. 1.39; $p < .0001$). Seven of the 12 medical conditions were more common in IBS families than control families (see Table). Amount of medical co-morbidities of IBS patients correlated robustly with co-morbidity amount in their mothers (Spearman's Rho = 0.42), fathers (Rho = 0.25) and siblings (Rho = 0.42); $p < 0.0001$ for all. These associations were also significant for male and female IBS patients analyzed separately. IBS patients also reported substantially higher rates of family IBS than controls: Overall 27.2% vs. 7.0%, Odds Ratio = 4.9; mothers 16.1% vs. 3.7%; fathers 6.9% vs. 1.3%; and siblings 13.8% vs. 2.6%; $p < 0.0001$ for all. The number of medical conditions in mothers and siblings of IBS patients was modestly but significantly correlated with more severe IBS (Rho = 0.15 and 0.20) and greater IBS-QOL impairment (Rho = -0.11 and -0.09) in the patients. VSI and Catastrophizing were unrelated to amount of family medical conditions.

Chronic medical diagnoses in families of IBS patients versus control subjects (* = $p < 0.05$):

	IBS families (%)	Control families (%)	Odds Ratio
Fibromyalgia	7.6*	3.0	2.64
Asthma	22.5	19.6	1.19
TMJ	14.8*	5.7	2.84
Chronic fatigue	5.3*	0.9	6.06
Migraines	38.3*	20.2	2.45
Tension Headaches	38.9*	18.5	2.81
Insomnia	27.9*	12.4	2.74
Back pain	32.7*	20.3	1.91
Chronic Pelvic Pain	3.2	1.2	2.60
Interstitial Cystitis	2.0	1.2	1.62
Prostatitis	5.3	3.0	1.79
Dysmenorrhea	5.5	2.7	2.08

Conclusion: IBS patients report an excess of chronic medical conditions in their immediate family compared to controls, and the illness amount in the family is correlated with patients' own co-morbidity load. No evidence of impact of family medical illness on maladaptive coping or visceral anxiety, nor of gender-specific modeling influences, were observed. Our findings need to be confirmed by surveying family members of IBS patients and controls directly about their medical history in future work. [Supported by grant RO1 DK31369]

Introduction: Irritable bowel syndrome is a prevalent disorder with a marked socioeconomic burden. Previous studies support the proposal that a subset of patients with features compatible with diarrhoea predominant IBS (IBS-D) have bile acid malabsorption (BAM).
Aims & Methods: The objective of this study was to perform a systematic review and meta-analysis to assess the prevalence of BAM in patients meeting accepted criteria for IBS-D. MEDLINE and EMBASE were searched up to February 2015. Studies recruiting adults with IBS-D, defined either by the Manning, Kruis, Rome I, II or III criteria and which used 23-seleno-25-homotaurocholic acid (SeHCAT) testing for the assessment of BAM were included. BAM was defined as 7 day SeHCAT retention of < 10%. We calculated the rate of BAM and 95% confidence intervals (CI) using a random effects model. The methodological quality of included studies was evaluated using the Quality Assessment for Diagnostic Accuracy Studies (QUADAS-2).
Results: The search strategy identified 6 relevant studies comprising 908 individuals. The rate of BAM ranged from 16.9% to 35.3%, with an unadjusted rate [AF1] of 29.3%. The pooled rate was 28.1% (95% CI 22.6-34%). There was significant heterogeneity in effect sizes (Q-test $\chi^2 = 17.9$, $p < 0.004$; I^2 72.1%). The type of diagnostic criteria used or study country did not significantly modify the effect.
Conclusion: These data provide evidence that in excess of one quarter of patients meeting accepted criteria for IBS-D have BAM. This distinction has implications for the interpretation of previous studies as well as contemporaneous clinical practice and future guideline development.

Contact E-mail Address: annikka.polster@gu.se

Introduction: Despite capacious research on IBS, the pathophysiology remains unclear and therapy options are sparse. Identifying subgroups of patients with a distinct profile may improve targeted research and development of individually tailored treatment options, as has been demonstrated in functional dyspepsia [1]
Aims & Methods: We included 164 patients with IBS defined by the Rome III criteria (mean age 34, range 18-62 years, 69% female). A crossvalidated Principal Component Analysis formed the basis for hierarchical clustering of patients based on symptom profiles. To model the symptom profile the following validated questionnaires were used: Gastrointestinal Symptom Rating Scale-IBS (GSRS-IBS) (individual items), bowel-related questions of the Rome III questionnaire, pain-related questions from the IBS Symptom Severity Score (IBS-SSS), and the average stool form during two weeks measured by the Bristol Stool Form Scale. An ANOVA with post-hoc t-tests (Bonferroni corrected) was applied to compare the clusters on the following measures: Pain intensity and pain thresholds measured by a rectal barostat procedure, oroanal transit time (radiopaque markers). Severity of anxiety and depression (Hospital Anxiety and Depression Scale (HAD), chronic fatigue (Fatigue Impact Scale (FIS), IBS-related quality of life (IBSQOL) and Sense of Coherence (SOC) were also compared between the clusters.
Results: The combination of symptom-based measurements was modelled with an optimized fit of three principal components, giving an R^2 of 0.4, regarded as a very robust model for patient data. Hierarchical clustering defined three major clusters: One group (16.5%) showed low severity scores for all modelled symptoms, two groups showed distinctly higher than average scores on either

constipation (48.8%) or diarrhea (34.8%) measures. The two distinct-symptom groups showed significantly higher pain intensity and lower pain threshold measures, higher anxiety, depression and fatigue levels and lower scores for SOC and QOL when compared to the low-symptom IBS patients. The high constipation group also had significantly longer oroanal transit time than the other two, but the high diarrhea group did not differ from the low symptom group.

	Constipation group	Diarrhea group	Low symptoms group	Significance
Oroanal transit time	1.9 days^#	1.1 days*	1.0 days*	<0.0001
Pain intensity(VAS)	52 mm^	52 mm^	18 mm*#	<0.0001
Pain threshold	26 mmHg	26 mmHg^	31 mmHg#	0.05
Anxiety (HAD)	8	9^	6#	0.03
Depression (HAD)	5^	5	3*	0.03
FIS	65^	56^	31*#	0.001
SOC	131^	127^	150*#	0.01
QOL	59^	54^	79*#	<0.0001
GSRS Abd Pain	4.4^	4.7^	2.5*#	<0.0001
GSRS Bloating	4.9^	4.6^	3.2*#	<0.0001
GSRS Constipation	3.9^#	2.1^*	1.7*#	<0.0001
GSRS Diarrhea	3.2^#	5.1^*	2.5*#	<0.0001
GSRS Satiety	2.8^	2.9^	1.6*#	0.001

*vs Const, # vs Diarr, ^vs low symptoms

Conclusion: Symptom-based cluster analysis confirms previous grouping into constipation- and diarrhea-predominant groups, but also shows a low overall symptoms group, similar to what has been shown in functional dyspepsia [1]. This might reflect differences in pathophysiology and thus have impact on therapy strategies.

P0432 THE OVERLAP BETWEEN CONSTIPATION PREDOMINANT IRRITABLE BOWEL SYNDROME AND FUNCTIONAL CONSTIPATION IN PATIENTS ASSESSED FOR PELVIC FLOOR DISORDERS

M. Beer-Gabel[1], E. Bardan[1], **D. Carter**[1]
[1]*Gastroenterology, Chaim Sheba Medical Center, Ramat Gan, Israel*

Contact E-mail Address: dr.dancarter@gmail.com

Introduction: According to ROME III criteria, Pelvic floor symptoms (PFD) are incorporated into functional constipation, and strictly differed from constipation related IBS (c-IBS). However, abdominal pain was previously reported in patients reporting PFD

Aims & Methods: The aim of this study was to assess the incidence and type of IBS-related symptomatology on registration of those patients presenting with PFD and symptoms of chronic constipation.

Methods: All patients referred for the assessment and evaluation of PFD were analyzed by specific questionnaires including the Rome III criteria and the bowel component of the Birmingham Bowel and Urinary symptom questionnaire – BBUS-Q22 for IBS symptomatology. Patients were further assessed with dynamic transperineal ultrasonography or X-ray defecography, conventional station pull-through anorectal manometry and balloon expulsion test.

Results: Two hundred consecutive patients were included in the study (mean age 51.6 years, range 22-85 years).Reclassification of patients resulted in 167 patients (83.5%) being designated with IBS. Sixty six percent of patients reported regular improvement of symptoms with defecation with 55% noting symptoms associated with a change of stool form and 71% with fewer stools. There were significant differences noted in reporting of hard stools by those patients redesignated as IBS-PFD and a high percentage of reported soft stool in the FC-PFD patients. Repeated straining was more common in the IBS-PFD group as was fecal urgency, a sensation of defecation block and episodes of reported incomplete bowel emptying. The frequency of bowel movements between the groups was similar. There was no significant difference between the IBS-PFD and FC-PFD groups in the incidence of pelvic floor abnormalities. Anismus was diagnosed frequently in both groups, but was more prevalent in the IBS group (P = 0.03).

Conclusion: The key outcome of this study is that PFD can be related to IBS as well as to FC. The reclassification of the majority of patients with PFD as also having significant IBS symptomatology might have important ramifications for eatment and functional outcome.

Contact E-mail Address: daniel.pohl@usz.ch

Introduction: Irritable Bowel Syndrome (IBS) is associated with an increased postprandial symptom response to a 25g combined lactulose nutrient challenge test compared to healthy controls (1). Co-morbid Functional Dyspepsia (FD) is highly prevalent in IBS, but is not regularly taken into account. Our aim was to investigate the relationship between co-morbid FD status and the time course of the postprandial symptom response to this test.

Aims & Methods: 205 IBS patients (Rome III), 94 (46%) of whom had co-morbid FD (Rome III), and 83 healthy volunteers (HV) consumed a 400-ml liquid breakfast (Nutridrink, 1.5 kcal/ml, 16% proteins, 49% carbohydrates, 35% fat, gluten free, lactose < 0.025 g/100 ml) combined with 25g of lactulose after an overnight fast. They completed graded rating scales (0-20) assessing severity of five gastrointestinal (GI) symptoms (abdominal pain, bloating, nausea, gas, urgency) and overall "digestive comfort" before breakfast and every 15 minutes up to 240 minutes postprandially. The relationship between subject status (HV, IBS, IBS + FD) and the course of GI symptom scores over time was analyzed using linear mixed models. "Time" was included as a categorical within-subject effect, "group" (HV, IBS, IBS + FD) was included as categorical between-subject effect, and the group-by-time interaction effect was also included. The main effect of group and the interaction effect are the effects of interest.

Results: A significant main effect of group, indicating a significant difference between the three groups in the average symptom level over time, was found for all symptoms (all p < .0001). Post-hoc tests showed significant differences for all pairwise comparisons between the three groups (all p < .05, stepdown Bonferroni corrected), including the IBS versus IBS + FD comparison. A group-by-time interaction effect was found for pain (p = .002), bloating (p = .0008), urgency (p = 0.019), and digestive comfort (p = .002), but not for gas (p = .07) or nausea (p = .52). Planned comparisons on the significant interaction effects showed that in HV, contrary to IBS and IBS + FD, no postprandial increase in ratings was found for any of the symptoms, resulting in significant differences at all time points (all p < .0001, stepdown Bonferroni corrected) between HV on one hand and both IBS and IBS + FD on the other hand. Differences between IBS and IBS + FD were found at all time points for pain and digestive comfort (all p < .001 and p < .05, stepdown Bonferroni corrected, respectively), up to 2 hours postprandially for bloating (all p < .05, stepdown Bonferroni corrected) and at 30 minutes postprandially only for urgency (p = .005, stepdown Bonferroni corrected).

Conclusion: In IBS, co-morbid FD is associated with increased GI symptom reporting, both preprandially and after a combined lactulose nutrient challenge test, particularly for the symptoms pain, bloating, urgency, and is associated with decreased overall digestive comfort reporting. These results indicate that presence of co-morbid FD is relevant for symptom reporting in IBS.

Introduction: This is the first study to assess the diagnostic and therapeutic management of moderate-to-severe IBS-C in six European countries (France, Germany, Italy, Spain, Sweden and UK). Here we present the pooled results from all participating countries.

Aims & Methods: Observational study in patients diagnosed with IBS-C (Rome-III criteria) in the last five years and moderate-to-severe disease severity at inclusion (IBS-Symptom Severity Scale [IBS-SSS] score ≥175), with a 12-month follow-up (6 months retrospective and 6 months prospective), in order to assess healthcare resource utilisation (HRU) and costs prior to and after an active phase of the disease. Diagnostic procedures were collected since the onset of symptoms. The study began in April 2012; last patient last visit: January 2014.

Results: 525 patients were included (60% severe, mean age [±SD] 45.3 ± 15.8 years old, 86.9% female). Mean time since diagnosis: 3.0 ± 5.2 years; mean symptom duration: 12.8 ± 13.1 years. Diagnostic procedures since the onset of symptoms were highly variable: the most common were blood tests (71.6%; range: 88.9% Sweden– 57.6% France); colonoscopy (62.9%; range: 78.4% Germany–41.1% Italy); abdominal ultrasound (54.7%; 62.7% Germany–36.1% Sweden).

Abstract number: P0436 Table 1: Serum cytokines and mucosal mRNA expression in healthy controls and IBS patients.

Serumcytokine(pg/ml)	IBS(n = 144)	Healthy(n = 42)	*p*-value†
IL-6	0.4 (0.28-0.68)	0.34 (0.24-0.54)	0.06
IL-8	11.3 (7.51-14.41)	9.1 (6.49-13.15)	0.12
IFN-γ	8.0 (5.1-12.1)	10.9 (6-15.3)	0.07
Mucosalcytokine($2^{-\Delta Ct}$)	**IBS(n = 109)**	**Healthy(n = 36)**	***p*-value†**
IL-10	$8.6x10^{-5}$ ($6.9x10^{-5}$-$1.1x10^{-4}$)	$9.6x10^{-5}$ ($7.8x10^{-5}$-$1.3x10^{-4}$)	0.05
FOXP3	$2.5x10^{-4}$ ($1.8x10^{-4}$-$3.5x10^{-4}$)	$3.1x10^{-4}$ ($2.2x10^{-4}$-$3.7x10^{-4}$)	0.07

†Mann Whitney U test. Data shown as median (25% > 75%)

The main associated comorbidities were anxiety (34.1%), dyspepsia (31.0%), headache (28.0%), and insomnia (27.0%). 62.1% (74.1% Italy–57.6% France) of patients had an average of 4.0 ± 2.7 diagnostic tests (4.5 ± 3.0 Italy–3.4 ± 2.7 France) during follow-up and 65.3% took prescription drugs for their IBS-C (90.4% UK–41.1% Italy). The most commonly prescribed medications were laxatives (48.8%), antispasmodics (19.8%), and prokinetics (18.9%). 20.4% took other medications. Specifically, laxatives were prescribed as a monotherapy (14.1%), in combination with antispasmodics (6.3%) or with another drug that was not an antispasmodic, antidepressant, or prokinetic (10.7%). Overall, 67.2% of patients took non-prescription medication for their IBS-C (82.1% Italy–56.3% Spain) (33.0% laxatives; 24.2% pre/probiotics, 19.6% herbal medicine) and 33.0% of patients sought complementary therapies (44.4% Sweden–27.5% Germany). Overall, marginal improvement was noted in symptom severity (IBS-SSS total score ± SD) between baseline (323.2 ± 84.3) and the 6-month visit (253.9 ± 105.6, 76.1% moderate-to-severe; 85.4% France–67.3% Italy).
Conclusion: IBS-C symptoms remain undiagnosed for an average of almost 10 years and there is a high degree of variability in diagnostic and management procedures between European countries. Over half of the patients continued to undergo diagnostic tests after a diagnosis has been reached and the degree of control did not improve over time despite a high level of prescription and non-prescription medication use. At the end of the study over three quarters of patients still suffered from moderate-to-severe IBS-C.

P0435 CLASSIFICATION OF IRRITABLE BOWEL SYNDROME – A CRITICAL EXPLORATION OF THE ROME III CRITERIA

K.-A. Wensaas[1], K. Hanevik[2], T. Hausken[2], G. E. Eide[3], N. Langeland[2], K. Mørch[3], G. Rortveit[4]
[1]*Research Unit for General Practice, Uni Research Health,* [2]*University of Bergen,* [3]*Haukeland University Hospital,* [4]*Uni Research Health, Bergen, Norway*

Contact E-mail Address: knut-arne.wensaas@uni.no
Introduction: The aims of this study is to explore the subtypes of irritable bowel syndrome (IBS) in a cohort three years after acute Giardia infection and in a control group with sporadic IBS. Further, to compare these subtypes according to Rome III criteria (based on stool consistency) to a classification based on stool frequency (diarrhoea or constipation).
Aims & Methods: Prospective cohort study of patients aged ≥18 years with confirmed giardiasis during a large outbreak in Bergen, Norway, in 2004 and a group of controls matched by age and gender. A postal questionnaire was mailed to all participants in 2007, three years after the acute infection. Outcomes were IBS according to Rome III criteria, and diarrhoea (defined as ≥4 bowel movements a day at least "sometimes") and constipation (defined as <3 defecations at least "sometimes").
Results: Response rates were 66% (781/1184) among exposed patients and 33% (1099/3380) among controls. The prevalence of IBS was 47% (346/781) and 14% (154/1095) respectively, with an adjusted relative risk 3.3 (95% CI 2.9 to 3.7). In the Giardia group the distribution of IBS based on stool consistency according to Rome III criteria was 38% IBS-D, 46% IBS-M, 10% IBS-C and 6% IBS-U, and in the control group 32% IBS-D, 34% IBS-M, 19% IBS-C and 14% IBS-U.
Of the IBS patients in the Giardia group 70% reported diarrhoea and 14% reported constipation, compared to 46% and 24%, respectively, in the control group. Subtyping IBS based on these characteristics yielded a different distribution than when subtyping based on stool consistency ($p < 0.001$ in both groups, Kappa-values 0.168 and 0.279). In the Giardia group 62% had IBS and diarrhoea, 7% had IBS and constipation and 7% had IBS and both, the corresponding numbers in the control group was 40%, 18% and 6%.

Table: Relationship between IBS subtyped according to Rome III criteria (based on stool consistency) and IBS subtyped by frequency of bowel movements (diarrhoea/constipation at least "sometimes") among exposed and controls three years after acute giardiasis.

		IBS with diarrhoea	IBS with constipation	IBS with diarrhoea and constipation	IBS without diarrhoea nor constipation	Total
Exposed	IBS-D	102	3	5	22	132 (38%)
	IBS-C	17	12	5	19	34 (10%)
	IBS-M	98	8	15	38	159 (46%)
	IBS-U	1	7	0	13	21 (6%)
Total		215 (62%)	24 (7%)	25 (7%)	82 (24%)	346 (100%)
Control	IBS-D	35	1	1	13	50 (32%)
	IBS-C	9	11	0	10	30 (19%)
	IBS-M	14	13	8	18	53 (34%)
	IBS-U	4	2	0	15	21 (14%)
Total		62 (40%)	27 (18%)	9 (6%)	56 (36%)	154 (100%)

Conclusion: In post-giardiasis IBS there was a larger proportion of IBS-D and IBS-M compared to sporadic IBS in the controls. Subtyping IBS based on diarrhoea and constipation, rather than on stool consistency according to Rome criteria, significantly changed how patients were classified, and the resulting changes appeared to be different in post giardiasis IBS compared to sporadic IBS. These results challenge the accuracy of the current Rome III criteria in characterizing IBS.

P0436 SERUM AND MUCOSAL CYTOKINE PROFILES DO NOT DISCRIMINATE BETWEEN HEALTH AND IBS, BUT INCREASED LEVELS OF PRO-INFLAMMATORY CYTOKINES CORRELATE WITH LONGER OROANAL TRANSIT TIME AND REDUCED PSYCHOLOGICAL WELL-BEING

S. M. P. Bennet[1,2], A. Polster[1], H. Törnblom[1], S. Isaksson[1,2], B. Le Nevé[3], M. Simrén[1], L. Öhman[1,2]

Contact E-mail Address: magnus.simren@medicine.gu.se
Introduction: Evidence suggests patients with irritable bowel syndrome (IBS) have an altered cytokine profile, although it is unclear if cytokines are associated with severity of symptoms. We therefore aimed to determine if global cytokine profiles differ between IBS and healthy and if cytokine expression is associated with IBS symptoms.
Aims & Methods: Serum from 144 IBS patients and 42 healthy subjects was analyzed for cytokine levels (IL-5, IL-6, IL-8, IL-10, IL-12p70, IL-13, IL-17A, IFN-γ, TNF) by MSD MULTI-ARRAY analysis. Sigmoid colon biopsies from 109 IBS and 36 healthy were analyzed for mRNA expression (IL-8, IL-10, TNF, FOXP3) by qRT-PCR. Global cytokine profile of serum and mucosal cytokines was evaluated by multivariate analysis (SIMCA-P+ software). Study subjects underwent rectal sensitivity test using a barostat, and oroanal transit assessment using radiopaque markers. IBS symptom severity and psychological symptoms were assessed using Patient Health Questionnaire-15, IBS Severity Scoring System and Hospital Anxiety and Depression scale.
Results: According to multivariate discrimination analysis, global cytokine profiles of IBS patients and healthy subjects overlapped, thus not able to discriminate IBS patients from healthy. However, serum levels of pro-inflammatory cytokines IL-6 and IL-8 tended to be increased, and IFN-γ tended to be decreased in IBS patients. Mucosal mRNA expression of IL-10 and FOXP3 tended to be lower in IBS patients (Table 1). Other measured serum and mucosal cytokines did not differ between IBS and healthy subjects. Subjects (including IBS and healthy) with longer oroanal transit had increased mucosal mRNA expression of IL-8 ($r = 0.33$; $p = < 0.0001$) and TNF ($r = 0.2$; $p = 0.02$). No correlation of rectal pain threshold and cytokine expression was recorded. Subjects with a higher degree of somatization tended to have

increased serum levels of IL-6 (r = 0.2; p = 0.01), IL-8 (r = 0.18; p = 0.01) and TNF (r = 0.15; p = 0.04). Subjects reporting more anxiety tended to have lower mucosal mRNA expression of IL-10 (r = -0.16; p = 0.05). Subjects reporting higher levels of depression had increased serum levels of IFN-γ (r = 0.18; p = 0.01) and IL-6 (r = 0.15; p = 0.04). IBS symptom severity tended to correlate positively with serum levels of IL-6 in IBS patients (r = 0.17; p = 0.05).

Conclusion: Global cytokine profiles were similar between IBS patients and healthy subjects, thus cytokine profiles do not discriminate between IBS and health. Nonetheless, increased levels of pro-inflammatory cytokines were associated with longer oroanal transit and reduced psychological wellbeing in IBS and healthy subjects.

P0437 AN APPRAISAL OF CLINICAL PRACTICE GUIDELINES FOR IRRITABLE BOWEL SYNDROME

Y. Gou[1], F. Li[2], W. Wang[1], A. Jin[1], Y. Zhao[3], **X. Huang**[1]
[1]*Digestive Department,* [2]*Clinical Laboratory,* [3] *Key Laboratory of Digestive System Tumors of Gansu Province, The Second Hospital of Lanzhou University, Lanzhou, China*

Contact E-mail Address: huangxiaojunlzu@163.com

Introduction: Irritable bowel syndrome(IBS) is a chronic gastrointestinal disorder with an estimated prevalence of 10-20%. Many countries lack appropriate clinical practice guidelines for the diagnosis and treatment of IBS. It can be painful and debilitating, lead to feelings of anxiety and depression, and negatively affect quality of life.

Aims & Methods: To determine and assess the quality of clinical practice guidelines on IBS. Four databases (included MEDLINE and EMBASE) and some guideline websites were searched till to March 2015. Methodological quality of selected guidelines was assessed by the AGREE II instrument.

Results: From 863 citations, 17 relevant guidelines were included. The overall agreement among reviewers was moderate (Intra-class correlation coefficient = 0.81; 95% confidence interval [CI], 0.56-0.76). Overall, the guidelines performed well in the clarity and presentation domain with a mean score of 56.12%, followed by scope and purpose (58.56%) and rigor of development (50.25%). In contrast, poor scores were given for the remaining domains: stakeholder involvement (23.25%), applicability (28.14%) and editorial independence (31.54%). Four sixths domains scores were lower when compared with international level. There are 5 (22.73%) guidelines described the systematic methods for searching. And only 5 (23.81%) guidelines reported methodological expertise were included in guideline developing teams.

Conclusion: Although existing guidelines may accurately reflect agreed clinical practice, many guidelines lack proper methodological quality. Greater efforts are needed to provide high-quality guidelines that serve as a useful and reliable tool for clinical decision-making in this field.

Introduction: Eluxadoline (ELX) is a locally active, mixed mu-opioid receptor agonist and delta-opioid receptor antagonist that demonstrated improvements in the symptoms of irritable bowel syndrome with diarrhoea (IBS-D) in two Phase 3 trials.

Aims & Methods: To examine the efficacy of ELX in abdominal pain in IBS-D, additional prospective analyses were performed for two double-blind, placebo (PBO)-controlled Phase 3 trials (IBS-3001, IBS-3002). Patients (pts) meeting Rome III criteria for IBS-D were randomised to twice-daily ELX (75 or 100 mg) or PBO. Both trials had identical designs through 26 weeks (wks) of treatment. The primary endpoint was a composite response based on simultaneous daily improvement in worst abdominal pain (WAP) and stool consistency over Wks 1–12 (US Food and Drug Administration [FDA] endpoint) and Wks 1–26 (European Medicines Agency [EMA] endpoint). Additional prospective analyses of WAP (0–10 scale) included: Cochran–Mantel–Haenszel (CMH) assessments of WAP responders, defined as pts with ≥50% of days with ≥30% improvement (study level and pooled); longitudinal analyses (LA) of WAP response rates, both at specific time points and at the study level; assessment of pooled data using CMH analyses of WAP responders over the two intervals based on ≥40% and ≥50% improvements in pain; and an analysis of covariance (ANCOVA) assessment of change from baseline (CFB) in WAP daily scores of pooled data at specific time points.

Results: A total of 2428 pts with IBS-D were enrolled across both trials. A significantly greater proportion of ELX-treated pts (75 or 100 mg) were FDA and EMA composite endpoint responders compared with pts who received PBO ($p < 0.05$), with the exception of ELX 75 mg in IBS-3001 over Wks 1–26. CMH analyses of the pooled data showed no significant differences for WAP responders (ie ≥30% pain improvement for ≥50% of days; Table 1) between ELX-treated pts and those who received PBO. Significant differences were observed for ELX 100 mg over PBO for WAP responders at both the ≥40% and ≥50% pain improvement levels. Findings were similar for the pooled data ANCOVA CFB in WAP scores at Wks 12 and 26. At the study level, LA of WAP daily response rates showed significant improvement with ELX 75 mg vs PBO at Wk 26 in IBS-3001 ($p = 0.016$), and significant improvements for both ELX doses at Wks 12 and 26 in IBS-3002 ($p \leq 0.013$).

Table 1: Pooled WAP analyses

	Wks 1–12			Wks 1–26		
	PBO	ELX 75 mg	ELX 100 mg	PBO	ELX 75 mg	ELX 100 mg
≥30% WAP improvement*	42.3	45.0*0.261*	46.8*0.069*	44.0	46.3*0.357*	48.3*0.086*
≥40% WAP improvement*	35.8	40.1*0.078*	43.2*0.003*	37.7	41.5*0.122*	44.2*0.008*
≥50% WAP improvement*	30.0	34.7*0.047*	36.0*0.011*	32.5	36.4*0.101*	38.7*0.009*
CFB in WAP**	-2.6	-2.8*0.060*	-3.0*<0.001*	-3.0	-3.3*0.023*	-3.4*0.002*

*Percent responders and p values compared with PBO**CFB in WAP score and p value compared with PBO

Conclusion: Phase 3 trial findings demonstrated that ELX improves abdominal pain in pts with IBS-D, particularly for ELX 100 mg with ≥40% and ≥50% pain improvement definition for responders. This was further supported by LA of WAP daily response rates and ANCOVA CFB in WAP score analyses.

P0439 ROBUSTNESS OF ELUXADOLINE FOR THE TREATMENT OF IRRITABLE BOWEL SYNDROME WITH DIARRHOEA: RESULTS FROM PHASE 3 COMPOSITE ENDPOINT ASSESSMENTS

B. E. Lacy[1], **L. S. Dove**[2], D. A. Andrae[3], J. M. Davenport[2], L. Turner[2], R. Lopez[2], P. S. Covington[2]

Contact E-mail Address: Brian.E.Lacy@hitchcock.org

Introduction: Eluxadoline (ELX), a locally active, mixed mu-opioid receptor agonist and delta-opioid receptor antagonist, has been shown to treat symptoms of irritable bowel syndrome with diarrhoea (IBS-D).

Aims & Methods: The robustness of ELX treatment was assessed by comparing the results of four composite efficacy endpoints across two double-blind, placebo (PBO)-controlled Phase 3 trials (IBS-3001, IBS-3002). Patients (pts) meeting Rome III criteria for IBS-D were randomised to twice-daily ELX (75 or 100 mg) or PBO. Efficacy was evaluated through 26 weeks (wks). Pts rated worst abdominal pain (WAP; 0–10 scale) and stool consistency (Bristol Stool Scale [BSS]) daily. The *primary efficacy* endpoint was a composite response (based on simultaneous daily improvement in WAP and stool consistency, with ≥50% of days demonstrating a response) evaluated over Wks 1–12 (Food and Drug Administration; with ≥60/84 days of diary compliance) and Wks 1–26 (European Medicines Agency; with ≥110/182 days of diary compliance). Other prospectively defined composite endpoints included: a *worst case* approach, using the same daily criteria but requiring an absolute ≥42/84 days or ≥91/182 days of response, respectively, regardless of diary compliance; weekly (wkly) *Method 1*, requiring a wkly average BSS of ≤5 if baseline average BSS ≥6, or a reduction in wkly average BSS scores of ≥1 point for pts with a baseline average BSS ≥5.5 and <6; wkly *Method 2*, requiring a ≥50% decrease in the number of days in a week when BSS was ≥6 compared with the number of days at baseline (Wk 1) when the BSS was ≥6. Both wkly methods used the same WAP criteria, ie ≥30% improvement in the wkly average of WAP scores compared with average baseline pain. Both wkly methods required improvement of WAP and BSS in the same wk for ≥6/12 wks for a pt to be considered a responder.

Results: A total of 2428 pts with IBS-D were enrolled across both trials. In general, significantly more pts receiving ELX were composite responders than those receiving PBO, regardless of the composite endpoint analysed ($p < 0.05$;

Abstract number: P0439
Table 1: Prospective study-specific results

Responders (%)*p value vs PBO* PBO	ELX 75 mg	IBS-3001 ELX 100 mg	PBO	ELX 75 mg	IBS-3002 ELX 100 mg		
Daily composite endpoint ***Primary efficacy***	Wks 1–12	17.1	23.9*0.014*	25.1 *0.004*	16.2	28.9 < *0.001*	29.6 < *0.001*
Wks 1–26	19.0	23.4*0.112*	29.3 < *0.001*	20.2	30.4*0.001*	32.7 < *0.001*	
Daily composite endpoint ***Worst case***	Wks 1–12	16.6	23.4*0.013*	24.2*0.006*	13.9	28.3 < *0.001*	28.3 < *0.001*
Wks 1–26	15.9	22.7*0.012*	26.3 < *0.001*	15.7	28.9 < *0.001*	30.6 < *0.001*	
Wkly composite endpoint ***Method 1***	Wks 1–12	25.8	33.5*0.013*	36.2*0.001*	26.4	36.2*0.004*	37.7 < *0.001*
Wkly composite endpoint ***Method 2***	Wks 1–12	31.1	38.4*0.026*	41.8 *0.001*	32.7	38.6*0.091*	45.0 < *0.001*

Table 1). Comparable results for composite endpoints were seen for both ELX dose groups, although results for the 75 mg group were slightly less robust than for the 100 mg group at the study level. Data from pooled analyses showed similar findings.
Conclusion: Results from two Phase 3 trials demonstrate that ELX is an effective treatment for IBS-D based on robust results across multiple composite endpoints and across time.

P0440 ADDITION OF GLUCOSE TO FRUCTOSE REDUCES BREATH HYDROGEN BUT NOT SYMPTOMS IN FRUCTOSE MALABSORBERS WITH A FUNCTIONAL BOWEL DISORDER

C. Tuck[1], L. Ross[1], J. Muir[1], J. Barrett[1], P. Gibson[1]
[1]*Department of Gastroenterology, Monash University, Prahran, Australia*

Contact E-mail Address: caroline.tuck@monash.edu
Introduction: Absorption of fructose is enhanced by the addition of equal amounts of glucose in healthy volunteers. The success of this strategy in improving absorption of fructose and in reducing abdominal symptoms when consuming free fructose or fructans in patients with functional bowel disorders is not known. This study aimed to address these issues by performing a randomised, double blind, cross-over trial.
Aims & Methods: Breath hydrogen and symptom response to six sugar solutions - glucose; sucrose; fructose; fructose + glucose; fructo-oligosaccharide (FOS); FOS + glucose – given in random order were assessed in patients with fructose malabsorption and a functional bowel disorder (Rome III). Following a 24 hour run-in period where participants consumed a diet low in fermentable carbohydrates (fibre and FODMAPs), participants collected breath samples at baseline and every 20 minutes for 4 h after consuming the sugar solution. A further 8 breath samples were collected hourly, during which only food low in FODMAPs was consumed. Breath hydrogen was calculated as area-under-the-curve. Symptom scores were recorded at the end of each day, using both 100 mm visual analogue scale and 4-point Likert scale.
Results: Of the 26 participants (3 female, aged 22-65 y), 21 had IBS, 3 functional bloating, 1 functional diarrhoea and 1 chronic constipation. Breath hydrogen response to 25 g fructose (775 ± 904 ppm.4 h (mean ± SD)) reduced during the first 4 h following the addition of 25 g glucose (84 ± 99; p = 0.012, t-test), which was similar to that after glucose alone (133 ± 175) or sucrose (155 ± 224). Breath hydrogen response to 10g FOS (3089 ± 1688) was not changed with the addition of glucose (2166 ± 1320; p = 0.559). Overall abdominal symptoms after fructose (median 15 mm, IQR 2-46) or FOS (19.2-32) were not changed with the addition of glucose (5.1-35; p = 0.236; 17.2-46, p = 0.926, respectively). Addition of glucose worsened abdominal pain when given with FOS (5.1-16 vs 13.2-18; p = 0.049) and nausea when given with fructose (1.0-2 vs 2.1-10; p = 0.018). When assessed by the Likert scale, addition of glucose to fructose increased nausea (p = 0.011) and to FOS increased nausea (p = 0.011) and wind (p = 0.027).
Conclusion: The results do not support the strategy of adding glucose to foods high in free fructose to reduce fructose malabsorption or to fructans as it does not reduce, and potentially worsens symptoms associated with consumption of these sugars in patients with functional bowel disorders.

P0441 TRANS-ANAL IRRIGATION THERAPY TO TREAT ADULT CHRONIC FUNCTIONAL CONSTIPATION: A SYSTEMATIC REVIEW

C. Emmett[1,2], H. Close[2], J. Mason[2], Y. Yiannakou[1,2]
[1]*University Hospital of North Durham,* [2]*Durham University, Durham, United Kingdom*

Contact E-mail Address: Christopher.Emmett@nhs.net
Introduction: Trans-anal irrigation (TAI) is used widely to treat bowel dysfunction, although evidence for its use in adult chronic functional constipation remains unclear. Long-term outcome data are lacking, and the effectiveness of therapy in this patient group is not definitively known[1].
Aims & Methods: Evidence for effectiveness and safety was reviewed and the quality of studies was assessed. Primary research articles of patients with chronic functional constipation, treated with TAI as outpatients and published in English in indexed journals were eligible. Searching included major bibliographical databases and search terms: bowel dysfunction, defecation, constipation and irrigation. Fixed- and random-effect meta-analyses were performed.
Results: Seven eligible uncontrolled studies[1-7], including 243 patients, of retrospective or prospective design were identified. The definition of treatment response varied and was Investigator-determined. The fixed-effect pooled response rate was 50.4% (95%CI: 44.3% to 56.5%) but featured substantial heterogeneity ($I^2 = 67.1\%$). A random-effects estimate was similar: 50.9% (95%CI: 39.4% to 62.3%). Adverse events were inconsistently reported but were commonplace and minor.
Conclusion: The reported success rate of TAI is about 50%, which may be adequate for chronic constipation. Findings may vary between studies due to methodological or contextual differences. Evidence for TAI in functional constipation is weak: there is a need for well-designed prospective trials to evaluate the effectiveness of treatment.

P0442 IN VITRO STUDIES ON THE ANTI-SPASMODIC AND ANTI-INFLAMMATORY POTENTIAL OF CHAMOMILE, MYRRH AND COFFEE CHARCOAL – COMPONENTS OF A TRADITIONAL HERBAL MEDICINAL PRODUCT (MYRRHINIL-INTEST®)

C. Vissiennon[1,2], K.-H. Goos[3], O. Goos[3], J. Arnhold[1], K. Nieber[2]

Contact E-mail Address: cica.vissiennon@uni-leipzig.de
Introduction: The herbal medicinal product Myrrhinil-Intest® consisting of myrrh, chamomile flower dry extract and coffee charcoal is marketed in Germany since 1959. Clinical data prove the effectiveness of this herbal

preparation for inflammatory intestinal disorders such as irritable bowel syndrome, functional diarrhea as well as inflammatory bowel disease (colitis ulcerosa) [1,2]. However, the underlying pharmacological mechanisms within the gastrointestinal system have not yet been fully elucidated.
Aims & Methods: Objective of this study was to assay the herbal components for their effect on intestinal motility and inflammation. Thus, spasmolytic activity was determined using isometric tension measurement in isolated rat small intestinal preparations. An *in vitro* TNBS inflammation model in rat small intestinal preparations was used to determine anti-inflammatory activity. Therefore, the effect of the plant extracts on TNBS induced inflammatory damage was characterised based on TNFα-gene expression analysis, isometric contraction measurement and histological analysis. Furthermore, TNFα release from LPS-stimulated THP-1 cells was assayed. Additionally, microarray gene expression analysis was performed in LPS/IFNγ stimulated native human macrophages to determine underlying mechanisms.
Results: Chamomile flower (KA) and ethanolic myrrh extract (MY) exerted a spasmolytic effect by inhibiting the acetylcholine-induced contractions to 56% (KA: IC50 = 160 µg/ml) and 10% (MY: IC50 = 158 µg/ml) respectively. Serial testing with increasing concentration of the calcium-channel agonist (BAY K8644, 10^{-10}–10^{-7} M) in the presence of different MY concentrations (0.15 - 0.35 mg/ml) demonstrated that MY acts via inhibition of L-type calcium channels.
With regard to anti-inflammatory activity, chamomile flower and aqueous myrrh extract (0.1–100 mg/ml) normalised the TNBS-induced overexpression of TNFα-mRNA as well as TNBS-induced loss of contractility and decrease in mucosa layer thickness concentration-dependently, whereas coffee charcoal (0.1-100 µg/ml) had no effect in the TNBS inflammation model. LPS-induced TNFα release from THP-1 cells was inhibited concentration-dependently by ethanolic myrrh extract (IC50 = 60.65 µg/ml), chamomile flower extract (IC50 = 439 µg/ml) and coffee charcoal extract (IC50 = 1886 µg/ml). Furthermore, chamomile flower (200 µg/ml) and coffee charcoal extract (500 µg/ml) markedly influenced the gene expression profile of LPS/IFNγ-stimulated human macrophages. Coffee charcoal inhibited the LPS/IFNγ-induced expression of genes associated with chemokine signalling.
Conclusion: The presented study demonstrates the pharmacological potential of the herbal ingredients of the fixed combination with respect to its spasmolytic and anti-inflammatory activities within a multi-target principle. Taken together, it could be demonstrated that the components are able to target gastrointestinal disorders by exerting antispasmodic and anti-inflammatory effects which reinforce the reported clinical effectiveness.

P0443 FOUR YEARS FOLLOW UP OF GUT-DIRECTED GROUP HYPNOSIS IN PATIENTS WITH REFRACTORY IRRITABLE BOWEL SYNDROME – A LONG TERM SUCCESS

G. Moser[1], B. Weiskopf[2], S. Ortmayr[1], J. Peter[1]
[1]*Internal Medicine III,* [2]*Medical University of Vienna, Vienna, Austria*

Contact E-mail Address: gabriele.moser@meduniwien.ac.at
Introduction: We previously showed that gut directed group-hypnosis (GHT) has a significant beneficial effect for patients with refractory irritable bowel syndrome (IBS).
Aims & Methods: Aim of this follow up (FU) study was to investigate long-term effects of GHT over four years. All 46 participants with GHT of our previous randomized controlled trial were invited to complete the IBS-impact scale (IBS-IS) for IBS related quality of life (higher values mean less complaints), the hospital anxiety and depression scale (HADS), visual analogue scales (VAS) for physical and psychological well-being as well as individual IBS symptoms.
Results: 30/46 patients (65%) completed all FU-questionnaires. After a mean duration of 4.13 years FU IBS-related quality of life and affective status showed a significant improvement compared to baseline (IBS-IS: 3.53 vs. 5.38 at FU, $p < .001$; HADS-depression: 6.28 vs. 4.14 at FU, $p < .05$; HADS-anxiety: 9.69 vs. 6.83 at FU, $p < .001$). Also VAS-scores for physical and psychological well-being, as well as individual symptoms revealed a significant improvement ($p < .001$, respectively $p < .01$). Gender, IBS-subtype and practising of hypnosis had no influence on this success of GHT.
Conclusion: The beneficial effects of GHT are long lasting over 4 years in patients with refractory IBS. Therefore GHT is a highly valuable therapy option and should be offered in tertiary centres.

P0444 A DOUBLE-BLIND RANDOMISED CONTROLLED TRIAL OF THE EFFECT OF DIETARY FERMENTABLE CARBOHYDRATES ON THE COLON USING MAGNETIC RESONANCE IMAGING: SUPPLEMENTARY OLIGOFRUCTOSE INCREASES COLONIC VOLUME BUT SO DOES THE LOW FODMAP DIET

G. Major[1], S. Krishnasamy[2], C. Mulvenna[2], S. Pritchard[3], C. Hoad[3], L. Marciani[1], M. Lomer[4], P. Gowland[3], R. Spiller[1], on behalf of the University of Nottingham GI MRI Research Group
[1]*NIHR Nottingham Digestive Diseases Biomedical Research Unit,* [2]*Nottingham Digestive Diseases Centre,* [3]*Sir Peter Mansfield Imaging Centre, University of Nottingham, Nottingham,* [4]*Diabetes and Nutritional Sciences Division, King's College, London, United Kingdom*

Contact E-mail Address: robin.spiller@nottingham.ac.uk
Introduction: Magnetic Resonance Imaging(MRI) can be used to assess gastrointestinal (GI) function non-invasively without the use of ionising radiation. An uncontrolled pilot study (UEGW2014) found that supplementing the diet of healthy volunteers for a week with oligofructose(OF) 5g bd increased fasting colonic volume by 18%. Adoption of a diet low in fermentable oligo-, di-, mono-saccharides and polyols (FODMAPs), such as OF, has been shown to reduce symptoms of irritable bowel syndrome.
Aims & Methods
Aim: to investigate the effect of altering the amount of fermentable carbohydrate in the diet on colonic physiology and fermentation. The hypotheses were 1) starting a low FODMAP diet would reduce colonic volume, 2) supplementing the diet with OF would abolish the effect.
Methods: A parallel group, double-blind, randomised controlled trial in adult volunteers without previous GI disorders. Subjects followed their usual diet for a week. At 0800 on day 7 they swallowed 5 MRI transit markers, were counselled on the low FODMAP diet by a registered dietitian and were given a standard food package (UK diet) for the rest of the day. At 0800 on day 8 they attended fasted for MRI scan and tests of breath hydrogen (H_2) and methane (CH_4). All subjects then followed the low FODMAP diet for a week, but were randomised to take Maltodextrin (MD) or OF 7g bd. On day 7 transit markers and testing were repeated with another standard food package (low FODMAP). Supplement was continued until the night before tests.
Primary endpoint: percentage change from baseline in colonic volume. Secondary endpoints: a measure of whole gut transit, the weighted average position score of the transit markers 24h after ingestion (WAPS24); breath H_2 and breath CH_4. Food diaries were kept for both weeks preceding MRI.
Results: Data presented as mean (95%CI). 37 subjects completed the study (19OF:18MD). One subject (MD) had corrupted images and was excluded from MRI analysis. Compliance with diet and supplements was good. Contrary to our hypothesis CV increased on MD from 650mL (558–742) to 740mL (616–865) or 15.5% (2.5–28.4, $p < 0.05$). The increase was greater in the OF group: from 693mL (620–765) to 803mL (732 —874) or 19.6% (6.5–32.7, $p < 0.01$) but the difference between groups was not significant. Breath H_2 response of the groups diverged ($p < 0.01$): on MD H_2 fell by 11ppm (3–18) but on OF H_2 rose by 16ppm (−2–35). WAPS24 and CH_4 did not change from baseline significantly in either group, with no difference between groups.
Conclusion: Fasting breath hydrogen fell on a low FODMAP diet and rose with OF use, confirming previous studies[1,2]. Contrary to the study hypothesis colonic volume increased significantly on the low FODMAP diet, an effect that may be due to the presence of replacement substrate for colonic bacteria in substituted foods (e.g. tapioca or potato). Since the low FODMAP diet did not lead to a reduction in colonic distension other mechanisms for any clinical effect, such as changes in the microbiota, may need consideration.

P0445 A SINGLE-BLIND STUDY EVALUATING THE EFFECTS OF A GLUTEN-FREE DIET IN DIARRHOEA PREDOMINANT IRRITABLE BOWEL SYNDROME

I. Aziz[1], J. North[1], N. Trott[1], R. Briggs[1], D. Sanders[1]
[1]*Academic Department of Gastroenterology, Royal Hallamshire Hospital, Sheffield, United Kingdom*

Contact E-mail Address: imran.aziz@sth.nhs.uk
Introduction: Gluten has been shown to alter bowel barrier function in patients with diarrhoea-predominant irritable bowel syndrome (D-IBS), particularly those who are HLA-DQ2 and/or DQ8 positive.
Aims & Methods: We aimed to assess the clinical response to a gluten-free diet (GFD) in D-IBS patients previously naïve to the effects of gluten and blinded to HLA-DQ status.
We enrolled 48 D-IBS patients (24 HLA-DQ negative and 24 HLA-DQ positive) to undertake a six-week GFD following dietetic input. Both patients and dietitian were blinded to HLA-DQ status. Validated questionnaires were self-completed at baseline and at week-6. The primary end-point was mean-change in IBS-severity scoring system (IBS-SSS), with a 50-point reduction conferring clinical benefit. Secondary end-points were change in hospital anxiety and depression score (HADS), fatigue impact score (FIS), and short-form 36 (SF-36).
Results: Data from 41 patients (74.4% women, mean-age 40.3yrs) was available for per-protocol-analysis. Of these, 21 were HLA-DQ negative and 20 HLA-DQ positive; baseline characteristics were similar other than worse pain-frequency ($p = 0.03$), physical-fatigue (0.04), and vitality (0.05) in the HLA-DQ positive group. Overall, a GFD reduced IBS-SSS $\geq$50 points in 71% ($n = 29$). In fact,

the mean-total IBS-SSS decreased from 286 to 131 points (change -155, $p < 0.001$), which was seen similarly across both HLA-DQ groups. However, HLA-DQ negative subjects showed a greater reduction in abdominal distension in the first four weeks compared to HLA-DQ positive ($P = 0.04$), although this was non-significant by week-6. There was a marked improvement in HADS, FIS, and SF-36 amongst both groups. However, HLA-DQ positive subjects showed a greater response to depression ($p = 0.02$), fatigue (physical, $p = 0.04$; cognitive, $p = 0.07$) and vitality ($p = 0.05$) compared to HLA-DQ negative subjects. On study completion, 90% ($n = 37$) were discharged and 61% ($n = 25$) continued with a GFD.

Conclusion: A GFD is a therapeutic option for the management of D-IBS. A clinical improvement was seen in 71% of patients undertaking a six-week GFD, with 61% opting to continue with a GFD for the foreseeable future. The pathophysiological mechanism may differ according to HLA-DQ status.

Introduction: Ibodutant, is a potent antagonist of neurokinin-2 receptors currently in phase III clinical development for Irritable Bowel Syndrome with Diarrhea (IBS-D). A phase II study (IRIS 2) tested the efficacy of 8-week oral treatment with 3 doses of ibotudant (1 mg, 3 mg, 10 mg) in 559 IBS-D patients defined by Rome III criteria. The treatment period was followed by a 2-week treatment-free withdrawal period. Based on the response to the binary question on the combined satisfactory relief of IBS symptoms and abdominal pain/discomfort a statistically and clinically relevant efficacy was demonstrated in the female subgroup ($n = 333$) at the 10 mg dose ($p = 0.003$ over placebo).

Aims & Methods: To evaluate the maintenance of treatment response in the female IBS-D population exposed to ibodutant after 2 weeks of treatment withdrawal versus placebo.

During the whole study, patients reported on a weekly basis their overall IBS symptom relief and abdominal pain/discomfort relief (binary yes/no question: "*Did you have satisfactory relief of your overall IBS symptoms during the last week?*" and "*Did you have satisfactory relief of your abdominal pain or discomfort during the last week?*"). The rate of responders (50% rule) developed during the 2-week withdrawal phase was compared versus the last two weeks of treatment to assess the maintenance of effect.

Results: The frequency of responders given at week 7 to 8 (last 2 weeks of treatment) and at the end of the withdrawal phase (week 9 to 10) is given below.

IBS-D Females (N = 333) No of Responders (%)	Ibodutant 1 mgN = 89	Ibodutant 3 mgN = 87	Ibodutant 10 mgN = 79	Placebo N = 78
Week 7-8	58 (65.2%)	52 (59.8%)	58 (73.4%)	41 (52.6%)
Week 9-10	51 (57.3%)	51 (58.6%)	47 (59.5%)	36 (46.2%)
Change %	7 (7.9%)	1 (1.2%)	11 (13.5%)	5 (6.4%)

The number of responders declined at the end of the 2-week treatment-free withdrawal phase in all treatment groups, with the maximum decline at the efficacious dose of 10 mg once daily (13.5% less patient who maintained their response during the withdrawal phase was lowest in the placebo group (approximately 6.4%)).

Conclusion: When ibodutant treatment was withdrawn and patients continued to report their IBS-symptoms the responder rates declined notably in the 10 mg treatment group, thus confirming the role of ibodutant as maintanance treatment in IBS-D. The highest decline at the 10 mg dose showing efficacy versus placebo, while comparatively well maintained response rate in the other treatment arms, gives additional evidence of the true treatment effect of ibodutant at 10 mg dose.

P0447 ONE-YEAR FOLLOW-UP OF NURSE–ADMINISTERED GUT-DIRECTED HYPNOTHERAPY FOR PATIENTS WITH IBS

J. Lövdahl[1], G. Ringström[1], H. Törnblom[1], M. Simren[1]
[1]*Internal Medicine & Clinical Nutrition, Institute of Medicine, Sahlgrenska Academy, Gothenburg, Sweden*

Contact E-mail Address: jenny.lovdahl@vgregion.se

Introduction: Gut-directed hypnotherapy is an effective treatment for patients with irritable bowel syndrome (IBS), but it is costly, time consuming and availability is a problem. We have recently reported good short-term effectiveness of nurse-administered, gut-directed hypnotherapy in a tertiary care centre (Lövdahl et al Am J Clin Hypnosis 2015).

Aims & Methods: Our aim was to determine the long-term results of nurse-administered, gut-directed hypnotherapy and to identify factors predicting treatment outcome at one-year follow-up. We included 85 patients with IBS (mean age 40 (20-70 years; 60 women) with symptoms refractory to standard management. Participants received hypnotherapy administered by a nurse once/week for 12 consecutive weeks. Response to treatment was assessed with the IBS Severity Scoring System, IBS-SSS before, during (6 weeks) and immediately after the hypnotherapy treatment period (12 weeks), as well as during follow-up at week 26 ($n = 77$) and one year ($n = 68$). Patients also completed questionnaires at baseline, week 12, 26 and one year assessing the severity of extracolonic symptoms, anxiety and depression and GI-specific anxiety.

Results: At the end of the treatment period, i.e. at week 12, 50 patients (59%) were responders (IBS-SSS score reduction ≥ 50). At follow-up (week 26 and one year), 86 and 79%, respectively, of responders at week 12, were still responders; in total the responder rate at both week 26 and one year was 62%. Compared to baseline, at the one-year follow-up patients reported marked improvement of IBS symptoms (IBS-SSS: 335 (253,384) vs. 212 (147,287) (median, (IQR); $p < 0.0001$) as well as of extra-colonic symptoms ($p < 0.0001$), GI-specific anxiety ($p < 0.0001$), general anxiety ($p < 0.0001$) and depression ($p < 0.001$) Responder status already at week 6 could predict the responder status of the patients at week 26 ($p < 0.0001$) and at one year ($p = 0.003$), but no baseline variables could predict the one-year outcome. Being a responder at the one-year follow-up based on IBS symptom improvement (IBS-SSS score reduction ≥ 50 vs baseline) was also associated with a greater improvement in depression ($p = 0.01$), GI-specific anxiety ($p < 0.0001$) and extra-colonic symptoms ($p = 0.002$).

Conclusion: Nurse-administered gut-directed hypnotherapy is an effective treatment option with good long-term results for patients with IBS symptoms refractory to other treatments. A rapid clinical response during hypnotherapy predicts good long-term results, and the IBS symptom improvement at one year is associated with improvement also in psychological and bodily symptoms.

P0448 LARGEST REPORTED PROSPECTIVE EVALUATION OF A LOW FODMAP DIET IN IBS PATIENTS IN A REGIONAL HOSPITAL

J. Arts[1,2], J. Tack[1], A. Holvoet[2], S. Decock[2], T. Lanssens[2], P. Van Hootegem[2]

Contact E-mail Address: joris.arts@stlucas.be

Introduction: The irritable bowel syndrome (IBS) is a highly prevalent condition with unclear underlying pathophysiology and for which no standard effective therapy is established. A number of recent studies have shown that fermentable oligo-, di-, mono-saccharides and polyols (FODMAPS) alter intestinal physiology and can trigger gastrointestinal symptoms, while a low FODMAP diet improves symptoms in tertiary care IBS patients.

Aims & Methods: Our aim was to perform a prospective study to determine whether a low FODMAP diet improves symptoms in IBS patients in the setting of a regional hospital in Belgium.

Consecutive IBS patients, seen at the gastroenterology outpatient clinic, were instructed how to take a low FODMAP diet by an experienced dietician. All patients were asked to score their symptom severity before and 8 weeks after the implementation of a low FODMAP diet. The intensity of 5 symptoms (bloating, abdominal cramps, borborygmi, stool disturbances, fatigue) was evaluated using 0 to 100 mm visual analogue scales (VAS). The global effect of the low FODMAP diet was also evaluated by means of a VAS (0mm = no improvement to 100mm = complete symptom resolution). VAS are reported as mean+/-standard deviation. Responses were compared using the Wilcoxon signed rank test. Results were considered significant if $p < 0.001$.

Results: Eighty-two patients with IBS according to Rome III criteria, 83% females, mean age 39 ± 12 years, were included in this prospective study. After 8 weeks of low FODMAP diet, we found a significant reduction of global symptom score (sum of all evaluated symptoms) (318 ± 61 vs. 131 ± 61; $p < 0.001$). An improvement of $>50\%$ of the global symptom score was observed in 65% of the patients. The low FODMAP diet also improved all cardinal IBS symptoms (abdominal pain, 63 ± 21 vs. 29 ± 20 mm; bloating 58 ± 20 vs. 30 ± 22mm; flatulence 69 ± 18 vs. 30 ± 20 mm and stool disturbances (64 ± 20 vs. 30 ± 20mm) (all $p < 0.001$). In addition, fatigue was significantly less with a low FODMAP diet (63 ± 20 vs. 41 ± 26mm, $p < 0.001$). The

global efficacy rating was 65 ± 24mm on the VAS. Of the 82 patients, 21 had a result of >90mm, these patients can be considered as complete responders.
Conclusion: A diet low in FODMAPs effectively reduces IBS symptoms and fatigue in secondary care practice. Robust symptom improvement occurs with a strict low FODMAP diet. To our knowledge, this prospective study is the largest reported trial in a regional hospital and confirms the results obtained in tertiary care centers. The results support the use of dietary intervention in IBS in general clinical practice.

P0449 LOW FODMAP ADVICE FOR PATIENTS WITH IRRITABLE BOWEL SYNDROME: LONG-TERM OUTCOMES FOR SYMPTOMS AND DIETARY INTAKE

L. Martin[1], C. J. van Vuuren[1], L. Seamark[2], M. Williams[2], H. Staudacher[1], P. Irving[1,3], K. Whelan[1], **M. Lomer**[1,4]
[1]*King's College London, Diabetes and Nutritional Sciences Division, London,* [2]*Community Dietetics Service, Somerset Partnership NHS Foundation Trust, Somerset,* [3]*Gastroenterology,* [4]*Dietetics, Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom*

Contact E-mail Address: miranda.lomer@kcl.ac.uk
Introduction: Short chain fermentable carbohydrate (FODMAP) restriction reduces symptoms of irritable bowel syndrome (IBS) and is routinely used in clinical practice. Comprehensive FODMAP education incorporates a low FODMAP exclusion diet for 4-8 weeks followed by FODMAP reintroduction to test individual tolerance. Patients are empowered to self-manage their diet and symptoms, however whether this approach is effective in the long term is unknown. Previous research has indicated that after 4 weeks of FODMAP exclusion, calcium intakes are low.
Aims & Methods: This study aimed to assess the long-term effectiveness of the low FODMAP diet and the impact on dietary intake in patients with IBS.
Patients with IBS (n = 375) from primary and secondary care were invited to take part in a prospective questionnaire study after completion of comprehensive FODMAP education from a dietitian as described above. Symptoms were assessed at baseline before FODMAP education, following FODMAP exclusion (4-8 weeks) and following FODMAP reintroduction (6-18 months) using the global symptom question "Do you currently have satisfactory relief of your gut symptoms?" and the Gastrointestinal Symptom Rating Scale. Dietary adherence to long-term FODMAP restriction was assessed using a Likert scale and dietary intake was measured using a validated FODMAP FFQ and compared to UK dietary reference values (DRVs). Statistical analyses used the chi-squared test.
Results: Questionnaires from 103 patients were received (age: mean ± sd; 48 ± 15 years, female: n = 76). Following FODMAP exclusion, 63 (61%) patients reported satisfactory relief. Of these, 44/63 (70%) continued to report satisfactory relief following FODMAP reintroduction in the long term. Of those who had satisfactory relief on initial FODMAP exclusion, significantly more reported absent or mild abdominal pain (n = 52 vs n = 20; P < 0.001), bloating (n = 46 vs n = 19; P = 0.009), flatulence (n = 45 vs n = 12; P < 0.001), borborygmi (n = 49 vs n = 21; P = 0.007), urgency (n = 48 vs n = 17; P = 0.001), sensation of incomplete evacuation (n = 49 vs n = 21; P = 0.007) and lethargy (n = 46 vs n = 20; P = 0.018) over the long term, than those who did not have satisfactory relief on initial FODMAP exclusion. In the long term, 78 patients continued to follow an adapted low FODMAP diet and their total mean ± sd FODMAP intake was 20.9g ± 15.1 compared to 29.4g ± 22.9 for 19 patients following a normal diet. The mean ± sd calcium and iron intakes for the whole group (n = 103) were 1130mg ± 682 and 13.7mg ± 4.6 respectively. Of the 78 who continued to follow an adapted low FODMAP diet, 59 (76%) and 55 (71%) patients met the calcium and iron DRVs.
Conclusion: The majority of patients who achieve satisfactory relief of symptoms following FODMAP exclusion continue to have satisfactory relief in the long term indicating that FODMAP education is useful for long-term symptom control and self-management. The majority of patients continue to follow an adapted low FODMAP diet and approximately three-quarters meet their calcium and iron requirements in the long term.

P0450 GUT-DIRECTED HYPNOTHERAPY IS NOT INFERIOR TO THE LOW-FODMAP DIET IN REDUCING SYMPTOMS ASSOCIATED WITH IRRITABLE BOWEL SYNDROME: A RANDOMISED CLINICAL STUDY

P. Gibson[1], S. Peters[1], C. Yao[1], S. Shepherd[1], H. Philpott[1], G. Yelland[1], J. Muir[1]
[1]*Gastroenterology, Monash University, Melbourne, Australia*

Contact E-mail Address: peter.gibson@monash.edu
Introduction: Obtaining high-quality evidence for efficacy of gut-directed hypnotherapy (GDH) in patients with irritable bowel syndrome (IBS) is constrained by the difficulty in designing a blinded placebo. An alternative is to compare GDH to a therapy with proven efficacy, such as the low FODMAP diet (LFD), which benefited 70% of such patients in a recent randomised, controlled trial[1]
Aims & Methods: This study aims to determine if GDH is non-inferior in efficacy to the LFD and to assess whether they have additive effects. A randomised controlled trial was performed in IBS patients (Rome-III) comparing (a) LFD: education at the beginning of week 1, review at week 6; (b) GDH: six weekly one-hour hypnosis sessions for 6 weeks; (c) a combination of both. The primary endpoint was the change in overall gastrointestinal (GI) symptoms as evaluated using a 100 mm visual-analogue-scale from baseline to week 6. Secondary endpoints were the change overall GI symptoms from baseline to 6-months post-treatment and the change in individual gastrointestinal symptoms (abdominal pain, bloating, wind, satisfaction with stool consistency and nausea), psychological indices including anxiety and depression as assessed by the Hospital Anxiety and Depression Scale (HADS) and IBS-related Quality Of Life (QOL) from baseline to week 6 and 6-months post treatment.
Results: Of 74 participants (mean age 40, SD 14 y; 14 male), 25 received GDH, 24 the LFD, and 25 combination therapy. The groups were well matched. Overall GI symptoms improved from baseline to week 6 by mean [95% CI] of 33 [25, 41], 30 [19, 42] and 36 [27, 45] mm, respectively (all $p < .0001$) with no differences across the groups ($p = .67$; one-way-between-groups ANOVA). Improvement (≥20 mm reduction) was achieved in 72% who received GDH, 71% LFD and 72% combined treatment. Overall symptoms remained improved from baseline to 6 months by 38 [27, 50], 30 [16, 43] and 27 [14, 40] mm ($p < .0001$). 74% receiving GDH, 82% LFD and 54% combined treatment maintained their response. Significant reductions in abdominal pain, bloating, wind and stool consistency, but not nausea were observed from baseline to week 6 and 6 months. No differences in improvement were observed for individual GI symptoms across treatment groups at either timepoint. Anxiety significantly reduced at week 6 and was maintained 6 months post-treatment in those who received GDH and LFD. Long-term improvement for depression was only observed following GDH. IBS-QOL significantly improved in all treatment groups from baseline to week 6 but was only maintained 6-months post-treatment for those who received the combined treatment. No difference in any psychological index was observed across treatment groups from baseline to week 6 or 6-months.
Conclusion: Efficacy of GDH is not inferior to that of LFD for relief of GI symptoms in IBS patients, but they do not show additive effects. Improvement in in psychological status was in general independent of the mode of treatment. GDH is an effective alternative to the LFD, but the lack of additive effect is unexplained.

P0451 GENDER RELATED DIFFERENTIAL EFFECT OF TACHYKININ NK2 RECEPTOR-MEDIATED VISCERAL HYPERALGESIA IN GUINEA PIG COLON

S. Meini[1], F. Bellucci[1], R. Bugianesi[2], A. Crea[2], V. D'Aranno[2], P. Santicioli[1], M. Tramontana[1], C. A. Maggi[1]

Contact E-mail Address: smeini@menarini-ricerche.it
Introduction: The tachykinin NK_2 receptor antagonist ibodutant is currently under clinical investigation for treating irritable bowel syndrome (IBS) with diarrhea, having shown a greater efficacy in female gender (Tack et al., 2013).
Aims & Methods: Aim of this study was to investigate the NK_2 receptor-related gender specificity in a model of colon visceral hyperalgesia. Colitis was induced by rectal instillation of TNBS (0.5 ml, 30 mg/ml in 30% ethanol) in female and male guinea pigs. Electromiographic visceromotor responses (VMR) to colorectal distension (CRD, 0.5-1-1.5-2 ml) was evaluated 3 days after. Ibodutant was evaluated at the doses of 0.33, 0.65, 1.9, and 6.5 mg/kg (s.c., 30 min before CRD) both in inflamed and control animals. The release of neurokinin A (NKA) following treatment (15 min superfusion) of KCl (80 mM) or capsaicin (10 μM) was measured by EIA in both mucosal and smooth muscle dissected distal colon tissues of control and inflamed animals. Pharmacokinetic parameters of ibodutant following a single s.c. administration (0.73 or 2.1 mg/kg .) were measured in the plasma (0-24h).
Results: Ibodutant did not affect VMR following CRD in control animals at any of the used doses. After TNBS-induced colitis ibodutant inhibited the increased visceral hypersensitivity (evident at the lower CRD volume) in female animals by 55 ± 15% at 0.33 mg/kg dose, and the inhibition was total at the higher doses. In male animals the ibodutant 0.65 mg/kg dose was uneffective, and the 1.9 mg/kg inhibited the VMR by 79 ± 9%. Ibodutant pharmacokinetic parameters did not differ between females and males at both tested doses (0.73 and 2.1 mg/kg). NKA was released following KCl and capsaicin treatment and it was generally greater in smooth muscle than in mucosal specimens. Differences dependent on the animal gender were evident in the release from distal colon and especially in the mucosal preparations: the NKA release induced by KCl in control males was 3.9-fold greater than in female preparations (P = 0.0469).
Conclusion: Present results indicate that ibodutant is effective in preventing abdominal pain in a model of visceral hypersensitivity in guinea pigs with a greater efficacy in females. The differences observed in mucosal nerve activation may reflect its participation in colonic visceral hypersensitivity (Hoffman, 2012), and possibly gender related differences.

P0452 EFFECTIVENESS AND TOLERABILITY OF LINACLOTIDE IN THE TREATMENT OF IBS-C IN A REAL-WORLD SETTING: RESULTS FROM A GERMAN NON-INTERVENTIONAL STUDY

V. Andresen[1], S. Diemert[2], S. Miehlke[3], E. Beck[4], A. Prechtl[2], P. Layer[1]
[1]*Israelitisches Krankenhaus, Hamburg,* [2]*Almirall Hermal GmbH, Reinbek,* [3]*Facharztzentrum Eppendorf, Hamburg,* [4]*Anfomed GmbH, Moehrendorf, Germany*

Contact E-mail Address: sebastian.diemert@almirall.com

Introduction: Recent studies suggest that symptom control of IBS-C is only rarely achieved with medications traditionally used for this disorder[1]. Linaclotide is the first compound licensed by the EMA for the treatment of moderate to severe IBS-C. In two phase 3 clinical trials, linaclotide has been shown to significantly improve major symptoms of IBS-C including abdominal pain/discomfort, bloating and constipation[2]. How clinical efficacy translates into effectiveness in a european real world setting, however, has not been investigated.

Aims & Methods: This study sought to elucidate the effectiveness and tolerability of linaclotide in the treatment of IBS-C in everyday clinical practice in Germany. The study was designed as a multicentre, non-interventional, prospective study, scheduled over 12 months. Patients included, were $\geq$18 years old and suffered from moderate to severe IBS-C. The decision for treatment with linaclotide was taken solely by the attending physician prior to study initiation. Data was recorded during regular patient visits (approx. 0, 4, 12, 24 weeks after start of treatment and in week 52 or at the end of treatment). Endpoints for measuring effectiveness include among others abdominal pain and bloating (11-NRS) and number of bowel movements. Tolerability was assessed recording the frequency and severity of adverse Events (AE) as well as the physician's evaluation of tolerability.

Results: 79 centers participated in the study, 375 patients were enrolled. The average time of observation was 4.4 months (median 5 months). Abdominal pain [11-NRS] improved by more than 50% compared to baseline (4.9 points at baseline vs. 2.4 points at 12 months (LOCF); $p < 0.0001$). Intensity of bloating [11-NRS] improved to a similar degree (5.3 points at baseline vs. 2.7 points at 12 months (LOCF); $p < 0.0001$). Bowel movements increased from 2.7 per week at baseline to 4.4 at 12 months (LOCF), $p < 0.0001$. A subgroup analysis revealed, that patients who had failed to receive symptom relief when taking a traditional IBS-C medication prior to study initiation, showed a similarly pronounced treatment response to linaclotide as the overall study population. More than 90% of physicians assessed the tolerability at 6 months as either excellent or good. 50 adverse events (AE) occurred in 27 patients. Three AE in two patients were reported as serious (diarrhea and abdominal cramps). Upon cessation of treatment both patients recovered within one day.

Conclusion: Linaclotide proved to be safe and effective in reducing major symptoms of IBS-C in everyday clinical practice. Further, this study indicated, that patients with a history of failed treatment attempts for IBS-C, alike may benefit from Linaclotide. The improvement of IBS-C symptoms in response to linaclotide, as found in this study, was comparable to that seen in clinical trials.

P0453 INCIDENCE OF COLON CANCER AFTER TREATMENT OF ACUTE COLONIC DIVERTICULITIS IN JAPAN

A. Mizuki[1], M. Tatemichi[2], A. Nakazawa[3], N. Tsukada[3], H. Nagata[1], T. Kanai[4]
[1]*Keiyu hospital, Yokohama,* [2]*Tokai University School of Medicine,* [3]*Saiseikai Central Hospital, Tokyo,* [4]*School of Medicine, Keio University, Tokyo, Japan*

Contact E-mail Address: amizuki@highway.ne.jp

Introduction: Although a few studies have reported the relation between colon cancer and acute colonic diverticulitis (ACD) in western countries, it had not yet been examined in Japan.

Aims & Methods: The purpose of this study was to determine the relationship between ACD and colon cancer in Japan. This study protocol was approved by the ethics committee at Tokyo Saiseikai Central Hospital (TSCH). Between January 1998 and January 2009, 420 ACD patients were diagnosed and treated in TSCH. ACD diagnosis was established by US and/or CT. Patients were treated conservatively and/or surgically. In tracking the patients, questionnaires were sent in order to obtain information on the development of colon cancer. The Cox proportional hazards model was performed to identify risk factors for colon cancer using information about family history of colon cancer, polyps, BMI (body mass index), physical exercise, dietary preferences (meat intake, fiber intake, etc.) smoking habits and alcohol consumption.

Results: One hundred and eleven patients answered the questionnaires, and their median (intraquarter range) follow-up periods were 9.3 (5.3) years. Nineteen patients had a history of recurrent ACD. The patient characteristics are summarized in Table 1. Three cases (2.7%) after treating ACD developed colon cancer. In this study, the incidence rate was calculated to be 276.3/year*-million (mean age 55.5 years-old), while the recent incidence rate of colon cancer among 55 to 60-year-old Japanese is estimated to be 90.975/year*million. Case 1: a 68-year-old male without a history of ACD was diagnosed with colon cancer and surgically treated 5 months after being treated for ACD. The severity of ACD was moderate and had been treated conservatively. Case 2: a 60-year-old female without a history of ACD was diagnosed with colon cancer and surgically treated a month after being treated for ACD. The patient's ACD was complicated by a small abscess and was treated conservatively. Colon cancer was not identified through a CT at admission, but was diagnosed by colonoscopy a month after ACD treatment. Case 3: a 68-year-old female with a history of ACD was diagnosed with colon cancer and surgically treated 43 months after being treated for ACD. She was also treated for colon polyps at the same time. The severity of ACD was moderate and treated conservatively.**Table1:** Patients Characteristics

Presenting features	n = 111
Mean (range) age (yr)	55.4 (18-91)
Gender (M/F)	72/39
Location of ACD (Rt/Lt)	75/36
Hx. of recurrent ACD	19
Complicated ACD	9
Treatment of ACD (conservative/surgery)	107/4
Family Hx. of colon cancer	9
Family Hx. of colon polyp	8
Occurrence of colon cancer	3
Occurrence of colon polyps	27

Conclusion: We found three cases of colon cancer post ACD. The incidence rate seems to be higher than that in the general population, but we are not able to conclude the relationship between ACD and colon cancer because of the small number of cases and the short duration of tracking time.

P0454 SYMPTOMATIC UNCOMPLICATED DIVERTICULAR DISEASE OF THE COLON DOES NOT SHOW ALTERATION OF FECAL MICROBIOTA

A. Tursi[1], W. Elisei[2], M. Picchio[3], G. Giorgetti[4], P. Mastromarino[5], D. Capobianco[5], M. Di Fonzo[6], G. Brandimarte[6]
[1]*Gastroenterology Service, ASL BAT, Andria,* [2]*Division of Gastroenterology, ASL Roma H, Albano Laziale (Roma,* [3]*Division of Surgery, "P. colombo" Hospital, ASL Roma H, Velletri (Roma),* [4]*Digestive Endoscopy and Nutrition Unit, "S. Eugenio" Hospital,* [5]*Department of Public Health, Section of Microbiology, "Sapienza" University,* [6]*Division of Internal Medicine and Gastroenterology, "Cristo Re" Hospital, Rome, Italy*

Introduction: Data on fecal microbiota in symptomatic uncomplicated diverticular disease (SUDD) of the colon are lacking. We assessed therefore fecal microbiota in SUDD, comparing it with patients with asymptomatic diverticulosis and with healthy people.

Aims & Methods: Seventeen female patients with SUDD (median age 64.5 ± 4.7 yrs, range 56-68 yrs), 16 female patients with asymptomatic diverticulosis (median age 61.6 ± 4.0 yrs, range 52-70 yrs) and 19 healthy women (median age 59.0 ± 5.0 yrs, range 563-69 yrs) were analysed. Patients came from the same residence area.

Stool samples were collected at least 4 weeks after colonoscopy. Real-time PCR was used to quantify targeted microorganisms using the Applied Biosystems 7500 Real-Time PCR instrument. *Bifidobacterium* genus, *Clostridium coccoides* group, *Bacteroides-Prevotella* group, *Escherichia* subgroup, *Lactobacillus* genus and *Akkermansia muciniphila* were assessed for the qualitative analysis.

Results: There were no differences in the demographic characteristics among the three groups. The overall bacterial quantity did not differ among the three groups. Thus, a colonic bacterial overgrowth was absent in SUDD ($p = 0.449$). The quantitative analysis of bacterial populations in feces assessed by real-time PCR showed no difference in the numbers of rRNA gene copies neither for the total bacteria nor for the different types analysed in the stool samples in the three study groups (*Akkermansia*: $p = 0.298$; *Bacterioides*: $p = 0.354$; *Bifidobacterium*: $p = 0.876$; *Clostridium*: $p = 0.463$; *Escherichia*: $p = 0.728$; *Lactobacillus*: $p = 0.633$).

Conclusion: SUDD does not show colonic bacterial overgrowth nor any significant qualitative alteration of the fecal microbiota. Further studies are requested to investigate whether bacterial imbalance involving other bacterial strains may be detected in those patients.

Introduction: Colonic diverticular bleeding (CDB) may require endoscopic therapy in the acute setting to stop the hemorrhage and avoid surgery. However identification of the bleeding diverticula with endoscopic hemostasis is not always feasible.
Aims & Methods: The aim is to evaluate the efficacy of endoscopic hemostasis in acute CDB in a period of 5 years. We performed a retrospective observational study of patients who underwent endoscopic therapy in CDB between January 2010 and December 2014.
Results: 156 admissions with CDB in this period were identified. In 15.4% of cases the bleeding diverticula was identified and endoscopic treatment was attempted in all of them. 79.1% were male patients with mean age 78.4 ± 7.3 years. Hemostatic modalities employed: combination of adrenaline injection plus hemoclips in 54.2%, hemoclips in 20.8%, adrenaline in 16.7% and argon plasma coagulation in 8.3%. The rate of rebleeding was in 12.5% within the first 72 hours. Endoscopic hemostasis was attempted again in all cases of bleeding recurrence and it was well succeeded in 66.7%. However, 33.3% (n = 1) needed urgent surgical treatment.
Conclusion: Endoscopic therapy in CDB is safe and has a high success rate. The choice of endoscopic technique did not appear to influence the success of therapy.
Disclosure of Interest: None declared

P0456 NATURAL HISTORY OF ACUTE COLONIC DIVERTICULAR BLEEDING

Introduction: Colonic diverticular bleeding (CDB) is a common cause of lower gastrointestinal bleeding. Treatment measures may include endoscopic, radiological and surgical options.
Aims & Methods: The aim is to characterize epidemiological, clinical and endoscopic features of patients with CDB in a period of 5 years. We performed a retrospective observational study of patients with CDB admitted in a Gastroenterology unit between January/2010-December/2014.
Results: We included 126 patients with a total of 156 admissions. 59.6% were men and the mean age was 78.7 years (range 51 – 96). The average length of stay in the gastroenterology unit was 5 days. 30.1% required blood transfusion with a mean of 2.7 units of packed red blood cell units per transfused patient. 33.4% were under anti-platelets or non-steroidal anti-inflammatory drugs (NSAIDs) and 12.1% under anticoagulant therapy. Bleeding location was identified in 15.4% patients and endoscopic treatment attempted in these cases. Rebleeding rate was 29.5% with only 32.7% of these rebleeding in the first 30 days. Mortality rate was 1.9%.
Conclusion: CDB is usually self-limited and tipically managed with conservative treatment. Rebleeding is frequent although global morbidity/mortality is low. Many patients with CDB are under anticoagulantor antiplatelet therapy.

Introduction: The pathogenesis of diverticular disease is still uncertain but it is thought to be multifactorial, involving environmental, colonic sensory-motor and structural factors. Symptomatic uncomplicated diverticular disease (SUDD) is a syndrome characterized by recurrent irritable bowel syndrome (IBS)-like symptoms attributed to diverticula in the absence of other macroscopically evident alterations. We hypothesized that colonic immune activation plays a role in symptom generation in patients with SUDD.
Aims & Methods: Thus, we characterized immune cells, nerve density and sprouting in patients with SUDD, diverticulosis and healthy controls (HC). For this, a total of 38 subjects were enrolled, of which 14 as HC, 16 with colonic diverticulosis, and 10 with SUDD. In patients with diverticula, mucosal biopsies were obtained close to diverticula and at least 20 cm from the last observed diverticula (normal mucosa). In HC, biopsies were performed at sigmoid and at descending colon. The expression of tryptase (mast cell marker), CD3 (T cell marker), CD68 (macrophage marker), neuronal specific enolase (NSE) [nerve marker], and growth-associated protein 43 (GAP-43) [neuronal outgrowth marker] was assessed by quantitative immunohistochemistry. IBS-like symptom severity and frequency were graded from 0 to 4, by means of validated symptomatic questionnaires.
Results: Mast cells were significantly increased in the peridiverticular mucosa of patients fulfilling the Roma III criteria for IBS, in comparison with HC (5.9 ± 0.7% vs 3.6 ± 0.5%; $P < 0.05$), but not in patients with SUDD as compared to diverticulosis or HC. No differences were detected in the T cell counts among the three groups. Macrophages were significantly increased in patients with SUDD and diverticulosis as compared to HC, both in the peridiverticular (5.8 ± 0.4%, 6.9 ± 0.6%, 4.9 ± 0.4%, respectively; $P < 0.05$) and in normal mucosa (7.1 ± 0.7%, 6.6 ± 0.4%, 4.0 ± 0.3%, respectively; $P < 0.001$). Similarly, the percentage of NSE+ fibers over lamina propria area was significantly enhanced in patients with SUDD and diverticulosis in comparison with HC (5.1 ± 0.7%, 5.5 ± 0.8%, 3.4 ± 0.4%, respectively; $P < 0.05$). Interestingly, GAP-43 immunoreactivity was significantly increased only in patients with SUDD as compared to HC (5 ± 0.6% vs 2.4 ± 0.7%, respectively; $P < 0.05$).
Conclusion: Mucosal immune activation, characterized mainly by macrophages, is a common characteristic of patients with diverticula regardless bowel symtpoms. Mast cells are increased only in patients with SUDD fulfilling Roma III criteria for IBS. Interestingly, nerve fiber sprouting is significantly increased only in patients with SUDD. Neuro-immune activation and sprouting may play a key role in symptom generation in patients with SUDD.

P0458 COLONIC DIVERTICULOSIS AND METABOLIC SYNDROME: A THREATENING ASSOCIATION?

C. Teixeira[1], D. Trabulo[1], S. Ribeiro[1], C. Martins[1], A. L. Alves[1], A. P. Oliveira[1], I. Cremers[1]
[1]*Gastrenterology, Centro Hospitalar de Setubal, Setubal, Portugal*

Contact E-mail Address: ac.corda.teixeira@gmail.com
Introduction: Colonic diverticulosis (CD) has been related with advanced age and lacking of diet fiber. Recently, several studies have shown that metabolic syndrome (MS) is also implicated in its etiopathogenesis.
Aims & Methods: This study aimed to assess the association between MS, obesity and CD. Prospective study within 1 year. Definition of MS according to NCEP-ATP III. Collection of demographic data, risk factors for MS and endoscopic findings of patients who underwent total colonoscopy in our department. Obesity was defined as BMI > 30 kg/m2. Informed consent was obtained. Local Ethic Committee and National Data Protection Committee approved the study. Statistical analysis was done with SPSS 21 and statistical significance was defined as $p < 0.05$.
Results: Two hundred and three patients, 95 males, mean age 65.5 years. CD was diagnosed in 30.5%. Right-sided diverticulosis was found in 3%, left-sided diverticulosis in 79% and pancolonic diverticulosis in 18%. Hypertension was present in 84%, dyslipidemia in 84%, diabetes mellitus (DM) in 47%, MS in 71.9%; 66.8% had increased waist circumference and 43% were obese. A significant association was found between CD and age ($p = 0$), hypertension ($P = 0.02$), dyslipidemia ($p = 0.046$), increased waist circumference ($p = 0.033$) and MS ($p = 0.003$). There was no association with gender ($p = 0.76$), obesity ($p = 0.47$) or DM ($p = 0.836$). There was no higher prevalence of adenoma or adenocarcinoma in patients with CD, in comparison with patients without CD.
Conclusion: In our series, MS was significantly associated with CD. The identification of risk groups is important since diverticulosis can have serious and potentially fatal complications. From our knowledge, this is the first European prospective study evaluating the association between MS and CD.

Introduction: Acquired colonic diverticulum is very common in developed countries and its prevalence increase with age. Colonic diverticulosis is associated with high intracolonic pressure and a weakened bowel wall. Chronic colitis is characterized by liquid stools with low intracolonic pressure and thickened bowel wall. And recently, several studies repoted mesalazine seems to be effective in preventing recurrence of acute uncomplicated diverticulitis.
Aims & Methods: The aim of this study was to assess the prevalence of colonic diverticulosis in inflammatory bowel disease patients, and to assess the prevalence of colonic diverticulosis in mesalazine-based treatment inflammatory bowel disease patients. We investigated that colonoscopy results (colonic diverticulosis) of patients with ulcerative colitis (UC) and Crohn's disease (CD) older than 30 years were retrospectively evaluated and compared with those of patients who underwent screening colonoscopy (control group) from April 2008 to April 2015 in our institution. And the prevalence of colonic diverticulosis was detected in the mesalazine-based treatment UC patients and CD patients compared with no mesalazine-based treatment UC and CD patients.
Results: UC patients were composed of 72 men and 68 women, with a mean age 51.3 years. CD patients were 30 men and 16 women, with a mean age 47.8 years. And control group were composed of 72 men and 68 women, with a mean age 52.3 years. The prevalence of colonic diverticulosis in UC patients was 20/140 (14%) and in CD patients was 3/46 (6%). And the prevalence of colonic diverticulosis in control group was 56/140 (40%). A significantly lower rate of colonic diverticulosis was detected in the UC patients and CD patients compared with the control group ($p < 0.001$). But, no significant difference in the prevalence of colonic diverticulosis was detected between the UC patients and the CD patients ($p < 0.14$). Next, the prevalence of colonic diverticulosis in mesalazine-based treatments UC patients was 14/120 (12%), no mesalazine-based treatments UC patients was 6/20 (30%). Mesalazine-based treatment UC patients was significantly lower percent of colonic diverticulosis was detected compared with no mesalazine-based treatments UC patients ($p = 0.01$). But, the prevalence of colonic diverticulosis in mesalazine-based treatment CD patients was 2/38 (5%), no mesalazine-based treatment CD patients was 1/8 (13%). No significant difference

in the prevalence of colonic diverticulosis was detected between the mesalazine-based and no-mesalazine treatment CD patients (p = 0.49).
Conclusion: Inflammatory bowel disease (UC and CD) patients were lower prevalence of colonic diverticulosis. And in UC patients, we suggested that mesalazine can prevent occurrence of colonic diverticulosis.

Introduction: The pathogenesis of diverticular disease (DD) is multifactorial. Although several aetiological cofactors have been implicated in its pathogenesis, a relevant role seems to be played by an abnormal neuromuscular function. Derangement of enteric innervation has been described consisting in a decrease in cholinergic nerves and nitric oxide content, reduced density of interstitial cells of Cajal and enteric glial cells. Extensive structural changes in the muscle layer have also been reported with thickening, increased collagen and elastin deposition. However data on muscle function are scarce.
Aims & Methods: The aim of this study was to investigate the morpho-functional and molecular alterations inherent to the sigmoid colonic muscle of patients affected by DD. Longitudinal and circular smooth muscle cells (SMC) and strips were isolated separately from surgical colon specimen of 9 patients (58 affected by sigmoid DD and 9 patients (61 surgery for colon cancer. Contractile effects for muscarinic agonist acetylcholine (Ach 1μM) for cells and Carbachol (0.01-1000 μM) for strips, were tested. Relaxant effects were tested in response to vasoactive intestinal peptide (VIP 1μM). qPCR analysis was performed for transcription of muscarinic M3, VIP (VPAC1/VPAC2), Natriuretic Peptide Clearance (NPR-C) receptors and endothelial nitric oxide synthase (eNOS). qPCR data were normalized to β-actin mRNA. Data are expressed as mean ± SE, $p < 0.05$ considered significant.
Results: In DD, an impairment in cholinergic-induced contraction was observed on longitudinal smooth muscle. A significant decrease contractile response was observed both on muscle cells (9.8%±1.4 *vs* 16.8%±1.8) and strips (830 ± 54 *vs* 1644 ± 173 mN/cm^2) and resulted associated to a significant decrease of transcripts for M3 receptors compared to control (6.8 ± 0.18 *vs* 7.98 ± 0.45). No alterations between normal and DD circular SMC were instead observed in contractile responses and cholinergic receptors expression. Relaxation in turn was impaired in circular, but not in longitudinal muscle. DD circular SMC presented a significant decrease in VIP-induced relaxation (33.3%±8.3) in respect to control (93.2%±1.4) that was associated to a significant decrease of transcripts for: VPAC1 (8.7 ± 4.4 *vs* 15.6 ± 0.1), VPAC2 (9.0 ± 0.4 *vs* 13.2 ± 1.0), NPRC (9.5 ± 0.03 *vs* 15.2 ± 0.3) and eNOS (10.3 ± 0.9 *vs* 14.7 ± 0.2).
Conclusion: Different molecular alterations occur in sigmoid longitudinal and circular muscle in DD that impair SMC response to enteric neurotransmitters. These myogenic alterations likely contribute to neuromuscular disorders in DD.
Disclosure of Interest: None declared

P0461 EVALUATION OF THE EFFECTS OF MESALAMINE AND PROBIOTICS ON FAECAL CALPROTECTIN LEVELS IN PATIENTS WITH SYMPTOMATIC UNCOMPLICATED DIVERTICULAR DISEASE

M. Bafutto[1], M. B. G. Costa[2], A. A. F. Bafutto[2], E. H. F. Bafutto[2], E. C. D. Oliveira[3], J. Rezende Filho[4]

Contact E-mail Address: maurobafutto@uahoo.com.br
Introduction: Recent observations suggest that symptomatic uncomplicated diverticular disease (SUDD) is related to change in the colonic microflora and to low-grade inflammation. Faecal calprotectin (FC) levels are related to intestinal inflammation. Mesalamine can improve symptoms and reduce FC levels to a normal range in many patients, but in some FC may persist elevated. The management of these patients is presently unknown.
Aims & Methods: Evaluate the effects of the combined use of mesalazine and probiotis or the increase of mesalamine dose in SUDD patients with persistent elevated FC after mesalamine treatment. One hundred and ten patients (18 y or more) were selected after a clinical interview, colonoscopy, abdominal CT and FC test > 150 microgr/gr. Patients with intestinal neoplasia, previous intestinal surgery, use of antinflammatory drugs and concomitant disease with intestinal inflammation were excluded. The patients were medicated with mesalamine 800 mg b.i.d. for 60 days, and another FC test was done. Patients that presented FC > 150 microgr/gr (32, 2 pts excluded) were divided in two groups – 1) Mp Group – 15 patients that used mesalamine 800mg b.i.d. and a mix of probiotics (*L. acidophilus, L.casei, L. lactis, B. lactis, B. bifidum*) b.i.d. for 8 days; 2) M3 Group – 15 patients that used mesalamine 800 mg t.i.d for 8 days, and another FC test was done. Paired t test was used for statistical analysis.
Results: After 60 days of treatment with mesalazine 800 mg b.i.d, 78/110 (71%) patients presented FC < 150 microgr/gr and 32/110 (29%) FC > 150 microgr/gr. There was a statistically significant decrease (51.8%) in FC levels after combined treatment (Mp Group) (309.70 ± 121.80 x150.80 ± 104.23, $p < 0.002$). There was also a statistically significant decrease in FC levels (42.2%) after treatment with higher dose of mesalazine (M3 Group) (455.40 ± 264.17 x 261.50 ± 209.16; $p < 0.01$). FC levels reduced more (51.8%) in Mp than in M3 group (42.2%), but no statistically significant differences in post treatment FC levels were seen when Mp and M3 groups were compared.
Conclusion: FC decrease to normal range in most SUDD patients after treatment with mesalamine 1.6g. The combined use of mesalamine and probiotics or increasing the dose of mesalamine to 2.4 g may decrease FC in SUDD patients that persisted with FC elevated.

P0462 PROTEASE-ACTIVATED RECEPTOR-1 SIGNALING DEEPLY PARTICIPATES IN THE ABILITY OF TUMORIGENESIS BY CONTROLLING HIPPO-YAP PATHWAY

D. Fujimoto[1], Y. Hirono[1], T. Goi[1], A. Yamaguchi[1]
[1]*First Department of Surgery, University of Fukui, Fukui, Japan*

Contact E-mail Address: fujimoto@u-fukui.ac.jp
Introduction: Control of cell number is important in animal development and tissue homeostasis, and its dysregulation may result in tumor formation or organ degeneration. The Hippo pathway plays crucial roles in organ size control and tumorigenesis. The activity of YAP/TAZ, a transducer of the Hippo pathway, is required to sustain self-renewal and tumor-initiation capacities in cancer stem-like cells (CSCs). But, upstream signals that control the mammalian Hippo pathway have not been well understand. Here, we reveal that the connection between Protease-activated receptor 1 (PAR1) signaling pathway and the Hippo-YAP pathway in gastric cancer.
Aims & Methods: MKN45 cells stably expressing PAR1 (MKN45/PAR1) were established in our laboratory(1). siRNA against PAR1 was synthesized. We studied the change in fraction of side population cell, compared the tumorgenesis in nude mice, and increased dephosphorylated YAP protein levels in nucleus, when PAR1-expressing cell line (MKN45/PAR1 and MKN74), PAR1-null expressing cell line MKN45 (control cell) and inhibited PAR1-expressing cell line MKN74 by PAR1 siRNA were treated with PAR1 agonist TFLLR-NH_2 or PAR1 agonist plus PAR1 selective antagonist SCH79797.
Results: The activity of PAR1 induces increase of the fraction of Side population cells which is enriched with CSCs. But the fraction of side population cells were not increased, when inhibited PAR1 activity. The statistical analysis of the ratios of tumor weight over total situs weight proved that PAR1 activated gastric cancer cell by TFLLR-NH_2 resulted in a significant increase of tumor burden (MKN45/PAR1 and MKN74 cells treated by TFLLR-NH_2 versus control, $P < 0.05$). The peritoneal dissemination tumor weight of MKN45/PAR1 and MKN74 cells treated by TFLLR-NH_2 plus SCH79797 were small as compared to MKN45/PAR1 and MKN74 treated by TFLLR-NH_2 alone. A TFLLR-NH_2 inhibits the Hippo-YAP pathway kinase Lats via Rho GTPase, thereby activates YAP by decreasing phosphorylation and makes YAP increased in nucleus localization.
Conclusion: Our research identifies that PAR1 signaling deeply participates in the ability of tumorigenesis by controlling Hippo-YAP pathway signaling in gastric cancer stem cell. We presume that inhibited YAP will be a new target to treat human gastric cancer invasion and metastasis by dysregulated PAR1 or its agonists.

Contact E-mail Address: elisabetta.trevellin@unipd.it
Introduction: Obesity is associated with an increased risk of cancer and it has been hypothesized that the action of adipokines may influence tumor

microenvironment in esophageal adenocarcinoma (EAC) [1]. Moreover, the adipose tissue stromal vascular fraction is a reservoir of adipose tissue-derived stem cells (ADSCs): a mesenchimal multipotent cell population able to express genes considered as ''stemness'' markers.
Aims & Methods: Our aim is to investigate if peritumoral adipose tissue may play a direct role by altering the expression of stemness genes in human adipose derived stem cells (ADSCs).
Human ADSCs were isolated from obese patients undergoing bariatric surgery and were cultured with conditioned medium (CM) derived from adipose tissue fragments of peritumoral and distal depots of 15 patients with EAC, undergoing surgical resection. After 48h we measured mRNA levels of CD34, CD90, OCT-4 and nucelostemin (NSTM) in ADSCs using Real Time quantitative PCR.
Results: Gene expression CD34, CD90, OCT-4 and NSTM was significantly increased in ADSCs cultured with CM, compared to control untreated cells. In particular, expression of CD34, OCT-4 and NSTM was significantly higher in ADSCs cells cultured with CM of peritumoral depot, in comparison with ADSCs cultured with CM of distal depot. Moreover, the mRNA expression of CD34, OCT-4 and NSTM was increased in cells cultured with CM of peritumoral depot derived from patients with lymph node involvement (N+), compared to peritumoral CM of patients without lymph node involvement (N-).
Conclusion: Our results suggest that peritumoral adipose tissue may directly influence ADSCs through the action of secreted factors. In particular, the mRNA expression of CD34, OCT-4 and NSTM is up-regulated in ADSCs cultured with CM of peritumoral depot derived from patients with lymph node involvement. These observations lead us to hypothesize that adipose tissue may influence stemness of peritumoral adipocytes by a local paracrine signaling, thus creating a more permissive microenvironment for tumor invasiveness.

Contact E-mail Address: franc.bianco19@gmail.com
Introduction: Severe panenteric dysmotility, mainly in the clinical phenotype of chronic intestinal pseudo-obstruction (CIPO), is a severe gut dysmotility characterized by recurrent sub-occlusion episodes with no evidence of any mechanical obstruction. CIPO is a heterogeneous term as it can be applied to a variety of patients for whom a diagnostic biomarker is still unavailable. The diagnosis of CIPO would certainly benefit from the identification of a biomarker. We recently showed an altered expression of APOB in familial CIPO patients carrying a novel RAD21 mutation and in a few sporadic CIPO patients. The aim of this study was to identify whether an altered APOB expression can be a possible biomarker for familial and / or sporadic CIPO by comparing CIPO patients to those with other conditions, e.g. Hirschsprung disease (HSCR, characterized by enteric neuron aganglionosis), irritable bowel syndrome (IBS) and motility unrelated disorders (i.e. celiac disease and non-celiac gluten sensitivity).
Aims & Methods: Sera and ileal biopsies of CIPO patients (n = 28; 18 F, age range: 17 - 67 years) and healthy controls (n = 10; 5 F, age range: 25-38) were used for western blot and quantitative immunohistochemistry. Sera from patients with HSCR, IBS and motility unrelated disorders (celiac disease and non-celiac gluten sensitivity, NCGS) (n = 40 each group) served as disease controls.
Results: Sera from idiopathic CIPO patients showed an elevated expression of APOB48, compared to healthy controls and to sera from patients with HSCR, IBS, celiac disease as well as NCGS. Consistently, the APOB48 signal was markedly increased at tissue level in ileum biopsies of CIPO cases compared to healthy controls and IBS ($32.9 \pm 9.2\%$ vs $7.2 \pm 2.5\%$ cases vs controls; $p = 0.0012$, Student' t test; $32.9 \pm 9.2\%$ vs $5.6 \pm 1.5\%$ CIPO cases vs IBS; $p = 0.0008$). Quantitative analysis performed in gut biopsies revealed also a significant reduction in the number of neuron specific enolase (NSE)- labeled myenteric ganglion cell bodies / ganglion in CIPO compared to control specimens ($p = 0.0039$).
Conclusion: APOB48 expression at serum and tissue level was homogeneously increased in sporadic CIPO highlighting a potential convergent mechanism on a gut-specific APOB isoform. The increased APOB48 can be exploited as possible biomarker to better differentiate CIPO from other diseases.

Contact E-mail Address: m.j.vanderwel@amc.uva.nl
Introduction: Management of Barrett esophagus (BE) relies heavily on the histopathological assessment of biopsies. This assessment is subjective and associated with significant intra- and inter-observer variation. Most guidelines recommend review of biopsies by expert pathologists in case of low-grade or high-grade dysplasia (LGD/HGD). Conventional review of microscopy slides, however, is impractical and does not allow intercollegiate conferences or annotations of relevant findings in images for feedback. A digital revision platform would overcome these practical limitations.
Aims & Methods: In preparation of a national BE digital revision platform we compared the diagnostic accuracy of conventional and digital microscopy for diagnosing BE+/-dysplasia by a panel of expert pathologists. Sixty BE biopsy slides (NDBE; n = 25, LGD; n = 20; HGD; n = 15) were scanned at x20 magnification. Five expert BE pathologists independently assessed all slides four times in 2 alternating rounds of digital and conventional microscopy. Assessments were supervised by a research fellow and the order of rounds as well as the order of the slides was randomized. Pathologists were blinded for the original diagnosis and identifying slide features. Intra-observer and pairwise inter-observer agreement were calculated using custom weighted Cohen's kappa in four categories (NDBE; IND; LGD; HGD). Kappa scores were expressed as fraction of maximum possible kappa score for each cross table.
Results: The mean intra-observer agreement was 0.63 for the 2 rounds of digital assessment and 0.74 for the two rounds of conventional assessment. Mean pairwise inter-observer agreement was 0.61 and 0.64 for first and second round of digital microscopy, respectively. For the two rounds of conventional microscopy, mean pairwise inter-observer agreement was 0.62 and 0.66 respectively. In 48/60 (80%) of digital and in 50/60 (83%) of conventional microscopy reviews a majority diagnosis was reached after the first reading.
Conclusion: Diagnostic agreement of digital microscopy is comparable to conventional microscopy in the setting of an expert pathology platform for BE histology. This study validates the use of digital histopathological assessment of BE biopsies and will be used as the underlying infrastructure for a nationwide, web-based BE revision platform in the near future. This will overcome many logistical and practical issues concerned with conventional histologic review by multiple pathologists.

P0466 INHIBITION OF BMP2 AND BMP4 BY A NOVEL LLAMA-DERIVED NANOBODY SUSTAINS INTESTINAL STEM CELLS IN ORGANOID CULTURES

S. Calpe[1], A. Correia[1], C. Zimberlin[2], J. P. Medema[3], K. K. Krishnadath[1]

Introduction: ''Intestinal organoids'' are structures that mirror the intestinal crypt-villus units. They recapitulate the complete intestinal stem cell differentiation hierarchy and therefore are powerful therapeutic tools in which to study human disease models.
Inhibition of BMP activity is one of the requirements to maintain intestinal stem cells in these *ex vivo* cultures, and is usually provided by the addition of the natural BMP-inhibitor Noggin to the media. Noggin inhibits several BMPs, including BMP2,4 and 7. It is therefore not clear which BMPs are expressed by the intestinal organoid cultures and which need to be inhibited to sustain the stem cell culture.
Aims & Methods: Since BMPs have diverse and opposing roles understanding their specific function in the intestine is of great importance. Here, we set out to investigate which BMPs are required to maintain and culture organoids.
Results: We first tested which of our newly generated and highly specific aBMP nanobodies (VHHs) were able to maintain *ex vivo* stem cell organoid cultures. The three unique llama-derived VHHs with different specificities to BMPs: anti-BMP4 (C4); anti-BMP2,4 (C8); and anti-BMP2,4,5,6 (E7), were used. Addition of these VHHs to the organoid cultures resulted in a decrease in the total BMP activity. Whereas specific BMP4 inhibition (by C4) resulted in a partial decrease in the BMP activity, concomitant inhibition of BMP2 and BMP4 (by C8) was sufficient to result in an almost complete blockage of BMP signaling, to the same level as Noggin and E7. This indicated that the intestinal organoids mainly secrete BMP2 and BMP4. Consequently, inhibition of BMP2 and BMP4, but not BMP4 alone, was enough to sustain self-renewal of crypts as organoids cultured with C8 presented the same morphological characteristics as the ones cultured with Noggin, manifested by the presence of several crypt-like budding structures. Inhibition of BMP2,4,5,6 by E7 did not provide superior growth advantage to the cultures when compared to C8, suggesting that BMP5 and BMP6 are redundant in these cultures.
Conclusion: These results have important implications. First, inhibition of both endogenous BMP2 and BMP4 is enough to sustain self-renewal of small intestine stem cells *in vitro* and this can effectively and selectively be provided by C8, our BMP2,4-specific VHH. Since recombinant Noggin is expensive, C8 offers an easy accessible and cheaper alternative for these cultures. Second, specific inhibition of BMP4 alone does not affect stem cell proliferation. Therefore, C4 antibodies

display important potential for therapeutic use in BMP4-mediated diseases, such as gastric cancer; as they would avoid the deleterious side effects of unchecked cancer stem cell proliferation observed by Noggin and other unselective inhibitors. Since inhibition of BMP5,6 is not required for intestinal stem cell cultures, future *in vivo* application of C8, would prevent detrimental effects of Noggin on for instance bone structures.

Introduction: Human α-thrombin, as a serine protease, catalyzes much coagulation-related reactions, and also promotes the activation of protease-activated receptors (PARs), a kind of G protein-coupled receptor, on the cell. We reported by using an immunohistochemical approach that PAR1 is expressing in the gastric cancer tissues, related poorer prognosis of patients, and its activation induces gastric cancer cells proliferation and invasion in vivo. Epithelial-mesenchymal transition (EMT) is defined as the process in which epithelial cells lose their cell-cell adhesion, and gain migratory and invasive properties to become mesenchymal stem cells, and plays a momentus role in cancer metastasis. These above facts underline the relevance of EMT and PAR1 acytivity to gastric cancer, but there are few reports on the role of PAR1 in EMT. This study investigates the role of PAR1 activity in EMT.
Aims & Methods: we investigated the expression levels of epithelial markers (Ecadherin and βcatenins) and mesenchymal markers (vimentin and fibronectin) by western blotting in the gastric cancer cells; pcDNA3.1 transfected MKN45 (MKN45/Mock), pcDNA3.1-PAR1 transfected MKN45 (MKN45/PAR1), and MKN74, stimulated by α-thrombin or α-thrombin with SCH79797, specific antagonist for PAR1. We observed that α-thrombin induced morphological changes, and immunofluorescence of E-cadherin and fibronectin expression in MKN45/PAR1 and MKN74 cells. We extracted these cells nuclear proteins and examined the binding of E-cadherin transcriptional factors to E-boxes (E1, E2 and E3) by means of EMSA and western blotting.
Results: Western blotting showed, epithelial and mesenchymal markers expression remains the same in MKN45/mock cells treated with α-thrombin for 24 h. But we observed the decreasing of epithelial markers expression and gain of mesenchymal markers expression in MKN45/PAR1 and MKN74 cells treated with α-thrombin. Furthermore, in MKN45/PAR1 and MKN74 cells, treated with α-thrombin and SCH79797, the decreasing of epithelial markers expression and gain of mesenchymal markers expression were suppressed. The morphological changes were observed from round- or epithelial-like to a spindle-like shape phenotype, and immunofluorescence showed the reduction of expression in E-cadherin and the gain of expression in fibronectin. EMSA showed the higher levels of Ebox13 protein complex bands in the MKN45/PAR1 and MKN74 cells treated a-thrombin, and in these cells treated with α-thrombin and SCH79797 showed suppressed levels of E-box complexes bands. We observed significant increase in nuclear levels of the Snail, one of the transcriptional factors of E-cadherin, by western blotting.
Conclusion: We found that α-thrombin induces PAR1 activation and undergo specifically EMT in gastric cancer cell lines. Inhibition of PAR1 signaling pathway may be a new strategy to prevent tumor invasion and metastasis.

Introduction: Glyprolines are family of regulatory peptides. PGP reduces ulcer formation and accelerates ulcer healing by altering cytokine gene expression of blood mononuclear cells. Cytokines are important regulators of inflammation.
Aims & Methods: To study the effect of Pro-Gly-Pro (PGP) and N-acetyl-Pro-Gly-Pro (AcPGP) on the cytokine level in the serum after the acetate ulceration with/without systemic inflammation. Experiments were carried out on male white outbred rats (250-300g). In the first series of experiments, acetate ulcer was caused by applique of acetic acid on the serosa of the stomach by the method of Okabe, in the second series - intraperitoneal injection of LPS and the acetate ulceration. Intranasal injection of peptides (3.7 μmol/kg/40μl, i/n) or saline solution was added during 1-3^{d} or 4-6th days after the acetate ulceration. Blood was collected from the jugular vein of the rats to determine the production of IL-1α, -17α, -4, IFNγ, MCP-1 and TNFα in the serum by means of flow cytometry.
Results: The area of ulcers (AU) on the 4th and 7th days in the first control group averaged 89.8 ± 15.1 mm^2 and 39.2 ± 6.4 mm^2, respectively. PGP reduced the AU significantly on the 4th and the 7th days namely by 80.9% and 87.5%, respectively. The antiulcer effect of AcPGP on the 7th day was equal to 76.0%. The AU on the 4th and 7th days was 33.8 ± 6.5 mm^2 and 42.7 ± 4.3 mm^2 in the second control group. PGP reduced the ulcers by 57.7% and 41.2% to the 4th and the 7th days, respectively. AcPGP had only the tendency to reduce it.
The concentrations of IL-1α and MCP-1 in the serum of the first intact group were 61.9 ± 15.1 pg/ml and 537.2 ± 82.2 pg/ml, respectively. In the second intact group the concentrations of IL-1α and MCP-1 were 718.7 ± 26.0 pg/ml and 803.9 ± 4.6 pg/ml. Other cytokines (CK) in rats of both groups were in minimum quantities (< 10 pg): TNFα, IFNg and IL-17α.
The acetate ulceration in the first control group has induced a significant increase of IL-1α and MCP-1 on the 4th day in the serum in 2.2 and 13.5 times, respectively. The level of the other CK has not changed. On the 7th day the concentration of IL-1α and MCP-1 has been increased. PGP has not affected on the level of elevated cytokines by the acetate ulceration the in the serum of rats. AcPGP has reduced the value of IL-1α in the serum of 37.2% and 41.7% on the 4th and 7th day after the acetate ulceration, respectively, and on the 4th day MCP-1 by 20.4% *vs* control.
The acetate ulceration in the serum of the second control group on the 4th and 7th days, on the contrary, has caused a significant decrease in IL-1α in 2.9 and 2.6 times, respectively. The level of the other CK has not changed. The peptides, PGP and AcPGP have reduced the production of IL-1α by 58.1% and 64.2% on the 4th day *vs* control, respectively. On the 7th day the changes were minor. The content of MCP-1 in the serum of all groups has remained high.
Conclusion: 1. Development of the acetate-induced ulcers in rats is accompanied by a significant increase in serum IL-1α and MCP-1. AcPGP inhibits IL-1α and MCP-1 in the serum on the 4th day and on the 7th day only IL-1α.
2. PGP and AcPGP reduce the production IL-1α on the background of systemic inflammation and acetate ulceration to the 4th day.

Introduction: Severe oxyntic gastric atrophy (OGA) is the classical phenotype of autoimmune gastritis (AIG) and occurs in a small subset of patients with *H. pylori* gastritis as well.
Aims & Methods: To assess characteristics of advanced (moderate to severe) OGA in AIG compared to advanced OGA as a consequence of *H. pylori* infection. Patients presenting for esophagogastroduodenoscopy (EGD) from July 2011 to October 2014 were prospectively included (N = 452). Gastric biopsies were obtained for histological analysis and *H. pylori* testing. Serum gastrin-17 (G17), pepsinogen (PG) I, PGII and antibodies against *H. pylori* and CagA were determined in all patients. In patients with advanced OGA, antibodies against parietal cells and intrinsic factor were also determined. Demographics, medical history, and current medication were recorded. Areas under the curves (AUCs) were calculated for serum biomarkers and compared to histology.
Results: Overall, 34 patients had advanced OGA by histology (22 women, age 61 ± 15, range 23-86). Current or past *H. pylori* infection and AIG were present in 14/34 and 22/34 patients, respectively. *H. pylori*-negative AIG patients (N = 18) were more likely to have another autoimmune disease (OR 18.8; 95%CI 2.0-173.9), severe corpus atrophy (OR 10.3; 95%CI 1.8-60.5), and corpus intestinal metaplasia (OR 37.4; 95%CI 3.8-364.6). The performance of G17, PG I and PGI/II was outstanding for AIG patients (AUC = 0.81, 0.95 and 0.96, respectively), but average for *H. pylori* positive patients with advanced OGA (AUC = 0.68, 0.77 and 0.73, respectively).
Conclusion: *H. pylori*-negative AIG has a distinct clinical, morphological and serological expression compared to advanced OGA in *H. pylori* gastritis.
Disclosure of Interest: None declared

P0470 EFFECT OF PGP AND N-ACETYL-PGP ON CON A-STIMULATED CYTOKINE PRODUCTION BY LYMPH NODES GASTRICUS CAUDALIS CELLS IN RATS ON THE BACKGROUND OF SYSTEMIC INFLAMMATION AND ACETATE ULCERATION

Z. V. Bakaeva[1], J. L. Wallace[2], A. D. Sangadzhieva[3], S. I. Pavlova[4], I. Kozlov[1]
[1]*Pirogov Russian National Research Medical University (RNRMU), Moscow, Russian Federation,* [2]*University of Calgary, Alberta, Canada,* [3]*Lomonosov Moscow State University, Moscow,* [4]*Ulyanov Chuvash State University, Cheboksary, Russian Federation*

Contact E-mail Address: zv.bakaeva@gmail.com
Introduction: Lymphocytes of regional lymph nodes are the main sources of cytokines which are involved in inflammation. Lymph node gastricus caudalis (*ln. gastricus caudalis)* is adjacent to gastroepiploic vein and drains the rat stomach through lymph vessels. Collagen hydrolysis in inflammation leads to the formation of glycine- and proline-containing peptides. PGP reduces the development and accelerates healing of the acetate ulcer.
Aims & Methods: The aims of this study were to examine the effects of Pro-Gly-Pro (PGP) and N-acetyl-Pro-Gly-Pro (AcPGP) on Con A-stimulated cytokine secretion by cells of *ln. gastricus caudalis* in rats on the background of systemic inflammation (SI) and acetate-induced ulceration. Acetate ulcer (AU) caused by the S. Okabe method with modifications (1971). To create SI in rats with/without ulcer was used i.p. injection LPS. Cells of *ln. gastricus caudalis* (10^6/well) were cultured in the presence of the mitogen Con A and peptide PGP/

AcPGP (10^{-5} M). The supernatant was collected after 24 and 48 hours after cell seeding and the cytokines was determined by flow cytometry.
Results: The peak values of IL-1α, MCP-1, IL-17α, IFNg, IL-4 and TNFα accounted for 48 h and were equal in intact cells *ln. gastricus caudalis* 23.8 ± 4.4, 6.0 ± 1.1, 500.8 ± 85.3; 566.0 ± 139.8, 55.6 ± 6.5, 59.2 ± 15.7 pg/ml respectively. On the background of SI secretion IL-1α, MCP-1, IL-17α, IFNg and IL-4 was 1.8, 1.5, 2.0, 1.5 and 12 times less respectively, TNFα was not detected.
On the 4th day after AU induction with SI cells of *ln.gastricus caudalis* produced IL-1α, IFNγ, IL-4 in 2.2, 2.5, 1.4 times more and MCP-1, IL-17α in 1.7, 1.5 times less respectively, than the same cells but without ulcers. It should be noted that in these cells the secretion of IL-1α, IL-17α, IFNγ was respectively in 2.3, 1.8, 4.6 times greater, and MCP-1 was less in 1.9 times than comparison with cells after AU formation, but without SI. On the 7th day after AU induction with SI secretion of MCP-1 and IL-17α increased almost 4.0 times. The values of IL-1α and IFNγ have not changed. IL-4, on the contrary, decreased by 1.7 times. TNFα production was very low.
On the 4th day of AU with SI the PGP reduced production of IFNγ and IL-4 respectively in 3.3 and 3.1 times *vs* control. The AcPGP reduced production on the 7th day IFNg and IL-4 respectively in 2.1 and 2.2 times *vs* control. Both peptides significantly reduced IL-17α production. IL-1α and MCP-1 showed no significant changes.
Conclusion: On the 4th day after the AU induction with SI increased secretion of IL-1α, IFNγ, IL-4 and reduced IL-17α and MCP-1 by cells of *ln. gastricus caudalis* was observed. While AU formation without SI was accompanied by an acute shortage of all these cytokines. PGP reduces AU formation and cell *ln.gastricus caudalis* production of IFNγ, IL-4 on the background of SI. On the 7th day after the AU on the background of SI there was significant increase of MCP-1 and IL-17α and decreased production of IL-4, which is accompanied by an even greater development of ulceration, whereas without SI on the 7th day usually there was a gradual ulcer healing. PGP accelerated ulcer healing by modulation of IL-17α.

P0471 THE RISK OF GASTROINTESTINGAL BLEEDING WITH NOVEL ORAL ANTICOAGULANTS IN A LARGE COHORT OF PATIENTS AT A DISTRICT GENERAL HOSPITAL

A. Kumar[1], B. Disney[1], R. Hipkins[2], S. Hughes[2], S. Ishaq[1], S. Jenkins[2]
[1]*Gastroenterology,* [2]*Haematology, Russells Hall Hospital, Birmingham, United Kingdom*

Contact E-mail Address: aditikumar@nhs.net
Introduction: Rivaroxaban, apixaban and dabigatran are novel oral anticoagulants (NOAC). NOACs have been used as first line treatment for atrial fibrillation since November 2012 and for VTE since December 2013. The trial data regarding the risk of gastrointestinal (GI) bleeding has been conflicting, although a meta-analysis found an increased risk of GI bleeding with NOACs as opposed to warfarin (2.3% versus 1.3%)[1]. However, little is known about the incidence of GI bleeding in the real-world setting. We aimed to evaluate the incidence of GI bleeding, endoscopic findings, time of onset of bleeding and the need for intervention in patients taking NOACs in our institution.
Aims & Methods: We performed a retrospective review of all patients at Russells Hall Hospital who received NOACs. These patients were identified from the anticoagulation database and cross-referenced with the GI database and patient notes. Basic demographic, clinical and laboratory data and endoscopic findings were collated.
Results: A total of 2490 patients were identified to be on NOACs, of which 64 were found to have an episode of GI bleeding. In this cohort of patients, this gives an incidence of 2.57%. 57 of 2337 patients were on rivaroxaban, 3 of 77 on apixaban and 4 of 76 on dabigatran with an incidence of GI bleeding of 2.4%, 3.9% and 5.3% respectively. There was a greater incidence found with females than males (55% vs. 45%) with the median age 79.6 years (range 53-95). The 30-day mortality rate was 10.9% (n = 11). The causes of death were stated as metastatic carcinoma (3), sepsis (3), pneumonia (2), and unknown (3).
Of these 64 patients, clinically 33 (51.6%) had an upper GI bleed (UGIB) and 31 (48.4%) had a lower GI bleed (LGIB). The median time from starting NOAC to having a GI bleed was 6.7 months (range 2 days-19.7 months). Endoscopy results were varied with the most common findings being haemorrhoids (15%), diverticular disease (14%), normal findings (11.8%), polyps (10.8%), peptic ulcer disease (9.7%), gastritis (8.6%), and other (30.1%). 9 patients (14%) required endoscopic intervention and 23 patients (35.9%) required the use of blood products. As compared to LGIB patients, UGIB patients required greater frequency of endoscopic intervention (15% versus 12.9%), were more likely to be inpatients (97% versus 35%) with a greater drop in haemoglobin (median Hb at presentation: 82 g/L versus 105 g/L) and increased use of blood products (55% versus 16%).
Conclusion: Although the results from our cohort of patients show a higher incidence of GI bleeding of 2.57% as compared to that observed in previous studies (2.3%), there were no deaths directly related to the bleeds, only 14% required endoscopic intervention and the use of blood products was relatively low at 35.9%. Whilst the incidence of GI bleeding is lower for rivaroxaban than apixaban and dabigatran, the data for the latter two is much smaller and thus further studies are needed to make a true comparison between the three NOACs.

P0472 ENDOSCOPIC VARICEAL LIGATION FOLLOWED BY ARGON PLASMA COAGULATION VERSUS ENDOSCOPIC VARICEAL LIGATION ALONE: A RANDOMIZED CONTROLLED TRIAL

A. A. Abd Elmoety[1], Y. Hamza[2], A. Zeid[1], A. Kamal[1]
[1]*Internal Medicine, Hepatology Unit,* [2]*General Surgery Department, Head and Neck Unit, Faculty of Medicine, Alexandria University, Alexandria, Egypt*

Contact E-mail Address: ahmed.kamal.med.scientific@gmail.com
Introduction: After the first attack of acute variceal hemorrhage patients have a very high risk of recurrent variceal bleeding and death. Rebleeding rates after endoscopic variceal ligation (EVL) are high, thus current recommendation is to combine non selective beta-blockers (NSBB) to EVL but side effects and relative contraindications to NSBB are common and hinder treatment or require discontinuation in 15-20% of cirrhotic patients. Induction of fibrosis of distal esophageal mucosa using argon plasma coagulation (APC) may suppress capillary proliferation and invasion of perforating veins thus decreasing esophageal varices (EV) recurrence.
Aims & Methods: This study included 40 subjects with post viral liver cirrhosis and previous history of upper gastrointestinal bleeding. They were submitted for EVL and obliteration of varices. Then patients were randomly assigned to either APC (group 1) or just observation (group 2).
Results: During 2 years follow up 20% of subjects in group 1 experienced EV recurrence but no one needed rebanding. In group 2, 68.4% experienced EV recurrence ($p = 0.002$) and 63.2% underwent rebanding ($P < 0.001$). (Figure) No subject in group 1 experienced rebleeding during the 2 year follow up, while 10.5% of subjects in group 2 experienced rebleeding from EV ($p = 0.231$). No subject in both groups showed development of gastric varices. 3 subjects in group 1 and 4 subjects in group 2 showed development of new severe portal hypertensive gastropathy ($p = 0.695$). One subject in group 2 (5.3%) experienced bleeding from severe portal hypertensive gastropathy during the 2 year follow up while no subject in group 1 experienced this ($p = 0.487$).
Conclusion: APC can decrease the risk of recurrence, the need for rebanding of EV and the frequency of endoscopic follow up after EVL. APC after EVL may be recommended in secondary prophylaxis against esophageal variceal bleeding especially in those who have contraindications, intolerant or incompliant to NSBB.

P0473 USEFULNESS OF THE NASOGASTRIC LAVAGE BEFORE EMERGENCY ENDOSCOPY IN THE PATIENTS WITH NON-VARICEAL UPPER GI BLEEDING

A. Ono[1], H. Hata[1], M. Toki[1], H. Mori[1], T. Hisamatsu[1], S. Takahashi[1]
[1]*The Third Department of Internal Medicine, Kyorin University Hospital, Mitaka-city, Japan*

Contact E-mail Address: akiko@orangejp.com
Introduction: Before treating emergency department patients with hematochezia, melena or hematemesis, it is important to predict the presence and location of a bleeding source. Moreover, fine visual field is necessary to find a bleeding point and achieve prompt hemostasis in emergency endoscopy. In Japanese clinical practice, nasogastric lavage is often performed before emergency endoscopy for gastrointestinal hemorrhage. However, it is not clear whether nasogastric lavage before emergency endoscopy is useful.
Aims & Methods: We estimate the validity of nasogastric lavage before endoscopy in emergency department patients with non-variceal upper GI bleeding. From May 2011 to January 2014, 92 patients with hematochezia, melena or hematemesis underwent emergency endoscopy (within 24 hours from onset) in Kyorin University Hospital. In 60 patients nasogastric lavage was performed (500-2000ml) before endoscopy (group A), and in 32 patients nasogastric lavage was not performed (group B). We retrospectively reviewed their medical records to analyze the following factors: age, sex distribution, systolic blood pressure and interval from onset to endoscopy, nasogastric lavage findings (bloody, "coffee ground", clear/bile), a vision score of the endoscopic field (1: No need to wash, 2: The fold of gastric greater curvature hidden, 3: Gastric fundus full of residue and blood, 4: Gastric angle not visible), detection of bleeding points, procedural time for treatment, duration of hospitalization, the success rate of endoscopic hemostasis, rebleeding rate and complications associated with nasogastric lavage.
Results: Between group A and B, there was no significant difference in mean age, sex distribution, systolic blood pressure and interval from onset to endoscopy. And the blood test of hemoglobin, serum albumin level and blood urea nitrogen on admission were also no significant difference between group A and B.
There were 48 bleeding points in group A (60) and 26 in group B (32), and the rate of bleeding point was the same (80%). In group (A), 35 bleeding points (97.2%) were detected out of 36 bloody lavage findings, and 8 bleeding points (88.9%) were detected out of 9 "coffee ground" lavage findings. On the other hand, only 5 lesions (33.3%:1 angioectasia/4 duodenal ulcer) were detected out of the 15 patients with clear/bile lavage findings.
An average of vision score (1.85 vs 1.88, $p = 0.89$) and the success rate of endoscopic hemostasis (91.7% vs 96.2% $p = 0.80$) was not significantly different between the two groups. The rate of rebleeding or conversion to transcatheter embolization were not significantly different between the two groups (rebleeding 4.2% vs 3.8% $p = 0.52$, transcatheter embolization 4.2% vs 0.0% $p = 0.76$). And the duration of hospitalization also did not differ between the two groups (19.7days vs 22.3 days $p = 0.70$). There was no complication associated with nasogastric lavage.
Conclusion: Nasogastric lavage before emergency endoscopy may be useful in predicting the presence of bleeding resources. However, it did not lead to the improvement of clinical outcomes, such as the success rate of endoscopic

hemostasis, and the rate of rebleeding or conversion to transcatheter embolization and the duration of hospitalization.

Contact E-mail Address: amrmoh_80@yahoo.com
Introduction: Variceal bleeding is the most common cause of acute upper gastrointestinal bleeding in Egypt and its management represents a significant economic burden. There are only few inconsistent reports on the incidence and prediction of outcome of acute variceal bleeding in Egypt. Admission Rockall Score (RS), full RS, and Glasgow-Blatchford Score (GBS) can all be used to stratify the risk but to our knowledge no studies were done to compare between them in prediction of outcome in variceal bleeding in our country.
Aims & Methods: To compare both admission and full RS and GBS in predicting outcomes in variceal bleeding patients in Upper Egypt. A total of 120 patients with variceal bleeding were enrolled in the study.
Patients were followed up 30 days after admission to emergency department to determine cases of rebleeding or death during this period. By using areas under the curve (AUC), we compared the 3 scores in terms of identifying the most predictive score of unfavourable outcome
Results: Rebleeding rate was 15% (18 patients), mortality rate was 14.7% (17 patients), transfusion was needed in 72 patients (60%). For prediction of rebleeding Blatchford score had the highest specificity 68.6% and the highest sensitivity 72.2% (AUC, 0.71) and it was superior to both the full RS (AUC, 0.67), and admission Rockall score (AUC, 0.60). Full Rockall score had the highest specificity 87.5%, (AUC, 0.79)in prediction of death and it was superior to both the admission RS (AUC, 0.72), and Blatchford score (AUC, 0.66). GBS had the highest specificity 75.0% and the highest sensitivity 66.7% (AUC, 0.76) in detecting patients who needed transfusion, it was superior to both the full RS (AUC, 0.57), and admission RS (AUC, 0.55).
Conclusion: Galasgow Blatchford score can be used to predict rebleeding and need for transfusion in patients with variceal bleeding while Full Rockall score was the most accurate score that predicted mortality risk in these patients

Introduction: Upper gastrointestinal bleeding (UGIB) secondary to peptic ulcer disease (PUD) is still a life-threatening condition and one of the greatest challenges in Gastroenterology. Different scoring systems have been developed to identify the patients with higher risk of adverse outcomes.
Aims & Methods: To assess the effectiveness of different scoring systems - Glasgow-Blatchford-Score (GBS), the Baylor College Score (BCS), Rockall Score (RS), Almela Score (AS), Cedars Sinai Score (CSS) – at predicting rebleeding, need for surgery and mortality.
Retrospective review of all UGIB admissions secondary to PUD that required hospitalization, from January 2010 to December 2014. We recorded demographic, clinical and laboratory data and we assessed the different scores and compared them by using areas under the curve (AUCs).
Results: We identified 377 patients, 249 males, with a mean age of 70 years. Duodenum ulcers (57%) were more frequent then gastric ulcers. When analyzed the predictors of recurrent bleeding: 47 patients (13%) presented gastric ulcers along the lesser curvature or duodenal ulcers along the posterior wall of the duodenal bulb; 67% had endoscopic high-risk stigmata for recurrent bleeding (≥Forrest IIB); 54% were described as Large ulcers (> 1 cm) on endoscopy. Rebleeding occurred in 20% of patients, need for surgery in 7% and mortality was 7%.
For the prediction of rebleeding, the scores that showed more discriminating power were AS (AUC: 0.811), CSS (AUC: 0.802) and RS (AUC: 0.743); although AS and CS weren't statistically different, they were both statistically superior to RS (respectively, $p = 0.010$ and $p = 0.031$).
For the prediction of mortality, the scores that demonstrated better discriminating power were RS (AUC: 0.874), the CSS (AUC: 0.869) and the GBS (AUC: 0.856), without statistically significant differences, when compared.
Given the need for surgery, the scores that revealed the highest discriminating power, were AS (AUC: 0.771), the RS (AUC: 0.707) and the CSS (AUC: 0.696); no statistically significant differences were observed when compared.
Conclusion: The set of our results favor the use of CSS and the RS, instead of the other scores, in the prediction of rebleeding, need for surgery, and mortality during hospitalization, with superiority of CSS in the prediction of rebleeding risk.

Introduction: Acute gastrointestinal bleeding is a potentially life-threatening condition which requires rapid assessment and dynamic management. Several scoring systems have been established to predict mortality and rebleeding.
Aims & Methods: The aim of this study was to compare three different scoring systems in order to predict short-term mortality, rebleeding rate, duration of hospitalization and need for blood transfusion in elderly patients with upper gastrointestinal bleeding. A retrospective analysis was undertaken in 335 elderly patients with upeer gastrointestinal bleeding. The pre and post endoscopic Rockall, Glasgow-Blatchford and AIMS65 scores were calculated, and the association between these scoring systems and patient outcomes such as rebleeding, mortality, and need for blood transfusion were assessed. The area under the receiver operating characteristic curve was calculated to assess the validity of scoring systems in predicting mortality, rebleeding, and duration of hospitalization.
Results: Pre (4.5) and post-endocopic (7.5) Rockall were superior to Glasgow-Blatchford (12.5) in terms of predicting mortality ($p = 0.006$, $p = 0.015$). Likewise, pre (4.5) and post-endoscopic Rockall were superior to Glasgow-Blatchford in terms of predicting rebleeding ($p = 0.013$, $p = 0.03$). There was an association between prolonged hospitalization and mortality. 94% of patients with an average 5 days of hospitalization were alive, while the percentage reduced to 56.1% for 20 days and 20.2% for 40 days.
Conclusion: The Rockall score is clinically useful in predicting mortality and rebleeding compared to Glasgow-Blatchford and AIMS65 systems. However, in predicting duration of hospitalization and need for blood transfusion, Glasgow-Blatchford scoring system was superior to Rockall and AIMS65 in elderly patients with upper gastrointestinal bleeding.

Contact E-mail Address: daisukehawks@gmail.com
Introduction: The endoscopic submucosal dissection (ESD) technique was introduced to obtain en bloc specimens of early gastric cancer. Endoscopic high-frequency soft coagulation is used to manage visible bleeding or nonbleeding vessels during ESD. Upper gastrointestinal bleeding (UGIB) is the most common gastroenterological emergency, and has a considerable morbidity and mortality. Recently, endoscopic high-frequency soft coagulation has been used to establish endoscopic hemostasis in patients with nonvariceal UGIB. This study aimed to compare the aetiology and clinical outcome of nonvariceal UGIB between two periods during the last 12 years.
Aims & Methods: We retrospectively investigated the medical records of 568 patients who underwent emergency endoscopy for nonvariceal UGIB from September 2002 to August 2014. The patients were divided into two periods: the first period was from September 2002 to August 2008 and the second period was from September 2008 to September 2014. We examined the characteristics of these patients and compared the efficacy of endoscopic hemostasis by soft coagulation using the ESD technique and hemoclips. We also compared the rate of endoscopic hemostasis by specialists and by trainees The specialists already had the fundamental skills and knowledge needed for ESD, and each specialist assisted in 40 gastric ESD procedures.
Results: Among the 568 patients with UGIB, 230 were in the first period and 338 patients were in the second period. The ratio of *Helicobacter pylori* infection was significantly lower in the second period than in the first period (62.8% vs. 77.4%, $p < 0.001$). The proportion of patients who took antithrombotics did not change between the two periods. Peptic ulcer lesions were the main cause of bleeding (85.2%) during the study period, but bleeding from other lesions, such as esophagitis, increased significantly in the second period ($p < 0.001$). Endoscopic hemostasis was successfully carried out in 220/230 (95.6%) patients in the first period and in 321/338 (95.0%) patients in the second period, with no significant difference between the periods. There were no differences in the incidence of rebleeding (13.0% vs. 9.1%) and mortality

(0.9% vs. 2.7%) between the two periods. In the modality of endoscopic hemostasis, the rate of endoscopic hemostasis by soft coagulation using the ESD technique was significantly higher in the second period than in the first period (77.9% vs. 10.6%, $p < 0.001$). The rate of endoscopic hemostasis by trainees was significantly higher in the second period than in the first period (75.7% vs. 56.1%, $p < 0.001$).
Conclusion: Endoscopic hemostasis by soft coagulation using the ESD technique is safe for trainees and effective with UGIB.

Introduction: Acute upper gastrointestinal bleeding is a common medical emergency worldwide and its major cause is peptic ulcer bleeding (PUB). Most therapeutic guidelines recommend performing endoscopy within the first 24 hours (early endoscopy).
Aims & Methods: The aim of the study is to evaluate the influence of time interval to perform endoscopy (endoscopy timing) on mortality rate, re-bleeding rate, needs of surgery, needs of transfusions and hospitalization time.
It is a prospective study done in a tertiary medical service with permanent access to Endoscopy Department, for 8 months interval (between November 2012 and July 2013). 201 patients with peptic ulcer bleeding were included in the study. The endoscopy was performed within the first 24 hours in all patients. The patients were followed the whole duration of hospitalization. Based on endoscopy timing the patients were divided into 2 groups: urgent endoscopy (UE) (within 3 hours) and early endoscopy (EE) (3-24 hours).
Results: In the studied group of 201 patients, 112 of them had UE (55.7%), while 89 had EE (44.3%). The mean age was 62.6 years (min 19 years, max 94 years), with a predominance of male patients (68.7%).
Mortality rate was 9.5%, it was 11.6% in patients with UE compared with 6.7% in patients with EE ($p = 0.35$).
Re-bleeding occured in 8% of the paientes, it was more frequent in UE group compared to EE patients (11.6% vs 3.4%), but the difference was without statistical difference ($p = 0.06$).
Surgery was needed in 4% of the patients, with a higher rate in patients with UE than patients with EE (6.3% vs 1.1%) ($p = 0.14$).
The average need of transfusions was higher in UE group compared to EE group (2.29 vs 1.69 blood units), without statistical significance ($p = 0.08$).
Even the hospitalization period is slighty prolonged in patients with EE vs UE group (8.26 days vs 7.27 days), this was not significantly influenced by the endoscopy timing ($p = 0.33$).
Conclusion: Urgent endoscopy compared to early endoscopy has not been significantly superior regarding the mortality rate, re-bleeding episodes, needs for surgery, needs of transfusions and hospitalization period in patients with UGIB.

Introduction: The wireless motility capsule (WMC) is a minimally invasive ambulatory technology that concurrently measures intraluminal pH, temperature and pressure as it traverses the gastrointestinal (GI) tract. Knowledge gaps remain concerning regional GI transit times with type 1 diabetes mellitus (T1DM) with established sensory neuropathy. Moreover, pH drop across the ileocaecal valve (ICV) has been recently proposed as a surrogate biomarker for bacterial fermentation in the caecum.
Aims & Methods: 24 patients with T1DM (17 male, mean age 54 years, range 36-66), with confirmed sensory neuropathy but no GI symptoms, and 22 healthy controls (17 male, mean age 54 years, range 38-72) ingested a WMC together with a standardized meal. Gastric emptying time (GET), small bowel transit time (SBTT), colon transit time (CTT) and whole gut transit time (WGTT) and pH drop across the ICV were calculated using the WMC.
Results: In patients with T1DM, GET (350 minutes $\pm$65.8 vs. 206 $\pm$11.8, $p = 0.05$), CTT (2188 minutes $\pm$235 vs. 1302 $\pm$155, $p = 0.004$) and WGTT (2831 minutes $\pm$271 vs. 1893 $\pm$199, $p = 0.009$) was longer in comparison to healthy controls. pH drop across the ICV was higher in T1DM patients when compared to controls (-1.73 ± 0.4 vs. -1.3 ± 0.5, $p = 0.005$) and was associated slower CTT ($r = -0.6$, $p = 0.002$). Multivariate linear regression, controlling for age, gender and glycaemic control were not associated with changes in regional or whole gut transit times.
Conclusion: In patients with T1DM with sensory neuropathy, but without GI symptoms, GET, CTT and WGTT are prolonged in comparison to controls and had a larger pH drop across the ileocaecal valve suggesting heightened caecal fermentation. Whether changes in the microbiota contribute to such changes in transit times in T1DM warrants further study as it may represent a potential therapeutic target prior to the development of symptomatic dysmotility.

P0480 ACHALASIA IN CHILDREN: COMPARISON BETWEEN THE IDIOPATHIC AND THE GENETIC FORM

A. Tebaibia[1], M. E. A. boudjella[1], N. oumnia[1], M. Boucelma[1]
[1]*Internal Medicine, Kouba Hospital, Algiers, Algeria*

Contact E-mail Address: tebaibia@hotmail.com
Introduction: Achalasia is a primary esophageal motor disorder rarely observed in children. It is most often isolated and called idiopathic achalasia or exceptionally associated with a genetic disorder.
Aims & Methods: To compare the epidemiological, clinical and paraclinical characteristics in the two entity.
This is a prospective study of 116 consecutive children (M : 62 (53%), F :54 (47%), mean age :10 $\pm$ 4 yrs ; range : 3 months -16 years) enrolled over a period of 24 years (1992-2014). All children underwent a complete clinical check up, an ophthalmologic check up with a Schirmer test, an adrenal hormone balance, an esophageal barium swallow, an upper endoscopy and an esophageal manometry. a neurological examination and EMG were performed in case of suspicion of Allgrove syndrome.
Results: Achalasia was isolated (group I) in 64 cases, it was associated to Allgrove syndrome (group II) in 52 cases. 3A syndrome (alacrima, achalasia, adrenal insufficiency) was observed in 36 cases, 2A syndrome (alacrima, achalasia) in 13 cases and 4 A syndrome (alacrima, achalasia, adrenal insufficiency, autonomic neuropathy) in 3 cases. The comparison between the two groups (Table 1) showed a significant differences between children in both groups. Two (4%) deaths, caused by acute adrenal insufficiency, were recorded in group II.

Table-1

	Isolated achalasia Group I : (n = 64)	Allgrove syndrome Group II : (n = 52)	P
Mean age (year)	11 $\pm$ 4.2	8 $\pm$ 5	<0.001
Consanguinity	0%	75%	-
Backwardness	13%	35%	<0.001
Chest pain	23%	0%	<0.01
Familial achalasia	0%	43%	<0.001
Growth retardation	13%	65%	<0.001

Conclusion: Achalasia in children is frequently associated with Allgrove syndrome. Consanguinity, backwardness, growth retardation and familial form are almost found in Allgrove syndrome. Prognosis is related to the acute adrenal insufficiency.
Disclosure of Interest: None declared

P0481 RELIABILITY OF A SINGLE MULTIPLE RAPID SWALLOWING SEQUENCE DURING HIGH RESOLUTION MANOMETRY

Contact E-mail Address: aurelio.mauro88@gmail.com
Introduction: Low (10ml) and/or high (200ml) volume multiple rapid swallowing (MRS) have been proposed as additional tests during oesophageal high resolution manometry (HRM) in order to assess pathophysiological alterations of clinical significance. Reproducibility of these tests has however been little explored, although, for low volume MRS, one report has suggested that a single sequence provides reliable information[1].
Aims & Methods: To assess concordance of two sequences of both 10 and 200 ml MRS in patients referred for HRM. Achalasia patients were excluded. One hundred and nine consecutive patients performed the two sequences for both tests, however only 91 of them (35 men, 48; 28-74 yrs) performed them adequately and were included in the study. Nineteen healthy volunteers (7 men, 28;23-33 yrs) provided the normal range of the following MRS related variables, which have been evaluated: 1) presence of motor inhibition, i.e. no pressure wave $>$ 20mmHg in the distal oesophageal body during MRS; 2) oesophago-gastric pressure gradient (OGPG) in the last 5s of MRS, as a measure of resistance to outflow; 3) 4s integrated relaxation pressure (4sIRP); 4) presence of after contraction, i.e. wave of $>$ 20 mmHg in the distal oesophageal body; 5) ratio between the distal contractile integral (DCI) of the identified after-contraction and the mean DCI of 10 single water swallows (MRS/SS DCI ratio), as a measure of motor reserve.
Results: Descriptive data and concordance between values of the two sequences, evaluated with Lin concordance correlation coefficient[2], are shown in table 1*. Concordance of the two sequences as to being inside or outside of our normal range was evaluated with kappa coefficient and was moderate to substantial for presence of motor inhibition, OGPG and 4s IRP during 10 ml MRS (k: 0.50, 0.78, 0.77 respectively) and 200 ml MRS (k: 0.52, 0.56, 0.63 respectively), but was disappointingly low for presence of after contraction wave and MRS/SS DCI ratio after 10 ml MRS (k: 0.28, 0.10 respectively) and 200 ml MRS (k: 0.31, 0.20 respectively).
* Lin coefficient not applicable for presence/absence of motor inhibition and after contraction as they are a nominal variable.

Table. 1: Descriptive data expressed as Median (IQ range) and Lin concordance correlation coefficient between the first and the second multiple rapid swallowing (MRS).

	10 ml MRS		Lin	200 ml MRS		Lin
	1st	2nd		1st	2nd	
OGPG (mmHg)	1 (−1 to 4)	1 (−1 to 4)	0.81	2 (1 to 5)	2 (0 to 4)	0.75
4s IRP (mmHg)	2.5 (0.6-5.2)	2.1 (0.6-4.7)	0.89	2.5 (0.7 – 5.2)	2.4 (0.2 – 5.0)	0.81
MRS/SS DCI ratio	1.3 (0.8 – 1.9)	1.4 (0.6 – 2.1)	0.54	0.7 (0.4-1.2)	1.0 (0.4 – 1.8)	0.01

Oesophago-gastric pressure gradient (OGPG), 4 second Integrated Relaxation Pressure (4s IRP), Multiple rapid swallowing/single swallow Distal Contractile Integral (MRS/SS DCI).

Conclusion: Inhibitory and resistance variables during low and high-volume MRS are reproducible, whereas strength of the after contraction is not. One sequence of MRS is not enough in order to evaluate the motor reserve; the optimal number of sequences needs to be determined.

P0482 MANOMETRIC CHANGES ASSESSED BY HIGH RESOLUTION MANOMETRY BEFORE AND AFTER LUNG TRANSPLANTATION

C. Ciriza De Los Ríos[1], F. Canga[1], I. Castel[1], G. Castellano[1]
[1]*Gastroenterology, Hospital 12 De Octubre, Madrid, Spain*

Contact E-mail Address: constanzacarpa@gmail.com

Introduction: Lung transplantation (LTx) is a good choice in most patients with end-stage lung diseases. Gastroesophageal reflux (GER) is associated with LTx rejection and can also impair the esophageal motility. However, is not very well known if other esophageal motor disorders (EMD) can also be contributed to LTx rejection. High resolution manometry (HRM) allowed a better characterization of EMD, upper esophageal sphincter (UES) and esophagogastric junction (EGJ).

Aims & Methods: To determine pre-transplant EMD and changes in esophageal motility observed after LTx. Observational cross-sectional study. 47 consecutive patients in which HRM (Manoscan; Given) was performed prior to LTx and six month after.

Results: Patients' characteristics and manometric parameters are expressed in the table. EMD were found in 36.2% and 44.7% of the patients before and after LTx respectively. There were no differences between lung disease, EGJ abnormalities and EMD before LTx ($p = 0.189$ and $p = 0.372$; respectively). Neither between lung disease and EGJ diagnosis after LTx ($p = 0.664$) but more esophageal dysmotility was observed after LTx ($p = 0.021$). There were no differences between the LTx type and EGJ abnormalities ($p = 0.064$) and EMD ($p = 0.994$). No differences were found in the EGJ diagnosis before and after LTx ($p = 0.387$), although EGJ morphology changed pre and post LTx ($p = 0.025$) as 38.3% had EGJ disruption before LTx compared to 17% after. Although there was no significant change in esophageal diagnosis pre and post LTx ($p = 0.082$), more EMD was observed after LTx at the expense of hypercontractile esophagus (1 (2.1%) pre LTx and 9 (19.1%) post LTx). There were no differences in the UES ($p = 0.506$).

Conclusion: Patients who are candidates for LTx had a high frequency of esophageal motor dysfunction. HRM changes were observed after LTx presenting more frequently higher LES pressure and hypercontractile disorder. These findings might be caused by indirect vagal nerve injury within the surgery.

Disclosure of Interest: None declared

P0483 EFFECT OF AZITHROMYCIN ON ESOPHAGEAL HYPOMOTILITY (EH) AND PREDICTION OF RESPONSE BY OESOPHAGEAL STIMULATIONS TESTS DURING HIGH RESOLUTION MANOMETRY

D. Sifrim[1], J. Jafari[1,2], E. Yazaki[1], T. Wong[2], P. Woodland[1]

Introduction: Patients with ineffective esophageal contractions and/or fragmented peristalsis during HRM are considered to have esophageal hypomotility (EH). Esophageal hypomotility is due to neural and/or muscular function impairment. In healthy subjects, esophageal stimulation tests like Multiple Rapid Swallows (MRS), increased outlet resistance at GEJ with abdominal compression (AC) and bread swallows (BS) trigger higher amplitude esophageal contractions, unravelling a "contractile reserve capacity" in the esophageal body. The response to these tests in patients with significant EH is unknown, and probably depends on severity and reversibility of neuro-muscular dysfunction. Prokinetic drugs have been used to treat HH with inconsistent results. Azithromycin (AZI) is a macrolide antibiotic with similar prokinetic effects as erythromycin, with fewer side effects and less tachyphylaxia.

Aims & Methods: We aimed to assess the effect of AZI in patients with EH and

Abstract number: P0482

Clinical data	Before LTx	After LTx	
Age	53.6 (50.6-56.6)	55 (51.9-58.1)	P < 0.001

the ability of stimulation tests to predict the response to AZI. In a placebo-controlled, parallel designed trial we studied 26 patients with esophageal hypomotility defined in the Chicago Classification V3.0 as 1) > 50% ineffective swallows with DCI < 450 mmHg-s-cm and/or 2) > 50% swallows with fragmented peristalsis. Patients underwent HRM pre and post treatment with AZI 250mg or placebo. Each HRM included MRS (5 water swallows), AC (10 water swallows during abdominal compression) and BS (10 bread swallows). DCI was used to assess strength of baseline contractions and during stimulation tests.
Results: AZI normalised EH in 5/9 patients with abnormal DCI and in 7/13 patients with fragmented peristalsis whilst placebo did not normalized EH. AZI increased DCI from 337.7 ± 286.2 mmHg.cm.s to 617.8 ± 384 mmHg.cm.s (P = 0.01). The % increase of DCI by AZI was 162.9 ± 361.2 and by placebo was 64.5 ± 92.8. DCI ratio (after MRS/baseline) > 1.2 segregated responders to AZI with a sensitivity of 78%, specificity 75%, PPV 87.5%, NPV 60% and LR of 3.11. A DCI after MRS of ≥395 mmHg.cm.s segregated responders to AZI with a sensitivity of 80%, specificity 75%, PPV was 80%, NPV 75% and LR 3.2. Combining the criteria for DCI after MRS and DCI during abdominal compression further increased sensitivity and negative predictive value. DCI during bread swallows could not predict response to AZI.
Conclusion: AZI but not placebo improved esophageal contractions in a subgroup of patients with significant esophageal hypomotility. Pre-treatment stimulation tests (MRS and AC) could identify with moderate accuracy those patients more likely to respond to AZI therapy.

P0484 ASSESSMENT OF ESOPHAGEAL CONTRACTILE PATTERN AND BOLUS TRANSIT BY USING DIFFERENT BOLUS CONSISTENCIES IN PATIENTS WITH GASTROESOPHAGEAL REFLUX DISEASE (GERD)

E. Coss-Adame[1], on behalf of Pinzon-Te Lol-Be, Zavala-Solares. Monica, Valdovinos-Díaz. Miguel Angel
[1]*Gastroenterology, Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico, Mexico*

Contact E-mail Address: enriquecossmd@gmail.com
Introduction: Conventional manometry protocol using ten 5 ml liquid swallows has been standardized for the diagnosis of peristaltic abnormalities being the basis for current classification of esophageal motor disorders. Recently, there are reports using multiple rapid swallowing and different bolus consistencies in order to detect more esophageal contractile abnormalities.
Aims & Methods
Aim: To investigate peristaltic contractility patterns and bolus transit (BT) by comparing different bolus consistencies in patients with GERD.
Methods: Patients with GERD were recruited consecutively and grouped as follows: Group 1, Erosive GERD (positive upper endoscopy and pHmetry) and group 2, non-erosive reflux disease (negative upper endoscopy and positive pHmetry). High Resolution Manometry (HRM, MMS, Netherlands with 22 sensors, water-perfused) in supine position was used and multichannel intraluminal impedance-pHmetry (MII-pH) with 6 impedance sensors (3,5,7,9,15,17 cm) and 1 pH sensor (5 cm above lower esophageal sphincter) was used (Given Imaging) to assess BT. Study protocol included: ten 5 ml liquid swallows (LS), three 5 ml applesauce swallows (AS) and three 7.5 grs of sliced-bread (SB), were provided during HRM and at the beginning of MII-pH recording separately. Peristaltic abnormalities were classified as follows: Small breaks (> 2 but < 5 cm gap), Large breaks (> 5 cm gap) and failed (< 3 cm wave integrity). A transit time > 8 s was defined as delayed and an incomplete bolus transit if exit from distal impedance sensor was not detected for each of the bolus consistencies. Data is summarized using median and ranges. Statistical analysis compared contractile patterns and BT between groups and after different bolus consistencies using non-parametric test.
Results: 38 patients were recruited, median age 45 (28-63), 18 Erosive (F 67%), and 20 non-erosive (F 75%). Overall, there were no differences in any of the manometric parameters between groups. However, there were significantly more peristaltic abnormalities (large breaks p = 0.03 SB; small breaks $p = 0.01$ AS and $p = 0.008$ SB) in non-erosive patients (small breaks$p = 0.01$ SB) and in erosive patients when comparing with LS. In addition, more incomplete BT occurred with AS ($p = 0.0001$) and SB ($p = 0.007$) when compared with LS in non-erosive group. Prolonged transit time was observed in AS ($p = 0.0001$) and SB ($p = 0.0001$) in non-erosive but not in erosive group.
Conclusion: Our data suggest that assessment of esophageal contractility and BT with different bolus consistencies may yield more abnormalities when compared with conventional protocol. Whether these findings are relevant for functional outcomes requires further study.

Contact E-mail Address: jan.brun@vgregion.se
Introduction: Long-standing diabetes mellitus (DM) is afflicted with a wide variety of complications that may cause symptoms from multiple organ systems including the gastrointestinal (GI) tract. Data from other centers have claimed that as many as 75% of patients attending DM clinics report significant GI symptoms.
Aims & Methods: The aim of our study was to understand the extent to which a defined cohort of Swedish patients with DM suffers from GI symptoms. Patients with insulin dependent DM type 1 (IDDM1) and type 2 (IDDM2) who attended the diabetic outpatient clinics at two county hospitals were included in the study. They were sent the Patient Assessment of upper GastroIntestinal Symptom Severity Index (PAGI-SYM) questionnaire for assessment of GI symptom severity which consists of 20 questions answered by use of a six-point Likert response scale, ranging from 0 (none) to 5 (very severe). The Gastroparesis Cardinal Symptom Index (GCSI) was calculated for nausea/vomiting, postprandial fullness/early satiety and bloating. Hospital anxiety and depression (HAD) scale was used for psychological assessment and the short form (SF) 36 questionnaire summary measures for physical and mental health. For those who answered the questionnaires, clinical information was retrieved from medical records regarding complications related to long-standing DM.
Results: We included 754 patients (mean age 48 years, range18-82 years). The questionnaires were answered by 434 patients (response rate 57.8%), and 363 (83.3%) of these had IDDM1 and 73 (16.7%) had IDDM2. The duration of insulin treatment was 21 ± 13 years. Ratings of individual symptoms are given in table 1. The mean GCSI total score in the cohort was 0.7 ± 0.8. Females with IDDM had significantly higher GCSI total score (0.853 vs. .622; p = 0.003), GCSI nausea/vomiting score (0.42 vs. 0.28; p = 0.019) and GCSI bloating score (1.2 vs. 0.81; p = 0.001) compared to males. There was a strong correlation (p = 0.001) between SF-36/HAD and the GCSI total, nausea/vomiting and bloating scores. There was no significant difference in GCSI scores comparing patients with IDDM1 and IDDM2, also not within sexes. Patients with one or more complications related to long-standing DM reported GI symptoms to the same extent as those with no complications and more complications was not associated with higher GCSI scores.**Table 1:** Proportion of patients reporting no (0), mild-moderate (1-3) or severe (4-5) intensity of individual symptoms included in the GCSI score.

PAGI-SYM (n = 434)	Non(%)	Mild-moderaten(%)	Severen(%)
Nausea	323 (75)	98 (23)	11 (2)
Retching	358 (83)	69 (16)	6 (1)
Vomiting	398 (92)	32 (7)	4 (1)
Stomach fullness	179 (41)	242 (56)	13 (3)
Unable to finish a normal-sized meal	329 (76)	96 (22)	9 (2)
Feeling excessively full after meals	244 (56)	167 (39)	23 (5)
Loss of appetite	296 (68)	140 (29)	15 (3)
Bloating	234 (54)	175 (40)	24 (6)
Stomach visibly larger	250 (58)	153 (35)	31(7)

Conclusion: Females with IDDM reported more GI symptoms compared with males. Although the total GI symptom burden in our study corresponded to "very mild" there was a highly significant correlation between the GCSI subscores; total, nausea/vomiting, bloating and mental and physical health and anxiety and depression. Furthermore it appears that the number complications to long standing DM do not per se imply an increase in reported GI symptoms.

Contact E-mail Address: 644353550@qq.com
Introduction: The postprandial proximal gastric acid pocket (PPGAP) is an unbuffered area which escapes neutralization by food and the pH is lower than 4 of the proximal stomach between nonacid segments distally (food) and proximally (lower esophageal sphincter or distal esophagus). It has been noticed in normal individuals and patients with gastroesophageal reflux disease (GERD). The PPGAP is believed to play an important role in GERD. However, it is still poorly understood.
Aims & Methods
Aims: In this study,we analyze the differences of PPGAP between patients with GERD and normal individuals in China.
Methods: 17 normal individuals and 20 patients with GERD participated in this study. All the subjects underwent a high-resolution manometry in a fasting state to identify the location of the lower border of the lower esophageal sphincter (LBLES).Then a station pull-through pH monitoring was performed from 5 cm below the LBLES to the esophagus in increments of 1 cm in a fasting state and 10 min after a standardized meal. The PPGAP was defined by the presence of acid reading (pH < 4) in a segment of the proximal stomach between non-acid segments distally (food) and proximally (lower esophageal sphincter or distal esophagus). The appearing time,disappearing time, length and pH of PPGAP were recorded.
Results: Our results show that a PPGAP is present in 100% of the patients with GERD and normal individuals. Compared to the normal individuals,the disappearing time of PPGAP in patients with GERD was significantly later (132.65 ± 45.22min vs 74.53 ± 30.64min, p < 0.01), the lasting time of PPGAP was significantly longer (118.50 ± 49.70min vs 55.59 ± 34.25min, p < 0.01), the length of PPGAP was significantly longer (5.00 ± 2.34cm vs 1.88 ± 1.11cm, p < 0.01), the lowest pH of PPGAP was significantly lower (1.01 ± 0.40 vs 1.67 ± 0.49, p < 0.01), and the mean pH of PPGAP was significantly lower (1.29 ± 0.47 vs 2.03 ± 0.43, p < 0.01). While there was no significant difference

Abstract number: P0489

	EGJ-CI cut-off value 13 (sens% > spec%)	EGJ-CI cut-off value 10 (sens% > spec%)	EGJ-CI cut-off value 5 (sens% > spec%)
Patients with GERD	**64% - 46%**	**74% - 54%**	**89% - 63%**
Patients with abnormal NRE	**63% - 24%**	**72% - 29%**	**79% - 51%**
Patients with abnormal AET	**66% - 35%**	**74% - 42%**	**87% - 54%**
Patients with positive symptom association	**58% - 48%**	**70% - 53%**	**87% - 61%**

in the appearing time of PPGAP between the patients with GERD and the normal individuals (14.25 ± 9.72min vs 18.47 ± 10.74min, $p = 0.218$).
Conclusion: The PPGAP is present generally in normal individuals and the patients with GERD. Compared to the normal individuals, in the patients with GERD, the lasting time of PPGAP is longer, the length of PPGAP is longer and the pH of PPGAP is lower. The PPGAP may be the reservoir from which acid reflux events originate. It may plays an important role in GERD. So in the future, the PPGAP may be an attractive target for GERD therapy.

Introduction: There is a scarcity of studies of motility disorders in morbidly obese patients with diabetes.
Aims & Methods: We aimed to assess esophageal motility in this group of patients. Patients with BMI ≥ 35 kg/m^2 and type 2 diabetes eligible for bariatric surgery were included from 01.01.2013 to 30.03.2015. All patients were recruited from a tertiary care obesity centre in Southern Norway. Gastrointestinal Symptom Rating Scale (GSRS) was applied to measure self-reported upper GI symptoms. High-resolution multichannel manometry was used to study esophageal motility.
Results: A total of 51 patients were included, mean age 47 years (range 32-61) and mean BMI 43 (range 35-58) kg/m^2. Esophageal manometry revealed dysmotility in 17 patients (33%), involving the esophageal body in 10 patients, with an abnormal mean DCI (distal contractile integral) in the range of 5000-8000 mmHg*sec*cm. Lower esophageal sphincter (LES) residual pressure was normal. The remaining 7 patients had ineffective esophageal motility (IEM) defined by at least 30% ineffective contractions out of 10 wet swallows. No patients reported difficulty with swallowing or chest pain according to GSRS.
Conclusion: Esophageal dysmotility was found in 1 out of 3 morbidly obese patients with type 2 diabetes, and the most prevalent finding was abnormal high DCI, consistent with the nutcracker esophagus, which was found in about 1 out of 5 (18%). None of the patients reported relevant symptoms. The present results demonstrate a high prevalence of asymptomatic dysmotility of the esophagus in morbidly obese patients with diabetes mellitus. A study of this patient group before and after bariatric surgery is indicated to elucidate the influence of change in body weight on esophageal dysmotility and related symptoms.

P0488 ARE THERE ANY EFFECTS AND CONCOMITANT FACTORS OF GERD WITH OBSTRUCTIVE SLEEP APNEA SYNDROME ?

A. Soylu[1], H. Kaya[2], S. Çakmak[1], I. Sevindir[1], Y. Okuturlar[3], A. Altıntas[2]
[1]*Gastroenterology,* [2]*E.N.T Clinic,* [3]*Internal medicine, Bakirkoy Dr Sadi Konuk Research and Training Hospital, Istanbul, Turkey*

Contact E-mail Address: aliyesoylu@superonline.com

Introduction: OSAS is one of the sleep disturbances in the society which has a prevalance of 1-5% and has various risk factors. General risk factors related to OSAS: age, gender, obesity, snoring, drugs, genetics, etc. Our objective was to study the OSAS cases which is concomitant with obesity and questioning other contributing factors.
Aims & Methods: We classified 62 patients (Female: 6, Male: 56) after GERD questioning into two groups: Patients having Reflux disease and the patients without reflux disease. We also questioned patients BMI scores, waist circumferance, smoking and alcohol consumption, reflux score, BECK anxiety and depressing score, sleep quality (good, medium, bad). We recorded Apnea and Hypopnea index and the mean O_2 saturation values of the patients. The Patients are divided into two groups as patients with reflux disease and the without reflux disease. We compared the data of the two groups.
Results: There was no difference between Reflux (+) and Reflux (-) patients mean ages ($p = 0.424$), mean BMI's ($p = 0.136$), mean waist circuference ($p = 0.343$), mean neck circumference ($p = 0.359$), mean Epworth Scale ($p = 0.107$), mean Apnea Hypopnea index ($p = 0.908$), mean Oxygen saturation ($p = 0.326$), alcohol consumption ($p = 0.620$), smoking ($p = 0.966$) .
There was significant difference in sleep quality between two groups (Reflux+, and Reflux -)($p = 0.037$). The bad and very bad sleep quality answer is higher in the reflux + group (56%) than reflux – group (27%).
There was no statistically significant correlation between Reflux Score, Epworth Scale, Apnea Hypopnea index and 0_2 saturation ($p > 0.05$).
There was significantly positive correlation between Reflux Score, BECK Anxiety Scale, and Beck Depression Scale ($r = 0.382$ $p = 0.002$, $r = 0.254$ $p = 0.046$ respectively).
Conclusion: The Apnea and Hypopnea index and Mean O_2 saturation is not affected in patients with reflux disease. Reflux disease worsens the sleep quality. Increased reflux score leads increased BECK anxiety and depression scores. The intensity of reflux is associated with anxiety and depression.

Introduction: The esophagogastric junction (EGJ) has been shown to play a major role as defensive mechanism against gastro-esophageal reflux. In keeping, a new metric, termed the EGJ-contractile integral (EGJ-CI), which can be assessed by high resolution manometry (HRM), has been validated in distinguishing proton pump inhibitors (PPIs) refractory patients with functional heartburn from those with PPI resistant gastro-esophageal reflux disease (GERD). However, data correlating EGJ-CI values with objective evidence of GERD is lacking.
Aims & Methods: We aimed to correlate the EGJ-CI values with impedance-pH and endoscopic findings in patients with GERD. Consecutive patients with typical GERD symptoms were enrolled. All patients underwent upper endoscopy, HRM and impedance-pH testing off-PPI therapy. EGJ-CI was calculated using the distal contractile integral tool box during three consecutive respiratory cycles. The value was then divided by the duration of these cycles. A value below 13 mmHg*s*cm was considered as a defective EGJ-CI according to medical literature (the 5th percentile measured in 75 healthy volunteers). We assessed esophageal acid exposure time (AET), number of reflux episodes (NRE) and symptom association analysis (SAA) using both symptom association probability (SAP+ if $\geq 95\%$) and symptom index (SI+ if $\geq 50\%$). A positive impedance-pH monitoring was considered in case of abnormal AET and/or NRE and/or positive SAA. Finally, we analyzed three different cut-off values of EGJ-CI (13 mmHg*s*cm, as the 5th percentile in healthy volunteers, 10 and 5 mmHg*s*cm, arbitrary set) with receiver operating characteristic (ROC) curve in order to provide the optimal balance between diagnostic sensitivity and specificity for impedance-pH detected GERD diagnosis, abnormal number of reflux, pathologic AET and positive symptom association.

Results: Among 130 [65M/65F; median age 53 (21-76)] prospectively enrolled patients, 91 had GERD (abnormal AET and/or elevated NRE and/or positive SAA) and 39 had functional heartburn (FH) (negative endoscopy, normal AET, normal NRE and negative SAA). GERD patients had a lower median value of EGJ-CI [11 (3.1-20.7) vs. 22 (9.9-41), $p < 0.02$] compared to FH patients. Patients with a defective EGJ-CI (<13 mmHg*s*cm) had more frequently a positive impedance-pH monitoring or esophageal mucosal lesions at upper endoscopy ($p < 0.05$ and $p < 0.05$, respectively) than patients with a normal EGJ-CI. As shown in the Table, an EGJ-CI cut-off value of 5 mmHg*s*cm yielded the best performance in identifying GERD at impedance-pH (sensitivity 89%, specificity 63%).
Conclusion: A defective EGJ-CI at HRM is associated with objective evidence of GERD at upper endoscopy and/or impedance-pH monitoring. An EGJ-CI cut-off value of 5 mmHg*s*cm yielded the best performance in diagnosing GERD at impedance-pH monitoring.

P0490 CORRELATION BETWEEN ESOPHAGOGASTRIC JUNCTION CONTRACTILE INTEGRAL AND GERD: A STUDY USING HIGH RESOLUTION MANOMETRY AND GERDQ QUESTIONNAIRE

S. Tolone[1], N. de Bortoli[2], E. Marabotto[3], C. de Cassan[4], S. Roman[5], M. Furnari[3], V. Savarino[3], L. Docimo[1], **E. Savarino**[4]
[1]*Department of Surgery, Second University of Naples, Naples,* [2]*Department of Internal Medicine, University of Pisa, Pisa,* [3]*Department of Internal Medicine, University of Genoa, Genoa,* [4]*Department of Surgery, Oncology and Gastroenterology, University of Padua, Padua, Italy,* [5]*Digestive Physiology, Lyon I University and Labtau, INSERM 1032, Lyon, France*

Introduction: Recently, a new high resolution manometry (HRM) metric, termed the EGJ-contractile integral (EGJ-CI), has been introduced in order to better identify a defective EGJ function and to distinguish proton pump inhibitors (PPIs) refractory patients with functional heartburn from those with PPI resistant gastro-esophageal reflux disease (GERD). To date, data correlating EGJ-CI values with reflux symptoms and HRM features is lacking.
Aims & Methods: We aimed to correlate the EGJ-CI values with symptoms and HRM features in suspected GERD patients. Consecutive patients with typical reflux symptoms were enrolled. Patients were invited to define their symptoms using the validated GerdQ questionnaire[1]. A positive GerdQ was considered when equal or >9 (range 0-18). Further, all patients underwent upper endoscopy, HRM and impedance-pH testing off-PPI therapy. EGJ-CI was calculated using the distal contractile integral tool box during three consecutive respiratory cycles. The value was then divided by the duration of these cycles. A value below 13 mmHg*s*cm was considered as a defective EGJ-CI according to medical literature (the 5th percentile measured in 75 healthy volunteers). Three morphological types of EGJ were defined based on the presence of axial cranial separation between lower esophageal sphincter (LES) and crural diaphragm (CD): Type I, no separation; Type II, minimal separation (>1 and <2 cm); Type III, >2 cm of separation. Manometric pattern was defined according to the Chicago Classification v. 3.0.
Results: We prospectively enrolled 130 [65M/65F; median age 53 (21-76)] patients. Sixty-four (49.2%) patients had a defective EGJ-CI (<13 mmHg*s*cm), whereas 66 (50.8%) had a normal value. Mean GerdQ score was greater in patients with a defective EGJ-CI compared to those with a normal EGJ-CI (15 vs. 8, $p < 0.02$). Moreover, a positive GerdQ (equal or >9) was more common in patients with a defective than normal EGJ-CI (54.9% vs. 35.9%, $p < 0.05$). At HRM, the study of LES-CD position allowed us to classify as Type I EGJ 60 (46.2%) patients, as Type II EGJ 50 (38.5%) patients and as Type III EGJ 20 (15.4%) patients. Type I EGJ showed the higher median value of EGJ-CI [20 (12.5-36) vs. 10.6 (3.9-17.9), $p < 0.001$, vs. 2.95 (0.2-8.4), $p < 0.001$] than Type II and III EGJ. A significant difference was also recorded between these latter two groups ($p < 0.008$). As to the motility pattern, patients with a defective EGJ-CI showed a lower frequency of normal motility (57.7%) in favor of ineffective esophageal motility (32.3%), whereas outflow obstruction pattern was present only in normative EGJ-CI patients. However, significant differences were not reached among the various groups.
Conclusion: A defective EGJ-CI at HRM is associated with the presence of more frequent and severe reflux symptoms and GERD-related HRM features (i.e. type II or III EGJ and ineffective esophageal motility pattern) compared to a normal EGJ-CI. Thus, our data suggest that a defective EGJ-CI plays a major role in GERD pathogenesis.

P0491 ACID-HYPERSENSITIVE OESOPHAGUS REFRACTORY TO PPI: RELEVANCE OF GAS-RELATED REFLUX EVENTS AND HYPERVIGILANCE

G. Amarasinghe[1], P. Woodland[1], J. L. S. Ooi[1], E. Yazaki[1], Q. Aziz[1], D. Sifrim[1]
[1]*Barts and The London School of Medicine and Dentistry, Queen Mary University of London, London, United Kingdom*

Contact E-mail Address: p.woodland@qmul.ac.uk
Introduction: Amongst patients who are refractory to PPI therapy who undergo reflux monitoring, there is a subgroup classified as having acid hypersensitive oesophagus. Hypersensitive oesophagus (HO) is defined as typical symptomatic perception of reflux events in the context of physiological levels of gastro-oesophageal reflux.
Within patients with acid hypersensitive oesophagus there are likely to be patients who have predominantly gas-related reflux episodes (supra-gastric belches/gastric belches) and those who have predominantly liquid only reflux episodes. There may also be those who are truly hyper-*sensitive*, and others who are more hyper-*vigilant* to reflux events. We anticipated that those patients with gas-related reflux events (particularly supragastric belching related) may be more hyper-vigilant, and that this may manifest as a shorter delay to pushing the symptom marker button after reflux events during 24 hour reflux monitoring.
Aims & Methods: Our aim was to assess the prevalence of gas-related and liquid only reflux events in patients with HO, and to assess time to symptom marker button press for these events.
36 consecutive patients with HO as defined as normal oesophageal acid exposure (<4.2%) with typical symptoms of heartburn or regurgitation and positive symptom-reflux association (SI >50% and/or SAP >95%) were identified. Reflux events related to symptoms were manually examined and the nature of the reflux event was characterised. Time from onset of reflux event to event marker press was measured in seconds.
Each patient was categorised as to the predominant reflux type (suprgastric belch, gastric belch or liquid only).
Relfux parameters were also measured in a comparison group of 50 consecutive patients *pathological* oesophageal acid exposure.
Results: 417 symptomatic reflux episodes were recorded by the 36 patients. The prevalence of gas related reflux events was 64% and liquid reflux events was 36%. Of the gas-related events, 139/267 (33% of total) were related to supragastric belches and 128/267 were related to gastric belches. Time to perception for liquid, supragastric belch, gastric belch, and liquid-related reflux events were not different.
10 patients (28%) had predominantly supragastric belch related reflux events, 10 had predominantly gastric belch related reflux, and 11 (30%) had predominantly liquid only reflux events. 5 patients had a mixed picture.
In the group of 50 patients with *pathological* oesophageal acid exposure, only 12% had predominant supragastric belching related reflux.
When time to recording of symptoms was analyzed on a per patient basis, no difference was seen.
Conclusion: In patients with acid hypersensitive oesophagus, the presence of gas associated reflux events related to symptoms accounted for 63% of total reflux events. Contrary to our expectation we could not see a difference in time to perception between liquid, supragastric belch and gastric belch related reflux events. It is possible that there is not a hypervigilant subset in these patients, or that the method used cannot distinguish them.
It was noteworthy that supragastric belching related reflux events accounted for nearly a third of all reflux events in patients with oesophageal hypersensitivity. This may present an opportunity for management of a subset of patients with refractory HO with behavioural therapy to reduce supragastric belching.

Introduction: We had earlier demonstrated that STW-5 and omeprazole affect multiple chemokine families on genome and proteome level and involve G-protein coupled receptor and MAP-kinase signaling to reduce inflammation in the esophageal tissue in our rat model for gastro-esophageal reflux disease (GERD)[1,2]. Pain is a prominent symptom of GERD and commonly related to acidic reflux. The mechanisms of acid induced activation of esophageal afferent nerves are not well understood. Recently it was shown that serotonin, which is the ligand for 5-hydroxytryptamine receptors, can also activate acid sensing ion channels[3].
Aims & Methods: We analysed in our subchronic refluxesophagitis (RE) rat model the transcript modulation of acid sensing ion channels and of 5-hydroxytryptamine (5-HTR) subtypes in the esophageal tissue.
Methods: Rats were pretreated with either STW 5 (0.5 or 2ml/kg) a multicomponent herbal preparation, or the PPI omeprazole (O) (30mg/kg) for 7 days. Esophagitis was induced surgically followed by a further 10d treatment. On day 10 animals were sacrificed. RNA was isolated from defined tissue areas of the esophagi for Agilent whole genome microarray (rat). Data were analysed by Ingenuity.
Results: Tissues of animals suffering from RE showed a small, but significant increase in the expression of the ASIC-subtype 4 (3.8f, $p < 0.001$) and of 5-HTR2A (3fold), 5-HTR2B (6.6f), and 5-HTR7 (9.3f) (<0.001) compared to sham. Thus, both – ASICs and distinct 5-HTR subtypes- were up-regulated

Abstract number: P0494

Table 1: Dietary pattern of GERD patients in Russia.

	Protein, g/dayM ± m	Total fat, g/dayM ± m	Total carbohydrates, g/dayM ± m	Dietary fiber, g/day,M ± m	Mono/disaccharides, g/dayM ± m	Starchg/dayM ± m
GERD (n = 124)	97.5 ± 4.0*	135.2 ± 5.6†	249.8 ± 9.5	7.19 ± 0.4‡	124.6 ± 5.7	113.8 ± 8.5
Controls (n = 41)	77.7 ± 4.0*	103.3 ± 5.1†	223.7 ± 14.1	11.4 ± 0.8‡	126.2 ± 9.6	97.7 ± 8.2

Note: *, †,‡ - $p < 0.05$

during the inflammatory process in our rat model. The higher expression of ASIC4 was not found in tissues of animals treated with either STW-5 (2ml/kg) or with O (30mg/kg). Minor differences, especially in the magnitude of down regulation, were seen for the 5-HTR subtypes after treatment with STW 5 and O. Interestingly serotonin is not only the ligand for 5-HTR subtypes, but also an inflammatory mediator which can activate ASICs in peripheral nerve tissue to activate a central pain response[2].

Conclusion: Acid-sensing ion channels and 5-hydroxytryptamine receptors may form a communication network involved in pain sensing and signaling in gastro-esophageal reflux disease. The down-regulation of ASIC4 and 5-HTR-subtypes in the esophageal mucosa may be responsible for the fast pain relief in responders to PPIs and to STW-5.

P0493 POSTURAL CHANGES INDUCE TRANSIENT LOWER ESOPHAGEAL SPHINCTER RELAXATIONS

J. Pérez De La Serna[1], A. Ruiz de León[1], P. Delgado Guillena[1], P. Mateos Sánchez[1], I. Pérez Enciso[1], C. Sevilla Mantilla[1], E. Rey Diaz-Rubio[1]
[1]*Gastroenterology, Hospital Clínico San Carlos, Madrid, Spain*

Contact E-mail Address: jperezsernab@gmail.com

Introduction: Transient lower esophageal sphincter (LES) relaxations (TLESR) constitute the major mechanism of physiological gastroesophageal reflux (GER). They are also responsible for 65% of reflux episodes in patients with mild esophagitis and they facilitate belching. They appear mainly after meals and are produced by a reflex mechanism triggered by distension of gastric fundus. They are easily detected by high-resolution manometry.

Aims & Methods: The aim of the study was to determine whether postural changes, without the effect of meals, facilitate the occurrence of TLESR.

Records of 143 patients (77 M, 66 M) (mean age 53 SD 15.8, range:18 to 90 years) referred to our Motility unit for assessment of dysphagia or GERD were retrospectively analyzed. All patients underwent high-resolution manometry (ManoScan, Sierra Scientifics). After fasting for at least 8 hours studies were conducted randomly in supine, right side, left side and seated position. The TLESR were identified as a decrease in LES resting pressure to the level of gastric pressure, inhibition of diaphragmatic crura and unrelated to swallowing.

Results: TLESR were recorded in 68 patients (47.55%) (35 M, mean age 55 SD 15 y. and 33 F, mean age 54 SD 15.8 y.). In 12 cases (8 M) esophageal shortening was appreciated. In the remaining 63 patients (40 F, 23 M) no modifications of the esophagogastric junction were observed except for variations in LES resting pressure referred to the gastric pressure. A total of 94 TLESR: 40 in the sitting position, 34 in the right lateral decubitus, 15 in the left lateral decubitus and 5 in the supine position were recorded. Most of TLESR occurred in the change from supine to a seated position or from supine or right lateral to left lateral decubitus.

Conclusion: TLESR are often triggered by postural changes, regardless of meals and may be associated with GER when the patient change their body position like going to bed, getting up or during movements lying down.

P0494 NUTRITIONAL PATTERN OF RUSSIAN GASTROESOPHAGEAL REFLUX DISEASE PATIENTS

M. Konovalova[1], S. Morozov[1], V. Isakov[1]
[1]*Dpt. Gastroenterology and hepatology, Institute of nutrition, Moscow, Russian Federation*

Contact E-mail Address: sunnysister@mail.ru

Introduction: There is a lot of controversies about probable influence of dietary patterns on the disease progression and success of treatment in GERD. Nutritional pattern of GERD patients in Russia have not been studied yet.

Aims & Methods: The **aim** of the study was to assess the nutritional pattern of GERD patients in Russia compared to healthy controls.

Methods: One hundred twenty-four GERD patients (54 men, 70 women, age (M ± m) 46 ± 17.7 yrs; BMI (M ± m) 28.5 ± 0.6 kg/m^2) and 41 controls (8 men, 33 women, age (M ± m) 42 ± 12.4yrs; BMI (M ± m) 28.3 ± 1.3 kg/m^2) were examined using validated [1] food frequency questionnaire. Diagnosis of GERD was confirmed by typical symptoms and validated GerdQ questionnaire. Non-parametric statistics (Statistica 10, StatSoft Inc, USA) was used to investigate the difference between dietary patterns in GERD patients and controls.

Results: The studied and the control group did not differ on BMI, age and sex distribution ($p > 0.05$).

Main studied parameters of dietary patterns are shown in the table 1. It was found that average total fat and protein intake was higher in GERD group compared to controls. In contrast, average total fiber intake was significantly higher in controls, but both groups consumed less fibers, then it generally recommended (20 g or more/day). There was no difference between two groups on the carbohydrates, starch and mono/disaccharides intake.

Conclusion: Nutritional pattern of Russian GERD patients are characterized by higher fat and protein intake compared to controls and insufficient consumption of dietary fiber that may influence pathogenesis of the disease.

Contact E-mail Address: pbanovcin@gmail.com

Introduction: Cough reflex sensitivity to inhaled irritants is thought to be related to the functional state of cough-triggering afferent nerve terminals in the larynx and large airways. Laryngopharyngeal reflux (LPR) causes larynx and potentially large airways irritation. However, the relationship between the cough reflex sensitivity and the LPR is not completely understood.

Aims & Methods: We hypothesized that the cough reflex sensitivity is positively correlated with the LPR. Our hypothesis predicts that patients with more frequent LPR will have lower cough reflex threshold. Consecutive patients referred by ENT physician for suspected LPR were evaluated. Laryngopharyngeal reflux was quantified by 24h pH-impedance monitoring using Given Imaging system. Proximal pH sensor was placed1 cm above upper esophageal sphincter as detected by high resolution manometry.

Cough reflex sensitivity was determined by single breath capsaicin inhalation challenge of doubling concentrations of capsaicin (0.49-500μmol/l) using KoKo PFT system. Cough threshold C2 was defined as the lowest concentration of capsaicin that evoked 2 or more coughs.

For statistical analysis C2 values were –log transformed and Pearson coefficients were calculated for correlation with reflux parameters.

Results: 13 consecutive patients with suspected LPR were evaluated. LPR episodes were detected by impedance monitoring in all patients. The number (median[interquartile range]) of LPR episodes was 15[19-29]. Cough sensitivity expressed as C2 concentration of capsaicin (geometric mean[95%CI]) was 13.4[6.6-27.1]μmol/l.There was a strong positive correlation between the cough sensitivity and the number of LPR episodes ($R = 0.77$, $P < 0.01$). In contrast there was no correlation between the total number of gastroesophageal reflux episodes in the esophagus ($R = 0.47$, $P > 0.1$). Total number of reflux episodes was detected by distal pH sensor placed 5 cm above manometrically determined lower esophageal sphincter. 5 of 13 patients had positive pH monitoring test based on DeMeester score > 14.72 indicating pathological distal esophageal acid exposure. The number of LPR episodes and cough sensitivity in these patients were virtually identical to those with negative pH monitoring test.

Conclusion: The number of laryngopharyngeal reflux episodes positively correlates with cough reflex sensitivity in patients with laryngopharyngeal reflux. These results may suggest a direct relationship between the intensity of laryngeal irritation and cough.

Contact E-mail Address: salvatore.tolone@unina2.it

Introduction: Obesity is a strong independent risk factor of gastroesophageal reflux disease (GERD), esophageal erosions and hiatal hernia (HH) development. Pure restrictive bariatric surgery should not be indicated in case of HH and GERD. In fact, if in most cases bariatric surgery can diminish reflux by losing a large amount of fat, on the other hand some restrictive procedure can worsen or cause the presence of GERD. Also, it is still unclear what is the real incidence of disruption of esophagogastric junction (EGJ) in patients candidate to bariatric surgery. Actually, high-resolution manometry (HRM) can provide accurate information about EGJ morphology, whereas impedance-pH monitoring (MII-pH) can highlight the presence of acid, weakly acid and weakly alkaline reflux and correlate it to symptoms.

Aims & Methods: Aim of this study was to describe the EGJ morphology determined by HRM in obese patients candidate to bariatric surgery and to verify if different EGJ morphologies are associated to GERD-related symptoms presence and to different GERD patterns determined by means of MII-pH. All patients underwent a standardized questionnaire for symptom presence and severity (GERDQ), upper endoscopy, HRM and MII-pH. EGJ was classified as: Type I, no separation between the lower esophageal sphincter (LES) and crural diaphragm; Type II, minimal separation (>1 and <2 cm); Type III, >2 cm separation. At MII-pH, total acid exposure time (AET, %) and total number of refluxes (TNR) were assessed. A healthy-volunteers group (HVs) was used as control.

Results: One hundred thirty-eight obese (BMI > 35) subjects and 15 HV (normal weight) were studied. Ninety-eight obese patients referred at least one GERD-related symptom, whereas 40 subjects were symptom-free. According to HRM features, EGJ Type I morphology was documented in 51 (36.9%) patients, Type II in 48 (34.8%) and Type III in 39 (28.3%). EGJ Type III subjects reported more frequently symptoms than EGJ Type I (38/39, 97.4%, vs. 21/59, 41.1% $p < 0.001$). Obese patients with EGJ Type I showed comparable mean LES pressure and peristaltic function than HV (30.5 ± 8.5 vs. 34 ± 5.2 mmHg, and 80 ± 10 vs. 90 ± 10 intact peristaltic waves with normal vigor, respectively). EGJ Type II and III patients showed a statistical significant reduction in LES pressure and peristaltic function (22.3 ± 12.2 vs. 34 ± 5.2 mmHg, $p < 0.05$ and 60 ± 10 vs. 90 ± 10 intact peristaltic waves with normal vigor, $p < 0.05$ respectively for Type II and 11.1 ± 5.3 mmHg, $p < 0.001$ and 40 ± 20 normal waves, $p < 0.001$ for Type III, respectively). At MII-pH, EGJ Type I patients showed similar reflux patterns to HVs (AET 3.4 vs. 2.3%, and TNR 27 ± 5 vs. 21 ± 6); EGJ Type II (AET 5.2, $p < 0.05$, and TNR 57 ± 21, $p < 0.05$) and III (AET 7.4, $p < 0.001$, and TNR 76 ± 33, $p < 0.001$) showed a significant increase in esophageal acid exposure and in TNR than HVs.

Conclusion: Obese subjects have a high risk of disruption of EGJ morphology. In particular, patients with HH often refer pre-operative presence of GERD symptoms. Thus, testing obese patients with HRM and MII-pH before undergoing bariatric surgery, especially for restrictive procedures, can be useful for assessing presence of HH and GERD.

P0497 EFFECTS OF OMEGA-LOOP GASTRIC BYPASS ON ESOPHAGOGASTRIC JUNCTION FUNCTION AND REFLUX

S. Tolone[1], K. Rodriguez[2], L. Docimo[1], E. Savarino[2]
[1]*Department of Surgery, Division of General and Bariatric Surgery, Second University of Naples, Naples,* [2]*Department of Surgery, Oncology and Gastroenterology, University of Padua, Padua, Italy*

Introduction: Several bariatric operations for morbid obesity have been developed in order to reduce excess body weight. In particular, omega-loop gastric bypass (OGB), consisting primarily of a long linear lesser-curvature gastric tube with a termino-lateral gastro-enterostomy 180–200 cm distal to the ligament of Treitz, was recently introduced with good results in terms of weight loss and improvement of obesity-related co-morbidities. However, concerns have been raised about the potential development of symptomatic biliary reflux gastritis/esophagitis and risk of gastric/esophageal cancer due to chronic biliary reflux. At present, no objective data are available on the effect of OGB on esophago-gastric junction (EGJ) function, reflux occurrence and symptoms.

Aims & Methods: We aimed to evaluate the possible effects of OGB on esophageal motor function and a possible increase in gastro-esophageal reflux. Consecutive obese patients underwent clinical assessment for reflux and dyspeptic symptoms by means of a validated questionnaire, and endoscopy plus high-resolution impedance manometry (HRiM) and 24-h impedance-pH monitoring off-therapy before and 1 year after OGB. During HRiM and impedance-pH tracings analysis we measured: intragastric pressure (IGP), gastroesophageal pressure gradient (GEPG), EGJ morphology, motility pattern according to Chicago classification, distal esophageal acid exposure, number of impedance-detected refluxes and symptom association probability. A group of obese patients who underwent sleeve gastrectomy (SG) was included as the control population.

Results: Fifteen OGB patients [5 males/10 females; mean age 38 ± 8.2 years; mean BMI 46.4 (38-60) kg/m^2] were included in the study. After surgery [mean BMI 31 kg/m^2 (28-42)], none of the patients reported "de novo" heartburn or regurgitation. At endoscopic follow-up 1 year after surgery, esophagitis was absent in all patients and no biliary gastritis nor presence of bile were recorded. Manometric features and patterns did not vary significantly after surgery, whereas IGPs and GEPGs statistically diminished (from a median of 15 to 9.5, $p < 0.01$ and from 10.3 to 6.4, $p < 0.01$, respectively) after OGB. In contrast, SG induced a significant elevation in both parameters (from a median of 14.8 to 18.8, $p < 0.01$ and from 10.1 to 13.1, $p < 0.01$, respectively). A dramatic decrease in the number of reflux events (from a median of 41 to 7; $p < 0.01$) was observed after OGB, whereas in patients who underwent SG a significant increase in esophageal acid exposure and number of reflux episodes (from a median of 33 to 53; $p < 0.01$) were noted.

Conclusion: In contrast to SG, OGB did not compromise the gastro-esophageal junction function and did not increase gastro-esophageal reflux, which explained by the lack of increased IGP and in GEPG as assessed by HRiM.

P0498 REFLUX TYPE AND NUMBER ARE RELATED TO NUTRITIONAL PATTERNS IN GERD PATIENTS

S. Morozov[1], M. Konovalova[1], V. Isakov[1]
[1]*Gastroenterology&Hepatology, Research Institute of Nutrition, Moscow, Russian Federation*

Contact E-mail Address: morosoffsv@mail.ru

Introduction: Little is known about the influence of nutrition on number and reflux type in GERD, therefore dietary recommendations for patients are mostly empirical.

Aims & Methods: The aim of the study was to assess the relationship between GERD patients' nutrition pattern,presence of the disease and esophageal pH-impedance parameters.

Methods: One hundred twenty four GERD patients (54 men, 70 women, age (M ± m) 46 ± 17.7 yrs; BMI (M ± m) 28.5 ± 0.6 kg/m^2) and 41 controls (8 men, 33 women, age (M ± m) 42 ± 12.4yrs; BMI (M ± m) 28.3 ± 1.3 kg/m^2) were examined using validated food frequency questionnaire. Number and types of gastro-esophageal refluxes evaluated by 24-hours esophageal pH-impedance recordings (Ohmega, MMS, the Netherlands; 2pH-6 impedance channels catheters, UnisensorAG, USA). Correlation analysis was performed between the number of reflux episodes, their acidity, duration and frequency and quantity of protein, carbohydrates, total fat, fiber and energy intake using non-parametric statistics (Statistica 10, StatSoftInc, USA).

Results: Direct, medium strength correlation was found between presence of GERD and total energy ($R = 0.23$, $p < 0.05$) and daily fat ($R = 0.21$, $p < 0.05$) intake. Inverse medium strength correlation was found between dietary fiber intake and presence of GERD ($R = -0.26$, $p < 0.05$). Proportion of time with pH < 4 at 5 cm over EGJ significantly correlated with total daily energy and total daily fat intake.Correlation coefficients (Spearmen rank R) between nutritional patterns and esophageal function testing parameters are shown in the table 1.

Conclusion: The obtained data may reflect influence of nutritional patterns on pathogenesis of GERD and should be taken into the account when dietary advice is given to the patient.

P0499 THE PHENOMENON OF LEPTIN RESISTANCE IN PATIENTS WITH GASTROESOPHAGEAL REFLUX DISEASE AND DIFFERENT TYPES OF OBESITY

T. Krolevets[1], I. Lapteva[2], **M. Livzan**[3]
[1]*Post-Graduate of Department of Therapy with the Course of Occupational (Professional) Diseases,* [2]*Assistant of Department of Therapy with the Course of Occupational (Professional) Diseases,* [3]*Department of Therapy with the Course of Occupational (Professional) Diseases, Russian Federation, Omsk, State Educational Institution of Higher Vocational Education "Omsk State Medical University", Omsk, Russian Federation*

Contact E-mail Address: mts-8-90@mail.ru
Introduction: Gastroesophageal reflux disease (GERD) is one of the most prevalent diseases in the world. Overweight and obesity are recognized as independent risk factors for the emergence and progression of GERD. It is known that visceral fat produced by the biological-active substance (adipokines) to influence the feeding behavior. Leptin is one of the most important adipokines, which acts on the hunger and satiety centers in the hypothalamus, involves in the regulation of energy homeostasis and body weight control. It is known that leptin plays a role in the formation of erosive GERD forms, Barrett's esophagus, which may be associated with its pro-inflammatory activity, proliferative power to induction of epidermal growth factor, as well as antiapoptotic effect.
Aims & Methods: We had an aim to determine the characteristics of the course of GERD based on the study of clinical and endoscopic manifestations of the disease, results of pH monitoring and the phenomenon of leptinresistance in patients with different types of obesity. We performed open comparative crosssectional studies. We examined 105 patients with GERD and obesity or overweight. We asked patients, assessed an anthropometric indices, did a biochemical analysis of blood, endoscope examination of the esophagus and stomach, pH monitoring, assessed levels leptin and its soluble receptor. We separated patients in two groups: the main group (n = 85) - patients with abdominal type of obesity, the comparison group (n = 20) - with normal volume of waist.
Results: Weight, height, body mass index, level of glucose was higher in main group ($p < 0.00003$, $p < 0.03$, $p < 0.(10)82$, $p < 0.02$, respectively). Leptin levels in patients with abdominal type of obesity was significantly higher and the level of its receptors was significantly lower (mediana of leptin levels 36,93 (14,69-47,60) in main group versus 9,59 (7,66-19,48), mediana of leptin's receptors 18,25 (14,69-24,26) versus 23,78 (18,83-32,67), respectively). Between these indicators in main group was revealed negative correlation of mild strength ($rs = (-0.424)$, $p < 0.002$). There were more patients with Nonalcoholic Fatty Liver Disease in main group ($p < 0.001$). According to the results of gastrointestinal endoscopy non-erosive GERD form was diagnosed in 92 (87.6%) patients and erosive form was revealed in 13 (12.4%). According to the results of endoscopy in patients with GERD comparison groups differences have not been identified. In group with abdominal type of obesity pH cardia and body of stomach was higher ($p < 0.04$, $p < 0.02$, respectively), but time of refluxate's contact with low pH (pH <4) in these departments was longer in the comparison group ($p < 0.05$). Positive relationship was found between leptin's receptors and contact's time in the range of pH from 3 till 6 in the stomach ($rs = (0.645)$, $p < 0.03$), in the range from 4 till 7 and less than 4 in the esophagus ($rs = (0.645)$, $p < 0.03$, $rs = (0.600)$, $p < 0.05$, respectively), the longest gastroesophageal ($rs = (0.624)$, $p < 0.03$) and alkaline refluxes ($rs = (0.640)$, $p < 0.03$).
Conclusion: The formation of leptinresistance in individuals with overweight and obesity based on the type of fat distribution is associated with course of the GERD.

P0500 ASSOCIATION BETWEEN THE FORM OF GASTROESOPHAGEAL REFLUX DISEASE, CARACTERISTICS OF ESOPHAGEAL PH-IMPEDANCE MONITORING AND CYTOKINES EXPRESSION

Y. Evsyutina[1], A. Trukhmanov[1], O. Storonova[1], V. Ivashkin[1], S. Lyamina[2], I. Malyshev[2]
[1]*Sechenov First Moscow State Medical University,* [2]*Moscow State University of Medicine and Dentistry, Moscow, Russian Federation*

Introduction: The gastroesophageal reflux disease (GERD) is one of the most common diseases, which affects about 15-25% of the world population. In GERD damage of the esophageal mucosa may occur as a result of different types of refluxate, i.e. gastric, biliary or duodenogastric/mixed. In patients with GERD, depending on the form of the disease, increased expression of pro-inflammatory or anti-inflammatory cytokines.
Aims & Methods: To determine correlations between the form of gastroesophageal reflux disease, parameters of esophageal pH-impedance monitoring and cytokines expression.
This prospective cohort study included 55 patients: 20 with non-erosive reflux disease (NERD) – 55% men; average age 37.7 ± 12.0, 20 with erosive esophagitis (EE) – 65% men; average age 38.3 ± 12.5, and 5 with Barrett's esophagus (BE) – 100% men; average age 34.2 ± 9.8, and 10 healthy volunteers. We performed on all patients an upper endoscopy, a 24-h esophageal pH-impedance monitoring and the determination of plasma cytokines (IL-4, IL-8, IL-10, IFN-γ, TNF-α) by flow cytometry. The statistical analyses were done using R Statistical Software.
Results: In patients with EE in comparison to patients with NERD and BE we registered a higher total number of acid reflux ($p < 0.0001$) and a higher esophageal acid exposure ($p < 0.0001$). Patients with BE, in comparison to patients with NERD and EE, had a higher total number of weakly acid reflux ($p = 0.01$) and higher esophageal weakly acid exposure ($p = 0.004$).
We found the correlations between the level of IL-8 and the total number of acid reflux (Kendall $\tau = 0.76$) and with esophageal acid exposure ($\tau = 0.42$). The level of TNF-α also correlated with total number of acid reflux ($\tau = 0.69$) and with esophageal acid exposure ($\tau = 0.48$). The level of IL-4 correlated with the total number of weakly acid reflux ($\tau = 0.48$) and with esophageal weakly acid exposure ($\tau = 0.50$) as well as the level of IL-10 ($\tau = 0.50$ and $\tau = 0.51$, respectively).
Conclusion: The levels of TNF-α and IL-8 correlated with total number of acid reflux and with esophageal acid exposure in patients with erosive esophagitis. The levels of IL-4 and IL-10 correlated with total number of weakly alkaline reflux and with esophageal weakly alkaline exposure in patients with Barrett's esophagus.

Contact E-mail Address: lars.lundell@karolinska.se
Introduction: Until recently only two therapeutic options have been available to control symptoms and to heal the esophagitis in chronic gastroesophageal reflux disease (GERD) patients, i.e. life-long proton-pump inhibitor (PPI) therapy or antireflux surgery. Lately, Transoral Incisionless Fundoplication (TIF) has been developed and found to have a potential to offer a therapeutic alternative for these patients. As part of a comprehensive and stepwise evaluation strategy for the clinical use of TIF, we performed a double-blind, multi-center, sham-controlled study in GERD patients who were chronic PPI users.
Aims & Methods: Patients 18-80 years old, on daily PPIs for > 6 months, with persistent GERD symptoms without PPI therapy (during the titration phase of the study), were included in the trial if they had evidence of two or more of the following while off PPI therapy (>10 days): esophagitis (Los Angeles grade A, B or C), abnormal ambulatory pH study, or moderate to severe GERD symptoms. For enrolment we also required normal or near normal esophageal motility (by manometry or impedance), patients' willingness to cooperate with postoperative dietary recommendations and assessment tests and signed informed consent. After randomization, those allocated to TIF had the procedure completed during general anesthesia by the TIF2.0 EsophyX system with SerosaFuse fasteners (EndoGastric Solutions, Inc., Redmond, WA, USA). Sham procedure consisted of upper GI endoscopy under general anesthesia. Neither the patient nor the assessor was aware of the treatment group affiliation. The primary effectiveness endpoint was the proportion of patients in clinical remission after 6 months (without being classified as treatment failure). Secondary effectiveness parameters were: PPI consumption, esophageal acid exposure, reduction in GERD symptom scores as assessed by the Quality of Life in Reflux and Dyspepsia and Gastrointestinal Symptoms Rating Scale instruments and healing of reflux esophagitis.
Results: Out of 121 patients screened we finally randomized 44 patients with 22 patients confined to each group. The study groups were well balanced regarding demographic and disease-specific characteristics. The time in remission, during the first six months, is detailed in the table demonstrating a significant superiority offered by the TIF procedure. Likewise, the secondary outcome measures were all in favor of the TIF procedure. As an example, acid reflux time improved from 8.89 (Standard Error of Mean, SEM = 0.84) to 3.73 (SEM = 0.84) by the TIF intervention ($p = 0.0002$) whereas the sham procedure did not change the acid reflux profile at all.

Group	In Remission (n = 22)	Treatment Failure (n = 22)
Transoral Incisionless Fundoplication, n (%)	14 (64)	8 (36)
Sham, n (%)	2 (9)	20 (91)
P (Fisher's Exact test)		= 0.0004

Conclusion: Transoral Incisionless Fundoplication (TIF) was found to offer chronic GERD patients, being on long-term treatment with PPI, an effective therapeutic alternative.
Disclosure of Interest: None declared

P0502 PATIENTS WITH NON-ACID REFLUX DISEASE AND THOSE WITH EROSIVE AND NON-EROSIVE REFLUX DISEASE HAVE SIMILAR RESPONSE TO ANTI-REFLUX SURGICAL THERAPY

E. Savarino[1], E. Marabotto[2], R. Salvador[1], C. de Cassan[1], M. Furnari[2], P. Zentilin[2], N. de Bortoli[3], S. Marchi[3], G. Camerini[4], V. Savarino[5]
[1]*Department of Surgery, Oncology and Gastroenterology, University of Padua, Padua,* [2]*Department of Internal Medicine, Division of Gastroenterology, University of Genoa, Genoa,* [3]*Department of Internal Medicine, University of Pisa, Pisa,* [4]*Department of Surgery,* [5]*Department of Internal Medicine, University of Genoa, Genoa, Italy*

Introduction: Combined impedance-pH monitoring is considered the gold standard for the detection of reflux episodes. Indeed, several studies demonstrated

the increased diagnostic yield of this technique in gastro-esophageal reflux disease (GERD) thanks to its ability to correlate symptoms with both acid and/or non-acid reflux episodes. However, limited data are available about the clinical usefulness of impedance-pH testing in GERD management.
Aims & Methods: We aimed to assess whether refractory GERD patients classified by means of endoscopy and impedance-pH as affected by non-acid reflux disease (NARD), erosive and non-erosive reflux disease (ERD and NERD) may benefit from anti-reflux surgery. Consecutive patients with persisting heartburn and/or regurgitation despite 8 weeks of proton pump inhibitors therapy, were prospectively enrolled in this open label trial. All patients underwent upper endoscopy and 24-hour impedance-pH testing off-therapy. We measured distal esophageal acid exposure time (AET), characteristics of reflux episodes (acid/non-acid) and symptom-reflux association. Then, patients with ERD (endoscopy+), NERD (endoscopy-, AET > 4.2% and/or SAP/SI+ for acid reflux) and NARD (endoscopy-, AET < 4.2% and SAP/SI+ for non-acid reflux or both kind of reflux) underwent laparoscopic Nissen fundoplication (LNF). Before LNF and at 1, 6 and 12 months after surgery, reflux symptoms and quality of life were assessed by using validated questionnaires. Upper endoscopy and impedance–pH monitoring was repeated 1 year after surgery. Surgical treatment failure was considered in case of: persisting typical reflux symptoms and/or objective evidence of GERD (esophagitis at upper endoscopy, abnormal AET and/or number of refluxes, positive symptom association) and/or poor quality of life.
Results: Out of sixty-five refractory patients, forty-eight (24F/24M; mean age 49; 14 ERD, 22 NERD and 12 NARD) were included. At 1 year follow-up after surgery, LNF had similar pathophysiological effects in all groups. Indeed, percentage of patients with abnormal AET (ERD 93% vs 7%, NERD 71% vs 0%) and/or increased number of reflux episodes (ERD 93% vs 0%, NERD 86% vs 0%, NARD 83% vs. 0%), mean AET (ERD 12.9% vs 1.8%, NERD 6.1% vs 0.7, NARD 0.7% vs 0.4%) and median number of total (ERD 100 vs 6, NERD 73 vs 9, NARD 72 vs 10), acid and non-acid refluxes significantly decreased (in all cases, $p < 0.01$). As to the surgical outcome, the percentage of patients with resolved or markedly improved typical symptoms at 12 months after surgery was similar among the study groups (ERD 93% vs. NERD 82% vs NARD 83%, p = ns). Quality of life similarly improved in all groups (p = ns). Finally, the percentage of failure and/or adverse events did not differ among the groups (ERD 21% vs. NERD 23% vs NARD 17%, p = ns).
Conclusion: Our data show that LNF was a safe and effective procedure in relieving typical reflux symptoms in PPI-refractory patients identified as affected by ERD, NERD and NARD, by means of endoscopy and impedance-pH monitoring. Therefore, impedance-pH testing allowed a more clear identification of refractory patients whose symptoms are related to reflux, thus improving their management and outcome.

P0503 INFLUENCE OF THORACIC AND ABDOMINAL BREATHING ON THE BASAL PRESSURE OF THE LOWER ESOPHAGEAL SPHINCTER

Introduction: The lower esophageal sphincter and the adjacent crura of the diaphragm form a functional unit preventing gastroesophageal reflux. Esophageal manometry describes the function of this esophagogastric junction. Active abdominal breathing activates the diaphragmatic crura thus contributing to esophagogastric junction pressure (pEGJ). We performed a controlled prospective study to determine the influence of abdominal versus thoracic breathing on pEGJ using esophageal manometry.
Aims & Methods: After routine High-Resolution esophageal manometry confirming normal esophageal function, 10 patients changed into a standing position. Subjects were then instructed to take 10 breaths targeted towards the thorax, followed by 10 breaths with active abdominal breathing, followed by 10 breaths of abdominal breathing with increased airway resistance (compression of one nostril). In addition to standard manometric measurements, we analyzed the fraction of time in percent of pEGJ over 10, 15, 20, 25 and 30 mmHg. Manometric recordings of esophageal motor function were evaluated with the Manoview™ software. ANOVA and Post-Hoc tests were used for statistical analysis.
Results: During thoracic breathing p_{max}EGJ (maximal pressure; median ± upper/lower quantile) showed normal values (39 mmHg ± 24/44) and significantly increased during abdominal breathing (62 mmHg; ± 52/85). Abdominal breathing with increased airway resistance did not show an additional effect (70 mmHg ± 63/92). During abdominal breathing with increased resistance the time of pEGJ over 20 mmHg, 25 mmHg and 30 mmHg was significantly longer compared to thoracic breathing (> 20 mmHg: 44% (39/50) versus 76% (42/93); > 25 mmHg: 38% (30/41) versus 57 % (36/69); > 30 mmHg: 28% (19/33) versus 48% (33/63)).
Conclusion: Our study clearly shows that the type of breathing significantly influences pEGJ. In addition, we found that pEGJ reaches longer time intervals with competent pEGJ in abdominal compared to thoracic breathing. Current recommendations for routine esophageal analysis do not include breathing type. We suggest that breathing type should be taken into consideration when interpreting esophageal manometric data. We have already shown that controlled breathing training can improve symptoms in patients suffering from gastroesophageal reflux. Our current data suggests that a direct training effect on diaphragmal muscles might be an explanation for the findings of our previous studies.

Contact E-mail Address: f-yano@jikei.ac.jp
Introduction: Laparoscopic fundoplication (LF) is an established surgical treatment for GERD. In our institution, about 95% of patients reported a high degree of satisfaction with surgery. On the other hand, some patients were expected to undergo redo surgery for reasons such as recurrence of hiatal hernia and/or reflux esophagitis.
Aims & Methods: The aim of this study was to investigate the outcomes of redo surgery for failed laparoscopic fundoplication in Japanese patients. Four-hundred and seventy-four patients underwent laparoscopic anti-reflux surgery between December 1994 and January 2015 in our institution. Among them, 11 patients who had redo surgery were studied. Their mean age was 57.7 ± 15.1 (range, 29-78) years, and 6 of them (45%) were female. Their clinical data were collected in a prospectively fashion and retrospectively reviewed. The outcomes were assessed in terms of indications for redo surgery, operative procedure, operation time, blood loss, perioperative complications, and postoperative course.
Results: No operative mortality occurred. The indications for surgery (some were overlapped) were dislocations of fundic wrap in 5 (45%), recurrence of paraesophageal hiatal hernia or erosive reflux esophagitis in 3 (27%) each, tight Nissen or esophageal motility disorder in 1 (9%) each. Ten (91%) were approached laparoscopically and another (9%) required conversion to open surgery. Eight (73%) underwent redo fundoplication, and the others underwent hiatal hernia repair alone. The mean operation time was 202 ± 46 (range 125-256) minutes and the mean blood loss was 56 ± 100 (range 0-292) ml. No patient required blood transfusion. Perioperative gastric wall injury was observed in 3 patients (27%). Almost all patients' postoperative courses were uneventful and the median time to start postoperative oral intake and the median post-operative hospital stay were post-operative day 1 and 8, respectively. Three patients (27%) required prescription of proton pump inhibitors (PPIs) despite surgery and 2 patients (18%) had recurrence of hiatal hernia. Postoperative questionnaire was answered by 7 of 11 patients (74%). All patients reported full points 5 (range 1-5) as a satisfaction to surgery.
Conclusion: Redo surgeries for failed laparoscopic fundoplication were safely performed under laparoscopy. Recurrence rate after redo surgery was about 20% and more than 70% of patients could be withdrawn from PPIs.

Contact E-mail Address: j.labenz@t-online.de
Introduction: The electrical stimulation of the lower esophageal sphincter (LES-ES) using the EndoStim® LES Stimulation System (The Hague, The Netherland) was shown to be effective and safe in clinical trials. So far there no data was reported in routine clinical practice.
Aims & Methods: An ongoing, prospective multicenter web-based registry for the evaluation of LES-ES is prospectively collecting data at baseline and at routine follow-ups for 5-year on patient undergoing LES-ES in routine clinical practice for disruptive GERD symptoms despite daily PPI use. Demographics, adverse events, GERD symptoms using daily diaries and GERD health related quality of life score (GERD-HRQL) for reflux symptoms, structured GI symptom questionnaire for extra-esophageal symptoms, recorded use of proton pump inhibitors (PPIs) and objective endoscopic and physiological data (esophageal pH / manometry) when available.
Results: Currently, data from 46 enrolled patients is available in the registry, of whom 24 had data at 6 months post-op. All but one (23/24; 96%) patient showed an improvement in their GERD-HRQL score. Overall, the median (IQR) composite GERD-HRQL score of 21.5 (17.5-25.5) preoperatively improved to 6.5 (3.0-10.5) after 6 months ($p < 0.0001$). The median distal esophageal acid exposure improved from 8.8 (3.4-18.5) % at baseline to 2.65 (1.6-5.1) % at 6 months (p = NS). The proportion of patients with moderate to severe regurgitation decreased from 72% on-therapy preoperatively to 29% after 6 months of LES-ES ($p < 0.04$). Bothersome reflux symptoms during sleep improved from 43%

pre-op to 4% ($p < 0.004$) at 6 months. Recurrent cough decreased from 21% patients preoperatively to none after 6 months. One patient reported severe dysphagia pre-op that was resolved post-op. There was no change in the rate of occasional dysphagia reported. All patients were on long-term PPI at baseline. At 6 months, 17 (70%) patients were completely free of PPI use, 4 patients (17%) were still taking daily PPI and another 3 patients (13%) used PPI occasionally or had reduced their dose by > 50%. There were two serious adverse events (both resolved) classified as unrelated to device or procedure: acute pain from pre-existing gall-stones and intestinal atony occurring two weeks post-op. There were no GI side-effects related to the procedure or stimulation therapy reported.

Conclusion: LES-ES is safe and effective in routine clinical practice with improved quality of life and elimination of a PPI maintenance therapy in most patients. LES-ES may be considered a viable treatment option for well selected GERD patients with bothersome symptoms on PPI.

Contact E-mail Address: J.Labenz@t-online.de

Introduction: Randomized controlled trials report about 30% of GERD patients complain of bothersome remaining symptoms (heartburn, regurgitation) despite PPI. General practice physicians estimate this to be an over-representation.

Aims & Methods: In a prospective, multicenter, observational study, which was conducted in 16 general practice clinics over 3 months, patients with GERD and taking PPI for over 1 year were asked to complete a questionnaire. Patients were asked the duration of their GERD, duration of PPI therapy, satisfaction with their condition on PPI, whether they have received diagnostic evaluation related to GERD (endoscopy, pH monitoring, manometry), whether they have received surgical consultation for GERD, and the frequency of any remaining complaints in the past week (i.e. heartburn, regurgitation, sleep disruption) as part of a validated questionnaire for the diagnosis of GERD (GerdQ). ''Lost Patients'' were defined as those likely to be suffering from true GERD as predicted by the GerdQ questionnaire, dissatisfied on their current PPI therapy, and had not previously received any specific GERD diagnostics (pH-metry or manometry).

Results: 323 consecutive patient responses were collected. Patients suffered from GERD for an average of 8.42 years and prescribed PPI therapy for an average duration of 6.26 years. 39% of patients reported heartburn at least 2 days per week (20% 4-7 days per week), 29% complained of regurgitation at least 2 days per week (13% 4-7 days per week), and 22% reported symptoms disrupting sleep at least twice per week (7% 4-7 days per week). 20% of patients were dissatisfied on their current PPI therapy (score of 1 or 2 on a scale of 1-5, 1 = very dissatisfied, 5 = very satisfied), and 13% were both dissatisfied and had a high likelihood of complaints correlating to pathological pH based on the GerdQ questions. A total of 85% of patients received an upper endoscopy in the past, but only 7% had a prior pH-metry and 2% manometry. Only 7% received prior surgical consult for GERD. The rate of ''Lost Patients'' was 10%.

Conclusion: Inadequate control of symptoms is common in GERD patients prescribed PPI therapy, and is often overlooked in daily practice. These patients with insufficient symptom control should be methodically identified and considered for further diagnostics and/or treatment modification, for example with a screening questionnaire.

Contact E-mail Address: stephenattwood@onetel.com

Introduction: Electrical Stimulation of the LES is emerging as a new theraputic modality for refractory GERD

Aims & Methods: To assess efficacy and safety of LES stimulation in GERD patients by performing an individual patient data meta-analysis.

A systematic literature search and contact with EndoStim confirmed that no additional clinical trials on LES stimulation in GERD patients other than the two open-label clinical trials were available [1,2]. The individual patient data from the 2 trials were used for this meta-analysis after it was shown that the two trials had identical design, with no significant differences in the baseline inclusion and exclusion criterial of the trials, and no heterogeneity in baseline and follow-up summary data. Each patient's baseline data was used as control data and 6-month data was used as on-treatment data.

Results: Sixty-six patients, with 43% women at 11 centers in Europe, South America and Asia, were included. Median age was 52 (IQR = 43-62) years. Ninety-five percent (63/66) of patients were using daily PPIs with one-third of them using PPIs twice daily. At their 6 months follow-up, 89% (58/65) were no longer using PPIs and 5% (3/65) were using PPIs on < 50% of days. Median distal esophageal acid exposure at baseline was 10.0% (IQR = 7.7-12.9), which had improved to 4.9% (IQR = 2.4-7.3) % at 6 months follow-up ($p < 0.001$). Median GERD-HRQL scores at baseline on-PPI were 10 (IQR 8-21) and off-PPI 28 (IQR 22-34) which improved to 4.0 (IQR 1-9) at 6 months on LES stimulation therapy ($p < 0.001$ vs. both on and off-PPI). Significant improvement in median days with heartburn and regurgitation at day and night vs. baseline both on- and off-PPI ($p < 0.001$), and near-complete elimination of regurgitation and nocturnal symptoms were observed. There were no statistically significant differences in efficacy outcomes between geographical locations (Europe vs. South America vs. Asia). In total, 2 SAEs related to the device or procedure (trocar perforation and asymptomatic lead erosion) were managed with device explant. There were 65 device and/or procedure-related non-serious adverse events, all typical of a laparoscopic implant procedure and resolving without any invasive intervention.

Conclusion: This meta-analysis confirms the results of previous trials on safety and efficacy of LES electrical stimulation in GERD patients and provides a robust estimate of the effect size among a larger number of patients and across multiple geographical locations.

Contact E-mail Address: pinghuei@ntu.edu.tw

Introduction: Previous studies have shown a complex relationship between sleep disturbances and gastro-oesophageal reflux disease (GORD). Since GORD could be further categorized into subgroups based on the endoscopic findings and the presence of typical reflux symptoms, whether the GORD spectrum are associated with different impact on the sleep quality remains unclear.

Aims & Methods: We aim to investigate the association of subjective and objective sleep disturbance with the heterogeneous manifestations of GORD in a Chinese general population. We prospectively recruited 561 subjects who voluntarily underwent an electrocardiogram-based cardiopulmonary coupling analysis as part of a comprehensive health check-up at the National Taiwan University Hospital during 2012-2013. All subjects received the Reflux Disease Questionnaire (RDQ) and an upper endoscopy to determine the presence of erosive oesophagitis (EO) and non-erosive reflux disease (NERD), defined as subjects with troublesome symptoms (a heartburn/regurgitation score > 3 by RDQ) but without definite endoscopic mucosa breaks. Subjective sleep quality was evaluated with the Pittsburgh Sleep Quality Index (PSQI) and sleep dysfunction was defined as a PSQI > 5. Sleep-disordered breathing was defined as the apnoea–hypopnoea index derived from the cardiopulmonary coupling analysis > 15 event/hour. Detailed demographics, anthropometrics, metabolic profile and psychological status were also obtained. Comparisons were made between subjects with and without GORD and subjects within the different categories of GORD spectrum for a range of subjective and objective sleep parameters.

Results: Of the 277 subjects (49.4%) who were diagnosed as having GORD, EO was found in 198 subjects (35.3%), in whom 123 (21.9%) were symptomatic and 75 (13.3%) were asymptomatic (RDQ = 0). NERD was diagnosed in 79 subjects (14.1%). Subjects with GORD had higher global PSQI scores (6.99 ± 3.97 vs. 6.07 ± 3.73, $P = 0.005$) and a higher prevalence of sleep dysfunction (60.6% vs. 49.6%, $P = 0.009$) than those without GORD. Subjects with EO had a significantly higher prevalence of sleep-disordered breathing than those without (42.9% vs. 33.9%, $P = 0.034$). Presence of troublesome reflux symptoms was independently associated with sleep dysfunction in the multivariate analysis (adjusted odds ratio = 2.05; 95% confidence interval = 1.39-3.00). Across the GORD spectrum, subjects with symptomatic EO had the highest PSQI scores (7.68 ± 3.93) as well as the prevalence of sleep dysfunction (70.7%), while the prevalences of sleep-disordered breathing among the subgroups were not significantly different.

Conclusion: We demonstrated a high prevalence of subjective and objective sleep disturbances among the GORD patients in this Chinese population. Different manifestations across the GORD spectrum were associated a variety of impairment on the sleep quality. Further interventional studies to explore the

effect of aggressive GORD treatment on the various aspects of sleep quality of GORD patients are warranted.

P0509 OUTCOME OF ESOPHAGO-GASTRIC JUNCTIONAL ADENOCARCINOMA TREATED BY ESD

A. Takahashi[1], T. Oyama[1]
[1]*Endoscopy, Saku Central Hospital Advanced Care Center, Nagano, Japan*

Introduction: Esophago-gastric junctional adenocarcinoma (EGJAC) was rare in Japan. However, recently the incident of EGJAC has been increasing. And the outcome of endoscopic submucosal dissection (ESD) for EGJAC is unknown.
Aims & Methods: The aim of study is to investigate the outcome of EGJAC treated by ESD.
EGJAC was defined as adenocarcinoma located between 1cm oral and 2cm anal from EGJ. 92 patients (80 males and 12 females) with EGJAC were treated by ESD from January, 2000 to December, 2011. Follow up examination including annual CT and EGD was performed. R0 resection rate, complications and prognosis were investigated. Additional therapy was recommended for the T1bSM2 (501 micrometer or deeper) patients. The median age and follow up period was 74 (32-89) and 65 (6-173) months, respectively. The median diameter of the resected lesions and specimens was 18 (3-61) and 40 (20-82) mm, respectively. Protuberant, flat and depressed type was 44, 4 and 44 lesions, respectively. Differentiated and poorly differentiated adenocarcinoma was 88 and 4 lesions, respectively.
Results: 1. Complete resection rate was 100%. R0 rate resection was 99% (91/92).
2. Complications: The bleeding during ESD and delayed bleeding required blood transfusion was 0% and 1% (1/92). The perforation during ESD and delayed perforation was 1% (1/92) and 0%. Stenosis was 11% (10/92), and all of 10 cases were treated by endoscopic balloon dilatation.
3. T1a-M, T1b-SM1(less than 500 micrometer) and T1bSM2 was 62, 15 and 15 lesions, respectively.
4. Local recurrence rate was 0% in any groups.
5. Prognosis.
5-1 T1a-M and T1b-SM1: No patient died of EGJAC.
5-2 T1bSM2: Additional gastrectomy was performed for 7 of 15 T1b-SM2. And, only one case had lymph node metastasis. 7 patients were followed up without gastrectomy. One patient was treated by additional radiation, and lymph node metastasis was found after radiation. Only this patient died of EGJAC.
Conclusion: T1a-M and T1bSM1 EGJAC are good candidate for ESD. However, additional therapy should be recommended for T1bSM2 EGJAC patients.

P0510 FEASIBILITY AND USEFULNESS OF EUS-FNA IN THE DIFFERENTIAL DIAGNOSIS BETWEEN MALIGNANT AND BENIGN LESIONS FOR RELATIVELY SMALL DUODENUM SUBMUCOSAL TUMORS

A. Aso[1], E. Ihara[1], K. Nakamura[1], T. Osoegawa[1], A. Goto[1], T. Iwasa[1], T. Ito[1], Y. Oda[2]

Contact E-mail Address: miro1124@gmail.com
Introduction: Duodenal submucosal tumors (SMTs) with malignant potentials including gastrointestinal stromal tumors (GIST) are relatively rare, but we sometimes need to make a differential diagnosis of duodenal SMTs. Although it is generally accepted that EUS-FNA is a gold standard for making a histological diagnosis of gastric SMTs, the feasibility and usefulness of EUS-FNA for duodenal SMTs have yet to be determined. In general, tissue sampling of duodenal SMTs by EUS-FNA is more difficult than that of gastric SMTs.
Aims & Methods: The aims of the present study were to assess feasibility, safety, and usefulness of EUS-FNA for duodenal SMTs. Between June 2009 and March 2015, a total of 17 patients with duodenal SMTs who had undergone EUS-FNA were enrolled in the present study and were retrospectively reviewed. A linear EUS scope (UCT260-AL5; Olympus, Tokyo, Japan) together with needle devices (22G, 25G) were used for EUS-FNA with rapid on-site evaluation (ROSE). We evaluated success rate of sampling, diagnostic yield and procedure-related complications.
Results: The mean diameter of duodenal SMTs was 22.4 mm in size ranging from 8 to 59 mm. The puncture could be completed in all 17 patients. The mean number of FNA passes was 3.8 ranging from 1 to 7. All samples were satisfactory for making a histological diagnosis. As a result, ten patients were diagnosed with GIST, one with gangliocystic paraganglioma, one with neuroendcrine tumor and five with benign tumors. There were no procedure-related complications. Although most samples obtained by EUS-FNA in the present study were smaller than those usually obtained with gastric SMTs, we could make a differential diagnosis between malignant tumors and benign lesions in all cases.
Conclusion: This is the first case series showing feasibility of EUS-FNA for relatively small duodenal SMTs. EUS-FNA could be a useful diagnostic tool for surgical decision making not only in gastric SMTs but also in duodenal SMTs.

Introduction: The incidence of gastric cancer has declined dramatically during last decades in western countries. In Finland, the age-standardized incidence being 6.3 / 100 000 for men and 3.6 / 100 000 for women [1]. Because of the low incidence, screening programs are not considered effective in the West. Early gastric cancer rarely causes symptoms, and, thus majority of gastric cancers are diagnosed in advanced, symptomatic stage.
Atrophic gastritis in the best known premalignant condition of gastric cancer, and it has been suggested that persons who have extensive atrophic changes in stomach should undergo surveillance.
Aims & Methods: Our aim was to evaluate the long-term gastric cancer risk in smoking men with atrophic gastritis.
Serum pepsinogens (SPGs) were measured from 22,436 smoking men (age 50-69 years) who participated The Alpha-Tocopherol, Beta-Carotene Cancer Prevention (ATBC) study in Finland [2-3]. Low serum pepsinogen I (SPGI) was measured in 2132 men, and they were invited to gastroscopy [4]. Endoscopy was performed to 1344 men, and after excluding the men with gastric cancer in a beginning of study, 1326 men were enrolled in this study.
The first gastroscopies were performed between years 1989-1993, and the surveillance continued until the end of year 2012, the gastric cancer diagnosis, or the death. The median follow-up time was 13.6 years (range 16 days – 23.3 years). Thirty three gastric cancers were diagnosed during the follow-up period.
Results: Most of the men (80.2%) had atrophic gastritis of some degree in the histological samples of the corpus (mild 11.4%, moderate 41.7%, marked 27.1%). Atrophic gastritis of the antrum was found only in 34.0% of the subjects. Mild to marked intestinal metaplasia appeared in 66.5% patients in corpus and 40.1% in antrum.
The gastric cancer incidence was 1.89 / 1000 patient-years. The incidence of gastric cancer increased as the grade of the atrophy of the corpus mucosa increased: 1.54/1000, 1.77/1000, and 2.05/1000 in mild, moderate, and severe mucosal corpus atrophy, respectively. In the antrum mucosa, the effect of the degree of the atrophy had similar effect on the gastric cancer incidence: 2.16/1000, 2.21/1000, and 3.44/1000 in mild, moderate, and severe atrophy.
The gastric cancer incidence was 1.35/1000, 2.27/1000, and 2.84/1000 in mild, moderate, and severe corpus intestinal metaplasia (IM), respectively. In the antrum, the incidence of gastric cancer was 1.87/1000, 2.23/1000, and 3.99/1000, in mild, moderate, and severe IM, respectively.
Conclusion: The risk of gastric cancer increased as the grade of the mucosal atrophy and intestinal metaplasia increased. The risk of gastric cancer seems to be within limits of previous publications (0.1-0.2% person years).

Contact E-mail Address: anna.a.nieminen@hus.fi
Introduction: Intestinal type of gastric cancer develops through precancerous changes, but minority of these changes progress to cancer. Endoscopical surveillance is allocated for patients with extensive gastric atrophy or intestinal metaplasia. To target endoscopy for high-risk patients, two staging systems (Operative Link for Gastritis Assessment [OLGA][1] and Operative Link on Gastric Intestinal Metaplasia Assessment [OLGIM][2]) have been created. The focus is on severity and topography of atrophy and intestinal metaplasia.
Aims & Methods: In our scope was to investigate the predictive value of OLGA and OLGIM staging systems in smoking males with atrophic gastritis.
Serum pepsinogens (SPGs) were measured from 22,436 smoking men, aged 50-69 years, who participated The Alpha-Tocopherol, Beta-Carotene Cancer Prevention (ATBC) study [3] in Finland. Low serum pepsinogen I (SPGI) was measured in 2132 men, and they were invited to gastroscopy [4]. Endoscopy was performed to 1344 men, and after excluding the men with gastric cancer in a beginning of study and 180 men with history of gastric surgery by benign cause, 1146 men were enrolled in this study.
The first gastroscopies were performed between years 1989-1993, and the surveillance continued until the end of year 2012, the gastric cancer diagnosis, or the death. The median follow-up time was 13.7 years (range 16 days – 23.3 years). Twenty seven gastric cancers were diagnosed during the follow-up period.
Results: Gastric cancers (n = 27) distributed by OLGA stages following: 1, 3, 17, 1, and 5 (stages 0-IV, respectively), and OLGIM stages: 2, 7, 10, 4, and 4 (stages

0-IV, respectively). By OLGIM staging system, gastric cancer risk elevated with stages ($p = 0.02$). The trend was not as distinct with OLGA staging ($p = 0.10$). Three gastric cancers developed to patients with OLGA / OLGIM stage 0, and histological type was known in only one of these patients, who had diffuse type of cancer.

Conclusion: Interobserver agreement is excellent with intestinal metaplasia, but weaker with atrophy and dysplasia [2;5]. Also in our study, OLGIM was more sensitive to predict gastric cancer risk over OLGA. Histological type can confound the interpretation, as cancerous cascade with atrophy and intestinal metaplasia are illustrated with intestinal, not diffuse, type of gastric cancer.

Introduction: Neo-adjuvant chemotherapy (CT) has been shown to improve survival in locally advanced gastric cancer. It has been suggested that the clinical outcome is associated with preoperative down staging. CT is also associated with toxicity and poor patient tolerance.

Aims & Methods: Our aim was to identify predictive factors of response to perioperative CT. We conducted a prognostic study using an academic centre retrospective cohort of patients with gastric adenocarcinoma diagnosed between January 2012-December 2014 and submitted to perioperative CT. Response to pre-operative CT was evaluated by radiologic criteria and on the surgical specimen. We built a prognostic model using logistic regression analysis including demographic, clinical and morphological characteristics. Explanatory variables were kept when $p < 0.20$.

Results: A total of 160 patients were diagnosed of which 42 were submitted to perioperative CT. Mean age was 68 ± 10 years-old, 28 (67%) were male. Esophagogastric junction was involved in 5 (12%), gastric body in 19 (45%) and antrum in 18 (43%). The histology was intestinal type in 31 (74%) and diffuse in 11 (26%). ECF/EOX was used in 34 (81%) and FOLFOX/XELOX in 8 (19%). Response was observed in 30 (71%) with complete pathological response in 3 (7%). Toxicity was reported in 27 (64%) cases with interruption in 16 (38%). Median follow-up was 15.5 months (IQR 8.75-19.25). Mortality was 15 (35.7%). The final model included the following predictors: age (OR 0.898, CI 0.787-1.024; $p = 0.109$), female gender (OR 27.676, CI 0.679-1127.883; $p = 0.079$), poor CT tolerability (OR 0.115, CI 0.028-0.468; $p = 0.002$) and gastric body tumor (OR 0.071, CI 0.005-0.989; $p = 0.049$) were included in the model. The AUROC for the model was 0.943. Histological type, microsatellite instability and E-cadherin immunoexpression didn't show association with response to CT.

Conclusion: Increasing age, male gender, poor CT tolerability and gastric body location were independent predictors of non-response. Our model was able to accurately predict pre-operative CT response. Prospective evaluation is warranted before clinical application.

Introduction: Chronic Atrophic Gastritis (CAG) is the most important independent risk condition for gastric cancer, histology being considered the gold standard for both diagnosis and follow up. The Operative Link for Gastritis Assessment (O.L.G.A) is an innovative histological system proposed for staging atrophic gastritis in a prognostic view.

GastroPanel® (Biohit, Helsinki, Finland) is a serological kit for a non-invasive diagnosis of chronic atrophic gastritis (CAG), including serum pepsinogen I (PGI), pepsinogen II (PGII), gastrin-17 (G-17) and IgG anti-*Helicobacter pylori* antibodies (IgG-*H.p.*).

Clinical practice is lacking of a non invasive instrument useful to predict and to follow the stage of atrophic gastritis.

Aims & Methods

Aim: To evaluate correlation between GastroPanel® and O.L.G.A stage, in a cohort of dyspeptic patients referred from a primary care setting.

Subjects and Methods: Histological evaluation of gastric biopsies was performed in 249 patients ($M = 129$, mean age 49 years, range 21-79 years). Atrophy was assessed according to the O.L.G.A staging system.

O.L.G.A stages III and IV are considered at high risk for gastric cancer development. From each subject, a blood sample was taken for GastroPanel® analysis.

Results: GastroPanel® analysis showed that 82 patients were normal (mean age 46 years, range 21-64 years, $M = 49$), 116 patients had a *H.p.*-related chronic gastritis (mean age 54 years, range 35-79 years, $M = 68$) and 51 had atrophic gastritis picture (mean age 61 years, range 21-79 years, $M = 22$).

Comparing GastroPanel® results to the histological findings, 77 patients had an O.L.G.A stage 0-II, 4 pts have an OLGA stage III, 1 stage IV.

Among the patients with Hp-related gastritis, 112 patients had an O.L.G.A stage 0-II, 3 patients had an O.L.G.A stage III and 1 patient had O.L.G.A stage IV.

Twenty-two out of the 51 patients with evidence of CAG at GastroPanel® had an O.L.G.A stage 0-II, 29 patients had an O.L.G.A stage III-IV. The negative predictive value (NPV) of GastroPanel® for CAG is 95,0%, being the positive predictive value (PPV) 75,0%.

O.L.G.A

Gastropanel®	**0**	**I**	**II**	**III**	**IV**
Normal values	46	17	14	4	1
H.p.-related gastritis	51	23	38	3	1
Chronic atrophic gastritis	1	5	16	19	10

Conclusion: GastroPanel® showed an high NPV to predict absence of atrophic gastritis.

The relationship beetween GastroPanel and O.L.G.A system seems to confirm the clinical performances of the test.

P0515 ENDOSCOPIC BAND LIGATION WITHOUT RESECTION IN SELECTED PATIENTS FOR SMALL AND SUPERFICIAL UPPER GASTROINTESTINAL TRACT LESIONS

G. Ibáñez[1], J. B. Gornals[1], L. Rivas[1], S. Salord[1], M. J. Paúles[1], M. C. Galán[2]
[1]*Hospital Universitari Bellvitge-Idibell,* [2]*Institut Català d'Oncologia DiR-Idibell, Barcelona, Spain*

Contact E-mail Address: jgornals@bellvitgehospital.cat

Introduction: Band ligation with electrosurgery of early small lesions of upper gastrointestinal (UGI) tract (dysplasia or T1a-b) or subepithelial tumors (neuroendocrine tumors (NETs) are associated with complications especially in duodenal lesions.

Aims & Methods: The aim of this study is to investigate the efficacy and safety of endoscopic band ligation (EBL) without electrosurgery in selected patients where surgery is contraindicated. Twelve patients from 2010 through 2015 with early UGI (upper gastrointestinal) lesions treated with EBL for autoamputation (1.83 rubber bands/session) were included prospectively and analyzed retrospectively. All were discussed in a UGI multidisciplinary cancer committee where it was concluded that owing to patient's conditions surgery was not possible and that not getting histology would not change the clinical management. Before the procedure, a CT and/or radial echoendoscope was performed. In flat lesions (Paris Classification: Is-IIa) chromoendoscopy with spray catheter and argon plasma coagulation were used to delimit the margins before the banding. With a Duette® Multi-Band Mucosectomy device the rubber bands were deployed. Second endoscopy with biopsies was planned in 4-8weeks. If there was no persistence of the lesion, a new control was programmed at 6 and then at 12 months. On the contrary, if there was histologic persistence a new treatment was applied.

Results: The group included 5 esophagus lesions (adenosquamous carcinoma ($n = 1$); carcinoma squamous ($n = 2$); adenocarcinoma ($n = 2$)); 4 gastric lesions (high grade dysplasia ($n = 1$); adenocarcinoma ($n = 2$); NET ($n = 1$)) and 3 duodenal lesions (NET ($n = 3$)). The mean tumor diameter was 9.3+/-3.7mm (range 4-17.5). Only 1 adverse event in one patient was described, which was mild chest pain. Observation for 8 hours was possible in all patients except in 2 cases. After a median of 7 weeks the treatment, there was endoscopic remission in 92% ($n = 11/12$) and histologic remission in 75% ($n = 9/12$). In the 6-month biopsies, there were 70% ($n = 7/10$) of negative biopsies and in the 12 months 80% ($n = 4/5$). The persisting lesions were T1 cancers (T1 esophagus ($n = 3$), T1 stomach ($n = 1$)) but with a new EBL two of the T1 cancers got negative

Abstract number: P0515

	Age, years	Sex	Comorbidity
1	83	M	Asthma, ischemic heart disease, peripheral vascular disease, low social support
2	59	M	Lung cancer in treatment, previous ORL cancer, esophageal stricture, trismus
3	68	M	Decompensated cirrhosis, COPD, peripheral vascular disease
4	77	F	Atrial fibrillation, cerebrovascular accident
5	82	F	Cognitive disorder, previous gastric ADK (Billroth I)
6	75	M	Previous oral carcinoma, intestinal ischemia twice
7	83	F	Asthma, ischemic optic neuropathy
8	80	M	Atrial fibrillation, pituitary adenoma, monoclonal gammopathy
9	69	F	Previous intestinal resection
10	77	F	Decompensated cirrhosis, hepatocellular carcinoma, systemic lupus erythematosus, vaginal cancer, peripheral vascular disease
11	76	F	Cognitive disorder, atrial fibrillation, previous, breast cancer
12	62	M	Decompensated cirrhosis, COPD

biopsies in the next endoscopy. The median follow-up is of 20.9 months (range 5.9-60 months).
Conclusion: EBL without electrosurgery is an easy and safe technique that should be considered in patients with multiple morbidities.

Contact E-mail Address: giancarla.fiori@ieo.it
Introduction: Duodenal neuroendocrine tumors (dNETs) are rare, being 1-3% of all primary duodenal tumors. With the widespread use of upper GI endoscopy, these tumors have been increasingly recognized.
Duodenal NETs not located in the periampullary region are suitable for endoscopic treatment if limited to the submucosal layer, without metastases and with a diameter less than 10 mm. Nevertheless, few data are available concerning the efficacy of this approach.
Aims & Methods: We reviewed our data about dNETs treated with endoscopic resection (ER).
Results: From January 2012 to December 2014, 11 dNETs were diagnosed during upper GI endoscopy. Five tumors underwent ER whereas 6 did not because of the presence of metastases (n = 2), patient's comorbidities (n = 1), papillary location (n = 1) and surgical treatment (n = 1).
ER was performed with a high definition single-channel endoscope (EG29i series, Pentax). The resection technique was chosen according to the endoscopist's preference, morphological characteristics, site and endosonographic features of each lesion. En-bloc resection was obtained in all cases. Endoscopic mucosal resection (EMR) was used for 3 bulb tumors and endoscopic submucosal dissection (ESD) for one bulb tumor. One tumor of the duodenal third part was treated with Hybrid-ESD (HESD). In 4 cases the resection site was closed with metal clips. The mean size of resected specimens was 14 mm (range 7-22 mm); histologically the tumor mean size was 9 mm (range 5-12 mm). The invasion depth was limited to the submucosal layer. Lateral or deep edge involvement occurred in 2 cases (one tumor treated with EMR and one with HESD). All lesions were well-moderately differentiated tumors with less than 1-2 mitosis per high power field. Ki67 proliferation index was 2-4% in 4 tumors and 16% in one.
One immediate perforation occurred and was treated conservatively. No patient underwent a second ER or surgical treatment. The mean follow up period was 17 months (range 6-31 months). No local recurrence was observed during endoscopic follow-up. A liver metastasis was detected at CT-scan one year after resection in one patient.
Conclusion: ER in the duodenum has a higher incidence of complications than in other sites of gastrointestinal tract because of the thickness duodenal wall. In order to avoid delayed perforation and bleeding, all resections except one, were treated with clips. Despite en-bloc resection was obtained in all cases, a complete pathological resection was confirmed in only 60% of cases. We suppose that such incomplete pathological resection is due to the paucity and laxity of submucosal duodenal tissue, which is destroyed during resection. In fact, because of the narrow duodenal lumen, can be technically difficult to avoid excessive burning of the peritumoral submucosal duodenal tissue. To support this hypothesis we did not observe any local recurrence at follow-up endoscopy. Our experience, although limited and retrospective, confirms the safety and efficacy of ER for the treatment of dNETs limited to the submucosal layers. However, additional studies with longer follow up are needed.
Disclosure of Interest: None declared

P0517 THE COMBINATION OF SERUM TREFOIL FACTOR 3 AND PEPSINOGEN TEST IS AN EFFECTIVE BIOMARKER FOR EARLY DETECTION OF GASTRIC CANCER

H. M. Yang[1], S. W. Jeon[1], H. S. Lee[1], S. Nomura[2]
[1]*Internal Medicine, Kyungpook National University Hospital, Daegu, Republic of Korea,* [2]*Gastrointestinal Surgery, Graduate School of Medicine, The University of Tokyo, Tokyo, Japan*

Contact E-mail Address: sw-jeon@daum.net
Introduction: The serum pepsinogen test has been used as a non-invasive biomarker for gastric cancer screening in Japan. However, there are limitations of its predictive power.
Aims & Methods: We aimed to investigate whether the combination of serum trefoil factor 3 (TFF3) and pepsinogen test could be an effective biomarker of gastric cancer screening. Two hundred and eighty-one gastric cancer patients who underwent endoscopic submucosal dissection in Korea were enrolled. And serum was collected from 708 healthy individuals without cancer in Japan. Serum levels of TFF3 were examined by enzyme-linked immunosorbent assays. Serum levels of pepsinogen I and pepsinogen IIwere measured using a latex-enhanced turbidimetric immunoassay.
Results: The mean serum TFF3 concentration in patients with gastric cancer was 9.36 ± 4.67 (95%CI [8.86,9.96]). For the prediction of gastric cancer presence, the area under the receiver-operating characteristic curve of TFF3 was 0.7489. Using cutoff of 6.728 ng/ml, patients with gastric cancer were detected with 80.4% sensitivity, and 57.3% specificity by the TFF3 test. One hundred and seventy-one of 281 patients were not identified as bearing gastric cancer with pepsinogen test. However, adding TFF3 test to the pepsinogen test, 136 of these 171 patients who were not identified by pepsinogen test could be detected by the TFF3 test. If the TFF3 was added to the pepsinogen test, the sensitivity (87.5%) for gastric cancer prediction was superior to the sensitivity (39.1%) of the pepsinogen test.
Conclusion: The combination of the serum TFF3 and pepsinogen test could be an effective non-invasive biomarker for gastric cancer screening.

P0518 CLINICAL OUTCOMES OF ENDOSCOPIC SUBMUCOSAL DISSECTION FOR SUBMUCOSAL INVASIVE EARLY GASTRIC CANCER

H. Suzuki[1], S. Maeda[1]
[1]*Department of Gastroenterology, Sapporo Kosei General Hospital, Sapporo, Japan*

Contact E-mail Address: suzukihajimeja@yahoo.co.jp
Introduction: The Japanese Gastric Cancer Association has proposed expanded criteria for the curative endoscopic resection of early gastric cancer as follows: a) differentiated intramucosal tumour without ulceration or scarring; b) differentiated intramucosal adenocarcinoma with ulceration or scarring, tumour $\leq$3 cm; c) differentiated adenocarcinoma with minimal submucosal invasion (SM1: $\leq$500 μm from the muscularis mucosae), $\leq$3 cm; and d) undifferentiated intramucosal adenocarcinoma without ulceration or scarring, $\leq$2 cm. However, it remains controversial whether endoscopic submucosal dissection (ESD) for submucosal invasive early gastric cancer (SM-EGC) is feasible or not.
Aims & Methods: The aim of our study was to assess the feasibility of ESD for SM-EGC. We retrospectively collected clinical data of 1030 consecutive patients with 1304 gastric lesions who had undergone ESD at our hospital between January 2005 and March 2015. Of these, 179 lesions (13.7%) were classified as SM-EGC by pathological evaluation using the ESD specimen; 87 lesions (48.6%) had submucosal invasion of less than 500 μm (SM1-EGC), and the remaining 92 lesions (51.4%) had invasion of 500 μm or more (SM2-EGC).
Results: There were no significant differences in patient age, gender, location, and histology or morphological type between patients with SM1-EGC and SM2-EGC. Tumour size in SM1-EGC and SM2-EGC was 19.8 ± 11 cm and 26.7 ± 16 cm, respectively ($p < 0.005$). Lymphovascular involvement was found in 13 patients with SM1-EGC (14.9%) and 49 patients with SM2-EGC (53.3%) ($p < 0.005$). The complete resection rates for SM1-EGC and SM2-EGC were 87.4% and 60.8%, respectively ($p < 0.005$). The procedure time for SM1-EGC and SM2-EGC was 74.6 ± 47 min and 101.9 ± 63 min, respectively ($p < 0.005$). There were no significant differences in post-procedure bleeding rate (6.9% vs. 6.5%) and perforation rate (4.6% vs. 6.5%). Twenty-three SM1-EGC patients

(26.4%) underwent surgical resection after ESD as an additional treatment, and lymph node metastasis was found in only 1 case with lymphatic invasion. Additional surgical resection was performed for 63 patients (68.5%) of SM2-EGC patients, and lymph node metastasis was observed in 8 of these patients. Of 29 patients who did not undergo additional curative surgical resection, 2 patients with SM2-EGC had recurrence of lymph node metastases and underwent surgery, but no patient with SM1-EGC had lymph node metastases or local recurrence.
Conclusion: ESD for SM-EGC based on expanded criteria may be feasible, but additional long-term follow-up data are needed.

P0519 CLINICOPATHOLOGIC FEATURES OF GASTRIC CANCER WITH SYNCHRONOUS AND METACHRONOUS COLORECTAL CANCER IN KOREA: ARE MICROSATELLITE INSTABILITY AND P53 OVEREXPRESSION USEFUL MARKERS FOR PREDICTING COLORECTAL CANCER IN GASTRIC CANCER PATIENTS?

H. J. Kim[1,2], N. Kim[1], D. H. Lee[1]

Contact E-mail Address: nayoungkim49@empas.com
Introduction: A large-scale study was performed to identify the risk factors for developing synchronous and metachronous colorectal cancer (CRC) in gastric cancer (GC) patients including microsatellite instability (MSI) and p53 overexpression.
Aims & Methods: A total 1041 GC patients who underwent endoscopic resection or surgery and who underwent colonoscopy simultaneously or during the surveillance of GC were consecutively included.
Results: Of the 1041 patients, CRCs were detected in 67 (6.4%) patients with GC. Forty six (4.4%) had synchronous CRC and 21 (2.0%) had metachronous CRC. Univariate analysis indicated that age $\geq$55 ($P < 0.001$), male ($P < 0.001$) and p53 overexpression ($P = 0.040$) had a higher incidence of CRC. However, body mass index, smoking, tumor location, tumor multiplicity, tumor histology, TNM stage and MSI were not significantly associated with the incidence of CRC. Age $\geq$55 (OR: 4.143; 95% CI: 1.863-9.213; $P < 0.001$) and male (OR: 2.951; 95% CI: 1.323-6.583; $P = 0.008$) were the risk factors of CRC in GC patients by multivariate analysis.
Conclusion: GC patients who are 55 years and older or male are recommended to receive colonoscopy to detect CRC. MSI and p53 overexpression were not useful molecular markers for prediction of CRC in GC.

Contact E-mail Address: mhs1357@cnuh.co.kr
Introduction: Gastric cancer is the fourth most common malignancy in the world, and the second leading cause of cancer-related deaths and the highest mortality rates are reported in East Asia. Early detection and surgery are currently considered the mainstay of treatment, and approximately half of gastric cancer patients can be treated by curative surgical or endoscopic resection. However, the rate of recurrence and metastasis following radical resection remains disappointingly high. Thus, improving the rates of survival and cure is a critical goal. Theoretically the administration of the neoadjuvant chemotherapy (NAC) appears to have potential benefits for locally advanced gastric cancer, while its survival gain and surgical benefit remains controversial.
Aims & Methods: The aim of this study was to evaluate the effectiveness of NAC in treatment of marginally and potentially resectable gastric cancer and find out the associated factor of resistance to NAC. We retrospective reviewed the patient medical record. This study enrolled 179 patients who underwent NAC followed by surgery (n = 41) or surgery only (n = 138) for treatment of stage IIIa or IIIb locally advanced gastric cancer. For sampling, we applied a random sample extraction method. We categorized the NAC group and the Surgery only group according to gender and age, then we applied a serial number to each category. We used two chemo-regemen FOLFOX (n = 28) and DCF (n = 13). The basal characteristics and clinical outcome were compared between two groups. NAC related objective response, safety and toxicity were also analyzed.
Results: The basal characteristics including mean age and sex was not significant difference between two groups. Initial stage was significantly high ($P = 0.001$) in NAC followed by surgery (3.12 0.56) than surgery only group (2.57 0.54). After NAC, the tumor down-stage rate was 58.5% (24/41). Both tumor size and differentiation were predictive factor of resistance to NAC. But overall survival ($P = 0.518$), disease free survival ($P = 0.621$) and recurrence rate ($P = 0.142$) were not statistically difference between two groups. In subgroup analysis we compared clinical outcome between doublet (n = 28) and triplet (n = 13) NAC group. As a result, age, sex, tumor down stage rate and recurrence were similar between two groups. But drug toxicity ($P = 0.019$) and initial stage ($P = 0.010$) were significant higher in triplet NAC than doublet NAC group.
Conclusion: Compared with surgery only versus NAC followed by surgery was not associated with a survival gain or lower recurrence rate. However, Down of N stage is significantly improved statistically. In our data, tumor size and differentiation was the important clinical predictor. Therefore NAC may be benefit for selective treatment option and assessing individual prognosis.

Contact E-mail Address: mhs1357@cnuh.co.kr
Introduction: Gastric adenoma(GA) is well known for premalignant lesion. Endoscopic treatment has been widely conducted for the treatment of gastric adenoma. However, the risk factors related to recurrence of adenoma and occurrence of adenocarcinoma after endoscopic mucosal resection (EMR) or endoscopic submucosal dissection (ESD) for gastric adenoma have not been reported so much.
Aims & Methods: The aim of this study was to evaluate these factors. We reviewed medical records of total 667 lesions from 641 patients who underwent EMR/ESD for gastric adenoma from January, 2007 to December, 2013 at Chungnam National University Hospital. For all subjects, the data collected included sex, age, site of lesion, morphology, treatment method, severity of atrophy, intestinal metaplasia, resection margin and degree of dysplasia.
Results: The median follow up period was 29th month (range, 12-81 months). There were 98 recurrence of adenoma (14.7%) and 31 occurrence of adenocarcinoma (4.6%). The risk factors related to the recurrence of gastric adenoma were male ($p = 0.024$), intestinal metaplasia ($p = 0.004$) and incomplete resection margin ($p = 0.004$). The risk factors related to the occurrence of gastric adenocarcinoma were male ($p = 0.015$) and High grade dysplasia ($p = 0.019$).
Conclusion: After EMR/ESD for gastric adenoma, the recurrence of gastric adenoma was associated with sex, intestinal metaplasia and resection margin, and the occurrence of adenocarcinoma was associated with sex and grade of dysplasia.

Introduction: As a minimally invasive therapy, endoscopic resection (ER) and laparoscopy endoscopy cooperative surgery (LECS) of superficial non-ampullary duodenal tumors (SNADT) have been performed recently. However, the indication criteria have not been clearly determined yet. It is difficult to carry out ER safely because of the thin wall of the duodenum, so ER of SNADT includes serious complications such as perforation. Uedo *et al.* reported that the location of the lesions in distal side from Vater's ampulla was associated with the occurrence of delayed perforation. At the cancer institute hospital, ER is done only for SNADT measuring ≧20mm, whose ulcer floor can be closed completely using endoclips. LECS is the treatment choice for SNADT not amenable to ER in terms of technical and/or oncological reasons.
Aims & Methods: The aim of this study was to examine the validity of the treatment based on analyzing the therapeutic outcome. At the cancer institute hospital, 74 patients with SNADT treated by ER and 14 patients by LECS between September 2006 and December 2014. The ER methods used to carry out en bloc resection were endoscopic mucosal resection (EMR: n = 35) or endoscopic submucosal dissection (ESD: n = 39). The procedure of LECS was to close the mucosal defect after ESD with seromuscular suturing by laparoscope. We analyzed the therapeutic outcome of ER and LECS for SNADTs according to the location of the lesions that is proximal or distal side of Vater's ampulla.
Results: First, we analyzed the clinical outcomes of ER by comparing the EMR group and the ESD group. We treated 36 SNADTs located in the proximal side from Vater's ampulla (PVA) (21 with EMR and 15 with ESD) and 38 SNADTs located in the distal side from Vater's ampulla (DVA) (14 with ER and 24 with ESD). In the gross type, most frequent types were 0-IIa in EMR, 0-IIc in ESD. ($p < 0.001$) The median tumor sizes were 9.5mm in EMR and 13mm in ESD, so the lesion treated with ESD was significantly larger than that of EMR. ($p < 0.024$) In R0 resection (negative margins), EMR was 15 lesions located in PVA (71%) and 12 lesions located in DVA (86%), ESD was 14 lesions located in PVA (93%) and 22 lesions located in DVA (92%). ESD was significantly higher than EMR in each lesion. No complication was found in EMR. Intraoperative perforation occurred in 2 patients (5.3%) and delayed perforation occurred in 2patients (5.3%) in ESD. All of the lesions were located in DVA. The lesion recurrence was found in 1 patient only in EMR. The lesion was also located in DVA. Then, in LECS group, the lesions located PVA and DVA were 4 and 10 patients, respectively. The median tumor size was 23.5mm. All of the lesions were achieved R0 resection. In the treatment of SNADTs located in DVA, postsurgical infection occurred in 2 patients (20%). Although they were cured with conservative management, a long hospital stay was required.
Conclusion: ER and LECS of SNADT are ideal and less invasive treatments compared with open surgical resection. However, these treatments include serious complications such as perforation, residual tumor and infection, especially in patients with lesions located in DVA. In the case of the lesions located in

DVA, we should consider that open surgical resection is one of the safe and reliable treatments. In contrast, ER and LECS should be considered for the treatment of the lesions located in PVA to avoid unnecessary surgery and preserve patient's quality of life.

Contact E-mail Address: psyro@juntendo.ac.jp
Introduction: Gastric adenocarcinoma of the fundic gland type (chief cell predominant type, GA-FG-CCP) has recently been proposed as a new variant of gastric adenocarcinoma. In 2010 and 2014, we described the clinicopathological and endoscopic features of GA-FG-CCP (Ueyama H. *Am. J. Surg. Pathol* 2010, Ueyama H. *Endoscopy* 2014). We found that GA-FG-CCP is rare but has distinct clinicopathological features, especially in terms of tumour location, histological findings, phenotypic expression, and low-grade malignancy. However, the treatment strategies and long-term outcomes of GA-FG-CCP have not been thoroughly investigated by studies with large sample sizes.
Aims & Methods: The aim of this study was to collect a large number of GA-FG-CCP cases and perform a detailed analysis of the clinicopathological features of GA-FG-CCP. A total of 70 GA-FG-CCP cases were retrospectively collected from 25 institutions between January 2008 and December 2014.
Results: A total of 70 patients [65.4 y (range 41-81 y), 50 male, 20 female] with 70 lesions were treated as follows: ESD/EMR/surgery = 48/11/11. A total of 88% of patients were negative for *H. pylori* infection. In regards to lesion location, 55 were detected in the upper stomach, 14 in the middle stomach, and 1 in the lower stomach. Macroscopically, 44 lesions had a protruded shape (SMT shape: 22, 0-IIa:18, 0-I:4), whereas 26 had a flat/depressed shape (IIb:7, IIc:19). The mean tumour size was 12.0 (2-85) mm. Histologically, there were 20 intramucosal cancers and 50 submucosal invasive cancers. The mean depth of the submucosal invasion was 476.7 (50-4000) μm. Lymphovascular invasion was observed in 4 cases (5.7%). Lymph node metastasis was only observed in one out of 11 patients who underwent surgery (9.1%, 1/11). Follow-up data were available for 38 cases, and during the follow-up period (median 28.7 (1-104) months), no local recurrence or metastasis was detected in any case. For 7 of the 38 patients with follow-up data, endoscopic resection was determined to be non-curative, and of those 7 patients, four did not undergo additional surgery. However, there was no local recurrence and metastasis at a median of 32 months (4-82) follow-up after endoscopic treatment.
Conclusion: The findings of high-grade atypism, lymphovascular invasion, and LN metastasis in some GA-FG-CCP cases indicate that GA-FG-CCP may alter the atypism and cell differentiation of the tumour during the course of tumour progression, resulting in the development of high-grade malignancy. However, endoscopic treatment appeared to be effective, because neither recurrence nor metastasis was detected in any case regardless of whether additional surgery was performed. Therefore, the prognosis of GA-FG-CCP may be better than those of more common gastric cancers. Moreover, GA-FG-CCP should be categorized as a gastric adenocarcinoma that occurs without *H. pylori* infection, because *H. pylori* infection was considered an accidental phenomenon in this case series. Further studies will be needed to elucidate the natural history and carcinogenesis of GA-FG-CCP.

Contact E-mail Address: hiroyukikomori219@gmail.com
Introduction: Recently, with the advent and widespread use of endoscopic submucosal dissection (ESD), *en bloc* resection of early gastrointestinal cancer has become possible irrespective of the location and diameter. However, the technical difficulty is greatly dependent on the condition of the lesion and the skill of the endoscopist; a lesion with scarring, in particular, is technically challenging. The Japanese Treatment Guidelines for Gastric Carcinoma suggests that presence or absence of scarring may become a decisive factor in curative resection and an important finding for judging whether expanded surgery might be required. In addition, some reports have indicated that it is difficult to determine if scarring is present before performing ESD. The clinical management, including diagnosis, of cases with scarring before ESD has not been well investigated.
Aims & Methods: This study aimed to investigate clinicopathological characteristics and clinical management of early gastric cancer with scarring. We analysed 315 lesions and 318 cases of early gastric cancer treated by ESD at our hospital between April 2009 and February 2015 (225 males and 93 females; mean age 69.7 y). According to the presence or absence of pathologically diagnosed scarring, the cases were divided into two groups for comparison: Group UL+, 28 lesions in 27 cases (18 males and 9 females; mean age 72 y); and Group UL-, 323 lesions in 291 cases (210 males and 81 females; mean age 71.7 y).
Results: Scarring was accurately diagnosed endoscopically before ESD in 13 of 28 cases (46%) in Group UL+. There was no significant difference between the two groups in the following parameters (Group UL+ vs. Group UL-): the location of the lesion (U/M/L), 11/13/4 vs. 141/147/35; the operation time, 89.3 min vs. 63.7 min; the tumor diameter, 17.9 mm vs. 15.7 mm; and the diameter of the resected specimen, 39.0 mm vs. 36.9 mm. Macroscopically, the depressed type was significantly more often observed in Group UL+ (flat and elevated type/depressed type = 11%/89% in Group UL+ and 45%/55% in Group UL-, $P < 0.01$). Histologically, the mixed type (differentiated and undifferentiated cancer) was observed significantly more often in Group UL+ (differentiated type/mixed type = 75%/25% in Group UL+ and 88%/12% in Group UL-, $P < 0.05$). Despite no significant difference in invasion depth, SM cancer tended to be observed more frequently in Group UL+ (M/SM = 71%/29% in Group UL+ and 86%/14% in Group UL-, $P = 0.06$). The curative resection rate was significantly lower in Group UL+ (57% in Group UL+ and 86% in Group UL-, $P < 0.01$).
Conclusion: This study elucidated that early gastric cancer with scarring has high malignant potential and aggressiveness. It is often difficult to diagnose depth of invasion before ESD in cases of early gastric cancer with scarring.
Disclosure of Interest: None declared

P0525 GIST OR NON-GIST, THAT IS THE QUESTION: BASKET-LIKE HYPERVASCULARIZATION IN DOPPLER ENDOSCOPIC ULTRASONOGRAPHY- A HIGHLY SPECIFIC CRITERION FOR THE DETECTION OF A GASTROINTESTINAL STROMAL TUMOR

H. Neye[1], K. Mönkemüller[2], R. Hiersemann[3], S. Rickes[3]
[1]*Department of Gastroenterology and Diabetology, HELIOS Hospital Emil von Behring Berlin, Berlin, Germany,* [2]*Division of Gastroenterology and Hepatology, University of Alabama at Birmingham, Birmingham, United States,* [3]*Department of Internal Medicine, HELIOS Börde Hospital, Oschersleben, Germany*

Contact E-mail Address: holger.neye@helios-kliniken.de
Introduction: Endoscopic ultrasonography (EUS) is the most important imaging method for diagnosis of subepithelial lesions of the gastrointestinal tract. However, it still has limits in the differentiation between Gastrointestinal Stromal Tumors (GISTs) from other malignant and benign tumors (Non-GISTs). As a result of the development of effective oncological therapy there is a high need for an imaging method to the diagnosis and follow-up of GISTs. In recent years Doppler EUS has been proposed as a method to distinguish GISTs from Non-GISTs. Therefore we initiated a prospective study to evaluate Doppler EUS criteria for the detection of a GIST.
Aims & Methods: Thirty-one patients (19 women, 12 men) with subepithelial lesions (n = 32) were prospectively investigated using the EUS platform Olympus GF-UCT140 (Olympus Europe, Hamburg, Germany) and HDI 5000 (Philips Ultrasound, Bothell, USA). All Doppler EUS examinations were performed by one operator unaware of the histological results. Defined ultrasound parameters were used to determine the Doppler EUS observations. All tumors were proven histologically. The exact Chi-square Test (Fisher's Test) was used to find significant differences between GISTs and Non-GISTs. P-values of less than 0.05 were considered to be significant. The study was conducted following the Good Clinical Practice Guidelines and according to the guidelines of the Helsinki Declaration.
Results: See table 1. Basket-like hypervascularization in Doppler endoscopic ultrasonography is a highly specific criterion in the differentiation between Gastrointestinal Stromal Tumors from other malignant and benign tumors (Non-GISTs). **Table 1:** Results of Doppler EUS examinations.

Criteria	GIST present	GIST absent	Non-GIST present	Non-GIST absent	p-value
Vessels detected	10	0	14	8	0.035
Afferent vessel	9	1	7	15	0.006
Basket-like hypervascularization	9	1	4	18	0.0002

Significance level: p-value less than 0.05

Conclusion: The differentiation of GISTs from other malignant and benign subepithelial lesions is a major issue in the management of these tumors. With this prospective study, we have addressed the need to evaluate diagnostic criteria for Doppler EUS criteria. The results demonstrated a basket-like hypervascularization is a highly specific criterion in the detection of a GIST. In the future, the direct detection of vessels could be the most important advantage of Doppler EUS contrary to other imaging methods.

Contact E-mail Address: lyi610@yuhs.ac
Introduction: Histologic discrepancy between specimens obtained by forceps biopsy and endoscopic resection (ER) often occurs in gastric adenomatous lesions. The purpose of this study was to investigate that gastric atrophy could be one of clinical diagnostic factor for predicting histologic discrepancy between forceps biopsy and ER.
Aims & Methods: This study involved 203 gastric low grade dysplasia (LGD) that were proven on the basis of forceps biopsy and checked serum pepsinogen I/II level. ER is composed of 17 endoscopic mucosal resection and 186 endoscopic submucosal dissection. The lesions were grouped according to the histologic

Abstract number: P0526

Table 1: Histologic discrepancy between specimens obtained by forceps biopsy and endoscopic resection.

Variables	Condordant(n = 179), n(%)	Discordant(n = 24), n(%)	Univariate analysis P value	Multivariate analysis P value	odds ratio (95% CI)
Atrophy around the lesion			0.012	0.036	3.106 (1.075-8.980)
Yes	83 (46.4)	18 (75.0)			
No	96 (53.6)	6 (25.0)

>30	4 (2.5)	1 (4.2) zx	0.496	0.916	1.267 (0.102-15.806)
Ulcer	12 (6.7)	2 (8.3)	0.674	0.790	1.287 (0.201-8.249)

discrepancies between forceps biopsy and ER; concordant or discordant. The definition of discordance is histologic upgrade from LGD of forceps biopsy to high-grade dysplasia (HGD) or differentiated adenocarcinoma of ER. Gastric atrophy was diagnosed when either a endoscopic atrophy was confined around the adenomatous lesion or both serum pepsinogen level I ≤ 70 and pepsinogen I/II ratio ≤ 3.0 was satisfied.

Results: Histologic discrepancy between forceps biopsy and ER in gastric adenoma was 11.8% (24/203). The histologic upgrade to HGD or differentiated adenocarcinoma accounted for 5.4% (11/203) and 6.4% (13/203), respectively. Atrophy around the lesion in endoscopy accounted for 49.7%(101/203) and satisfaction of both serum pepsinogen I ≤ 70 and pepsinogen I/II ratio ≤ 3.0 accounted for 44.3%(90/203). In univariate analysis, atrophy around the lesion, upper third located lesion, erythema of the lesion, and satisfaction of both pepsinogen I ≤ 70 and pepsinogen I/II ratio ≤ 3.0 was found to be statistically significant factors affecting histologic discrepancy. In multivariate analysis, atrophy around the lesion (odd ratio [OR], 3.106; 95% confidence interval [CI], 1.075-8.980; P = 0.036), upper third located lesion(OR, 5.641; 95% CI, 1.35-23.567; p = 0.018) were significant factors associated with histologic discrepancy.

Conclusion: We should consider histologic discrepancy and tentative endoscopic resection for gastric LGD that is located upper third or accompanying atrophy around the lesion.

Introduction: Clinical outcome of early gastric cancer (EGC) is excellent, attributable to the progress in diagnostic and therapeutic methods. However, there is no relevant guideline for surveillance endoscopy and/or computed tomography (CT) scan, especailly for EGC.

Aims & Methods: The aim of this study was to investigate the role of regular endoscopy and CT scan surveillance after treatment of EGC. A total of 603 patients with EGC treated either by endoscopic [endoscopic mucosal resection (EMR) or endoscopic submucosal dissection (ESD)] or surgical treatment (gastrectomy with lymph node dissection) between January 2007 and December 2009 were retrospectively reviewed. All of the gastric lesions were completely resected and all of them had one or more endoscopy and CT scan examination during the follow-up.

Results: In the gastrectomy group (n = 492; mean follow-up, 46.1 months), 10 patients revealed tumor recurrence during the follow-up, including 3 cases with metachronous gastric adenoma, 1 with anastomosis site cancer recurrence, 1 with regional lymph node metastasis, and 5 with distant metastasis. All metachronous gastric adenomas were detected by endoscopy with biopsy. Six cases (5 distant metastases and 1 regional lymph node metastasis) were diagnosed by abdominal CT; the anastomosis site recurrence case was detected by both CT and endoscopy; all of these 7 cases were sm cancers and 2 of them had regional lymph node metastasis in the initial surgical pathology. In EMR/ESD group (n = 111; mean follow-up 51.3 months), 3 revealed metachronous gastric adenocarcinoma during the follow-up, all of which were deteced by endoscopy with biopsy; 2 of them also showed tumor recurrence in abdominal CT scan. All of these 3 cases meet the absolute criteria of ESD (< 2cm in size, m cancer, differentiated pathology) according to the initial resection specimen.

Conclusion: According to our preliminary report, regular follow-up of both endoscopy and CT scan is recommended after the surgery in the EGC patients. Especially, CT scan seems to be more valuable in case of sm cancers and/or lymph node metastasis. After endoscopic resection of EGC, all the recurrence could be detected by endoscopy with biospy, so CT scan might have a limited role for the surveillance of EGC after endoscopic resection of EGCs which meet the absolute criteria. However, further study is warranted in this issue.

Introduction: The aim of this study was to evaluate the clinicopathological characteristics and factors that lead to residual tumors in patients who underwent additional gastrectomy for incomplete endoscopic resection in Korea.

Aims & Methods: Between 2003 and 2013, the medical records of patients underwent additional gastrectomy after incomplete ER were retrospectively reviewed. Those diagnosed with the presence of histologic residual tumor in specimens obtained by gastrectomy were assigned to the residual tumor (RT) group (n = 47); those diagnosed with the absence of histologic residual tumor in specimens obtained by gastrectomy were assigned to the non-residual tumor (NRT) group (n = 33). We analyzed comparison of the clinicopathologic characteristics of RT and NRT group, clinical factors influencing the presence of residual tumor, pathologic discrepancies between ER and additional gastrectomy, relationship between positive margins, depth of invasion with residual tumors and lymph node metastasis, cases of lymph node metastasis.

Results: The frequency of additional gastrectomy due to incomplete resection after ER for EGC was 8.7% (80/911), and 58.7% (47/80) of those patients had residual tumors. The rates of *H. pylori* infection, mixed macroscopic finding, tumor size over 2cm, endoscopic piecemeal resection, submucosal invasion, both (lateral and vertical) margin involvement were significantly higher in the RT group than in the NRT group ($p < 0.05$). In the multivariate analysis, endoscopic piecemeal resection (Odds ratio [OR]: 5.02, 95% confidence interval [CI]: 3.78-6.24), H. pylori infection (OR: 1.45, 95% CI: 0.98-1.92), large tumor size (> 2cm, OR: 2.96, 95% CI: 2.37-3.55), and both (lateral and vertical) marginal involvement (OR: 4.96, 95% CI: 4.13-5.79) were independent factors, predictive of the presence of residual tumor in additional gastrectomy after incomplete resection ER for early gastric cancer ($p < 0.05$)

Conclusion: Before ER, endoscopic examination along with EUS and MDCT should be used to accurately determine the GC invasion depth and the presence of LN metastasis. During ER, surgeons should attempt to perform en bloc resection when performing ER and attempt to resect the mucous membrane with adequate safety margins to prevent tumor invasion into the lateral and vertical margins. After ER, effort should be made to ensure timely and accurate decisions about whether additional gastrectomy is needed using the pathological findings of the resected tissues, to ensure that there is no delay in surgery.

Introduction: Endoscopic submucosal dissection (ESD) is widely accepted as treatment for early gastric cancer (EGC) due to its minimal invasiveness, and better quality of life associated with preserving gastrointestinal function. However, there is no consensus on ESD for mixed adenocarcinoma. This study aimed to evaluated the risk factor of lymph node (LN) metastasis and validate the ESD criteria as a curative resection for mixed adenocarcinoma in EGC.

Aims & Methods: Of 692 EGC patients who had undergone gastrectomy with LN dissection between 2001 and 2013, 60 were diagnosed as mixed adenocarcinoma after histological evaluation in surgical specimens and were analyzed retrospectively.

Results: LN metastasis was detected in 13 (21.7%) of 60 mixed adenocarcinoma. There were no significant differences in the gender ratio of male to female (74.5%: 25.5% in LNN group vs. 53.8%: 46.2% in LNP group, $p = 0.181$) and age (58.9 ± 11.7 in LNN group vs. 57.8 ± 12.3 in LNP group, years, $p = 0.770$) between LN negative group (LNN group) and LN positive group (LNP group). The histological evaluation showed that the size of EGC was significant larger in LNP group than in LNN group (26.1 ± 10.0 in LNN group vs. 36.1 ± 8.7 in LNP group, mm, $p = 0.002$). The rates of LN metastasis were different according to the tumor size (35.1% in tumor > 20 mm vs. 0% in tumor ≤ 20 mm, $p = 0.003$) and the presence of submucosal invasion (32.5% in submucosal cancer vs. 0% in mucosal cancer, $p = 0.006$). None of mucosal cancer ≤ 20 mm and 48.1% of submucosal cancers > 20 mm in size had LN metastasis.

Conclusion: The risk of LN metastasis is high in mixed adenocarcinoma with more than 20 mm in size and submucosal invasion. Therefore, additional surgical treatment should be recommended in mixed adenocarcinoma with high risk factors even after complete resection by endoscopic procedures.

Introduction: Exact measurement of lesion extent in gastric epithelial neoplasm is critical for deciding treatment strategy. Although maximal diameter of the lesion is usually indicated as an actual tumor burden in early gastric cancer (EGC), certification of its validity has not been determined.

Aims & Methods: The purpose of the study was to evaluate the validity of lesion diameter and calculated lesion area for predicting actual tumor burden. We also aimed to assess the clinicopathologic factors related to discrepancy between PTE and ATE. We prospectively enrolled 302 EGCs from 290 consecutive patients who underwent endoscopic submucosal dissection as a primary treatment modality and in whom histologic results showed complete resection. Biopsy forcep method was used to measure the pre-sectional long and short diameter of the lesion. Predictive tumor extent (PTE) was calculated using pre-resectional long and short diameter (long diameter x short diameter x 0.5, mm^2). Actual tumor extent (ATE) was measured as mm^2 unit using histologically constructed report and ImageJ Program (NIH Image version 1.55). Correlation between pre-resectional long/short diameter, PTE and ATE were analyzed. The well-estimated group was defined as lesion with ratio of PTE/ATE from 0.7-1.3. The underestimated and overestimated groups were defined as lesions with ratios of PTE/ATE less than 0.7 and more than 1.3, respectively.

Results: Correlation coefficient between pre-resectional long diameter and ATE, and PTE and ATE were 0.67 ($P < 0.01$) and 0.69 ($P < 0.01$), respectively. There was no significant different between PTE and ATE (167.00 ± 13.08 mm^2 vs 166.12 ± 10.89 mm^2). Number of well-estimated, underestimated and overestimated groups were 89 (29.5%), 94 (31.1%) and 119 (39.4%), respectively. Elevated macroscopic morphology and absence of adenomatous component were significant independent factors for well-estimation. Depressed or flat macroscopic morphology, presence of adenomatous component and histologic lesion size less than 1 cm were significant independent factors for overestimation. Histologic lesion size was the only independent factor related to underestimation

Conclusion: Endoscopically measured tumor extent using long and short diameter can be a useful indicator for actual tumor extent in EGC. Marcoscopic morphology, presence of adenomatous component and histologic lesion size were the significant clinicopathlogic factors related to accurate endoscopic estimation of actual tumor extent.

P0531 THE USEFULNESS OF MAGNIFYING ENDOSCOPY WITH NARROW-BAND IMAGING FOR PREDICTION ON PRE- AND POST-RESECTIONAL HISTOLOGIC DISCREPANCIES IN GASTRIC LOW-GRADE DYSPLASIA DIAGNOSED BY ENDOSCOPIC BIOPSY

Introduction: MENBI categorical classification systems were suggested by the Japanese enscopitsts. Vessel plus surface (VS) classification, suggested by Yao et al, was known as useful tool for differential diagnosis between gastric adenoma with LGD and EGC, but few reports have evaluated about the feasibility of this classification system for predicting histologic discrepancy between pre-treatment endoscopic biopsy and post-treatment specimens, especially in other place than Japan.

Aims & Methods: The aim of this study was to evaluate the validity of the parameters of conventional endoscopic and magnifying endoscopy with narrow-band imaging (MENBI) for the prediction of histologic discrepancies between pre- and post-resectional histology in cases of gastric adenoma with low-grade dysplasia (LGD) that were diagnosed based on endoscopically biopsied specimens. The medical records of 149 consecutive patients with gastric LGD and 160 total lesions that were diagnosed based on an endoscopic forceps biopsy were retrospectively reviewed. These patients all underwent a MENBI examination. The incidence of histologic discrepancies and histologic heterogeneity were then analyzed. The relationship between conventional endoscopic/MENBI parameters and the presence of histologic discrepancies were also analyzed.

Results: Histologic discrepancie between the pre- and post-resectional histology were found in 49 cases (30.62%). Among those cases, the histology was upgraded in 47 cases, whereas the histology was downgraded in two cases. Older age, the presence of erythema, positive MENBI findings and the presence of discontinuous lesions were independent factors for the prediction of upgraded histologic discrepancies (p value = 0.046, 0.004, <0.001 and 0.038, respectively). Positive MENBI findings showed the highest predictive value, with a multivariate adjusted odds ratio of 19.812. Histologic heterogeneity in post-resectional specimens was found in 27.7% of cases with upgraded histologic discrepancies. Positive MENBI findings ($p = 0.008$) and the presence of discontinuous lesions ($p = 0.031$) were significant independent factors for the presence of histologic heterogeneity.

Conclusion: Endoscopic resection is recommended in cases of gastric adenoma with LGD that is diagnosed by forceps biopsy that demonstrate (1) surface erythema on conventional endoscopy or (2) a positive finding on the MENBI examination, irrespective of the lesion size. A careful histologic analysis for the presence of discontinuous lesions may be valuable for the detection of histologic heterogeneity.

Introduction: A high preoperative neutrophil-to-lymphocyte ratio (NLR) has been reported to be a prognostic factor for patients with gastric cancer after treatment. However, the clinical implication of postoperative NLR change remains unclear.
Aims & Methods: Three hundred forty-seven patients diagnosed as gastric adenocarcinoma between 2003 and 2014 from two institution (Eulji and hallym hospital) were included. Each subject underwent endoscopic submucosal dissection or gastrectomy. The NLR was recorded within 1 months before and 8 month after surgical procedure. Baseline characteristics, overall survival (OS) and disease-free survival (DFS) were compared according to preoperative NLR and/or postoperative NLR change.
Results: Compared with preoperative NLR, postoperative NLR decreased in 205 patients and increased in 141 patients after surgical treatment. Receiver operating characteristic (ROC) curve exhibited good discriminatory power considering the overall survival for postoperative NLR than preoperative NLR (area under the ROC = 0.744 and 0.54), respectively. Comparing to preoperative NLR, increased postoperative NLR was significantly associated with poor OS and DFS ($p < 0.001$). The 1, 3, 5 years OS was 92.7%, 83.4%, 80.5% for NLR decreased group, and 83.8%, 71.8%, 63.4% for NLR increased group respectively; the corresponding RFS was 92.7%, 85.9%, 33.8% and 83.8%, 69.7%, 63.4% respectively. The survival of patients with lower or higher preoperative NLR can be distinguished more accurate by postoperative NLR change. Multivariate analysis showed that postoperative increased NLR change was an independent prognostic factor for both OS ($P < 0.001$, HR = 2.552, 95% CI 1.744–3.734) and RFS ($P < 0.001$, HR = 2.442, 95% CI 1.609–3.707).
Conclusion: After operation, increased NLR change was an independent prognostic factor for gastric adenocarcinoma undergoing surgical procedure, comparing with decreased NLR change.

Introduction: Novel therapies are necessary to improve outcomes for patients with peritoneally disseminated gastric cancer. Vaccinia virus has been shown to be an effective oncolytic agent, and genetic manipulations of this virus make it possible to monitor noninvasively therapeutic efficacy and potential toxicity.
Aims & Methods: We examined the therapeutic effects of genetically engineered vaccinia as an oncolytic agtent against peritoneally disseminated gastric cancer. GLV-1h153 was modified from parental vaccinia virus GLV-1h68 to carry hNIS via homologous recombination. GLV-1h153 was tested against human gastric cancer cell line OCUM-2MD3 for replication via viral plaque assays. Viral cytotoxicity and tumore regression of treated OCUM-2MD3 tumor xenografts in nude mice was also determined. Tumor radiouptake in xenograft was assessed via 99mTc pertechnetate scintigraphy and 124I positron emission tomography.
Results: GLV-1h153 infected, replicated within, and killed OCUM-2MD3 cells efficiently. GFP expression conformed viral infection by 24 hours. In vivo, GLV-1h153 was safe and effective in a peritoneal cancer model that simulates clinical disease. A single injection of GLV-1h153 into peritoneal cancer model exhibited intratumoral luciferase activity peaking at days 5-7, with gradual resolution over 10 days. Intraperitoneal injection of GLV-1h153 facilitated imaging of virus replication in tumors via 99mTc pertechnatate scintigraphy and 124I PET.
Conclusion: These results demonstrate significant oncolytic efficacy by gentically GLV-1h153 virus for infecting and lysing peritoneally disseminated gastric cancer both in vitro and in vivo, and support its contined investigation in future clinical trials.

Introduction: Chronic ulcer of stomach is a main risk for gastric cancer. The mechanisms underlying transformation of gastric ulcer to cancer are not well established but there is much epidemiological data suggesting that stress and exogenous N-nitroso-compounds (NOCs) from diet play a major role in these pathological processes. In our previous studies we showed that chronic social stress causes ulcer formation that is associated with pathological changes in local mechanisms of microcirculatory regulation such as nitric oxide (NO) and adrenomediated vasorelaxation. In our clinical work we obtained the abnormal effect of adrenalin on gastric vessels (relaxation) and the hyperteactivity of NO-system in epithelium of stomach in patients with gastric cancer.
Aims & Methods: Here we studied the nitrergic and adrenergic mechanisms of cancerogenic effect of chronic stress (overpopulation, immobilization) and exogenous nitrites/NOCs in rats with gastric stress-related ulcer. The experiments were carried out on six groups of rats: 1) intact (n = 12) and 2) stressed (n = 23) rats without nitrites/NOCs administration; 3) intact (n = 25) and 4) stressed (n = 25) rats with daily administration of N-methylaniline (2g/kg of diet) in the feed with sodium nitrite in the drinking-water (1 g/L); 5) intact (n = 20) and 6) stressed (n = 25) rats with daily administration of N-methylaniline without sodium nitrite. In all groups we analyzed gastric blood flow by LSCI, expression of beta2-adrenoreceptors (B2-AR – a key factor of microcirculatory regulation) by immunohistochemistry and NO/beta-arrestin-1 (co-factors of B2-AR activation) level in epithelium of stomach using spectrophotometry and immunoassay.
Results: Chronic stress (overpopulation) during 5 months was accompanied by primarily erosions in 64% of rats (2d group - stress), 72% (6^{th} group – stress + NOCs) and 93% (4^{th} group – stress + nitrites/NOCs). Additional daily stress (4h immobilization) during 1 month induced development of ulcers in stomach in all rats with stress-related injury of gastric mucosa that was more pronounced in 4^{th} group vs. 2d and 6^{th} groups. The gastric epithelial dysplasia as a sign of pre-cancer formation we found only in 4^{th} group of stressed rats (stress + nitrites/NOCs). In other groups we identified ulcer injures but not mutagenic changes in epithelium of stomach. In intact rats of 1,3,5 groups, gastric tissues were not changed. In all groups of stressed but not in intact rats we observed increase in the level of NO in gastric epithelium. Only stressed rats with gastric epithelial dysplasia demonstrated increase in gastric perfusion that was associated with overexpression of B2-AR, high level of beta-arrestin-1 and more higher level of NO in gastric epithelium that in other groups.
Conclusion: Combination of chronic stress and exogenous nitrites/NOCs are factors for transformation of stress-related gastric ulcer into cancer of stomach. The pathological mechanisms of microcirculatory regulation such as overexpression of B2-AR and the increase in production of co-factors of B2-AR activation – NO and beta-arrestin-1 play an important role in cancerogenic effect of stress and nitrites/NOCs in rats with gastric ulcer.
Research was supported by grant from Russian Ministry of Science and Education (GK-17.488.2014/K).

P0535 LONG NONCODING RNA MALAT1 PROMOTES AGGRESSIVE GASTRIC CANCER THROUGH MMP1 OVER-EXPRESSION AND TRANSCRIPTIONALLY ACTIVATED BY C-JUN

W. Jin[1]
[1]*The First Affiliated Hospital of Nanjing Medical University, the First Affiliated Hospital of Nanjing Medical University, Nanjing, China*

Contact E-mail Address: zhouxiaoying0926@sina.cn
Introduction: Recently long non-coding RNAs (lncRNA) have emerged as new gene regulators and prognostic markers in several cancers including gastric cancer (GC). In this study, we investigated the contributions of the lncRNA MALAT1, a highly conserved long noncoding RNA, in GC and its posttranscriptional regulation.
Aims & Methods: We analyzed MALAT1 expression levels by qRT-PCR and in four GC cell lines compared with epithelial cells. Transient RNAi-mediated knockdown and pcDNA-mediated overexpression of MALAT1 was performed. Stable shRNA-mediated knockdown and lentiviral-mediated overexpression of MALAT1 was to study the role of MALAT1 on in vivo tumorigenicity and metastatic burden in the context of xenograft assays. Proteomic profiling was performed to decipher differential protein expression in cells with different MALAT1 expression levels. One of the differentially regulated proteins, MMP1 was subsequently validated and its function evaluated through xenograft assays.
Results: We found that MALAT1 expression was higher in human GC tissues where it was associated with reduced patients' survival. MALAT1 silencing decreased GC cell proliferation and invasion and increased apoptosis. Mechanistic investigations showed that MALAT1 was transcriptionally activated by c-Jun and that it interacted with MMP1. MMP1 and MALAT1 had a positive relationship, both at expression level and in function. Direct interaction between the two was confirmed through RNA immunoprecipitation coupled with quantitative real time PCR. MMP1 was confirmed to be promoter of GC pathogenesis and as functionally similar to MALAT1 lncRNA.

Conclusion: We found that MALAT1 expression was higher in human GC tissues where it was associated with reduced patients' survival. MALAT1 silencing decreased GC cell proliferation and invasion and increased apoptosis. Mechanistic investigations showed that MALAT1 was transcriptionally activated by c-Jun and that it interacted with MMP1. MMP1 and MALAT1 had a positive relationship, both at expression level and in function. Direct interaction between the two was confirmed through RNA immunoprecipitation coupled with quantitative real time PCR. MMP1 was confirmed to be promoter of GC pathogenesis and as functionally similar to MALAT1 lncRNA.

P0536 CLINICAL ROLE OF CIRCULATING MIR-223 AS NOVEL BIOMARKER IN EARLY DIAGNOSIS OF CANCER PATIENTS

X. Zhou[1]

[1]*Gastroenterology, the First Affiliated Hospital of Nanjing Medical University, Nanjing, China*

Contact E-mail Address: zhouxiaoying0926@sina.cn

Introduction: Current procedures for diagnosis and biomarker examination of cancers are invasive and non-specific. MicroRNAs (miRNAs) have become promising molecular markers for GC predication. However, there have been inconsistencies in the literature regarding the suitability of circulating miRNAs for early detection of cancers.

Aims & Methods: We performed a comprehensive meta-analysis to integrate an evaluation index for diagnostic accuracy of miR-223 in diagnosing cancer patients. Furthermore, we conducted an independent validation set of 50 gastric cancer patients and 50 healthy controls comparing miR-223 expression.

Results: A total of 11 studies met the criteria and included in this meta-analysis. We found that miR-223 yielded a pooled area under ROC curve (AUC) of 0.89 (sensitivity: 81%, specificity: 84%) in discriminating cancer from controls. In our validation analysis, plasma miR-223 levels in GC patients were significantly higher than that in healthy controls ($p < 0.01$). ROC curve analysis showed that AUC was 0.812 with sensitivity of 70% and specificity of 80%. Moreover, the expression trend of miR-223 in plasma samples was in accordance with that of tissue and cell samples.

Conclusion: In conclusion, current evidences suggest that plasma miR-223 could be a reliable and non-invasive biomarker for cancer diagnosis. Further large-scale prospective studies are necessary to validate their potential applicability in human cancer diagnosis.

P0537 IDENTIFICATION OF THE LONG NON-CODING RNA H19 IN PLASMA AS A NOVEL BIOMARKER FOR DIAGNOSIS OF GASTRIC CANCER

X. Zhou[1], G. Zhang[1]

[1]*Gastroenterology, the First Affiliated Hospital of Nanjing Medical University, Nanjing, China*

Contact E-mail Address: zhouxiaoying0926@sina.cn

Introduction: Recent studies have demonstrated that long non-coding RNAs (lncRNAs) are regarded as useful tools for cancer detection, particularly for the early stage; however, little is known about their diagnostic impact on gastric cancer (GC).

Aims & Methods: We hypothesized that GC-related lncRNAs might release into the circulation during tumor initiation and could be utilized to detect and monitor GC. 8 lncRNAs which previously found to be differently expressed in GC were selected as candidate targets for subsequent circulating lncRNA assay. After validating in 20 pairs of tissues and plasma in training set, H19 was selected for further analysis in another 70 patients and 70 controls.

Results: Plasma level of H19 was significantly higher in GC patients compared with normal controls ($p < 0.0001$). By receiver operating characteristic curve (ROC) analysis, the area under the ROC curve (AUC) was 0.838; $p < 0.001$; sensitivity, 82.9%; specificity, 72.9%). Furthermore, H19 expression enabled the differentiation of early stage GC from controls with AUC of 0.877; sensitivity, 85.5%; specificity, 80.1%. Besides, plasma levels of H19 were significantly lower in postoperative samples than preoperative samples ($p = 0.001$).

Conclusion: In conclusion, plasma H19 could serve as a potential biomarker for diagnosis of GC, in particular for early tumor screening.

P0538 THE INTERACTION BETWEEN MIR-141 AND LNCRNA-H19 IN REGULATING CELL PROLIFERATION AND MIGRATION IN GASTRIC CANCER

X. Zhou[1]

[1]*Gastroenterology, the First Affiliated Hospital of Nanjing Medical University, Nanjing, China*

Contact E-mail Address: zhouxiaoying0926@sina.cn

Introduction: Non-coding RNAs including miRNA and lncRNA had been reported to regulate gene expression and were both related to cancer progression. MicroRNA-141 (miR-141) has been reported to play a role in the epithelial to mesenchymal transition (EMT) process and H19 has also been demonstrated to promote malignancy in various cancers.

Aims & Methods: We aimed to determine the correlation between miR-141 and H19 and their roles in gastric cancer in this study. H19 and miR-141 expression were detected by qRT-PCR. By bioinformatic analysis and luciferase assay, we examined the correlation between H19 and miR-141.

Results: H19 expression was found to be inversely correlated to miR-141 expression in gastric cancer cells and tissues. H19 promotes malignancy including proliferation and invasion whereas miR-141 suppresses malignancy in human cancer cells. MiR-141 binds to H19 in a sequence specific manner, and suppresses H19 expression and functions including proliferation and invasion. MiR-141 could also regulate H19 target genes and miR-141 inhibitor restores H19 siRNA function, while H19 regulates miR-141 target gene ZEB1.

Conclusion: These results were the first to demonstrate that H19 and miR-141 could compete with each other and affect their target genes in gastric cancer, which provide important clues for understanding the key roles of lncRNA-miRNA functional network in cancer.

Contact E-mail Address: cho_hourin@yahoo.co.jp
Introduction: A limited number of studies have reported on the long-term recurrence and mortality in acute esophageal variceal bleeding. This study aimed to elucidate the rates of re-bleeding and mortality and the associated risk factors in patients with esophageal variceal bleeding.
Aims & Methods: A cohort of 174 patients emergently hospitalized for esophageal variceal bleeding was analyzed. All patients underwent endoscopic variceal ligation (EVL) within 12 h of onset. The co-morbidities, drugs use, initial vital sign, laboratory data, follow-up endoscopy were assessed. The Kaplan-Meier method was used to estimate the cumulative re-bleeding and mortality. The Cox proportional hazards model was used to estimate hazard ratio (HR) for mortality. In the re-bleeding risk analysis, we calculated the subdistribution hazard ratio (SHR), treating death without re-bleeding as a competing risk.
Results: Re-bleeding was identified in 49 patients with a mean follow-up of 18 months. The cumulative re-bleeding rate at 1 month, 1 and 5 years was 10.2%, 30.0% and 51.0%, respectively. In univariate analysis, re-bleeding was associated with Child-Pugh class C ($p = 0.03$), alcoholic liver cirrhosis ($p = 0.001$), none follow-up endoscopy ($p < 0.001$), and none follow-up EVL ($p = 0.004$). Multivariate analysis revealed alcoholic liver cirrhosis (SHR, 3.03; $p = 0.003$) and none follow-up endoscopy (SHR, 3.13; $p = 0.001$) as independent risk factors for re-bleeding. During the mean follow-up of 22 months, 69 patients died, 17 due to bleeding. The cumulative mortality rate at 1 month, 1 and 5 years was 12.2%, 26.6% and 63.0%, respectively. In univariate analysis, mortality was associated with age ≥ 65 years ($p = 0.009$), Child-Pugh class C ($p < 0.001$), coexistence of hepatocellular carcinoma (HCC) ($p = 0.013$), none follow-up of endoscopy ($p < 0.001$), and none follow-up of EVL ($p = 0.001$). Multivariate analysis revealed Child-Pugh class C (HR, 2.91; $p < 0.001$), coexistence of HCC (HR, 1.92; $p = 0.013$), none follow-up endoscopy (HR, 25.0; $p < 0.001$) as independent risk factors of mortality.
Conclusion: This study demonstrated more than 50% cumulative re-bleeding and mortality in the 5-year period after hospitalization for acute esophageal bleeding. Alcoholic liver cirrhosis and none follow-up endoscopy increased risk of re-bleeding, whereas Child-Pugh class C, coexistence of HCC, and none follow-up of endoscopy increased risk of mortality.

P0540 ENDOSCOPIC VISIBLE LIGHT SPECTROSCOPY IN PATIENTS WITH CHRONIC GASTROINTESTINAL ISCHEMIA AND HEALTHY CONTROLS

J. Harki[1], L. J. van Dijk[1], D. van Noord[1], E. T. Tjwa[1], E. J. Kuipers[1,2], M. J. Bruno[1]
[1]*Gastroenterology and Hepatology,* [2]*Internal Medicine, Erasmus MC University Medical Centre, Rotterdam, Netherlands*

Contact E-mail Address: j.harki@erasmusmc.nl
Introduction: Chronic gastrointestinal ischemia (CGI) is the result of decreased mucosal perfusion, in most cases due to atherosclerotic stenosis of the supplying mesenteric arteries. Visible light spectroscopy (VLS) enables direct measurement of mucosal oxygenation saturations during upper endoscopy (1,2). Limited data are available on VLS measurements in patients with CGI compared to a healthy population (2). We aimed to investigate the difference in mucosal oxygen saturation determined by VLS between patients with clinical suspicion of CGI and healthy controls.
Aims & Methods: Consecutive patients with a clinical suspicion of CGI referred to a tertiary care center were prospectively included between September 2014 and April 2015. All patients received the standard work-up for CGI, consisting of assessment of medical history and symptoms, radiological imaging of the gastrointestinal arteries, and VLS measurements. The results were discussed in a multidisciplinary expert panel leading to a consensus diagnosis, which was monitored during follow-up. Healthy, non-smoking volunteers with patent gastrointestinal arteries and unremarkable medical history were after informed consent included as controls. VLS measurements were performed during gastroscopy at three specific locations: gastric antrum, duodenal bulb, and descending duodenum.
Results: We performed 279 VLS measurements in 19 patients with clinical suspicion of CGI (mean age 59.9 (IQR 44.2-66.7) years, 53% male) and 12 controls (33.7 (IQR 29.0-41.2) years, 42% male). CGI was diagnosed in ten (53%) patients and excluded in nine (47%) patients. There was a significant difference in VLS measurements in all locations between patient with CGI and no CGI (antrum 57% (IQR 53-60) vs. 61% (IQR 60-62), $p = 0.04$; duodenal bulb (51% (IQR 47-54) vs. 58% (IQR 54-59), $p = 0.004$; descending duodenum 50% (IQR 45-52) vs. 54% (IQR 52-58), $p = 0.008$, respectively). VLS measurements were significantly lower in the gastric and duodenal bulb of patients with CGI compared to healthy controls (57% (IQR 53-60) vs. 61% (IQR 59-65), $p = 0.04$ and 51% (IQR 47-54) vs. 55% (IQR 53-62), $p = 0.007$, respectively).
Conclusion: Patients with CGI have significantly lower mucosal oxygen saturation levels than patients without CGI as well as healthy controls. VLS can adequately assess mucosal oxygenation. This study confirms the diagnostic value of VLS in distinguishing patients with CGI from patients without CGI and healthy subjects.

P0541 KAPOSI SARCOMA INVOLVING THE GASTROINTESTINAL TRACT

M. Gravito-Soares[1], E. Gravito-Soares[1], S. Lopes[1], L. Tomé[1], C. Sofia[1]
[1]*Gastroenterology, Centro Hospitalar e Universitário Coimbra, Coimbra, Portugal*

Contact E-mail Address: ms18498@gmail.com
Introduction: Kaposi sarcoma (KS) is a low-grade vascular tumour associated with type-8 human herpes virus infection (HHV-8). In pre-antiretroviral therapy era, gastrointestinal involvement was frequent, up to 40% at the diagnosis and up to 80% at the autopsy. In our days, gastrointestinal affection is uncommon.
Objective: Characterization of gastrointestinal involvement by KS.
Aims & Methods: Of 38 biopsies with histologic KS diagnosis, between 2000-2014, it was selected KS cases with gastrointestinal affection. The analysed variables were clinic, analytic, etiologic, endoscopic features, histologic, therapeutic, therapeutic response and mortality.
Results: Nine cases of gastrointestinal KS was identified in fifteen years of study and 25.0% of them happened in 2014. All patients were males, black (22.2%) with diagnosis mean age of 50.4 ± 13.4 years old. The most common type was epidemic/HIV-associated (88.9%), followed by iatrogenic (11.1%). The first type was associated with HIV (100.0%), sexual promiscuity (62.5%), mean CD4+ 136.6 ± 233.1 cells/mm^3 and CDCC3 stage (87.5%). Oral cavity and cutaneous involvement were present in 77.8%, affecting lower limbs in 85.7% and thorax in 71.4%. The main gastrointestinal clinic was dysphagia/odynophagia (44.4%) and nausea/vomiting (33.3%). Esophagogastroduodenoscopy was performed in all patients, with stomach involvement in all cases, mainly in the body (77.8%), followed by duodenum (44.4%) and oesophagus (33.3%). Endoscopy classic features identified were isolated or forming conglomerates violet papules/nodules. Colonoscopy was done in 33.3% of patients with ileocolic lesions in 33.3%. Histopathological features were fusocelular proliferation, storiform pattern, intra-cytoplasmic hyaline globules and vascular slits. Imunohistochemical profile showed CD34 and HHV-8 positivity. Doxorubicin treatment was applied in 66.7% patients (7.8 ± 1.9 cycles). Mortality occurred in 22.2% and was not directly KS-related.
Conclusion: KS is a rare tumour, with male predominance, HIV-associated and CD4+ < 200cells/mm^3. Gastrointestinal involvement was more common in stomach body, with good response to chemotherapy. Diagnosis and treatment should be considered in symptomatic patients.

Introduction: Antibacterial resistance is one of the main causes of failed eradication attempt in the management of *H. pylori*.
Aims & Methods: To evaluate the resistance rates encountered by European Gastroenterologist in their routine clinical practice. A Local Coordinator was selected from each country with more than 10 *H. pylori* references in PubMed. Each Coordinator selected a representative group of recruiting investigators from his/her country. An e-CRF was created to systematically register all adult patients infected with *H. pylori*. Variables included: *H. pylori* diagnostic test used, use of culture and antibiogram, or molecular tests for the evaluation of antibiotic resistance.
Results: So far 11,272 patients have been included and 9,181 have finished follow-up. Culture was performed in 14% of *naïve* patients (prior to first-line treatment), 14% in second-line, 31% in third-line, and 25% in fourth-line. molecular tests to evaluate resistance were only performed in 0.3% of the cases. Table shows antibiotic resistance per antibiotic and line of treatment.
Conclusion: The mean rate of *H. pylori* clarithromycin resistance in European *naïve* patients reaches the threshold established by consensus conferences (15-20%) in which empirical use of standard triple therapy should be discarded. There is a strong acquisition of antibiotic resistance after failed treatments.

P0543 EFFICIENCY OF 14-DAY AND SEQUENTIAL THERAPHY WITH LEVOFLOXACIN IN *HELICOBACTER PYLORI* ERADICATION

A. Soylu[1], S. Cakmak[1], Y. Okuturlar[2], I. Sevindir[1], S. Poturoglu[3]
[1]*Gastroenterology,* [2]*Internal Medicine, Bakirkoy Dr Sadi Konuk Research and Training Hospital,* [3]*Gastroenterology, Haseki Research and Training Hospital, Istanbul, Turkey*

Contact E-mail Address: aliyesoylu@superonline.com
Introduction: *Helicobacter pylori* currently has different antibiotic combinations that are among therapy protocol options. In this study we researched levels of success of the 14-day and sequential therapy methods and whether previous experience of being treated in different combinations and existence of chronic ulcer are effective in eradication.
Aims & Methods: *H. pylori* cases were classified as the 14-day therapy group and the sequential therapy group in a randomized manner. Colloidal bismuth substrate (4x300mg) was used for 4 weeks, Esomeprazole (2x40mg) for 2 weeks, Amoxicillin (2x1000) and Levofloxacin (2x250mg) were used in the 14-day therapy group; and Colloidal bismuth substrate (4x300mg) for four weeks, Esomeprazole (2x40mg) for 2 weeks, Amoxicillin (2x1000) for the first week and Levofloxacin (2x250mg) for the second week and Metronidazole (3x500mg) were used in the sequential therapy group. Eradication success in each group was evaluated by means of a urea breath test conducted 8 weeks after the therapy.
Results: A total of 436 cases were included in the study. The cases were classified into two groups as the 14-day (118 female) and the sequential therapy group (128 female) ($n = 218$). Average age group was 42.24 ± 13.046 in the 14-day therapy groups; while it was 45.10 ± 13.510 in the sequential therapy group. There were no difference of dispersion between groups in terms of gender ($p = 0.407$) or number of previously-received (1,2 or 3) therapies ($p = 0.428$). The ratio of the cases that had received previous therapy was 31.7% in the 14-day group; whereas in was 33.7% ($n = 69$) in the sequential therapy group. The ratio of cases excluded from the study due to the side effects of drugs was determined to be 2.5% in the 14-day therapy group; whereas it was 2% ($n = 4$) in the sequential therapy group; and there were no statistical differences between the groups ($p = 0.719$). Eradication by therapy was 84.2% in the 14-day therapy group; and 80% in the sequential therapy group ($p = 0.274$). Response to the therapy among those that had received previous therapy was 81.3% in the 14-day therapy groups and 72.5% in the sequential therapy group ($p = 0.055$). Moreover; there was no meaningful correlation detected between the number of previous therapies received and response to the therapy [14-day ($p = 0.742$), sequential ($p = 0.077$)]. Non-response to the therapy in cases with ulcer/deformation in bulbus was 34.8% in the 14-day therapy group and 16% in the sequential therapy group. The side effects that were observed more in the sequential therapy in comparison with the 14-day therapy were bad taste in mouth ($p = 0.014$), fatigue ($p = 0.026$), inaccetence ($p = 0.006$) and nausea ($p = 0.046$).
Conclusion: Patient compliance in both therapy protocols was good. Having received standard therapy previously has no effect on eradication success. In spite of the frequent side effects of the therapy, they are well-tolerated and therapy cessation rate is low. High level of success in eradication was achieved in the 14-day and sequential therapies with the therapy combination with Levofloxacin. Nevertheless, eradication success level is lower than expected in quad therapy.

P0544 LACTOBACILLUS BULGARICUS GLB44 AND *HELICOBACTER PYLORI* INFECTION – INHIBITION OR POSSIBLE ERADICATION: PRELIMINARY CLINICAL RESULTS

B. Vladimirov[1], **Y. Valerieva**[1], I. Terziev[2], L. Boyanova[3]
[1]*Clinical Centre of Gastroenterology,* [2]*Department of Pathology, University Hospital "Queen Joanna - ISUL",* [3]*Department of Microbiology, Medical University of Sofia, Sofia, Bulgaria*

Contact E-mail Address: yana_valerieva@abv.bg
Introduction: To evaluate the effect of *Lactobacillus delbrueckii subsp. bulgaricus* GLB44 in commercially available form on *Helicobacter pylori* infection in combination with a proton-pump inhibitor.
Aims & Methods: Fourteen patients (57.1% male and 42.9% female) at mean age 42 ± 13.2y were enrolled in our study after esophagogastroduodenoscopy. All patients were *Helicobacter pylori* (HP) positive diagnosed either by rapid urease test, stool antigen test and histology examination, or by a combination of these methods. Every patient was given *Lactobacillus bulgaricus* GLB44 (capsules and tablets) in daily doses of $15x10^9$ living cells together with Rabeprazol 20 mg bid for 7 days, followed by GLB44 alone for 3 days at the same dose. Control stool immunochromatographic antigen tests were performed in all patients after at least 43 days.
Results: After the course of treatment 92.9% of the previously HP positive patients had negative control stool antigen tests. The single case still positive had two unsuccessful antimicrobial eradication courses in the past, while the rest of the group was treatment-naive.
Conclusion: *Lactobacillus delbrueckii subsp. bulgaricus* has in vitro inhibitory properties against H. pylori.[1] Per oral route of administration of adequate probiotic dose in combination with PPI is a promising treatment modality in HP positive patients.

Contact E-mail Address: monthira.man@mahidol.ac.th

Introduction: Eradication rates following standard triple therapy for *Helicobacter pylori* (HP) infection are declining worldwide. Studies suggest that high-dose proton-pump inhibitor (PPI)-based triple therapy and sequential therapy for HP infection may yield higher cure rates than standard triple therapy.
Aims & Methods
Objectives: To compare the efficacy and tolerability of high dose PPI-based triple therapy and sequential therapy in adults with *Helicobacter pylori* associated functional dyspepsia.
Methods: One hundred twenty patients with HP positive functional dyspepsia (FD) were prospectively randomized to receive 10-day high dose PPI triple therapy (HD PPI TT) group [60 mg of lansoprazole, 500 mg of clarithromycin, and 1 g of amoxicillin, each administered twice daily for 10 days] or 10-day sequential therapy (ST) group [30 mg of lanzoprazole, 1 g of amoxicillin, each administered twice daily for the first 5 days, followed by 30 mg of lanzoprazole, 500 mg of clarithromycin, and 500 mg of metronidazole, each administered twice daily for the remaining 5 days]. HP status was determined at the 4th week post treatment by the ^{14}C-urea breath test. Eradication rates, antibiotic resistance rates, dyspeptic symptoms, drug compliance, and adverse effects were compared.
Results: The eradication rates in the ST and HD PPI TT groups, were comparable by the ITT analysis [85% (95% CI 73.4-92.9) vs. 80% (95% CI 67.7-89.2), P = 0.471] In the PP analysis, although ST yielded a higher eradication rate than HD PPI TT [94.4% (95% CI 84.6-98.8) vs. 81.4% (95% CI 69.1-90.3), p = 0.035]. Clarithromycin resistance was identified in 10% of isolates. Cure rates with ST were significantly higher than HD PPI TT in patients with clarithromycin-resistant HP strains (100% vs. 33.3%; P = 0.02). Compliance with the treatments was similar (98.3% with HD PPI TT and 93.1% with ST; P = 0.20). Nausea (p = 0.03) and dizziness (p = 0.03) were more common with ST group than HD PPI TT.
Conclusion: In Thailand, ST yielded higher eradication rate than HD PPI TT, in HP associated functional dyspepsia. This was in both in overall FD patients and in a subgroup of clarithromycin resistance. However, the eradication rate of sequential therapy was declined from 94.4% (PP analysis) to only 85% (ITT analysis). The adverse effects of sequential therapy caused lower adherence and might compromise the overall efficacy of ST.

Introduction: Empiric triple therapy to eradicate *Helicobacter pylori* (Hp) in Portugal has shown a high failure rate. As such, quadruple regimens should be adopted as first-line therapy. However, due to the simultaneous resistance rate to metronidazole and clarithromycin (5,8%), the efficacy of the sequential therapy may be compromised.
Aims & Methods: Our objective was to evaluate the success rate, in current clinical practice, of the sequential quadruple scheme in *naïve* patients. Additionally, we searched for factors that could influence Hp eradication rates. A total of 250 patients (female – 148; average age – 51.7 ± 15.6 years-old) were treated with sequential scheme (PPI and amoxicillin for 5 days, followed by PPI plus clarithromycin and metronidazole/tinidazole in the next 5 days). Bacterial eradication was checked by Urea Breath Test (UBT). Several clinical and demographic variables that could affect the success rate were analyzed (age, gender, smoking habits, dosage and type of PPI used, metronidazole regimen, use of metronidazole vs tinidazole).
Results: The overall success rate was 90.4% (IC95%: 86.1-93.5%). The most frequent indications for eradication were dyspepsia (58.4%), evaluation before bariatric surgery (12.4%) and peptic ulcer disease (10.8%). Both in the univariate and multivariate analysis, taking metronidazole every 8 hours was more effective than the 12-12 hour regimen (96.5% vs 53.8%, p = 0.002) and the same was noted for full-dose of PPIs when compared to of half-dose (97.8 vs 41.7%, p = 0.002). No other factor had a significant impact on the success rate.
Conclusion: Despite the described high primary resistance rates to both clarithromycin and metronidazole, sequential therapy was quite effective in clinical practice. However, full-dose PPI and an 8-8 hour metronidazole regimen must be adopted to achieve a positive outcome. It is fundamental to conduct another prospective study comparing different quadruple regimens.

P0547 COMPARISON OF *H.PYLORI* ERADICATION RATE IN TWO QUADRUPLE REGIMEN "AMOXICILLIN, BISMUTH SUBCITRATE, PANTOPRAZOLE, CLARITHROMYCIN "WITH "AMOXICILLIN, BISMUTH SUBCITRATE, PANTOPRAZOLE AND GEMIFLOXACIN"

Contact E-mail Address: ghanaie@yahoo.com
Introduction: *H.pylori* infection is the most bacterial infection in human. Gastritis, peptic ulcer, lymphoma and gastric adenocarcinoma are the outcomes of *H.pylori* infection. According to increase of drug resistance some studies have been done about the role of Floroquinolons in the treatment of *H.pylori* infection. In vitro studies showed the efficacy of Gemifloxacin against *H.pylori* infection.
Aims & Methods: The aim of this study was comparison of *H.pylori* eradication rate in two quadruple regimens "Bismuth subcitrate, Pantoprazole, Amoxicillin, Clarithromycin" with "Bismuth subcitrate, Pantoprazole, Amoxicillin, Gemifloxacin".
In a randomized clinical trial, a total of 182 *H.pylori* positive patients older than 18 years and less than 80 years were enrolled. For all patients information form includes name, age, sex, smoking history was recorded. 91 patients (50%) were treated with BPAC regimen (Bismuth subcitrate 240mg BID, Pantoprazole 20mg BID, Amoxicillin 1gr BID, Clarithromycin 500mg BID) and 91patients (50%) were treated with BPAG regimen (Bismuth subcitrate 240mg BID, Pantoprazole 20mg BID, Amoxicillin 1gr BID,Gemifloxacin 320mg daily) for 10 days. 12 weeks after completion of therapy the eradication was confirmed by a C14 urease breath test.
Results: Three patients were excluded from the study due to drug complications that were a man and a woman due to severe diarrhea, severe Nausea and Vomiting from BPAC group and a woman due to severe Nausea and mouth sores from BPAG group. Thus, 179 patients completed the course of treatment. The eradication rates in the BPAC and BPAG regimens with per-protocol and intention-to-treat analysis was reported 91% vs 77.8%, P-value = 0.015 and 89% vs 76.9%, P-value = 0.03, respectively. No relation between age, sex and smoking with eradication rates was reported, except association of age with BPAG regimen (P-value = 0.03).
Conclusion: In this study, the eradication rates with BPAG regimen in PP and ITT analysis were 77.8% and 76.9% respectively, therefore BPAG regimen was not succeeded in eradication of *H.pylori* infection.

P0549 A NEW GENERATION OF COLD-SHOCK EXPRESSION VECTOR DERIVED FROM PCOLD I (PCOLD I-LZ) FOR DIRECTIONAL CLONING AND RECOMBINANT EXPRESSION OF ANTI-HELICOBACTER PYLORI AND ANTI-GASTRIC CANCER STEM CELLS (GCSCS) SMALL PEPTIDES

H. Latifi-Navid[1], S. Latifi-Navid[1], S. Zahri[1]

Contact E-mail Address: hlatifin@gmail.com
Introduction: Current treatment of *Helicobacter pylori* infection has several inherent problems such as the emergence of resistance to the antibiotics used and associated adverse effects, the risk of reinfection or recrudescence, and the high cost of treatment. On the other hand, cancer stem cells (CSCs) have the ability to create tumour and promote its regeneration. These cells are responsible for gastric cancer progression, recurrence, and metastasis. It seems that the use of anti-*H. pylori* and anti-gastric CSCs peptides can provide a new therapeutic strategy for the treatment of this disease. Today, the recombinant expression approach is a useful and economical tool to the high-scale production of therapeutic nano-peptides. However, the short length of the peptides is a limiting factor in the realization of this approach. This is because one or more amino acid residues are added during the cloning process that leads to the loss of the original peptide folding and influences its function.
Aims & Methods: The aim of the present study was to change the structure of the pCold I vector using site-directed mutagenesis in order to do the directional cloning of each target gene and express/purify the small peptides and native proteins with no any additional N-terminus amino acids.
Results: In fact, the structure of the vector was changed such that the cut sites of both the first restriction enzyme at the multiple cloning site (at the nucleotide level) and factor Xa (at the amino acid level) to be the same. The TEE, His6-tag, and factor Xa site were removed by using the factor Xa, leaving no extra N-terminal residues.
Conclusion: The modified vector can be widely used to a fast and more convenient cloning and expression of the native proteins and short peptides, including anti-*H. pylori* peptides (e.g. Magainin 2 and Odorranain-HP) and anti-angiogenesis (e.g. Anginex), gastric anti-CSCs and anti-metastatic peptides.

Contact E-mail Address: mhs1357@cnuh.co.kr
Introduction: *Helicobacter pylori* (*H. pylori*) eradication is the first-line therapy for *H. pylori*-positive localized gastric mucosa-associated lymphoid tissue (MALT) lymphoma. But the management of the *H. pylori*-negative gastric MALT lymphoma remains controversial.
Aims & Methods: Therefore we assess the efficacy of eradication therapy according to *H. pylori* infection status and find out a predictive factor for resistance to treatment. We retrospectively reviewed the chart with gastric MALT lymphoma between January 2001 and June 2014. The basal characteristics and clinical outcome was compared between *H. pylori*-positive and *H. pylori*-negative gastric MALT lymphoma groups.

Results: Total 54 patients were enrolled and 12 patients were *H. pylori*-negative. *H. pylori*-negative patients were significantly multiple lesion ($P = 0.045$) and the lesion presence of both proximal and distal part of stomach ($P = 0.001$) than *H. pylori*-positive patients. 47 patients received eradication as an initial therapy. 85% (35/41) *H. pylori*-positive patients achieved complete remission and 50% (3/6) *H. pylori*-negative patients obtained regression after eradication therapy. Eradication therapy efficacy was no significant difference between two groups ($P = 0.133$). Multiple lesion was predictive factor for unresponsiveness to *H. pylori* eradication ($P = 0.024$).
Conclusion: In case of *H. pylori*-negative gastric MALT lymphoma eradication therapy could be considered as an initial therapeutic option especially for patients with a single lesion.

Contact E-mail Address: medfd@naver.com
Introduction: Since the efficacy of the standard triple therapy for *Helicobacter pylori* eradication has decreased, there have been attempts to increase the eradication rate by the addition of a potentially helpful drug to the standard triple regimen. Among these, the standard triple therapy plus probiotics (STP) and the concomitant therapy (CT) were introduced and showed encouraging results.
Aims & Methods: We aimed to compare the efficacies and analyze the influencing factors of both regimens. From Mar. 2013 to Feb. 2014, a total of 363 patients who received one of the STP regimen (n = 288, standard-dose proton-pump inhibior + clarithromycin 500mg + amoxicillin 1g + probiotic preparation, b.i.d. for 1 week) and the CT regimen (n = 75, standard-dose PPI + clarithromycin 500mg + amoxicillin 1g + metronidazole 500mg, b.i.d. for 1 week) for *H. pylori* eradication were included. Probiotic bacteria composed of *Bacillus subtilis* and *Lactobacillus rhamnosus*. *H. pylori* status was evaluated at least 4 weeks later, after completion of treatment by ^{13}C-urea breath test.
Results: The intention-to-treat and per-protocol eradication rates were 83.3% (95% CI, 78.8-87.5) and 86.9% (95% CI, 82.6-91.1) in the STP group, and 86.7% (95% CI, 78.7-94.7) and 91.4% (95% CI, 84.5-97.3) in the CT group. There were no significant between-group differences, in regard to the eradication rates and compliance. In the STP group, however, the incidence of side effects was significantly lower than the CT group (13.0% vs 28.2%, $p = 0.002$). The most common side effects were dyspepsia, nausea and dry mouth. In the multivariate analysis, older age in the STP group, and female sex, diabetes and alcohol drinking in the CT group were independent factors associated with eradication failure.
Conclusion: Both treatment regimens showed encouraging efficacies for *H. pylori* eradication. In the aspect of side effects, the addition of probiotics to the standard triple therapy may be a reasonable option. More large sample sized prospective study will be needed.

Introduction: To compare the efficacy of 14- and 7-day bismuth-based quadruple therapies as second-line eradication treatment for *Helicobacter pylori* infection.
Aims & Methods: Between 2004 and 2014, the medical records of 790 patients who had experienced failure of first-line proton pump inhibitor (PPI)-based eradication therapy and were then treated with bismuth-based quadruple therapy were retrospectively reviewed. Those who received bismuth-based quadruple therapy (PPI, bismuth, metronidazole, and tetracycline; PBMT) for either 7 days or 14 days were assigned to a PBMT-7 group (n = 543) or a PBMT-14 group (n = 247), respectively. The eradication rates for both groups were determined by intention-to-treat (ITT) and per-protocol (PP) analyses. ITT analysis compared the treatment groups as originally allocated while the PP analysis including only those patients who had completed the treatment as originally allocated. Successful eradication therapy for H. pylori infection was defined as a negative 13C-urea breath test 4 weeks after the end of eradication treatment.
Results: The overall ITT eradication rate was 69.1% (546/790). Final ITT eradication rates were 67.4% (366/543; 95% confidence interval [CI]: 63.1–71.7%) in the PBMT-7 group and 72.8% (180/247; 95% CI: 67.4–78.2%) in the PBMT-14 group (p = 0.028). The overall PP eradication rate was 80.0% (546/682), and the final PP eradication rates were 78.2% (366/468; 95% CI: 72.1–84.0%) in the PBMT-7 group and 84.1% (180/214; 95% CI: 76.8-90.8%) in the PBMT-14 group (p = 0.009). The *H. pylori* eradication rates in the PBMT-14 group were significantly higher than in the PBMT-7 group according to both ITT (p = 0.028) and PP analysis (p = 0.009). Compliance was similar in both groups (PBMT-7 group: 97.9%; PBMT-14 group: 96.4%). Adverse event rates were 10.7% (51/478) and 17.1% (38/222) in the PBMT-7 and PBMT-14 groups, respectively (p = 0.487).
Conclusion: The *H. pylori* eradication rates in the PBMT-14 group were significantly higher than in the PBMT-7 group according to both ITT and PP analysis. The 14-day bismuth-based quadruple therapy is a significantly more effective second-line eradication treatment for *H. pylori* infection than the 7-day alternative.

Contact E-mail Address: alrentien@gmail.com
Introduction: Patients with primary gastric MALT lymphoma (GML) are at risk of developing gastric carcinoma GC even after completing remission. The aim of this retrospective study was to assess the prevalence and the course of preneoplastic lesions in patients with GML as compared with gastric diffuse large B-cell lymphoma (GDLBCL) and *H. pylori*-associated chronic gastritis (*Hp*G).
Aims & Methods: From 1990 to 2013, 179 patients with GML, 70 with GDLBCL and 152 patients with *Hp*G, were included. Clinical, biological, endoscopic and histopathological parameters were reviewed. To assess the presence or absence of preneoplastic lesions, we reported the Sydney score in 3 gastric areas (antrum, corpus and lymphoma site). Atrophy $\geq$ 2 was only considered as significant. Preneoplastic lesion-free survival was assessed using Kaplan-Meier method, log-rank test and Cox model. Patients' characteristics were compared using chi^2 and Wilcoxon-Mann-Whitney tests.
Results: The median follow-up of GML patients was 6.5 (0.1-33.7) years. At the time of diagnosis, 119 (66%) patients presented with a *H. pylori* infection. GML was located at the junction of the body with antrum in 43% of the cases with a pseudogastritis appearance in 57%. At the inclusion, atrophy and metaplasia were observed in 35% and 25%, respectively. Both atrophy and metaplasia were more frequently located in the lymphoma site as compared with antrum and corpus. Dysplasia was observed in 3% of the cases. To assess the course of preneoplastic and neoplastic lesion, we analysed a subgroup of 104 patients followed-up for at least five years. Although the overall prevalence of atrophy remained stable over time with the evidence of incidental and regressive atrophy, the prevalence of metaplasia tended to increase at the lymphoma site. In the overall population of 179 patients, the probabilities of atrophy were 24%, 39% and 48% at 1, 5 and 10 years. The probabilities of metaplasia were 12%, 30% and 36% and the probabilities of dysplasia or GC were 9, 16 and 22%, respectively. Nine cases (5 women, 4 males) presented with a gastric cancer during follow-up, all associated with underlying preneoplastic gastric lesions. The median delay before the occurrence of GC was 2.49 (0-16.66) years. At diagnosis, significant atrophy and metaplasia were significantly more frequent in GML group vs. GDLBCL group (19% and 14%) and versus *hp*G (8% and 15%), respectively. No dysplasia was observed in both control groups.
Conclusion: The occurrence of preneoplastic and neoplastic gastric lesions in patients with GML is frequent and still increases overtime at the lymphoma site despite complete remission of the lymphoma. The occurrence of such lesions is higher than in patients with GDLBCL and HpG suggesting a deleterious effect of GML on the gastric epithelia cells that lead to the occurrence of these lesions. Long-term follow-up is warranted to detect gastric neoplasia at an early stage.
Disclosure of Interest: None declared

P0554 PRIMARY GASTRIC LYMPHOMA – EXPERIENCE OF A TERTIARY CENTER

A. G. Antunes[1], M. Eusébio[1], A. Vaz[1], P. Queirós[2], T. Gago[1], B. Peixe[1], H. Guerreiro[1]
[1]*Gastroenterology Department, Centro Hospitalar do Algarve, Faro,*
[2]*Gastroenterology Department, Centro Hospitalar do Algarve, Portimão, Portugal*

Contact E-mail Address: sergiogiao@hotmail.com
Introduction: In the immunocompetent patient, the gastrointestinal tract is the most common extranodal site for lymphoma. However, primary gastrointestinal lymphomas are very rare, accounting for only 1-4 % of all gastrointestinal malignancies. The stomach is the most commonly affected site, corresponding to less than 3% of gastric malignancies and 10% of all lymphomas. Approximately 90% of cases of primary gastric lymphomas (PGLs) are either mucosa-associated lymphoid tissue (MALT) lymphoma or diffuse large B-cell lymphoma (DLBCL). Although it's well established the relation between MALT lymphoma and *Helicobacter pylori* (Hp) infection, significant controversy exists regarding the role of Hp infection in the pathogenesis of DLBCL (specially, in those that develop from a MALT lymphoma).

Aims & Methods: (1) To describe the experience of a tertiary center in the diagnosis, management and follow-up of PGLs; (2) To compare clinical, laboratorial, histological (Hp infection) and endoscopic features at presentation, between the MALT and DLBCL subtypes.
All new cases of PGL were retrospectively evaluated between 1996 and 2014. Primary gastrointestinal lymphoma was defined according to Dawson criteria. Staging was established according to Lugano staging system, and for risk assessment International Prognostic Index (IPI) was used. We recorded demographic, clinical, laboratorial endoscopic and radiological data.
Results: We identified 31 patients, with a mean age of 65 years old, a male preponderance (n = 20) and 5 patients had ECOG ≥2. The most common subtype was MALT (n = 18), followed by DLBCL (n = 11). The most frequent symptom was abdominal pain (62%), followed by anorexia (55%), while the classical B symptoms were only present in two patients; 10 patients had Hb < 12.0 g/dL at presentation (none with DLBCL subtype).
At diagnosis, 80% of the cases were classified as limited disease (Lugano: I-II) and 84% as having low or intermediate risk (IPI ≤ 2), with no statistically significant differences between MALT and DLBCL subtypes. The most common endoscopic pattern was ulcerative type (62%), and gastric body was affected in 69%, with no statistically significant differences between the subtypes.
The variables age, Leukocyte count, serum LDH, Albumine, Urine Acid and β-2 microglobuline weren't statistically different between MALT and DLBCL subtypes. Hp infection was present in 11 patients (MALT: 10; DLBCL: 1; p = 0.022). The mean survival was 67 months (MALT: 80.7 versus DLBCL 38).
Conclusion: Although the small number of patients, our data does not support the role of Hp in the pathogenesis of DLBCL lymphoma. Beside anemia, none of the studied variables at presentation, was statistically different between the subtypes. The results agree and strengthen the scarce available literature about PGLs.

P0555 *HELICOBACTER PYLORI* VACA GENOTYPES PREDICT RISK OF INTESTINAL- AND DIFFUSE-TYPE ADENOCARCINOMAS IN A VERY HIGH-RISK AREA IN IRAN

E. Abdi[1], S. Latifi-Navid[1], S. Zahri[1], A. Yazdanbod[2]
[1]*Department of Biology, Faculty of Sciences, University of Mohaghegh Ardabili, Ardabil,* [2]*Gastrointestinal Cancer Research Center, Ardabil University of Medical Sciences, Ardabil, Iran, Islamic Republic Of*

Contact E-mail Address: abdi.esmat@yahoo.com
Introduction: Gastric cancer (GC) is the fifth commonest malignant disease throughout the world and the third-leading cause of cancer-related mortality, and histo-morphologically is divided into two groups; intestinal- and diffuse-type carcinomas. *Helicobacter pylori* infection is one of the main risk determinants of both the type of GC. Ardabil in Northwestern Iran has the highest rates of *H. pylori* infection (89%) and stomach cancer, in which it constitutes the 31% of all malignancies seen in this area with the ASRs of 51.8/100,000 for males and 24.9/100,000 for females. In this province, greater than 90% of adults aged 40 or older are suffering from chronic gastritis related to *H. pylori* infection.
Aims & Methods: We aimed to investigate the frequency of the *H. pylori vacA* (vacuolating cytotoxin A) gene polymorphisms and their associations with the intestinal- or the diffuse-type adenocarcinomas in Ardabil. We determined the presence of the *H. pylori 16S rDNA* gene, and also the *vacA* s-, m-, i-, and d-region genotypes in gastric biopsies, and performed histopathological evaluations. Associations between the *H. pylori vacA* allelic variants and whether the intestinal- or the diffuse-type adenocarcinomas were assessed by the $\chi 2$ test or Fisher's exact test where appropriate. Odds ratios (ORs) and the corresponding 95% confidence intervals (CIs) were computed. The Forward Stepwise LR (Likelihood Ratio) multiple logistic regression was used for each genetic variant individually, with adjustment for age and sex.
Results: Of 135 patients, 57 with non-atrophic gastritis and 78 with gastric cancer (GC), 103 were infected by *H. pylori*. In patients with the intestinal-type adenocarcinoma of the stomach, the *vacA* s1, m1, i1, and d1 genotypes were detected in the 47.8%, 63.2%, 84.2%, and 76.5% of *H. pylori* strains, respectively, while in patients with the diffuse-type adenocarcinoma of the stomach, the *vacA* s1, m1, i1, and d1 genotypes were present in the 73.3%, 42.9%, 66.7%, and 76.9% of strains, respectively. The frequency of the *vacA* i1 and d1 genotypes was significantly higher in patients with the intestinal-type adenocarcinoma (84.2%, and 76.5%, respectively) than in those with NAG (47.1% and 45.0%, respectively); the OR was 6.00 (95% CI, 1.47-24.45; P = 0.01) and 3.97 (95% CI, 1.10-14.31; P = 0.042), respectively. However, in multiple logistic regression with adjustment for age and sex, only the *vacA* i1 genotype was significantly associated with an increased risk of the intestinal-type adenocarcinoma (OR = 14.04, 95% CI, 2.15-91.77; P = 0.006). Although the adjusted OR of 4.08 (95% CI, 0.95-17.50) was obtained for d1, the difference did not reach significance (P = 0.058). The presence of the *vacA* d1 genotype was significantly associated with an increased risk of the diffuse-type adenocarcinoma in the multiple logistic regression (OR = 7.71, 95% CI, 1.13-52.28; P = 0.036).
Conclusion: It is proposed that the *vacA* i1 and d1 genotypes might be important for the prediction of the risk of the intestinal- and the diffuse-type adenocarcinomas, respectively.

P0556 *H. PYLORI* INFECTION WITH ATROPHIC GASTRITIS IS AN INDEPENDENT RISK FACTOR FOR ADVANCED COLONIC NEOPLASM

J. Y. Lee[1], H. W. Park[1], J. Y. Choi[1], J.-S. Lee[1], J. E. Koo[1], E. J. Chung[1], H.-S. Chang[1], J. Choe[1], D.-H. Yang[2], S.-J. Myung[2], H.-Y. Jung[2], S.-K. Yang[2], J.-S. Byeon[2]
[1]*Helath Screening and Promotion Center,* [2]*Gastroenterology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Republic of Korea*

Contact E-mail Address: living_stone@hanmail.net
Introduction: *Helicobacter pylori (H. pylori)* infection is a major risk factor for atrophic gastritis (AG) and gastric cancer and can induce various extragastric malignancies, but its relationship to colorectal neoplasm (CRN) remains unclear. The correlation between AG and CRN has been little studied and is inconclusive.
Aims & Methods
Aim: The aim of this study was to investigate the association between *H. pylori* infection status, AG, and advanced CRN.
Methods: This cross-sectional study investigated the relationship between the presence of serum anti-*H. pylori* IgG antibody, AG, and advanced CRN in 6,351 consecutive asymptomatic subjects who underwent screening colonoscopy. Multivariate analysis was performed including clinical variables such as gender, age, family history of colorectal cancer, smoking status, alcohol consumption, presence of metabolic syndrome, and endoscopic findings.
Results: A total of 316 participants (5.0%) had advanced CRN. *H. pylori* seropositivity was found in 61.3% of these cases. In univariate analysis, the presence of *H. pylori* infection was associated with overall CRN (OR 1.33, 95% CI 1.19–1.48; p < 0.001) and advanced CRN (OR 1.49, 95% CI 1.17–1.91; p = 0.001). *H. pylori* infection was associated with an increased risk of advanced CRN after adjusting clinically relevant confounders (OR 1.34, 95% CI 1.04–1.72; P = 0.023). *H. pylori*-related AG was significantly associated with the risk of advanced CRN (OR 1.40, 95% CI 1.03–1.91; p = 0.030), whereas *H. pylori* infection without AG was not.
Conclusion: *H. pylori* infection increases the risk of advanced CRN, especially when combined with AG. Strict colonoscopy screening and surveillance may be warranted in *H. pylori*-positive AG patients.

P0557 INCIDENCE OF SECOND CANCERS IN PATIENTS WITH GASTRIC MALT LYMPHOMA

J. Moleiro[1], S. Ferreira[1], **P. Lage**[1], A. Dias Pereira[1]
[1]*Gastroenterology, Instituto Português de Oncologia de Lisboa Francisco Gentil, E.P.E., Lisboa, Portugal*

Contact E-mail Address: joana_moleiro@hotmail.com
Introduction: Gastric mucosa-associated lymphoid tissue (MALT) lymphoma is closely associated with *Helicobacter pylori* infection. The incidence of second cancers, namely gastric carcinoma, seems to be increased in this group of patients. However, the evidence is still controversial.
Aims & Methods: To determine the incidence of second cancers in patients with gastric MALT lymphoma who achieved complete remission, we evaluated consecutive patients admitted with gastric MALT lymphoma (1994-2014), staged according to the Ann Arbor staging system modified by Musshoffs. Patients' characteristics, the diagnosis of second cancers and survival were recorded. Standardized incidence ratio (SIR), using age- and sex-specific incidence rates from the Cancer Registry, was calculated.
Results: A total of 143 patients (76 men) were included with a mean age of 56 years (18-83); 103, 24 and 16 patients were diagnosed at stages EI, EII and EIV, respectively. Complete remission was achieved in 128 patients. After a mean follow-up of 109 months (6-246), a second cancer was diagnosed in 14 (9.8%) patients (11 men, mean age of 66 years), in whom complete remission was achieved after eradication therapy (n = 12), surgery (n = 1) and chemotherapy (n = 1). A total of 7 solid (lung (n = 1), brain (n = 1), liver (n = 1), breast (n = 1), pancreas (n = 1), sarcoma (n = 1) and colon (n = 1)) and 7 hematologic cancers (non-Hodgkin lymphoma (n = 4), Hodgkin lymphoma (n = 1), multiple myeloma (n = 1) and chronic myelomonocytic leukemia (n = 1)) were reported. The non-Hodgkin lymphomas diagnosed were diffuse large B-Cell lymphoma (n = 2), chronic lymphocytic leukemia (n = 1) and parotid MALT lymphoma (n = 1). There was an increased incidence of an additional cancer (SIR = 1.4, p = 0.0001) and non-Hodgkin lymphomas (SIR = 9.3, p = 0.04). The 10-year overall survival of the 128 patients that achieved complete remission was 82%. The cause of death was the second cancer in 11/24 (45.8%) patients.
Conclusion: Patients with gastric MALT lymphoma are at an increased risk for a second cancer, particularly non-Hodgkin lymphoma, which highlights the importance of a long-term follow up. There were no patients with gastric

carcinoma. The overall prognosis was good but the occurrence of second cancers, mainly hematologic, were an important cause of death.

P0558 APPLICATION OF ABC SYSTEM INTO CLINICAL PRACTICE IN KOREA: IS IT WORTHWHILE?

J. Heo[1], S. W. Jeon[1], S. K. Kim[1], H. M. Yang[1]
[1]*Internal Medicine, Kyungpook National University Hospital, Daegu, Republic of Korea*

Contact E-mail Address: hero797@hanmail.net
Introduction: ABC method, which using a combination of serum *Helicobacter* (Hp) immunoglobulin G (IgG) and pepsinogen (PG) level, has been expected as a promising simple screening tool for gastric cancer. Group A is Hp infection-free subjects, Group B is Hp infected, but has no or minimal changes of atrophy, Group C has both positive result of serum value. Group D is the advanced infected type, which has extensive atrophy and negative Hp IgG which means relatively prior Hp infection.
Aims & Methods: We aimed to validate the ABC method for gastric cancer patients in clinical practice. The presence of Hp infection is determined by serum Hp IgG. The positive PG is defined as PG I level less than 70 ng/ml and the ratio of PG I/II is less than 3.0. According to our strategy for gastric tumor since 2007, we have conducted the serum Hp IgG and PG level for the patients who plan to undergo endoscopic resection. We retrospectively reviewed the patients who underwent serum Hp IgG and PG level between October 2007 and November 2013 in Kyungpook National University Hospital in Korea.
Results: 1,146 cases were possible to be analyzed in ABC method. 717 patients were male and the mean age was 61.4 ± 10.3 years. Among 429 patients with gastric cancer, 82 patients (19.1%) were classified into Group A, 230 (53.6%) into Group B, 89 (20.7%) into Group C, and 28 (6.5%) into Group D, respectively. Group A also occupied considerable portion (15.9%) in gastric tumor including adenoma.
Conclusion: Considering relatively high prevalence of *Helicobacter* in Korea, the ABC method needs reconsideration before application in the screening for gastric cancer. In addition, other gastric cancer risk factors or confounding factors should be revealed, especially for group A patients in further study.

Introduction: Disease progression to gastric cancer (GC) occurs in only a small proportion of *H. pylori*-infected patients. A considerable differences in the vacuole-creating activities are observed between *H. pylori* strains, which is attributed to the extensive polymorphisms within the vacuolating cytotoxin gene A (*vacA*). These variations may determine the clinical consequences; however, the association evidence is not totally consistent both between and within continents, and thus the actual influence of each allelic variant is still controversial.
Aims & Methods: We examined the strength of this association in adult-infected populations and modeled the impact of mean age-standardized incidence rates (ASRs) of GC as a hypothesized moderator variable. Pooled relative risk (RR) estimates were calculated. Subgroup, sensitivity, and meta-regression analyses were conducted.
Results: Totally, 33 studies, including 1446 cases and 2697 controls, were analyzed. The *vacA* s1 genotype was significantly associated with an increased risk of atrophic gastritis (AG), intestinal metaplasia (IM), and GC (RR = 1.116, 95% CI,1.019-1.222, RR = 1.418, 95% CI,1.035-1.942, and RR = 1.333, 95% CI,1.115-1.593, respectively); however, the *vacA* m1 genotype strongly increased the risk of IM and GC, but not AG (RR = 1.571, 95% CI,1.247-1.980 and RR = 1.431, 95% CI,1.180-1.735, respectively). The *vacA* s1m1 allelic combination was linked to an increased risk of GC. The m1-type of *vacA* was more potent than s1 for predicting the risk of GC within the subgroups with mean ASRs 11/100,000-19/100,000 and less than 10/100,000, which was confirmed either by excluding the studies with the largest variance or by performing a leave-one-out analysis. The meta-regression analysis indicated that the ASR of GC modified the association between *H. pylori* genotypes and GC risk. When the ASRs of GC were used as a moderator variable, the estimated coefficient in predicting the logit was -0.0142, -0.0162, and -0.0160 for the *vacA*-s1, -m1, and –s1m1 genotypes, respectively, indicating that the estimated risk was significantly decreased with increasing the mean ASRs of GC (*P*-values = 0.025, 0.00009, and 0.0005 for s1, m1, and s1m1,respectively).
Conclusion: *H. pylori vacA*-s1 and -m1 allelic variants strongly increased susceptibility to IM and GC; however, only s1 showed an association with AG. This association was largely influenced by geographic variation in the GC incidence rate.

Introduction: Gastric adenocarcinomas account for almost 90% of all gastric malignancies that are classified based on the anatomical site of tumor, including cardia gastric adenocarcinoma (CGA) and non-cardia gastric adenocarcinoma (NCGA).
Aims & Methods: We have recently identified a novel polymorphic site in the 3'-end region of *H. pylori* vacuolating cytotoxin gene A (*vacA*), denoted by c1/-c2 (c1: with deletion of 15 bp); thus we aimed to assess its association with the risk of CGA and NCGA in an Iranian population. A total of 593 patients who were of the rural and urban areas of Iran were participated in the study. Gastric biopsy specimens were taken from the antrum and/or the corpus, whether or not positive for rapid urease test, and then were cultured. The colonies were identified based on Gram staining, typical cell morphology, and positive reactions to catalase, oxidase, and urease, as well as PCR amplification of *H. pylori 16S rDNA*. The genotyping of the *H. pylori vacA* gene and histopathological examination and classification of subjects were then performed.
Results: Patients included 496 with non-atrophic gastritis (NAG), 41 with CGA, and 56 with NCGA. Of the 593 patients, 390 (65.8%) were positive for *H. pylori* infection, whereas 203 (34.2%) were negative. Statistical analysis showed no significant associations between the prevalence of *H. pylori* infection and sex, age, rural or urban areas and the risk of the CGA or the NCGA. The NCGA was more prevalent in rural areas [odds ratio (95% confidence interval) = 3.49 (1.86-6.57), $P = 0.00$]. Both the age > = 55 and male gender were significantly associated with the CGA [OR (95% CI) = 17.85 (6.89-47.61) and 4.04 (1.89-8.62), respectively; $P = 0.00$] and the NCGA [OR (95% CI) = 17.24 (7.57-38.46) and 3.75 (1.97-7.19), respectively; $P = 0.00$]. A total of 173 *H. pylori* isolates, including 120 with NAG, 24 with CGA, and 29 with NCGA, were successfully obtained from biopsy cultures and genotyped. The frequency of the c1-type of *vacA* was higher in patients with both the CGA (83.3%) and the NCGA (71.4%) than in those with gastritis (NAG) (24.1%). The results of simple logistic regression analysis showed that this genotype was significantly associated with an increased risk of both the CGA and the NCGA; the OR (95% CI) was 15.71 (4.23-58.26), and 7.85 (3.12-19.78), respectively ($P = 0.00$). Finally, the multiple logistic regression analysis showed that the *vacA* c1 genotype was significantly associated with the age- and sex-adjusted risk for the CGA and the NCGA; the OR (95% CI) was 16.85 (3.83-67.61), and 8.14 (2.83-23.38), respectively ($P = 0.00$).
Conclusion: The present study showed the determinant role of the *H. pylori vacA* c1 genotype in the development of both the CGA and the NCGA in Iran. This is the first report of an association of *H. pylori* genotype with an increased risk of the CGA.

P0561 DECREASE OF SERUM TOTAL GHRELIN IN EXTENSIVE ATROPHIC GASTRITIS: COMPARISON WITH PEPSINOGENS IN HISTOLOGICAL REFERENCE

S. E. Bae[1], J. H. Lee[1], H. J. Song[1], H.-Y. Jung[1], K. D. Choi[1], D. H. Kim[1], J. Y. Ahn[1], G. H. Lee[1]
[1]*Gastroenterology, Asan Medical Center, Seoul, Republic of Korea*

Contact E-mail Address: space0425@naver.com
Introduction: Ghrelin is mainly secreted from the gastric oxyntic mucosa and the production is impaired in chronic atrophic gastritis. This study aimed to evaluate serum total ghrelin levels according to the extent of histological atrophy, and to compare the performance as a serologic atrophic marker with pepsinogen.
Aims & Methods: Data were analyzed from 154 patients with atrophic gastritis. Histological extent of atrophic gastritis was assessed by three paired biopsies from antrum, corpus lesser, and corpus greater curvature. Fasting serum concentrations of total ghrelin, pepsinogen I, and II were measured with enzyme immunoassay. Regression analysis was performed to evaluate factors associated with serum levels of total ghrelin. The serologic performance was compared with pepsinogen using receiver-operating characteristic curves.
Results: *H. pylori* infection rate was 85.1% and extensive atrophic gastritis involving corpus greater curvature was found in 24.0%. Serum total ghrelin concentrations were decreased significantly in patients with extensive corpus greater curvature atrophy (median value, 170.4 pg/mL; vs 201.1 pg/mL in patients without corpus greater curvature atrophy; $p < 0.001$), and the levels were correlated with pepsinogen I and pepsinogen I/II ratio. The decrease of serum total ghrelin in corpus greater curvature atrophy was independent of age, gender, body mass index, and *H. pylori* infection status. Sensitivity and specificity of serum total ghrelin to predict extensive corpus greater curvature atrophy was 56.8% and 78.9%, respectively. The discriminatory ability was similar to pepsinogen I/II ratio ($p = 0.612$) and lower than pepsinogen I ($p = 0.040$).
Conclusion: Serum concentration of total ghrelin is decreased in extensive CGC atrophy. The serologic performance is lower than that of PG I.

Introduction: MicroRNAs (miRNAs) are widely studied non-coding RNAs that modulate gene expression. MiRNAs are deregulated in different tumors including gastric cancer (GC) and have potential diagnostic and prognostic implications. The aim of our study was to determine miRNA profile in GC tissues, followed by evaluation of deregulated miRNAs in plasma of GC patients. Using available databases and bioinformatics methods we also aimed to evaluate potential target genes of confirmed differentially expressed miRNA and validate these findings in GC tissues.
Aims & Methods: The study included 51 GC patients and 51 controls. Initially, we screened miRNA expression profile in 13 tissue samples of GC and 12 normal gastric tissues with TaqMan low density array (TLDA). In the second stage, differentially expressed miRNAs were validated in a replication cohort using qRT-PCR in tissue and plasma samples. Subsequently, we analyzed potential target genes of deregulated miRNAs using bioinformatics approach, determined their expression in GC tissues and performed correlation analysis with targeting miRNAs.
Results: Profiling with TLDA revealed 15 deregulated miRNAs in GC tissues compared to normal gastric mucosa. Replication analysis confirmed that miR-148a-3p, miR-204-5p, miR-223-3p and miR-375 were consistently deregulated in GC tissues. Analysis of GC patients plasma samples showed significant down-regulation of miR-148a-3p, miR-375 and up-regulation of miR-223-3p compared to healthy subjects. Further, using bioinformatic tools we identified targets of replicated miRNAs and performed disease-associated gene enrichment analysis. Ultimately, we evaluated potential target gene *BCL2* and *DNMT3B* expression by qRT-PCR in GC tissue, which correlated with targeting miRNA expression.
Conclusion: Our study revealed miRNA profile in GC tissues and showed that miR-148a-3p, miR-223-3p and miR-375 are deregulated in GC plasma samples. Target gene analysis demonstrated that *BCL2* and *DNMT3B* expression in GC tissue correlated with their targeting miRNA expression.

Contact E-mail Address: elisa.boschetti@unibo.it
Introduction: Chronic intestinal pseudo-obstruction (CIPO) is a rare condition characterized by gastrointestinal (GI) impairment that is so severe to cause a clinical picture suggestive of a mechanical obstruction in the absence of any occlusion. Although degenerative or inflammatory neuro-interstitial cells of Cajal (ICC)-muscular abnormalities are the main pathogenetic mechanisms underlying gut dysfunction, other factors, i.e. intestinal epithelial barrier (IEB) abnormalities, may represent the initial insult contributing to symptoms and clinical manifestations
Aims & Methods: The present study aims to assess the expression of occludin and zonula occludens-1 (ZO-1), two major components of tight junctions (TJs), as markers of IEB integrity in patients with CIPO. A number of $n = 26$ clinically and histopathologically well characterized CIPO pts (15 F; age range: 16 - 75 yrs) were studied. CIPO cases were subdivided according to the histopathological analysis (IHC) in 3 groups: A) apparently normal $n = 7$; B) inflamed $n = 8$; C) degenerative $n = 10$. Patients ($n = 8$; 3 F, age range: 48 - 73 yrs) undergoing elective surgery for uncomplicated neoplastic diseases served as controls. CIPO and control jejunal full thickness biopsies were processed to assess occludin and ZO-1 mRNA and protein expression using q-PCR and WB.
Results: Compared to controls, total occludin protein showed a marked decrease in CIPO pts ($P < 0.05$); also, a tendency to a decreased occludin mRNA expression was found in CIPO vs. controls. Moreover, occludin oligomers, an index of occludin assembly in rafts TJs, were detected only in 19% of CIPO pts while all controls showed normal oligomerization. ZO-1 protein and mRNA expression did not change in CIPO vs controls. Interestingly, the three histologically identified groups of CIPO showed a selective reduction of only one of the two analyzed components. Specifically, in group A and B occludin expression decreased, while in group C only ZO-1 content decreased.
Conclusion: IEB integrity was altered in patients with CIPO as identified by the reduction of at least one of the TJ components. Moreover, the abnormal occludin oligomerization is indicative of TJ dysfunction, which increases the possibility of noxious agents passing through the intestinal wall in these patients. A better knowledge of IEB altered molecular mechanisms is expected to be translated in targeted therapeutic interventions.

Introduction: Serotonin (5-HT) is a neuromodulator mainly synthesized in the intestinal epithelium. 5-HT regulates the whole intestinal physiology and it has been shown to be essential in intestinal homeostasis. In fact the excess of extracellular 5-HT has been described to contribute to intestinal inflammation. 5-HT availability is in part mediated by the serotonin transporter (SERT), which is responsible for the 5-HT reuptake inside the enterocytes. Recent results have demonstrated that bacteria resident in the intestinal lumen may affect intestinal pathophysiology by acting on the serotoninergic system. This effect is in part carried out through the activation of Toll-like receptors (TLRs) which regulates SERT in the intestinal epithelium. *Listeria monocytogenes* is a Gram-positive bacteria that causes in humans a serious infection (listeriosis) mainly through the consumption of ready-to-eat foods. Following ingestion, *L. monocytogenes* has been described to cross the intestinal epithelium and to invade intestinal epithelial cells. However, the effect of *L. monocytogenes* on intestinal epithelium activity remains unknown.
Aims & Methods: 5-HT has been shown to be an essential regulator of the intestinal physiology. 5-HT availability has been shown to be modulated by the activity of SERT expressed in intestinal epithelial cells. Therefore, the aim of the present study was to analyze whether the pathogen *L. monocytogenes* affects the intestinal epithelial activity, by focusing on the analysis of SERT in intestinal epithelial cells. In this study human enterocyte-like Caco-2/TC7 cell line was used. These cells express SERT and TLRs. Caco-2/TC7 cells were treated with *L. monocytogenes*, and 5-HT uptake by SERT and transepithelial resistance (TER) were measured. The molecular expression of SERT, TLR2 and TLR10 were analyzed by measuring both, mRNA levels by RT-qPCR, and protein expression by western blotting.
Results: *L. monocytogenes* did not appear to affect TER in the Caco-2/TC7 cells, but the treatment showed to inhibit 5-HT uptake by reducing SERT expression in the cells. However, *L. monocytogenes* inactivated by heat or by pulsed electric fields did not affect SERT activity. Moreover, factors secreted by this bacteria did not seem to be involved in effects on SERT. TLR2 expression in Caco-2/TC7 cells resulted down-regulated by *L. monocytogenes*, however, TLR10 expression appeared to be increased. In this context, TLR10 seemed to be involved in the effect of *L. monocytogenes* on SERT, since the effect disappears by treating the cells with TLR10 specific antibody.
Conclusion: *L. monocytogenes*, a known powerful pathogen bacteria, may induce an alteration of the intestinal homeostasis by inhibiting SERT function and expression. This effect might cause an increase in the level of extracellular 5-HT and, thereby, might contribute to an intestinal proinflammatory effect. Our results demonstrate that *L. monocytogenes* requires be alive to alter SERT, and they show for the first time that this effect may be mediated by TLR10. Moreover, *L. monocytogenes* seemed to yield TLR2 and TLR10 transcriptional effects in intestinal epithelial cells.

P0565 MAGNETIC RESONANCE IMAGING-QUANTIFIED SMALL BOWEL MOTILITY IS A SENSITIVE MARKER OF RESPONSE TO ANTI-TNFA THERAPY IN CROHN'S DISEASE

A. Menys[1], A. Plumb[1], E. Russo[2], D. Prezzi[1], G. Bhatnagar[1], R. Vega[3], S. Halligan[1], T. Orchard[4], S. A. Taylor[1]

Contact E-mail Address: alex.menys.09@ucl.ac.uk
Introduction: Dynamic imaging in Magnetic Resonance Enterography (MRE) is increasingly used as a non-invasive method of assessing small bowel (SB) motility. The purpose of this study was to determine if improvements in segmental SB motility can detect clinical response to anti-TNFα therapy, both after induction therapy and longer term.
Aims & Methods: ***Patient demographics:*** 46 patients underwent MRE pre- and post-treatment with anti-TNFα agents:
- 11 recruited prospectively (imaged after a median of 12 weeks of treatment, median age 40 years (range 22 to 57), 6 Male, median disease duration 4 years (range 1 to 30)) and,

- 35 identified retrospectively (median = 55 weeks of treatment, median age 23 years (range 15 to 65), 21 Male, median disease duration 16 years (range 6 to 53)).
Scanning protocol: Patients in both groups were prepared with 1-2L oral contrast (2% mannitol) depending on their tolerance. Dynamic motility scans were acquired using a 3T Siemens (prospective cohort) and across 1.5T Siemens and 3T Philips scanners (retrospective cohort). Temporal and spatial resolution across all scanners was standardized prior to analysis.
Motility Analysis: Data was processed using a validated optic-flow registration technique to provide quantitative motility maps describing the deformation from bowel wall motion. A consultant radiologist (4 years MRE experience) assessed the two MRI time points and placed a region of interest over diseased small bowel (identified on the basis of mural thickening), blinded to other imaging sequences. The study coordinator (4 years experience with MRE) performed the quantitative analysis.
Therapeutic response: Response was defined using a composite of all available clinical data for the retrospective group; and by a $\geq$3 point drop in the Harvey-Bradshaw Index for the prospective group.
Statistical analysis: The small bowel motility score took the form of a numerical arbitrary unit value. The higher the score, the greater motility with values typically occurring between 0 (no motility) and 0.6 (high motility). The percentage change in motility score between the two scans was calculated and compared between responders and non-responders using the Mann-Whitney U test. Receiver-operating characteristic (ROC) curves were calculated to assess the sensitivity and specificity of motility as a predicator of therapeutic response.
Results: Anti-TNFα responders had significantly greater improvements in motility (median change = 68.6% increase from baseline) than non-responders (median change = 25% reduction, $p < 0.001$).
Improved MRI-measured motility was 89.7% (95%CI 73.6-96.4%) and 82.5% specific (95%CI 59.0-93.8%) for response to anti-TNFα treatment, in both the prospective (Sn:85.7%; Sp:100%) and retrospective groups (Sn: 90.9%; Sp:76.9%).
The area under the ROC curve for motility changes to discriminate responders from non-responders was 87.9% (95%CI:77.2-98.6%).
Conclusion: Improved MRI-measured SB motility accurately detects response to anti-TNFα therapy for CD, even as early as 12 weeks. MRI may permit early identification of response/non-response to anti-TNFα agents, allowing personalized treatment regimes.

Introduction: Gluten-related disorders are activated by the ingestion of gluten-containing grains by individuals with a genetic and/or immunologic predisposition to these conditions. The best-known diseases, wheat allergy (WA) and celiac disease (CD), are mediated by the adaptive immune system. In wheat allergy, immunoglobulin E (IgE) is cross-linked by repeat sequences in gluten peptides (e.g. Ser-Gln-Gln-Gln-(Gln-)Pro-Pro-Phe), inducing the release of immune mediators such as histamine from basophils and mast cells. In contrast, CD has characteristics of an autoimmune disorder. Besides CD and WA, reactions have been reported to gluten-containing grains that involved neither allergic nor autoimmune mechanisms. These are generally termed NCGS. Given the uncertainties about this clinical entity and the lack of diagnostic biomarkers, several reports concluded that NCGS could be defined as a clinical entity induced by the ingestion of gluten-containing grains leading to intestinal and/or extra-intestinal symptoms that resolve once gluten-containing grains are eliminated from the diet, provided that CD and WA have been ruled out. One of the most controversial and highly debated discussions about NCGS concerns the role of gluten in causing NCGS and the hypothesis that some NCGS patients might also have a form of WA that is not detected with conventional serologic or skin tests.
Aims & Methods
Aim: To investigate the local IgE response in the duodenal mucosa of NCGS patients.
Methods: The intestinal mucosa from 7 healthy controls (HC), 13 active CD, 8 active NCGS, and 4 atopic patients was analyzed for the expression of genes involved in class switch recombination to IgE and IgG subclasses, such as ϵ germline transcripts (GLT) and activation-induced cytidine deaminase (AICD), and established regulators of IgE production and IgE-dependent inflammation, such as IL-4, IL-5, and IL-13, by real-time RT-PCR.
Results: The level of ϵ GLT in the mucosa of NCGS patients was significantly lower relative to atopic patients ($p = 0.009$). IL-4, IL-5, and IL-13 mRNA expression was also significantly reduced in NCGS patients ($p < 0.05$), whereas GLT expression for IgG1, IgG3, IgG4, and IgM was similar in all groups of patients. Finally, the level of the B-cell activation marker AICD was also significantly reduced in NCGS compared to the atopic mucosa ($p = 0.04$).
Conclusion: These findings support and extend the idea that the three gluten-associated disorders, CD, NCGS and WA, are different clinical and pathogenetic entities, whereby NCGS is a condition prevalently associated with wheat-induced activation of the innate, rather than adaptive, immune response.

Introduction: Enhanced mucosal humoral immunity has recently been implicated in the pathophysiology of diarrhea-prone irritable bowel syndrome (IBS-D). Intestinal barrier dysfunction is associated with mucosal immune activation, likely induced by luminal antigens, however little is known about the antibody response in the intestinal mucosa in functional bowel disorders.
Aims & Methods: We aimed at characterizing the isotype of mucosal immunoglobulins (Ig) being produced in IBS-D. Mucosal jejunal biopsies, stool and blood samples were obtained from healthy volunteers (H; n = 18) and age-matched naïve participants meeting diarrhea-IBS Rome III criteria (IBS-D; n = 20). Bowel movements, stool consistency and abdominal pain were monitored in the prior 10 days to the biopsy. The number and ultrastructure of plasma cells in the jejunal mucosa was determined by transmission electron microscopy, and mucosal IgG^+ cells were quantifed by immunofluorescence. Stool and blood samples were assayed for IgG, IgM and IgA quantification by ELISA technique.
Results: The number of plasma cells was higher in IBS-D patients (IBS-D: $1,257 \pm 966$) respect to H participants (H: 266 ± 199; $P < 0.05$). In both groups, plasma cells displayed signs of activation and Ig production such as massive amount of endoplasmic reticulum and enlarged cisternae, however the presence of plasma cell clusters was more abundant in the IBS-D group. The number of IgG^+ cells was higher in the IBS-D group (H: 240 ± 149; IBS-D: 650 ± 150 cells/mm^2; $P < 0.05$). The amount of IgG in feces was also higher in the IBS-D group (H: 165 [31-1,767]; IBS-D: 553 [76-2,291] ng/mg protein $P < 0.05$), as well as IgA concentration, the later not reaching statistical significance (H: 580 [70-3,565]; IBS-D: 1,455 [201-11,056] µg/mg protein, $P = 0.059$). Differences in mucosal Ig were not detected in systemic circulation. In IBS-D, the concentration of IgG in feces positively correlated with abdominal pain ($r^2 = 0.538$; $P < 0.05$).
Conclusion: IgG production rises as a distinctive marker of mucosal immune activity in association with abdominal pain in IBS-D. Studies aimed at determining IgG subtype and antigens eliciting such responses warrant further investigation.

Introduction: The intestinal epithelium presents an innate immune system and a serotoninergic system, which interact to contribute to the intestinal homeostasis. The deregulation of this interaction has been described to be involved in intestinal inflammation. Intestinal innate immune system recognizes the microbiota through host recognition receptors, such as Toll-like (TLR) and Nod-like (NOD). These receptors trigger host responses to develop either a tolerant or a defense effect. Inflammatory Bowel Diseases (IBDs) are the result of an inappropriate response to the microbiota, in part mediated by deregulation of NODs and TLRs. Additionally intestinal serotoninergic activity mediated by an increase of extracellular serotonin (5-HT) has been observed to contribute to IBDs. Serotonin transporter (SERT) modulates intestinal 5-HT availability, therefore SERT activity has been considered as an essential tool to be analyzed in intestinal inflammatory processes.
Aims & Methods: The aim of present study was to analyze whether NOD1 and NOD2 alter SERT expression and activity. Furthermore, we aimed to study a possible cross-talk between NOD1 and NOD2, TLR2 and TLR4. Finally, we have assessed NOD1, NOD2, TLR2, TLR4 and SERT expression in a mice colitis model. The human enterocyte-like cell line Caco-2/TC7 was used. Ileum and colon from C57BL6 mice wild type (WT) and Dextran Sodium Sulphate treated (DSS colitis model) were also analyzed. SERT activity was determined by

5-HT uptake measurement. SERT, NOD1, NOD2, TLR2 and TLR4 mRNA were measured by RT-qPCR. Protein expression of SERT, NOD1 and NOD2 were quantified by western blot.
Results: NOD1 and NOD2 activation decreased SERT activity and expression (mRNA and protein) in Caco-2 cells. In this context, TLR2 activation showed to increase both NOD1 and NOD2 mRNA levels, while NOD1 and NOD2 protein expression did not seem to be affected. On the contrary, TLR4 activation showed to decrease NOD1 and NOD2 mRNA and NOD1 protein level with no effect on NOD2 protein level. In relation to the analysis of NODs and TLRs mRNA in mice intestinal tract, the results have shown that in ileum of DSS mice, NOD1, NOD2, TLR2 and TLR4 did not seem to be modified compared with WT. In contrast, in colon of DSS mice, NOD2 and TLR2 mRNA resulted increased, whereas NOD1 and TLR4 mRNA did not show to be affected. Analysis of SERT expression in mice intestine has shown that mRNA and protein expression resulted decreased in both ileum and colon of DSS mice compared with WT.
Conclusion: NOD1 and NOD2 activation seems to regulate intestinal 5-HT level by acting on SERT in the intestinal epithelium. Moreover, the expression of NOD1 and NOD2 in intestinal epithelial cells may be regulated by TLR2 and TLR4 activation, which confirms a cross-interaction between several components of the innate immunity system in intestinal epithelium. Finally, both innate immune and serotoninergic system resulted altered in colitis intestinal tract, thus suggesting a synergy between both systems in intestinal inflammatory processes.

Introduction: Irritable bowel syndrome (IBS) is characterized by psychological stress and altered intestinal barrier function. Peripheral corticotropin-releasing factor (CRF) and neuropetides such as Substance P (SP) are involved in stress-induced gut dysfunction and CRF has been related to mucosal eosinophils. However, the role of eosinophils in IBS remains unknown.
Aims & Methods: To identify the role of mucosal eosinophils in IBS-D, and to evaluate the mechanisms underlying the stress response using an eosinophil in vitro model.
Methods: Healthy (H) subjects (n = 18) and age-matched, naïve participants fulfilling diarrhea-prone IBS (IBS-D) Rome III (n = 23) were included. Jejunal biopsies were obtained by Watson's capsule in all participants. Mucosal eosinophil ultrastructure, CRF inmunolabelling, activation and secretory activity, were evaluated by transmission electron microscopy or gene expression (microarray and quantitative RT-PCR). Psychological stress, abdominal pain, the number of bowel movements per day, and the stool form were obtained in all participants. The eosinophil cell line 15HL60 was differenciated and stimulated with SP, and secretory activity and CRF content were assessed by RT-PCR, immunofluorescence.
Results: Microarray and IPA analysis revealed eosinophil activity ($P < 0.0001$) in IBS vs H. Array validation revealed decreased eotaxin, EDN and ECP gene expression, but increased synaptosomal-associated protein SNAP-23 ($P < 0.05$) in IBS-D compared to H. CRF was identified only in cytoplasmic eosinophil granules, with increased content in IBS-D (IBS-D = 7,3 [2,99;11,4]; H = 1,9 [0,75; 4,10] particles/granule; $P < 0.01$). Notably, the amount of CRF significantly correlated with baseline level of stress ($r_s = 0.70$; $P = 0.018$), depression ($r = 0.61$; $P = 0.037$), the number of bowel movements ($r_s = 0.78$; $P = 0.007$) and the stool consistency ($r_s = 0.67$; $P = 0.027$). In vitro, eosinophils expressed NKR1 and responded to SP by relocation of SNAP-23, VAMP2 and CRH from the cytoplasm to the plasma membrane, without changes in gene expression profile of pro-inflamatory proteins.
Conclusion: CRF is stored in jejunal mucosal eosinophils and its increase correlates with clinical symptoms in IBS-D. Similarity between mucosal eosinophils and in vitro response to SP, suggests eosinophil contribution to IBS through neuroimmune mechanisms.

Introduction: Recently, gluten and gliadin have been identified as a key environmental factor in different human disorders (celiac disease, food allergies and non celiac gluten sensitivity).
They induce different biological alterations into the cell. In particular, the gluten-cell interaction increases the expression and the cellular content of transglutaminase type 2 enzyme (TG2) and altering the pro-oxidant–antioxidant balance in the intestinal mucosa, accompanied by ROS overproduction.
Aims & Methods: Evaluation of gliadin effect on oxidative/reductive balance and assessment of the possible genotoxic damage caused by free radicals
Caco2 cells were treated with gliadin (digested according to the method: S. Friis, *Gut* 1992; 33:1487-1492) at different concentrations (range 15 μg/mL-1mg/mL) for 24h. We investigated: i) cytotoxicity (MTT test); ii) oxidative stress through the evaluation of reactive oxygen species (ROS, flow cytometry with DCFDA); iii) DNA damage by means of comet test, to detect single, double strand breaks and alkali labile sites; iv) TG2 activity in different cellular compartment (colorimetric assay).
Results: After 24h of gliadin treatment we observed a decrease in cell viability of about 50% at the dose of 1mg/mL. ROS levels showed a 30% increase also using low gliadin doses (30μg/mL). A DNA damage was observed at comet assay as demonstrated by an increase of tail moment particularly visible at 1mg/mL of gliadin concentration. Following the doses indicated by ROS, the activity of TG2 was increased after gliadin treatment (30μg/mL) with a translocation from the cytoplasm to the nucleus, suggesting an apoptotic phenomenon.
Conclusion: Gliadin induces a cellular oxidative stress. Moreover, our findings demonstrate a DNA damage and a TG2 activity translocation from the cytoplasm to the nucleus.

P0571 THE DEPLETION OF MURINE MICROBIOTA BY BACITRACIN AND NEOMYCIN REDUCES THE INTESTINAL PERMEABILITY BY INCREASING THE LEVELS OF ZO-1, JAM-A AND OCCLUDIN

L. Grasa[1], R. Nevado[1], R. Forcén[1], E. Layunta[1], E. Latorre[1], A. I. Alcalde[1], M. D. Murillo[1]

Introduction: Oral bacitracin has been used for the treatment of *Clostridium difficile*-associated diarrhoea and colitis. Oral neomycin is indicated for suppression of intestinal microbiota in patients undergoing colorectal surgery. Antibiotics may alter the intestinal microbiota and affect the intestinal permeability. The intestinal epithelial permeability is regulated by the tight junctions (TJs) proteins. The TJs complex consists of transmembrane (occludin, junctional adhesion molecule (JAM), claudins) and intracellular scaffold (ZO-1) proteins[1].
Aims & Methods: The aim was to investigate the effects of the oral administration of bacitracin and neomycin on murine intestinal permeability and the expression of TJs proteins.
Female C57BL/10 mice of 5-7 weeks old were divided into two groups: control and treated with antibiotics. Mice were gavaged for 7 consecutive days with water (controls) or a combination of antibiotics (bacitracin 20 mg and neomycin 20 mg) per mouse and day (treated mice). This combination of antibiotics has been shown to deplete the intestinal microbiota[2]. *In vivo* paracellular permeability assay to assess barrier function was performed using an FITC-labelled dextran method. Mice were gavaged with 60 mg per 100 g body weight of FITC-dextran and at 4 h serum samples were obtained. Fluorescence intensity was measured (excitation, 485 nm; emission, 535 nm) and FITC-dextran concentrations were determined. TJs protein gene expresion (mRNA) was determined in ileum and colon by quantitative RT-PCR.
Results: Control mice showed levels of FITC-dextran of 378.45 ± 60.20 ng mL^{-1} of blood. In comparison, there was a reduction to the half in FITC-dextran levels in antibiotics treated mice (208.09 ± 25.84 ng mL^{-1}), suggesting increased barrier function in these mice. The treatment with bacitracin and neomycin increased the expression of ZO-1, JAM-A and occludin in mice ileum and colon. However, the treatment with these antibiotics reduced the levels of claudins-3, 4 and 7 in ileum, but increased the levels of claudins-3 and 4 in colon.
Conclusion: Microbiota may regulate the intestinal permeability. The oral treatment with bacitracin and neomycin enhances the barrier function by increasing the levels of the tight junction proteins ZO-1, JAM-A and occludin.

Introduction: Near-infrared spectroscopy (NIRS) is a noninvasive method for monitoring in real time regional tissue oxygenation status. NIRS has the ability to continuously and simultaneously monitor tissue perfusion in various organs, without interrupting daily care. Research has demonstrated its usefulness in monitoring cerebral, intestinal and renal perfusion, in detection of potential ischemic episodes.
Aims & Methods: NIRS was used in comparation, through somatic regional oxygen saturation (rSO2S), cerebral saturation(rSO2C) and cerebro- somatic oxygenation ratio (ROCS) in a group of 30 newborns with gestational age(GA) between 24-39 weeks, birth weight 600- 3100 grams, from day 3 until day 21 of life, over a 1-5 day, period required for causal diagnosis, in which we clinically presumed a decrease in mesenteric blood flow. The group included 12 newborns with ulceronecrotic enterocolitis (NEC), 6 newborns with intrauterine growth retardation (IUGR), 6 newborns with congenital heart malformation (CHM) and 6 infants with sepsis. rSO2-S and ROCS were compared with each other to determine which of the two parameters are faithful for detecting changes in tissue perfusion. To verify statistical hypothesis which states that there are significant differences regarding rSO2S value and ROCS depending on the type of the disease were used ANOVA statistical tests, Bonferroni option and Pearson correlation
Results: In the NEC group the rSO2S average was 40.37 compared with 44.94 for CHM group, 51.86 in IUGR group and 53.08 for the sepsis group. The ROCS average achieved was 0.59 for NEC, 0.68 in CHM group, 0.97 in sepsis group and 0.73 for IUGR. No statistically significant differences were found for rSO2S ($F = 1.69$, $p = 0.18$, p?0.05) inside the group and between groups values but were significant for ROCS ($F = 2.82$, $p = 0, 04$, $p < 0.05$).
Conclusion: The study shows that continuous noninvasive monitoring with NIRS technology can show that impaired intestinal perfusion increases with decreasing GA. Decreases of the two parameters are influenced by GA (rSO2S: $p = 0.008$; ROCS: $p = 0.03$). The lowest values of intestinal perfusion are in NEC (rSO2 = 40.37, ROCS = 0.59), followed by CHM (rSO2S = 44.94, ROCS = 0.68), IUGR (rSO2S = 51.86, ROCS = 0.73) and sepsis (rSO2S = 53.08, ROSC = 0.97). rSO2S value is less statistically significant ($F = 2.82$, $p = 0.18$) compared with ROCS ($F = 2\ 82$ $p = 0.04$) in patients with NEC compared to those with CHM, sepsis or IUGR.
ROCS is the most accurate parameter in determining intestinal perfusion changes and the use of NIRS remains a very good method for early detection of lower intestinal perfusion in various diseases.

Introduction: Nonsteroidal anti-inflammatory drugs (NSAIDs), besides exerting detrimental effects on the upper digestive tract, can also damage the small and large intestine. Although the underlying mechanisms remain unclear, there is evidence that enteric bacteria could play a prominent role. In particular, NSAIDs increase mucosal permeability, thus facilitating the entrance and action of bacteria, which trigger the inflammatory cascade *via* activation of Toll-like receptors (TLRs).
Aims & Methods: The present study examined the effects of rifaximin, a poorly absorbed antibiotic, on enteric bacterial load and composition as well as small bowel inflammatory responses in a rat model of diclofenac-induced enteropathy. Enteropathy was induced in male rats (40-weeks old) by intragastric diclofenac administration (4 mg/kg BID) for 14 days. Control animals received drug vehicle (0.3 ml of 1% methylcellulose). A group of rats received Rifaximin-EIR (enteric coated microgranules of rifaximin), (50 mg/kg BID), 1 hour before diclofenac ($n = 6$-7 per group). At the end of treatments, feces were collected to quantify calprotectin content by ELISA. Ileum was excised and processed for the evaluation of: 1) tissue myeloperoxidase levels (as an index of neutrophil infiltration); 2) bacterial total load and quantitative analysis of strains, *via* 16S real-time PCR; 3) expression of TLR-2/4 and activation of downstream signaling as phosphorylated nuclear factor kB subunit p65 (NF-kB p65) and myeloid-differentiation primary response-gene 88 (MyD88), by Western blot.
Results: In control animals, myeloperoxidase and calprotectin levels were 6.0 ± 1.1 ng/mg and 2.5 ± 0.2 ng/mg, respectively. These parameters were significantly increased (by 290% and 52%) in diclofenac-treated rats. Ileal specimens from control animals were found to contain a total bacterial load of $4.66 \pm 1.01 \times 10^{10}$. In particular, the Bacteroidetes phylum was $0.14 \pm 0.05 \times 10^{10}$ and the Firmicutes phylum was $0.26 \pm 0.03 \times 10^{10}$. All these bacterial loads increased after treatment with diclofenac. The expression of TLR-2/4, NF-kB p65 and MyD88 in diclofenac-treated animals was higher, as compared with control animals (+104%, +23%, +147% and +71%, respectively). In rats treated with diclofenac plus Rifaximin-EIR, myeloperoxidase and calprotectin levels were lower in comparison with diclofenac alone (-74% and -89%, respectively). In this setting, the bacterial total load decreased by 88%, with a significant reduction of Bacteroidetes and Firmicutes, while the increased expression levels of TLR-2/4, NF-kB p65 and MyD88 returned towards control values.
Conclusion: In the small bowel, treatment with diclofenac leads to quantitative and qualitative alterations of enteric bacteria that are associated with increased expression/activation of TLR-2/4 and consequent tissue inflammation. Under these conditions, Rifaximin-EIR counteracts the bacterial changes and promotes a normalization of related inflammatory responses. These peculiar pharmacological actions of rifaximin may represent the underlying mechanism(s) of its preventive activity against NSAID-induced intestinal damage, recently shown in rats[1] and humans[2] in our Institutions.

P0574 WHEAT ALPHA-AMYLASE/TRYPSIN INHIBITORS (ATIS) EXACERBATE AUTOIMMUNE ENCEPHALOPATHY IN MICE

V. F. Zevallos[1], N. Yogev[2], A. Nikolaev[2], A. Waisman[2], D. Schuppan[1]
[1]*Institute of Translational Immunology,* [2]*Institute for Molecular Medicine, University Medical Center of the Johannes Gutenberg-University Mainz, Mainz, Germany*

Contact E-mail Address: zevallos@uni-mainz.de
Introduction: We identified wheat alpha-amylase/trypsin inhibitors (ATIs) as main activators of innate immunity by engaging the toll like receptor 4 (TLR4)-MD2-CD14 complex in cells of the mononuclear phagocyte system. ATIs play a fundamental role in the pathogenesis of celiac disease (CD) and other autoimmune diseases.
Aims & Methods: The aim of this study is to evaluate the effects of dietary ATIs on murine experimental autoimmune encephalitis (EAE), a preclinical model of human multiple sclerosis (MS). Female mice (C57BL/6) were fed with a gluten/ATI-free diet for 4 weeks and thereafter EAE was induced by injecting 50 µg of MOG 35-55 peptide emulsified in CFA and supplemented with heat-inactivated *M. tuberculosis* (day 0) in the tail base and 200 ng pertussis toxin i.p. on day 0 and 2. On day 0 the protein (casein) adjusted diet was continued as follows: 1) gluten/ATI-free; 2) 25% gluten (ATIs equivalent to the human wheat based diet); 3) 25% gluten de-enriched of ATIs; 4) purified ATIs. Mice were monitored daily for clinical signs of EAE (graded on a scale from 0 to 5) and euthanized at the peak of EAE for molecular, histological and immunohistological studies on gut, brain, spinal cord, lymph nodes and spleen. In addition, lymphoid organs were harvested for analysis of immune cell specific markers using flow cytometry.
Results: Mice on a gluten/ATI-free diet and on a diet containing 25% gluten de-enriched of ATIs had a significant lower clinical score compared to animals on a diet containing 25% gluten (and ATIs) or purified ATIs. We also observed that both intestinal and CNS-infiltrating total and encephalitogenic T cells ($CD4^+IFNg^+IL\text{-}17^+$) were significantly increased in the ATI fed groups, paralleled by significantly increased tissue and circulating levels of MCP-1, IL-8 and IL-6.
Conclusion: 1) Nutritional wheat ATIs exacerbate EAE in mice; 2) a gluten/ATI-free diet ameliorates the course of EAE; 3) gluten depleted from ATIs fails to exacerbate the development of EAE, indicating that ATIs are important nutritional activators of innate immunity in EAE.

Contact E-mail Address: onozawa@koto.kpu-m.ac.jp
Introduction: The prophylaxis and treatment for acetyl salicylic acid (ASA)-induced small intestinal injury is urgently required. Recently, we found that rebamipide (Reb), a gastro muco-protective drug, protects small intestinal mucosa from ASA-induced injury in human clinical trial using a capsule endoscopy (PLoS ONE 2015). However, the precise mechanism by which Reb protects ASA-induced small intestinal injury is not clear yet. Although MUC2, a main component mucin secreted by goblet cells, has been reported to play an essential role in the protection of epithelial cells, the effect of Reb on MUC2 production has not been investigated.
Aims & Methods
Aim: In this study, we investigated whether Reb affects on mucin secretion of goblet cells.
Materials and Methods: We used LS174T cell as a goblet cell line. The concentration of Reb (1-100µM for 24hrs) we used in this study did not affect cell viability. After Reb addition to LS174T cells, samples were taken for the following analysis at 6hr and 24hr. Subsequent mucin production was assessed by PAS staining, and MUC2 expression was assessed by PCR and WB (whole cell). Since, the mucin secretion is hard to detect by WB, we used dot-blot for the detection of secreted MUC2.
Results: Reb strongly up-regulated the positivity of PAS staining in LS174T, suggesting the increased production of intracellular mucin production. To confirm this phenomenon we assessed the MUC2 expression by PCR and WB and found that Reb significantly increased MUC2 mRNA and its protein expression in whole cell lysate of LS174T. In order to assess the subsequent secretion of mucin by LS174T, we assessed MUC2 protein expression in the supernatant of

Reb conditioned LS174T using dot-blot method, and found that Reb significantly increased the secretion of MUC2 in a concentration dependent manner.
Conclusion: Taken together, the protective effect of Reb on ASA-induced mucosal injury in small intestine might depend on its ability to increase mucin secretion by small intestinal goblet cell.

Contact E-mail Address: acarroccio@hotmail.com
Introduction: Non-celiac wheat sensitivity (NCWS) has raised great interest but little is known about the risks linked to this condition. We evaluated the frequency of autoimmune diseases (AIDs) and of serum anti-nuclear antibodies (ANA) in NCWS patients.
Aims & Methods: A group of NCWS patients, composed of 131 subjects (121 F, mean age 39.1 years), belonging to a historical cohort retrospectively evaluated, was studied. These patients had been recruited at two Internal Medicine Institutes. Two groups of age- and sex-matched controls, respectively composed of celiac (CD) and irritable bowel syndrome (IBS) patients, were also chosen. A pre-structured questionnaire was used to record any co-existent AIDs. ANA titers were evaluated by immuno-fluorescence.
Results: An associated AID was observed in 29% of NCWS patients (Hashimoto's thyroiditis 29 cases, psoriasis 4 cases, type 1 diabetes 4 cases, mixed connective tissue disease 1 case, ankylosing spondylitis 1 case), in 21% of CD (not statistically significant) subjects and in 4% of IBS controls ($P < .0001$). Serum ANA were positive in 46% of NCWS (median titer 1:80), in 24% of CD ($P < .0001$) and in 2% of IBS ($P < .0001$) cases. An association between ANA positivity and the presence of the DQ2/DQ8 haplotypes and with the presence of duodenal lymphocytosis was found.
Conclusion: Our data showed a strong tendency towards autoimmunity in the NCWS patients, characterised by both associated AIDs and serum ANA positivity and raised the question of an overlap between NCWS and CD.

P0577 ROUTINE SMALL BOWEL BIOPSIES IS A COST EFFECTIVE STRATEGY IN THE INVESTIGATION OF IRON DEFICIENCY ANEMIA

E. Broide[1,2], S. Matalon[1], M. Leshno[3], H. Shirin[1,2]
[1]*Gastroenterology, Assaf Harofeh Medical Center, Zerifin,* [2]*Tel Aviv University, Tel Aviv, Israel,* [3]*Buiseness of Administration, Tel Aviv University, Tel Aviv, Israel*

Contact E-mail Address: efibroide@yahoo.com
Introduction: Iron deficiency anemia (IDA) is a common disorder. Half of the celiac disease (CD) patients have IDA at diagnosis. There is no consensus regarding the need for routine small bowel biopsies (SBB) in IDA patients.
Aims & Methods: To compare two strategies; strategy A- routine SBB during EGD in any patient with IDA regardless celiac serology status vs. strategy B- SBB only in IDA patients with positive serology. The main outcomes were quality adjusted life years (QALY), average cost and the incremental cost effectiveness ratio (ICER).
We used a state transition Markov model. Patients were placed into 5 health states in each cycle; No CD, undiagnosed CD, potential CD, CD under normal diet, CD under gluten-free diet, death. One way sensitivity analyses was performed on all variables and two way sensitivity analyses on selected variables were done.
Results: Performing SBB regardless the serological results yielded 19.888 QALY in strategy A compared to 19.887 if performed only in patients with positive serology. Prevalence of CD in IDA patients, utility of CD and probability of identifying CD due to symptoms were the most influential parameters. The average cost of strategy A was 218.10$ vs. 234.17$ in strategy B. As long as the cost of SBB is less than 67$, performing SBB to all patients with IDA dominates the strategy of strategy B, performing SBB only in positive serology patients. These results are independent of the costs of serological test (within a range of 60-80). However, when the cost of SBB is higher than 67$, the dominant strategy depends on both the cost of SBB and the cost of the serological tests. In terms of ICER, as long as the cost of biopsy stays under 77$, conducting routine SBB in all patients with IDA is still the preferred strategy. Monte Carlo simulation demonstrated that SBB to all IDA patients yielded the same QALY but with lower costs than the strategy of selected SBB.
Conclusion: Our model suggests that EGD with routine SBB appears to be a cost-effective approach with improved QALYs in patients with IDA when the prevalence of CD is 5% or greater. SBB should be a routine screening tool for CD among patients with IDA, regardless of their celiac antibody status.

P0578 AND WHEN IS NOT CELIAC DISEASE?: DIAGNOSIS DILEMMA IN SERONEGATIVE VILLOUS ATROPHY

E. Gravito-Soares[1], M. Gravito-Soares[1], C. Lérias[1], C. Sofia[1]
[1]*Gastroenterology, Centro Hospitalar e Universitário Coimbra, Coimbra, Portugal*

Contact E-mail Address: es18497@gmail.com
Introduction: Celiac disease is an immune-mediated pathology in individuals with genetic susceptibility to gluten that leads to variable degrees of villous atrophy. However the villous atrophy seronegative to celiac disease (SNVA) implies a diagnosis and therapy dilemma in clinical practice.
Aims & Methods: Retrospective study of all biopsies with villous atrophy, performed between 2000 and 2015. That was conducted a research of the words 'villous/villousity atrophy' in pathology database. Of the total of 374 results, were excluded biopsies with extra-duodenal histology (126), absence of duodenal villous atrophy (97), no search/positive serology for celiac disease (79), no medical records (26) and multiple biopsies for the same patient (17). Of the remaining 29 patients with villous atrophy and negative serology for celiac disease were recorded clinical and analytical characteristics, diagnosis and therapy.
Results: Patients with SNVA had a mean age 50.1 ± 17.2years, without gender differences (15♂:14♀). Approximately 86.2% ($n = 25$) had symptoms, mainly diarrhea, weight loss and anorexia. The malabsorption syndrome occurred in 72.4% (21/29) with microcytic anemia in 71.4% (15/21). Twelve patients had other autoimmune diseases (41.4%). Endoscopic findings consistent with celiac disease were present in 62.1% ($n = 18$). The villous atrophy were mild-moderate in 75.9% (22/29) and severe in 24.1% (7/29). The villous atrophy associated with intraepithelial lymphocytosis occurred in 37.9% (11/29). Only 2 patients did HLA DQ2/8, both positive. The main identified etiologies were drug iatrogenic ($n = 6$), seronegative celiac disease and common variable immunodeficiency ($n = 5$), refractory celiac disease, duodenal Crohn's disease, Whipple's disease and unclassified sprue ($n = 2$). Therapy was made in 26 patients, with response in 69.2% (18/26), being complete in 61.1% (11/18).
Conclusion: Duodenal villous atrophy is the final common event to several aggressor agents. Excluding celiac disease, differential diagnosis must be made with multiple pathologies, in order to establish the appropriate directed therapeutic, with clinical and histologic improvement in the most cases.

Introduction: Our aim was to quantify the risk of community-acquired infective pneumonia (CAP) among patients with coeliac disease (CD), vaccinated and unvaccinated against pneumococcus, compared to the general population.
Aims & Methods: We identified all subjects with diagnosed CD within the Clinical Practice Research Datalink linked with Hospital Episodes Statistics between 1st April 1997 and 31st March 2011 and up to 10 controls per CD patient by frequency matching within 10-year age bands. We calculated rates per 1000 person-years of the first CAP among all patients with CD and controls, separately in those vaccinated and unvaccinated against pneumococcus, and in CD patients before and after their diagnosis. We used a Cox regression model to estimate the hazard ratio (HR) of pneumonia among CD patients compared to the controls.
Results: Among 9,803 CD patients and 101,755 controls, respectively there were 179 (1.82%) and 1864 (1.83%) CAP events. The overall rate of CAP in CD was 3.42 per 1000 person-years and 3.12 per 1000 person-years in controls. We found an increased risk of pneumonia among the unvaccinated CD patients compared to unvaccinated controls (HR 1.28, 95% CI 1.02-1.60), but not in vaccinated CD patients compared to vaccinated controls (HR 0.88, 95% CI 0.70-1.10). The increased risk in unvaccinated CD subjects was limited to those younger than 65 years, was particularly increased around the time of diagnosis (HR 2.31, 95% CI 1.03-5.19 within 1 year after diagnosis) and was maintained for more than 5 years after diagnosis (Table).

Table. Pneumonia risk: timing from CD diagnosis (unvaccinated subjects younger than 65 years old)

Time period	N events in CD	Rate in CD per 1000	UnadjustedHR	Adjusted HRa
Before diagnosis				
+1 year	**21**	1.43	1.45 (0.93-2.24)	1.62 (1.04-2.53)
within 1 year	**13**	4.62	4.66 (2.68-8.10)	4.69 (2.69-8.18)
After diagnosis				
within 1 year	**6**	2.28	2.33 (1.04-5.21)	2.31 (1.03-5.19)
1-4 years	**19**	2.12	2.14 (1.35-3.39)	2.11 (1.39-3.35)
+ 5 years	**31**	1.59	1.60 (1.11-2.31)	1.63 (1.13-2.36)

a: adjusted for gender, calendar year; body mass index; smoking; Charlson index; socioeconomic status; Reference is controls group

Conclusion: Unvaccinated people with CD under the age of 65 have a higher risk of CAP compared to the general population around the time of diagnosis and subsequently. Pneumococcal vaccination in people with CD following diagnosis and treatment would appear to be good medical advice.

P0580 REVISITING DIAGNOSTIC FEATURES OF REFRACTORY CELIAC DISEASE OF TYPE I

G. Malamut[1], P. Rompteaux[1], B. Meresse[2], S. Khater[1], N. Brousse[3], V. Verkarre[3], C. Derrieux[3], E. Macintyre[3], N. Cerf-Bensussan[2], C. Cellier[1]
[1]*Hôpital Européen Georges Pompidou,* [2]*UMR1163 Institut Imagine,* [3]*Hôpital Necker Enfants Malades, Paris, France*

Contact E-mail Address: georgia.malamut@egp.aphp.fr
Introduction: A small group of celiac patients becomes refractory to a gluten-free diet (GFD). In contrast with refractory celiac disease of type II (RCDII), characterized by clonal expansion of intraepithelial lymphocytes with abnormal phenotype, RCDI can be scarcely distinguished from active celiac disease at diagnosis.
Aims & Methods
Aim: We aimed to assess RCDI for its clinical, biological, histopathological features and precise phenotype of intestinal lymphocytes at diagnosis.
Patients and Methods: 202 patients, with intestinal villous atrophy refractory to a GFD, were investigated in European Georges Pompidou Hospital between 2000 and 2013. Clinical and histopathological study allowed diagnosis of RCDI in 20 patients.
Results: In our institution, diagnosis of RCDI is performed in 10% of patients with intestinal villous atrophy refractory to a GFD. Main patients (17/20) with RCD I (15F/5M; mean age at diagnosis of celiac disease (CD): 41 years) were primary refractory to a GFD. Three patients were secondary refractory to a GFD within 25 years [14-35 years] after diagnosis of CD. At diagnosis of RCDI, persistent positive serology was found in 8 patients. One third of RCDI patients had severe malnutrition with low albuminemia and iron deficiency. Except one patient HLA-DQ8, all others were HLA-DQ2 and six patients (30%) were HLA-DQ2/DQ2. Seven patients (35%) had extra-intestinal autoimmune diseases, mainly autoimmune thyroiditis, 44% (7/16) of patients had serum auto-antibodies mainly, anti-nuclear antibodies. At diagnosis, half RCDI patients (10/20) had severe intestinal villous atrophy with increased count of IEL (CD3 + CD8+: 69 %) and thickened collagenous subepithelial layer was found in duodenal mucosa of 25% of them (5/20). Increased frequency of CD3 + CD4+ IEL (10.5%) was found in comparison with active celiac patients (4.5%; $p = 0.01$) or CD patients under GFD ($p < 0.05$). Microscopic colitis, of collagenous or lymphocytic type, was observed in 86% (6/7) of patients investigated with colonoscopy.
Conclusion: Increased intestinal CD4+ IEL count, collagenous sprue (25%) and microscopic colitis (86%) are histopathological and phenotypic features of diagnosis of RCDI. High frequency of HLA-DQ2 homozygosity (30%) and associated extra-intestinal autoimmune diseases (35%) suggest an autoimmune mechanism.

P0581 SMALL INTESTINE DIGITAL HISTOMORPHOMETRY FOR CELIAC DISEASE

J. Taavela[1], A. Popp[1,2], R. P. Anderson[3], J. Isola[4], M. Mäki[1]
[1]*Tampere Center for Child Health Research, University of Tampere and Tampere University Hospital, Tampere, Finland,* [2]*University of Medicine and Pharmacy "Carol Davila", Bucharest, Romania,* [3]*ImmusanT, Inc., One Kendall Square, Building 200, LL, Suite 4, Cambridge, MA 02139, United States,* [4]*Institute of Biosciences and Medical Technology, University of Tampere, Tampere, Finland*

Contact E-mail Address: juha.taavela@uta.fi
Introduction: Digital image analysis of small intestinal biopsies, allowing quantitative villus height crypt depth ratios measurements (VH:CrD) and CD3-positive cell counts, holds promise in celiac disease research. We validated our morphometric procedures using virtual microscopy of small intestinal biopsy sections and compared the results to those of conventional microscopy.
Aims & Methods: Standard H&E stained biopsy specimens ($n = 144$) from adult celiac disease patients and non-celiac disease controls were scanned and analyzed using a dedicated virtual microscopy platform - Celiac Slide Viewer. The specimens, which comprised different grades of mucosal injury, were evaluated morphometrically on computer screen by two accredited evaluators. Specimens with tangential cutting were included. The intra- and interobserver variations for VH:CrD and CD3+ densities (IELs/100 epithelial cells) were analyzed with the Bland-Altman method and intraclass correlation.
Results: Both observers measured 93 samples out of 144 (65 %) for VH and CrD readings. The rejected samples were evaluable neither for morphometry measurements or Marsh-Oberhuber classes because of tangential biopsy cuttings. CD3+ stained specimens were available from 107 patients. The intraobserver analysis of VH:CrD showed a mean difference of -0.019 with limits of agreement from −0.394 to 0.432; the standard deviation (SD) was 0.211. The mean difference in interobserver analysis was 0.0047, limits of agreement −0.544 to 0.554, and SD 0.280. The intraclass correlation coefficient in intraobserver variation was 0.985 and that in interobserver variation 0.970. $CD3^+$ IEL density showed a SD of 18.5% and an intraclass correlation coefficients of 0.957.
Conclusion: The results indicate that digital morphometry is a powerful tool for measuring even small injury changes of small intestinal mucosa. Virtual microscopy allows image sharing via internet, saving and tracking of measurements. A conversion table between Marsh-Oberhuber grouped classification and quantitative morphometry is shown.

Contact E-mail Address: julio.valle@telefonica.net
Introduction: Celiac disease diagnosis can be difficult in patients with minimal histologic changes (Marsh 0-1) or when there is disagreement between serology and histology. Celiac disease is characterized by an increase in the total number of intraepithelial lymphocytes (IELs) in the small bowel mucosa, with an increase in the subset of γ/δ T-cell receptor-bearing IELs along with a decrease in the subset of CD3-CD103+ IELs (celiac immunophenotype).
Aims & Methods: Our aim was to assess the role of the analysis of IELs by flow cytometry in the diagnosis of celiac disease, both in adults and children.
Material and Methods: 317 patients with suspicion of celiac disease (194 adults and 123 children) were included in the study. In all patients serum IgA tissue transglutaminase antibody levels were determined and six biopsy samples from the second part of duodenum were obtained during an upper gastrointestinal endoscopy. Four biopsies were fixed in 10% formalin for histologic assessment and two biopsies were placed in cold 0.9% saline solution for flow cytometric analysis of IELs. Celiac disease diagnosis was based in a positive serology and compatible changes in duodenal biopsy (Marsh 2-3). In doubtful cases, diagnosis of celiac disease was supported by a positive clinical and serological response to a gluten-free diet.
Results: 68 adults (45 female; median age: 35 years; range: 14-74 years) and 96 children (54 female; median age: 7 years; range: 0–13 years) were diagnosed of celiac disease. Histology had a 89% sensitivity and a 97% specificity for the diagnosis of celiac disease. The presence of a compatible celiac immunophenotype in the flow cytometric assessment of IELs had a 93% sensitivity and a 96% specificity. Considering the presence of either Marsh 2-3 in duodenal biopsies and/or a compatible immunophenotype as diagnostic of celiac disease, we obtained a sensitivity of 99% and a specificity of 97% (Table 1). Flow cytometry allowed us to diagnose celiac disease in 10 adults and 6 pediatric patients with mild histologic changes (Marsh 0-1).**Table 1:** Diagnostic accuracy of the combination of histology and flow cytometry of IELs in suspected celiac disease.

Marsh 2-3 and/or celiac immunophenotype	Celiac disease	No celiac disease
Positive (%)	162 (98.8%)	4 (2.6%)
Negative (%)	2 (1.2%)	149 (97.4%)
Sensitivity (95%CI)	99% (96-100%)	
Specificity (95%CI)	97% (93-99%)	
PPV (95%CI)	96% (94-99%)	
NPV (95%CI)	97% (95-100%)	

CI: confidence interval. PPV: Positive predictive value. NPV: Negative predictive value.

Conclusion: In patients with suspicion of celiac disease the combined use of histology and flow cytometry of IELs increases diagnostic sensitivity without decreasing specificity.

P0583 THE CORRELATION BETWEEN INCREASED LEPTIN CONCENTRATIONS AND PECULIARITIES OF GASTRIC MUCOSA IN PATIENTS WITH PROLONGED USE OF NSAIDS

A. Antonenko[1], T. Beregova[2], A. Svintsitskyi[1]
[1]*Department of Internal Medicine №3, Bogomolets National Medical University,* [2]*Department of Pharmaco-Physiology, Taras Shevchenko National University of Kyiv, Kiev, Ukraine*

Contact E-mail Address: tonyaant@yandex.ua
Introduction: Leptin is a hormone produced primarily by adipocytes and plays important role in nutritional status and in obesity. Recently, the presence of leptin as well as the expression of its receptors was detected in rat and human stomach. It is known that the level of leptin in males with DU is increased. Data about the correlation between the leptin levels with severity of gastritis, *H. pylori* (Hp) and sex are controversial (Roper J.L. et al. 2008; Khudlur S. et al. 2011).
Aims & Methods: The aim of our study was to determine a correlation between leptin levels with sex, Hp status, BMI and histological features of gastric mucosa (GM) in patients with prolonged use of non-selective NSAIDs. We examined 94 patients who regularly during the last month used non-selective NSAIDs. Excluded from this study were those who had used proton pump inhibitors or antibiotics in the previous month, patients with prior history of gastroduodenal surgery and pregnant or lacting women. The mean-age of these patients was 63.2 ± 6.0. For all of these individuals gastroscopy with further morphological examination, laboratory examinations were performed. All patients were divided in two groups: with erosive gastropathy and without visible changes of GM. The serum leptin levels were determined in all patients using sandwich leptin solid phase ELISA (DRG-instrument GmbH-Germany). Endoscopically obtained biopsies were stained with hematoxylline and eosine. Severity of inflammation was graded according to modified Sydney classification. The presence of Hp was determined by rapid urease test/CLO test. Normal distribution of studied parameters for each sampling was checked using Shapiro-Wilka's criteria. Average value (M) error and standard deviation (SD) were calculated to discover significant changes of investigated indices. Sampling comparison was performed using the paired t-test and ANOVA. Differences among values were considered statistically significant if $p < 0.05$. Correlations were analyzed using the Pearson test.
Results: NSAIDs-gastropathy was detected in 63 patients, in 31 patients visible changes of GM were absent. As expected, leptin correlated significantly with BMI ($r^2 = 0.43$) and it was higher in women (15.59 ± 6.69) vs men (11.05 ± 6.6), $p = 0.023$. Serum leptin level was increased on 25 % in patients with erosive changes of GM ($p = 0.04$). Of the 63 subjects 17 were Hp+ and 46 were Hp-. Of 31 subjects 18 were Hp+ and 13 were Hp-. The groups were not significantly different in terms of gender, height, weight or BMI. Serum leptin levels were significantly lower in Hp+ (9.78 ± 4.83) vs Hp- (16.57 ± 6.19) patients with NSAID gastropathy ($p = 0.004$). The changes between Hp+ vs Hp- patients without visible changes of GM were not statistically valid ($p = 0.891$). Correlation between the level of leptin and the severity of gastritis was not observed in our study ($p = 0.86$).
Conclusion: Serum leptin correlates with BMI, sex and presence of erosions. Hp colonization is associated with reduced serum leptin levels, independent of BMI. An increase in serum leptin in patients with NSAIDs-gastropathy may be a defense mechanism that can be used as prognostic factor for the prediction of the erosive NSAIDs-gastropathy in patients with prolonged use of NSAIDs.

Contact E-mail Address: g.addolorato@rm.unicatt.it
Introduction: Morbidly obesity is characterized by physical and psychological comorbidities which are associated with reduced quality of life. Bariatric surgery has been linked to a reduction of psychopathology other than to a reduction of weight and improvement in physical functioning
Aims & Methods: Aim of the present study was to compare psychological features of morbidly obese patients, before and after bariatric surgery, assessing social phobia and quality of life. A total of 46 morbidly obese patients were enrolled in the study. 20 patients were waiting for bilio-pancreatic diversion (group A), while 26 patients had already undergone surgical procedure (group B). Social phobia, fear for the body-shape and quality of life were assesed using appropriate psychometric tests.
Results: The percentage of patients showing social phobia was significantly higher compared to a sample of healthy controls ($p = 0.004$), both in group A ($p = 0.003$) and in group B ($p = 0.029$). No differences in percentage of patients affected by social phobia were found between two groups. A significantly higher percentage of patients affected by distress about the body ($p < 0.0001$) was found in group A with respect to group B. A reduction of quality of life was found in both groups.
Conclusion: The present study shows a high prevalence of social phobia in a population of morbidly obese patients, both before and after surgery. A general reduction of quality of life was also observed, with a partial improvement after surgery. Future studies are needed to clarify the relationship between social phobia and quality of life in surgically-treated morbidly obese patients.

P0585 INCREASED EXPRESSION OF PPARΓ IN CD24 KNOCKOUT (KO) MICE AND GENDER-SPECIFIC METABOLIC CHANGES: A UNIQUE MODEL OF INSULIN-SENSITIVE OBESITY

S. Shapira[1], D. Kazanov[1], N. Maharshak[1], R. Dankner[2], I. Zvibel[3], F. Bedny[4], S. Kraus[5], **A. Nadir**[5]
[1]*Integrated Cancer Prevention Center, Tel Aviv Sourasky Medical Center,* [2]*Epidemiology and Preventive Medicine, The Gertner Institute for Epidemiology and Health Policy Research, Sheba Medical Center,* [3]*The Research Center for Digestive Tract and Liver Diseases, Tel-Aviv Sourasky Medical Center, and The Sackler Faculty of Medicine, Tel-Aviv University,* [4]*Pathology Institute,* [5]*Integrated Cancer Prevention Center, Sourasky Medical Center, Tel Aviv, Israel*

Contact E-mail Address: nadira@tlvmc.gov.il
Introduction: Background: The heat stable *(HSA)/CD24* gene encodes a heavily-glycosylated cell surface protein. CD24 expression is high in immature precursor cells and low/absent in terminally differentiated cells. It plays an important role in the adaptive immune response and homeostasis in autoimmune diseases. CD24 is highly expressed in a large variety of human cancers. The association between cancer, diabetes, and obesity is not clear. Peroxisome proliferator-activated receptor gamma (PPARγ) is a nuclear receptor and regulator of adipogenesis that plays a role in insulin sensitivity, lipid metabolism, and adipokine expression in adipocytes.
Aims & Methods
Aim: To assess gender-dependent changes in *CD24/HSA* KO mice fed with normal and high-fat diet (HFD).
Methods: Body weight (BW), water and food consumption were closely monitored from birth in $HSA^{+/+}$ and $HSA^{-/-}$ mice for one year. The trial was repeated twice). Insulin (0.5IU/kg) sensitivity and glucose (1gr/kg) tolerance was determine thrice**.** Adipose tissue from kidney (KF), testicular (TF), and liver (LF) were isolated from KO and WT mice. High-throughput sequencing of stool 16S rRNA genes was assessed in the enteric microbial populations of the KO and WT mice, male and female, normal and HFD consumers. $N = 10$ in each group. Taxa analysis was performed on the core taxa prevalent in more than >25% of samples. Extraction of vascular fraction from adipose tissues was performed and primary cultures of adipocytes were established.
Results: Water and food consumption was similar for the KO and WT mice in normal and HFD. Mean BW of the KO was higher than that of their WT littermates, particularly in males and surprisingly with greater insulin sensitivity (10-20%) and glucose uptake (30%). It remained valid for mice fed with HFD. No such differences were observed among females. Significant differences in BW, KF, TF and LF were demonstrated between *CD24* KO and WT mice. Aadipocytes size of the KO (8258 ± 2359 uM^2) was significantly higher than that of the WT (5471 ± 2030 uM^2) mice ($P < 3.51E\text{-}09$). PPARγ expression was higher (x1.5) in *CD24* KO mice. Enteric bacterial populations were significantly different between KO and WT mice (normal diet) by unweighted ($R = 0.32$, $P < 0.01$) β-diversity analysis. These differences became much more apparent when mice were kept on HFD by weighted ($R = 0.43$, $P < 0.01$) and un-weighed β-diversity analysis ($R = 0.31$, $P < 0.01$) as well as by specific bacterial taxa.
Conclusion: 1. CD24 negatively regulate PPARγ expression in male mice. 2. The association between CD24 and insulin sensitivity, and the oncogenic potential of CD24, suggest a possible mechanism for diabetes as a cancer risk factor. 3. *CD24* KO male mice may serve as a model of male early obesity and insulin sensitivity.

Contact E-mail Address: brunosander@hotmail.com
Introduction: The weight regained has been a described growing problem in patients after bariatric surgery, especially at long term. This weight regained is multifactorial and often associated with dilation of Gastrojejunostomy (GJ), allowing a faster gastric emptying and therefore greater food intake. For the patients with significant weight regain after failed conservative approach, some revisional procedures are attempted and more recently endoscopic revisional procedures have been described.
Aims & Methods: To evaluate the safety and effectiveness of argon plasma coagulation (APC) decreasing the diameter of the gastro-enteric anastomosis in patients who have undergone Roux-and-Y Gastric Bypass (RYGB) for morbid obesity and regained weight associated to dilation of the GJ.
From jan-2014 to jan-2015 215 RYGB subjects with weight regain, a dilated anastomosis (more than 18mm in diameter) and at least 2 years from procedure were submitted APC application at GJ had their data reviewed from a prospective designed databank. Interval between an APC session applications was 60 days, with a maximum of 03 applications. APC set was at 2-3L/m with 65-75W. GJ diameter target was to reduced it up to 8-12mm estimated with premeasured open grasper. At first APC session pre-op weight and BMI, post-op weight nadir, actual weight and BMI and estimated diameter of GJ were the

Abstract number: P0589 Table 1: Average and standard deviation or median, minimum and maximum of adipokines, inflammatory and insulin resistance markers of patients who underwent liver transplantation according to metabolic syndrome

Characteristic	Adiponectin (mg/mL)	Resistin (ng/mL)	TNF-a(pg/mL)	MCP-1(pg/mL)	IL-6(pg/mL)	HOMA IR	FFA (mEq/L)

No	3.2 ± 1.2	5.3 ± 2.3	40.0 (16.7-495.9)	260.9 ± 208.5	18.2 (2.0-305.2)	1.6 ± 0.8	0.5 ± 0.3

*$p < 0.05$; **$p < 0.01$.

variables collected. At each following session weight, BMI and estimated GJ diameter were taken. Complications during treatment were also collected. Data were analyzed with descriptive statistics, student's t test and Spearman correlation.

Results: Of the 215 patients, 82.8% were women and 17.2% were men. Average time between bariatric surgery and the first APC was 97.42 months (±41.64. Range: 25–175) and average weight regained in this interval was 20.25kg (±9,95. Range: 3-63). The mean diameter of the anastomosis was 24.81mm (±5,34. Range: 16-40) and the average number of APC sessions were 1.36 times (±0.52. Range: 1-3). The average reduction of anastomotic diameter was 13.52mm (±6,19. Range: 4-34) and the final average diameter was 11,3mm (±3,32. Range: 5-28). The average weight loss between the first and last APC was 13,77kg (±6,99. Range: -4,55-35,62) and the average decrease of BMI was 4,66kg/m^2 (±2,55. Range: -1,69-11,07). 69 patients (32,1%) did not achieve the target GJ diameter and 01 patient (0.5%) did not lose weight even with the desired GJ diameter. From the 27 subjects followed up to 6 months no regain weight was noted. Of the 215 patients APC, 35 (16.27%) required dilatation balloon due to symptomatic stenosis at least once. No further complications were reported.

Conclusion: Argon Plasma Coagulation (APC) has been shown to be an effective and safe endoscopic technique for the reduction of gastro enteric anastomosis in patients undergoing bariatric surgery who have regained weight with dilation of the anastomosis.

Contact E-mail Address: ricfittipaldi@hotmail.com

Introduction: Endoscopic methods, especially the intragastric balloon (IGB), have been shown to be effective for the treatment of excess weight.

Aims & Methods

Objective: To assess the efficacy and complications of excess weight treatment with an IGB in patients seen at the Endogastro Med Service clinic and Sander clinic.

Methods: A total of 2727 patients were analyzed. A liquid-filled IGB with a volume of 600 to 700 ml was used. The patients had a minimum initial body mass index (BMI) of 27 kg/m2 and were followed up by a multidisciplinary team consisting of a nutritionist, a doctor and a psychologist. For statistical analysis, the patients were divided into groups according to sex and degree of excess weight (overweight and grade I, II and III obesity). Data were analyzed using descriptive statistical methods, the Student t-test, and analysis of variance followed by the Tukey post-test. The level of significance was set at $p < 0.05$.

Results: 188 patients were excluded from the analysis: 114 (4.18%) due to early IGB removal, 27 (0.99%) due to absence of weight loss or weight gain, 9 (0.33%) due to incomplete data. The incidence of contamination of the balloon liquid filling was 0.22% (n = 6) and the incidence of leakage was 0.55% (n = 15); pregnancy was 0.33% (n = 9); Wernick Korsakoff syndrome due to excessive vomiting was 0.03% (n = 1), pancreatitis, early removal due to intake non steroidal anti inflammatory drugs necessity, gastric perforation and upper digestive bleeding was 0.03% each (n = 1). 0.11% (n = 3) removed balloons were from other teams' patients. Of the 2539 remaining patients, 1908 were women and 631 were men. Mean age was 37.56 years. The patients showed a significant weight loss, with a significantly lower final BMI (mean: 28.91 ± 7,83 kg/m2; range: 18.98-58) than the initial BMI (mean: 36.23 ± 5.70 kg/m2; range: 27-74.74) ($p < 0.0001$). Mean BMI reduction was 7.38 ± 3.99 kg/m2 (range: 0.25-29.79). Mean percent weight loss was 20.09 ± 7.61% and mean percent excess weight loss (EWL) was 74.23 ± 36.71% (range 3.99-336.14). The treatment success rate (%EWL > 25) was 94,7%. Percent EWL was higher in the overweight group (147%EWL), followed by obesities grades I (82.91%), II (62.12%) and III (51.44%) sequentially ($p < 0.0001$). Percent EWL was also higher in women (76.31%EWL) than in men (68.08%EWL) ($p < 0.0001$).

Conclusion: Endoscopic treatment of excess weight with an IGB has been established as an excellent therapeutic option for patients of both genders with overweight or different degrees of obesity.

P0588 A NEW APPROACH IN THE TREATMENT OF WEIGHT REGAIN AFTER BARIATRIC SURGERY: THE ARGON PLASMA COAGULATION OF THE ANASTOMOSIS

R. J. Fittipaldi-Fernandez[1], **C. F. Diestel**[2], B. Sander[3], A. F. Teixeira[4], E. Usuy[5]
[1]*Digestive Endoscopy, Endogastro Med Service,* [2]*Nutrition Division, Rio de Janeiro State University, Rio de Janeiro,* [3]*Digestive Endoscopy, Sander Clinic, Belo Horizonte,* [4]*Digestive Endoscopy, Gastros Bahia, Feira de Santana,* [5]*Digestive Endoscopy, Usuy Clinic, Florianópolis, Brazil*

Contact E-mail Address: ricfittipaldi@hotmail.com

Introduction: The weight regain is a problem after bariatric surgery, it is multifactorial, and occurs, in part, by dilatation of the gastro-jejunal anastomosis, which causes a faster gastric emptying and increased food intake.

Aims & Methods

Objective: To evaluate the efficacy of endoscopic argon plasma coagulation (APC) of the anastomosis and of the gastric pouch aiming to reduce the diameter thereof.

Methods: We analyzed 40 patients. 35 of them underwent at least 03 sessions of APC. Two patients underwent only one session and three patients underwent only two sessions, due to an immediate reduction of the anastomosis to a diameter smaller than 12 mm after the first or the second session, which is the procedure target. The APC was held at the anastomosis and in gastric pouch. 80w power was used in the 1st session, and 70w power APC in the following, with an Argon flow of 2L/min. The time interval between sessions was eight weeks. The objective is to obtain an anastomosis with a diameter between 8-12 mm. The patient's weight had been evaluated in each APC session and six months after the latest APC session. Data were analyzed with descriptive statistics, student's t test and Spearman correlation.

Results: Of the 40 patients, 87.5 % were women (n = 35). The mean regained weight in relation to the maximum weight lost (Nadir) after bariatric surgery was 46.60 % (16.45-123.68). There was a significant reduction in body mass index (BMI) at the end of the analysis (30.78 ± 4.81 kg/m2) compared to the initial mean BMI (mean BMI = 36.34 ± 4.78 kg/m2) ($p < 0.0001$). The average loss of the regained weight was 71.44% (12.09-169.57). The average weight loss in Kg was 15.47 (4-40.5). The average diameter of the anastomosis in the beginning of the treatment was 36,18 mm (25-50mm) and at the end of the treatment 11.02 (6-12mm).

Conclusion: The APC has demonstrated great efficacy in the treatment of weight regain after bariatric surgery of gastric bypass in Roux-Y.

Contact E-mail Address: evilela@medicina.ufmg.br

Introduction: Metabolic syndrome (MS) and obesity are widely prevalent among liver transplant (LTx) recipients. Although there is lot of data on the role of adipokines in these diseases, studies after LTx are scarce.

Aims & Methods

Aim: To investigate the concentrations of adipokines, inflammatory and insulin resistance markers among liver recipients according to MS and its components.

Methods: This was a cross-sectional study in which serum samples from 34 patients (55.9% male; average age 54.9 ± 13.9 years; average time of 7.7 ± 2.9 years after LTx) were evaluated for analysis of adiponectin, resistin, tumor necrosis factor-alpha (TNF-a), monocyte chemoattractant protein-1 (MCP-1), interleukin-6 (IL-6), C-protein reactive (CPR), HOMA-IR and free fatty acids (FFA) in 2012/2013. The dosages were uni and multivariate analyzed considering metabolic syndrome (using the Harmonizing the MS criteria) and its components.

Results: Half of the patients evaluated had MS (n = 17). Higher concentration of adiponectin was observed among liver recipients that had MS (6.7 ± 4.5 mg/mL versus 3.2 ± 1.2 mg/mL; $p < 0.01$). Low HDL and high waist: hip ratio were considered independent predictors of adiponectin concentrations. Lower amounts of resistin were observed in those patients with high blood pressure (4.5 ± 1.6 ng/mL versus 6.2 ± 2.3 ng/mL; $p < 0.01$) and higher, in those with abdominal obesity (5.5 ± 4.2 ng/mL versus 4.3 ± 1.6 ng/mL). Increased FFA

(0.8 ± 0.3 mEq/L *versus* 0.5 ± 0.3 mEq/L, $p < 0.05$) and HOMA-IR (4.9 ± 3.8 *versus* 1.6 ± 0.8) were observed in patients with MS. Independent risk factors were not identified for TNF-a, MCP-1, IL-6 and FFA.
Conclusion: MS and its components are related to increased FFA concentration and HOMA-IR. Adiponectin, resistin and inflammatory markers, such as TNF, IL-6, MCP-1 and CRP, were not good markers of metabolic syndrome in this sample of patients who underwent liver transplantation.

P0590 THE IMPACT OF VEGETARIAN AND VEGAN DIET ON THE INCIDENCE OF GASTROINTESTINAL SYMPTOMS

A. Budzynska[1], E. Nowakowska-Dulawa[1], M. Hartleb[1]
[1]*Dept. of Gastroenterology&Hepatology, Medical University of Silesia, Katowice, Poland*

Contact E-mail Address: budzynskaagnieszka@poczta.onet.pl

Introduction: More than a million of Polish citizens and about 420 millions of people worldwide use vegetarian diet.
Aims & Methods: To assess the impact of a vegetarian and vegan diet on the incidence of gastrointestinal symptoms.
Material: The study involved 1209 persons (73% from Poland and 27% from US), 702 (58%) used vegetarian diet, 365 (30%) vegan diet and 142 (12%) non-restrictive diet.
Methods: All participants replied to online questionnaire comprising 31 questions.
Results: People using exclusive diets were older than those without dietary restrictions (28.3 vs. 23.8 yrs, $p < 0.001$). American responders had higher BMI than Polish subjects (25.6 vs. 22.0 kg/m^2, $p < 0.001$), but vegetarian diet had reducing effect on body weight only in Polish population ($p < 0.001$). Participants from USA remained on vegetarian diet longer (81.5 vs. 63.4 months, $p = 0.001$) and their monthly diet-related supplementary expenses were higher (199.8 vs. 111.0 €, $p < 0.001$) than in Polish population. 57% of vegetarians and 66% of vegans introduced their diets for healthy motives. Vegetarians and vegans reported improvement (74% and 84%), deterioration (4% and 3%) or no change (22% and 13%) in prevalence of gastrointestinal symptoms ($p = 0.002$). In the respective groups the incidence of bloating and/or abdomen fullness decreased from 52% to 13% and from 60% to 12%, of heartburn, nausea and vomiting from 25 to 2% and from 32% to 4%, of constipation from 35% to 8% and from 44% to 4%, and taste alterations or anorexia from 11% in both groups to 2% and 3%, respectively. By contrast, after introduction of vegetarian or vegan diet the incidence of skin lesions increased from 2% to 16% and from 3% to 10%.
Conclusion: More than half of responders introduced vegetarian/vegan diet for healthy reasons and in the majority these diets reduced severity of gastrointestinal symptoms.

P0591 MOTIONS IN ICU: A PROSPECTIVE STUDY ON THE PREVALENCE OF DIARRHOEA IN A TERTIARY ICU

A. Elzubeir[1]
[1]*University Hospital Birmingham, Birmingham, United Kingdom*

Contact E-mail Address: amera.elzubeir@doctors.net.uk

Introduction: Diarrhoea is a frequently reported problem in Intensive Care Units (ICU). Little is known about diarrhoea prevalence and the role of different risk factors in ICU at Queen Elizabeth Hospital Birmingham (UHB) – a large tertiary centre with one of the largest single-floor ICUs in Europe.
Aims & Methods: To identify prevalence of diarrhoea in intensive care patients with a length of stay (LOS) greater than 24 hours receiving any type of enteral nutrition, in addition to determining its clinical impact i.e. on length of stay in ICU, timing of diarrhoea onset, and risk factors for diarrhoea focusing on its association with hypoalbuminemia.
A prosective study of 109 patients consecutively admitted into a mixed medical-surgical ITU during a 2-month period (October 2014- December 2014) were included into the study according to the following criteria:
1. Length of stay > 24 hours
2. No diagnosis or evidence of diarrhoea on admission
3. Absence of parenteral nutrition
4. No recent admission to ICU at UHB.

Diarrhoea was defined as 3 or more liquid stools per day, or that which warranted Clostridium Difficile Toxin to be sent for microbiological analysis (such patients were presumed to have had diarrhoea).
Results: A total of 109 patients were analysed. Diarrhoea was observed in 35 patients (32%). The median day of diarrhoea onset was on the ninth day, and 66% of those had diarrhoea for four days or more. The incidence of *C. Difficile* infection was 3%, this occurred in a patient who was previously known to have had *C. Difficile* infection on a previous admission. Those with diarrhoea had double the length of stay in ICU than there non-diarrhoea counterparts (44.7 vs 22.6 days), with just under a third (31%) of their stay ICU stay being with ongoing diarrhoea. Of those with diarrhoea 29% died on ICU compared to 16% of its non-diarrhoea counterparts.
If all those with acute or chronic liver disease were excluded- 100% of patients with an albumin level of less than or equal to 26 g/L had diarrhoea. Furthermore it was noted that diarrhoea occurred in all patients with an albumin level less than 30 g/L except for those with known acute or chronic liver disease, in fact one patient with chronic liver disease awaiting liver transplant had an albumin level as low as 14 without evidence of diarrhoea.
Conclusion:
Diarrhoea was common in our ICU, its prevalence (32%) being consistent with established literature. It was associated with significantly increased ICU LOS and mortality, although any single direction of causality still remains to be established. A low stool investigation yield and low prevalence of *C. difficile* suggests that other non-infective causes of diarrhoea need excluding. The results from this study conclude that there may indeed be a causal link between hypoalbuminemia and prevalence of diarrhoea in ICU, with hypoalbuminemia-related diarrhoea being significantly higher in patients with an albumin level of less than or equal to 26 g/L. It remains unexplained why those with acute or chronic liver disease are not as susceptible to diarrhoea despite low albumin levels. Further research is required to establish the prevalence and pathogenesis of diarrhoea on UK ICUs, in order to develop evidence-based management plans for reducing its incidence, and its clinical and financial impact.
Disclosure of Interest: None declared

P0592 SIGNIFICANT GASTROINTESTINAL PATHOLOGY AND THE INCIDENCE OF SUBSEQUENT ANEMIA IN YOUNG MALES PRESENTING WITH IRON DEFICIENCY WITHOUT ANEMIA

D. Carter[1], E. Bardan[1], B. Avidan[1]
[1]*Gastroenterology, Chaim Sheba Medical Center, Ramat Gan, Israel*

Contact E-mail Address: dr.dancarter@gmail.com

Introduction: The etiology of iron deficiency (ID) without anemia in young males is unclear, and there are no evidence-based recommendations for the required gastrointestinal (GI) evaluation
Aims & Methods: To examine the incidence of significant GI pathology and the development of anemia during the follow-up of young males presenting with ID, but without anemia.
All young males (18-30 years) who served in the Israel Defense Forces during the years 2005-2013 and had at least a single laboratory test indicative of ID without anemia were followed until the diagnosis of significant GI pathology or discharge from military service.
Results: The study population included 2061 young males (mean age 20.7 ± 1.8 years). During follow-up of 3150 person years, significant GI pathologies were diagnosed in 39 patients: inflammatory bowel disease in 25 (1.2%), celiac disease in 8 (0.4%) and peptic disease in 4 (0.1%). No cases of gastrointestinal related cancer were diagnosed. Iron deficiency anemia developed during follow-up in 203 (9.8%). Lower baseline hemoglobin levels, lower ferritin levels and younger age at diagnosis were more common among those who developed anemia. The development of anemia was a predisposing factor for diagnosis of GI pathology (RR = 3.60, 95%CI 1.34-8.32, $p = 0.012$)
Conclusion: Significant GI pathology is very uncommon in young males presenting with ID. Overt anemia developed in close to 10% of the study cohort. Therefore, we advise simple GI evaluation (celiac serology, CRP and urease breath test) as well as follow-up in this population.

P0593 PREBIOTIC EFFECT OF FODMAPS IN PATIENTS WITH CROHN'S DISEASE: A RANDOMISED CONTROLLED TRIAL

E. Halmos[1], C. Christophersen[2], A. Bird[2], S. Shepherd[1], J. Muir[1], P. Gibson[1]
[1]*Monash University, Melbourne,* [2]*CSIRO, Adelaide, Australia*

Contact E-mail Address: Peter.Gibson@monash.edu

Introduction: A low FODMAP (fermentable oligosaccharides, disaccharides, monosaccharides and polyols) diet is commonly used in patients with Crohn's disease and functional gut symptoms, however, its putative negative effects on microbiota[1] is concerning in a population at high risk of dysbiosis.
Aims & Methods: This study aimed to investigate the effects of altering FODMAP intake on markers of colonic health in patients with Crohn's disease. Nine patients with clinically quiescent Crohn's disease underwent evaluation of their habitual diet followed by randomisation to 21 days of provided diets containing low or typical amounts of FODMAPs ('Australian diet') and matched for other nutrients in a cross-over design with > 21-day washout. Five-day faecal samples were collected and pooled during each diet and analysed for calprotectin, pH, short-chain fatty acids (SCFA) and bacterial abundance. Gastrointestinal symptoms were recorded daily using 0-100mm visual analogue scale.
Results: Eight participants collected faeces and were adherent to the diets. FODMAP intake differed across the 3 diets with mean daily oligosaccharide and polyol content 1.8g on low FODMAP, 4.8g on habitual (lower than previous estimations of typical intake) and 9.7g on Australian diet. Calprotectin, SCFA, pH, and total bacterial abundance remained unaltered, but the Australian diet increased relative abundance of butyrate-producing *Clostridium* cluster XIVa by 7-fold and mucus-associated *Akkermansia muciniphila* by 10-fold compared to the other diets and reduced *Ruminococcus torques* compared to the low FODMAP diet (Table). These changes were similar to a similarly studied IBS/healthy cohort[1]. Symptoms were increased by the Australian diet (mean[95%CI] 24.8 [12.6-37]mm compared to low FODMAP 13.5 [5.9-21.1]mm and habitual diet 12.5 [8.7-16.3]mm; $P < 0.001$ repeated measures ANOVA).

Table: Relative abundance of faeces. Differences between provided diets are shown in bold and between habitual diet indicated with an asterisk ($P < 0.05$; Wilcoxon matched-pairs signed rank test)

Bacteria	Australian diet	Low FODMAP	P-value	Habitual diet
Clostridium cluster IV	2.70 [0.63-4.78]	2.69 [0.93-4.46]	0.383	3.02 [0.77-5.26]
Faecalibacterium prausnitzii	0.47 [0.21-0.72]	0.66 [0.14-1.19]	0.250	0.81 [0.09-1.54]
Clostridium cluster XIVa	**19.2* [11.2-27.3]**	**2.81 [1.88-3.74]**	**0.008**	**2.90 [1.80-4.01]**
Roseburia	0.94 [0.21-1.68]	0.81 [0.18-1.44]	1.00	0.68 [0.23-1.13]
Akkermansia muciniphila	**0.15* [-0.05-0.35]**	**0.01 [-0.02-0.04]**	**0.016**	**0.01 [-0.01-0.03]**
Ruminococcus gnavus	1.17 [-0.25-2.59]	1.39 [-0.38-3.17]	0.461	2.26 [-1.51-6.03]
Ruminococcus torques	**0.10 [-0.04-0.24]**	**0.16 [-0.03-0.34]**	**0.039**	0.15 [-0.05-0.35]

Conclusion: The increase in FODMAPs on the Australian diet induced a prebiotic effect in patients with Crohn's disease, but increased symptoms. No 'anti-prebiotic' effect was seen on a low FODMAP diet compared to the habitual diet, which was lower in FODMAPs than expected. The promotion of increased FODMAPs for gut health may be at the cost of inducing functional symptoms and caution should be taken in reducing FODMAP intake below an estimated typical diet.

P0594 CHANGES IN GASTRIC AND GALLBLADDER DYNAMICS AFTER A GLUTEN-CONTAINING VERSUS GLUTEN-FREE MEAL: AN ULTRASONOGRAPHIC STUDY

S. Massironi[1], **F. Branchi**[2], A. Baccarin[2], M. Fraquelli[1], D. Conte[2], M. T. Bardella[1], L. Elli[3]
[1]*Gastroenterology and Endoscopy Unit, Fondazione IRCCS Ca' Granda - Ospedale Maggiore Policlinico,* [2]*Department of Pathophysiology and Transplantation, Università degli Studi di Milano,* [3]*Gastroenterology and Endoscopy Unit, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milano, Italy*

Contact E-mail Address: federica.branchi@gmail.com
Introduction: Gluten ingestion has been reported to be involved in a broad spectrum of gastrointestinal symptoms even in absence of a detectable immunologic response. However, data concerning the pathophysiological effects of gluten on the upper gastrointestinal tract are limited.
Aims & Methods: Aim of the study was to assess the effect of gluten ingestion on gastric emptying or gallbladder contraction and relaxation.
Between June and October 2014, 10 healthy subjects underwent ultrasound (Philips iU22, Bothell, WA, USA) evaluation of gastric emptying dynamics and gallbladder contraction at base line and at 30 minutes intervals after a standard solid meal (250 kcal, 70% carbohydrates), until the antral area returned to the basal value. The evaluation was performed in all subjects both after a gluten-containing and a gluten-free meal.
Results: Overall, the pattern of gastric emptying was similar after both types of meal, but differed in terms of postprandial filling peak, which was significantly wider (median area 5.1, range 3.7-7.9 vs 3.7, range 2-6.3 cm^2, $p = 0.006$) after the gluten-containing than the gluten-free meal. Gastric emptying time was longer after the gluten-containing meal (median 225 min, range 90-360 vs 180 min, range 60-230, $p = 0.2$) although this finding did not reach statistical significance. The pattern of gallbladder contraction was different after the gluten-free meal ($p < 0.05$), with higher gallbladder volumes observed in the late refilling phases.
Conclusion: The present data support the hypothesis of a relevant effect of gluten intake on both gastric and gallbladder motility. Although the underlying pathophysiological mechanism is still unknown, these results could account for some of the gluten related symptoms.

P0595 CYSTIC FIBROSIS CHILDREN WITHOUT GASTROOESOPHAGEAL REFLUX DISEASE HAVE FUNCTIONAL IMPAIRMENT OF OESOPHAGEAL MUCOSA AS DETERMINED BY COMBINED OESOPHAGEAL IMPEDANCE-PH MONITORING

J. Brecelj[1], R. Orel[1]
[1]*Department of Pediatric Gastroenterology, Hepatology and Nutrition, University Children's Hospital, Ljubljana, Slovenia*

Contact E-mail Address: jernej.brecelj@gmail.com
Introduction: CF patients are prone to gastrooesophageal reflux disease (GORD). Main pathogenetic mechanism is stronger gastrooesopgaheal reflux during transient lower oesophageal sphincter relaxations due to a larger pressure difference between abdominal and thoracic cavity. It is not clear if there are additional pathogenetic mechanisms apart from gastrooesophageal reflux affecting oesophageal mucosa.
Aims & Methods: The aim of this study was to compare functional parameters measured by combined oesophageal impedance-pH (MII-pH) monitoring in CF patients without GORD with a group of non-CF children without GORD.
The study was retrospective re-analysis of stored MII-pH recordings. In the study group were included children with CF who underwent combined oesophageal impedance-pH (MII-pH) monitoring due to the signs of GORD but had a normal investigation result. As the control group we included children who underwent MII-pH due to extraintestinal symptoms of GORD but who had a normal MII-pH, too. We compared standard MII-pH parameters (No. of acid, weakly acid and non-acid refluxes, total acid exposure index, DeMeester score) and recently proposed additional parameter of epithelial integrity called baseline impedance. Groups were compared with nonparametric Mann-Whitney U test was used (small sample, not-normal data distribution).
Results: We identified 13 children with CF (1-18 y, median age 10 y, 5 males) and 17 children without oesophageal disease (1-15y, median age 8 years, 6 males) who underwent MII-pH (Ohmega measurement system, MMS, Netherlands) between 2009 and 2014 and re-analysed recordings using same analysis strategy. There were no differences between the groups regarding age ($p = 0.645$), weight ($p = 0.965$), height ($p = 0.908$), and body mass index ($p = 0.447$). According to the inclusion criteria, impedance and pH parameters were normal and equally distributed in both groups (No. of acid refluxes ($p = 0.057$), non-acid refluxes ($p = 0.085$), total acid exposure index ($p = 0.530$), DeMeester score ($p = 0.722$)), except from weakly acid refluxes ($p = 0.011$) which were more prevalent in the cystic fibrosis group. The baseline impedance between upper two (Z1; $p = 0.023$) and lower two (Z6; $p = 0.006$) electrodes were significantly lower in CF group.
Conclusion: Despite not having GORD and having the same standard MII-pH parameters except weakly acid refluxes, in the group of children with CF and without GORD we measured lower baseline impedance in Z1 and Z6. This indicates either greater importance of weakly acid refluxes than previously thought or an additional, probably local factor influencing membrane integrity which is reflected in the baseline impedance. The exact pathogenetic mechanism and the importance of this finding have yet to be determined.

P0596 *HELICOBACTER PYLORI* RESISTANCE TO ANTIBIOTICS IN CHILDREN

R. Auzbikiene[1], **J. Zalyte**[1], J. Kirsliene[1], V. Urbonas[2]
[1]*Children's Hospital, Affiliate of Vilnius University Hospital Santariskiu Klinikos,* [2]*Children's Hospital, Affiliate of Vilnius University Hospital Santariskiu Klinikos, Vilnius, Lithuania, Clinic of Childrens' diseases of Vilnius University Faculty of Medicine, Vilnius, Lithuania*

Contact E-mail Address: renata.jakubkaite@gmail.com
Introduction: Increased *H. pylori* resistance to antibiotics is observed in many countries, especially in children. The amount of antibiotic consumption influences their resistance to microbes (1). Clarithromycin consumption in Lithuania from 2009 to 2014 has increased from 1,375 to 1,514 (the average daily therapeutic dosage/1000 citizens/per day).
Aims & Methods: To evaluate *H. pylori* primary resistance to antibiotics in children and to compare this data with previous results. *H. pylori* susceptibility to antibiotics were tested in children to whom *H. pylori* eradication has not been applied before. From 2013 until 2015 March at tertiary Vilnius University Children's Hospital, Lithuania upper gastrointestinal tract endoscopy with antrum biopsies were performed in children with abdominal pain, dyspepsia symptoms or anemia. Biopsies from 137 children (80 girls, 57 boys) with positive urease test were sent for *H. pylori* micriobiological investigation. Samples were grown microaerobically at 37°C on horse agar. The E-tests were performed for amoxicillin (Amo) (MIC $\geq$0.125 mg/l), clarithromycin (Cla) (MIC $\geq$0.5 mg/l), metronidazole (Met) (MIC $\geq$8 mg/l), levofloxacin (Lev) (MIC $\geq$1 mg/l).
Results: *H. pylori* grew in 82 (60.4%) of 137 microbiological samples. Resistance to at least one antibiotic was in 41 (50%) cases. Resistance to Cla in 33 (40.2%) cases, to Met - 18 (22%), to Lev 2 (2,4%). Combination of Cla and Met in 11 (13,4%) cases. No cases of Amo resistance have been detected. We compared this data with the previous study results performed in 2007-2008 in Lithuania (2). The

results revealed that resistance to Cla has increased from 16,8% to 40.2% ($p < 0.05$), to Met - from 20.7% to 22% ($p = 0.88$), resistance to both antibiotics from 4,2% to 13,4% ($p = 0.089$).
Conclusion: 1. From 2007-2008 to 2013-2015 *H. pylori* resistance to Cla has increased 2,4 times and to Met increase was statistically not significant. Resistance to Lev was observed in isolated cases.
2. The increased resistance to Cla could be associated with increased consumption of Cla in the country.

P0597 PECULIARITIES OF IRON DEFICIENCY ANEMIA ASSOCIATED WITH HELICOBACTER PYLORI INFECTION IN CHILDREN

M. Gurova[1], V. Novikova[2]
[1]*Department of Pediatrics, Belgorod State National Research University, Belgorod,* [2]*Department of Pediatrics, Federal Centre of the Head, Blood and Endocrinology named after V.A. Almazov, Saint-Petersburg, Russian Federation*

Contact E-mail Address: itely@mail.ru

Introduction: Iron deficiency anemia (IDA) is the most common nutritional disorder in children, but little information is available about peculiarities of course of the IDA and approaches in treatment in children with *Helicobacter pylori* (Hp) infection.
Aims & Methods: This study is aimed at assessing the role of *Helicobacter pylori* infection in children with iron deficiency anemia and effectiveness of the eradication of Hp in treatment of IDA.
For this purpose were examined 67 children with IDA aged 11-15 years, separated into 2 groups: 22 children Hp (+) (1^{st} group) and 45 Hp (-) children (2^{nd} group). Diagnosis of IDA was based on follow parameters: level of Hb, RBC, MCV, RDW, serum iron and ferritin level. Presence of Hp was confirmed by rapid urease test and/or gastric biopsy. As eradication therapy patients received 10 days of triple therapy (proton pump inhibitor plus amoxicillin and nifuratel in age dependent dosages).
Results: Hp was found in every third children with IDA. Initial ferritin and Hb level was lower in children with Hp infection (9.4 ± 0.1 g/dl vs 10.6 ± 0.47 g/dl, $P < 0.001$; 87.4 ± 10.56ng/ml vs 118.12 ± 16.38 ng/ml, $P < 0.001$). In this group IDA had refractory course of the disease and not respond on the basis treatment of IDA compare with children of the 2^{nd} group. The level of Hb in 1 month after using of iron supplementation wasn't changed compare with the 2^{nd} group (increase in Hb > 4 g%). Successful eradication was received in 81.8% children with Hp infection. In 1 month after eradication and basis therapy the mean Hb level was increased more than 4 g/% in 52.9% children, more than 2 g/% in 29.4%, the rest – less than 2 g/%.
Conclusion: *H. pylori* infection was found in 32.8 % children with IDA. In this group of children anemia characterized by refractory course of disease, lower level of Hb and ferritin compared to children without Hp infection. After successful eradication of *H. pylori* infection in children with IDA significantly increase the level of Hb.

P0598 MUCOSAL MORPHOMETRY AND INFLAMMATION OF DUODENAL BULB BIOPSIES IN COELIAC DISEASE

A. Popp[1,2], J. Taavela[1], M.-L. Lähdeaho[1], P. Hiltunen[1], T. Ruska[1], I. Anca[2], M. Mäki[1], K. Kurppa[1]

Contact E-mail Address: Alina.Popp@uta.fi

Introduction: Recent coeliac disease guidelines recommend including duodenal bulb specimens in the diagnostic evaluation. However, previous studies exploring the value of bulb in diagnostics have shown inconsistent results. Further, clinical experience suggest that bulb might be more difficult to interpret than distal duodenum due to inferior specimens and differences in the mucosal morphology. We addressed these issues in a prospective pediatric cohort with our validated histological methods.
Aims & Methods: 133 consecutive children with positive serum transglutaminase 2 (TG2) and/or endomysial antibodies were evaluated in clinical centers in Finland and Romania. Upon gastrointestinal endoscopy 6-8 biopsies were taken from anatomic duodenal bulb and distal duodenum irrespective of the macroscopic findings. Special attention was devoted to representative biopsies and correct orientation and cutting of the paraffin-embedded specimens. Quantitative villous height: crypt depth (VH:CrD) ratio was used for the morphometric measurements (normal ratio > 2.0). Further, density of mucosal CD3+ and $\gamma\delta$+ intraepithelial lymphocytes (IEL) and presence of TG2 targeted IgA-deposits were evaluated in frozen mucosal samples.
Results: Altogether 118 (88%) out of the 115 children had diagnostic mucosal lesion in at least one biopsy site (median age 7 years, range 1.6 -17.9, 67% girls). Although several samples were taken, in 45% of the patients the bulb specimens were of inadequate quality for accurate morphometric measurements; altogether reliable evaluation was possible from both bulb and duodenum biopsies in only 75 (63%) patients. Four patients (3.4%) showed mucosal damage only in bulb specimens and 3 (2.5%) only in the distal duodenal specimens. There was no significant difference in the mean VH:CrD ratio between the bulb and duodenum (0.4 vs 0.6, $p = 0.281$) but the crypts were deeper in bulb ($p = 0.020$). Also, no differences were observed in the mean density of either CD3 + IELs (76.5 vs 70 cells/mm, $p = 0.678$) or $\gamma\delta$+ IELs (23.6 vs 23.3 cells/mm, $p = 0.339$) between the bulb and duodenum. All coeliac disease patients showed TG2 targeted mucosal IgA deposits in both bulb and distal duodenum samples.
Conclusion: We confirmed previous observations that coeliac patients may have lesions only in the duodenal bulb. However, diagnosis based solely on bulb histology should be used with caution because the samples are often more difficult to interpret and may also differ morphologically from the distal duodenum. Markers of mucosal inflammation and coeliac disease-specific IgA deposits are valuable in both biopsy sites. $p = 0.020$). Also, no differences were observed in the mean density of either CD3 + IELs (76.5 vs 70 cells/mm, $p = 0.678$) or $\gamma\delta$+ IELs (23.6 vs 23.3 cells/mm, $p = 0.339$) between the bulb and duodenum. All coeliac disease patients showed TG2 targeted mucosal IgA deposits in both bulb and distal duodenum samples.

Introduction: In 2011, the European Society for Pediatric Gastroenterology, Hepatology, and Nutrition (ESPGHAN) has released its updated guidelines on coeliac disease (CD) diagnosis. According to these new guidelines, symptomatic children with anti-transglutaminase (anti-tTG) antibody levels ≥ 10 times upper limit normal (ULN) coul avoid duodenal biopsies if the HLA test and serum anti-endomysial antibodies (EMA) are positive. So far, both symptomatic patients with anti-tTG2 titer < 10 times ULN and those asymptomatic should undergo upper endoscopy with "multiple" duodenal biopsies to confirm a suspected CD.
Aims & Methods: The aim of the study was to calculate the positive predictive value (PPV) of anti-tTG levels ≥ 10 ULN in discovering a severe mucosal damage in asymptomatic children, identified by salivary screening. From March 2007 to February 2014, 11698 children (age range: 5-10-years) were enrolled in Rome and Civitavecchia. A total of 8871 salivary samples were collected and tested for anti-tTG, using a fluid-phase radioimmunoassay (RIA). Salivary anti-tTG-positive children were analyzed for serum antibodies (EMA and enzyme-linked immunosorbent assay (ELISA) anti-tTG). Positive children underwent upper gastrointestinal endoscopy; histological lesions were graded according to the Marsh-Oberhuber (MO) criteria.
Results: Among the 8871 screened children, 68 (0.76%) had positive anti-tTG antibodies both in serum and salivary samples. Among them, 57 (83.82%) had anti-tTG titers ≥ 10 times ULN; of these, 56 (98.24%) showed severe lesion degree (3a, 3b, 3c MO) and 1 (1.75%) received a diagnosis of potential CD (MO1). On the contrary, 11 out of 68 (16.17%) children had anti-tTG titers < 10 times ULN; 10 (90.90%) of them had severe mucosal damage (3a,3b, 3c MO) and 1 (9.09%) was classified as potential CD patient (MO 0).These results suggest that anti-tTG ≥ 10 times ULN are remarkably reliable of severe histological damage in asymptomatic children (PPV = 98.2% CI: 90.0% > 100%)
Conclusion: If proved in larger and multi center studies, our results suggest the possibility to apply the "biopsy-sparing" protocol also in asymptomatic patients with anti-tTG titer ≥ 10 times ULN.

Contact E-mail Address: doronyab@gmail.com

Introduction: Syndecan-1 (SDC1) is essential for maintaining normal epithelial barrier. Shedding of SDC1 ectodomain, reflected by serum soluble syndecan-1(*S*SDC1) levels, is highly regulated by inflammation. Increased intestinal

permeability plays a central role in celiac disease (CD). The association between *S*SDC1 level and mucosal damage in CD has not been evaluated.
Aims & Methods: Our objectives were to compare serum levels of *S*SDC1 in children with CD to healthy controls and to determine its relationship with histological grading classified by modified Marsh criteria.
Cross-sectional, pilot study, in which serum concentrations of *S*SDC1 were analyzed by ELISA in a cohort of 50 consecutive untreated children with CD, 11 children with latent CD and 11 healthy controls. CD was diagnosed based on positive celiac serology and classical small intestinal histology. *S*SDC1 levels at the day of biopsy were compared with the intestinal damage of the biopsy.
Results: *S*SDC1 levels were significantly higher in pediatric CD, compared to healthy controls (107.2 ± 150 vs. 44.5 ± 21.1 ng/ml, respectively, $p < 0.01$). *S*SDC1 levels were significantly higher in patients with Marsh 3c lesion compared to patients with latent celiac (153.1 ± 186.9 vs. 48.9 ± 34.6 ng/ml, respectively, $p < 0.05$). *S*SDC1 concentrations correlated significantly with mucosal injury defined by Marsh ($r = 0.28$, $p = 0.027$).
Conclusion: This is the first study demonstrating elevated levels of serum *S*SDC1 in patients with celiac disease compare to healthy controls. Our results suggest that *S*SDC1 is a potentially novel marker of intestinal mucosal damage in patients with CD. Its applicability as a diagnostic and a surrogate biomarker in CD remains to be determined.

Contact E-mail Address: Laila.Tata@nottingham.ac.uk
Introduction: Our aim was to quantify the risk of clinically diagnosed coeliac disease (CD) in children of mothers with coeliac disease to assess this burden in the general population of the United Kingdom.
Aims & Methods: We used a large population-based general practice database (The Health Improvement Network) to obtain data pertaining to all children born between 1990 and 2010 registered with general practices whose records were linked to their mothers' medical records. We identified all mothers and children diagnosed with CD and assessed the maternal-child CD association using logistic regression with generalised estimating equation modelling, adjusting for potential confounders.
Results: There were 708 children diagnosed with CD in the study population of 798,343 children up to 16 years of age. Among children with CD, 10.3% had mothers who also had CD whereas maternal CD diagnoses were 0.3% among the children without CD. This equated to offspring CD risks of 3.2% versus 0.1% among mothers with CD versus those without. The odds ratio for offspring CD associated with maternal CD was 36.7, 95% confidence interval 28.2-47.7 after adjusting for child sex, socioeconomic deprivation, year of birth, caesarean delivery, and maternal age.
Conclusion: A child born to a woman with CD is almost 40 times more likely to be diagnosed with CD than if the mother does not have CD. In absolute terms, 3.1% more children will receive a diagnosis, considerably raised from the average population risk. This could be due to genetics, shared environmental risk factors within families or ascertainment bias.

Contact E-mail Address: giovanni.marasco4@unibo.it
Introduction: The inflammatory response in celiac disease (CD) is mediated by mechanisms of adaptive immunity and of innate immunity. The activation of the innate immunity takes place by the binding of toll-like receptor (TLR). The inflammatory response is generated only with the initial activation of innate immunity. In CD patients an increased expression of TLR was also found. The intestinal microbiota regulates the intestinal immune system homeostasis through TLR. Recent researches have shown an altered gut microbiota in CD patients compared with healthy controls (HC). On these basis a role of gut microbiota in the pathogenesis of CD and of its symptoms has been hypothesized.
Aims & Methods: To evaluate the composition of the microbiota on duodenal biopsy of CD patients, to compare CD patient faecal microbiota with that of HC and to correlate clinical data with bacterial levels in CD patients.
Subjects were enrolled as outpatients from Pediatric Gastroenterology Unit referring suspected symptoms for CD. At enrolment a sampling of stool and, in patients with suspected CD, of a fragment of the duodenal mucosa during upper endoscopy was performed. Microbiota evaluation was performed by HTF-Microbi.Array [1-2].
Results: Thirty-two (32) subjects enrolled: 21 CD patients and 11 HC. HTF-Microbi.Array of duodenal biopsy specimen revealed a total dominance of Enterobacteriaceae in CD patient biopsies (in 50% of samples belonging to the genus Proteus) and a subdominance of Bacteroidetes and/or Streptococcus. In stools there was a significantly greater abundance of the cluster of Lactobacillaceae ($p < 0.01$) and Streptococcaceae ($p < 0.02$) and a lower abundance of Bacteroides-Prevotella cluster ($p < 0.01$), Akkermansia ($p < 0.01$) and Staphylococcaceae ($p < 0.01$) in CD patients compared to HC. Correlating clinical data with faecal bacterial abundance, an inverse correlation was found between Clostridium cluster XIVa and the presence of diarrhea ($p = 0.04$) and the presence of growth failure ($p < 0.02$). Diarrhea was directly associated with Clostridium cluster IX ($p < 0.01$), Bacillaceae ($p = 0.03$) and of Fusobacterium ($p < 0.05$). The presence of abdominal pain was associated with the abundance of Bacillaceae ($p < 0.01$) and of Enterobacteriaceae ($p = 0.01$). Furthermore, the abundance of Enterobacteriaceae was associated with IgA anti-tTG antibody levels($p < 0.05$).
Conclusion: The intestinal microbiota of CD patients is different from that of HC. In CD there is a particular abundance of potentially pathogenic species such as Enterobacteriaceae and Streptococcaceae. A depletion of Akkermansia, which has a mucosal barrier-protective function and a decrease of Bacteroides-Prevotella, which has an immunomodulatory function, has been demonstrated in CD patients. Moreover, the presence of gastrointestinal symptoms was associated with a decrease of 'healthy' species and an increase in potentially harmful species.

Contact E-mail Address: orogyor@gmail.com
Introduction: Celiac disease (CD) remains underestimated in many regions of Europe. Rapid point-of-care tests (POCT) have been previously described to enable detection of new cases at primary care or community-based screening studies.
Aims & Methods: It was our aim to evaluate the prevalence of CD in pre-school children in Vas County in SW Hungary.
1062 pre-school children (age 6-7 years, 462 girls) from 25 kindergartens in Vas County were invited to participate in CD screening using commercially available rapid finger prick test for detection of CD specific antibodies in capillary blood. 62 parents refused testing. All children tested positive and all IgA deficient children were referred for further confirmatory tests to Vas county teaching hospital. Tissue transglutaminase antibodies ELISA based serological tests and total IgA determination was performed and all children also were offered intestinal biopsy to confirm CD.
This study was a part of LQ-CELIAC project partially EU financed by the Operational Programme of Cross-border Cooperation Slovenia-Hungary.
Results: Among 1000 tested children 19 (1.9%) were detected positive with rapid test and another 9 (0.9%) were IgA deficient. Among positive children 7 (43%) had unspecific gastrointestinal symptoms. They had not been tested for CD previously. The remaining 12 positive children were asymptomatic.
CD was confirmed serologically and histological in 16 children (1.6%). Serology was negative in two positive children, and in one histology was negative. This child was HLA DQ2 positive. All three will be further followed.
Conclusion: Rapid testing for CD in young children in Vas County in Hungary has detected unexpectedly high number of affected children, with figures similar to those from a previous study in Jasz-Nagkykun-Szolnok County in Hungary. To our surprise almost half of detected children were symptomatic, and could have been detected earlier.
Rapid testing for CD has shown to be a valuable tool for community-based screening even in young children. At the same time the awareness about CD must increase in order to detect symptomatic children before the onset of preventable complications of the disease.

Introduction: Coeliac disease and type-1 diabetes mellitus (T1D) are often associated but a causative relationship is not yet confirmed.
Aims & Methods: Aim of this study was a prospective intervention to investigate whether undetected coeliac disease can cause T1D diabetes mellitus. The prevalence of T1D was studied in 2014 in a county among schoolchildren (n = 21724) in five school year birth cohorts born between 1.6.1996 and 31.5.2001 using local school nurse registries and data from diabetes centres. The middle birth cohort born between 1.6.1998-31.5.1999 received screening for anti-transglutaminase and anti-endomysial antibodies in 2005, at the age of 6 years (BMJ 2007;335:1244-7), where 78% of the total population took part. Screen-detected coeliac disease cases were confirmed by small bowel biopsy, treated by a gluten-free diet and followed by regular serology monitoring at the local gastroenterology unit. The screened and not screened children used the same schools and were exposed to identical other environmental factors.
Results: None of the screen-detected & treated coeliac cases (n = 45) developed T1D. The prevalence of T1D was 2.69/1000 children (95% confidence intervals [CI] 1.92-3.46) in the not screened control birth cohorts comprising children 1&2 years older as well as 1&2 years younger than the screened cohort. The prevalence of T1D was 0.93/1000 children (95% CI 0.02-1.85) in the screened/treated cohort, odds ratio 0.35 (95% CI (0.13-0.96). Half of the T1D cases in the birth cohort where the screening took place actually did not participate in the screening due to lack of parental consent. Eighty-two percent of all paediatric T1D cases in the population appeared after the age of 6 years.
Conclusion: Early detection and treatment of coeliac disease is able to prevent a substantial fraction of paediatric-onset T1D cases.

Introduction: Microvillus inclusion disease (MVID) is a rare intestinal enteropathy with an onset within a few days to weeks after birth, resulting in persistent watery diarrhoea. Mutations in the myosin Vb (*MYO5B*) gene have been identified in the majority of MVID patients. However, the exact pathophysiology of MVID still remains unclear.
Aims & Methods: To address the specific role of MYO5B in the intestine we generated and analysed an intestine-specific conditional *Myo5b*-deficient deficient (*Myo5b*$^{fl/fl}$*;Vil-CreERT2*) mouse model. We analysed intestinal tissues and cultured organoids of *Myo5b*$^{fl/fl}$*;Vil-CreERT2* mice by electron microscopy (EM), immunofluorescence and immunohistochemical methods.
Results: *Myo5b*$^{fl/fl}$*;Vil-CreERT2* mice developed severe diarrhoea within 4 days after tamoxifen induction. Periodic Acid Schiff (PAS) and alkaline phosphatase (ALP) staining revealed subapical accumulation of intracellular vesicles in villus enterocytes. Analysis by electron microscopy (EM) showed an almost complete absence of apical microvilli and the appearance of microvillus inclusion bodies in induced *Myo5b*$^{fl/fl}$*;Vil-CreERT2* intestines. In addition, we showed that MYO5B is involved in not only apical, but also basolateral recycling of proteins. The analysis of the intestine during the early onset of the disease revealed that subapical accumulation of secretory granules precedes entrapment of recycling endosomes, indicating involvement of MYO5B in early differentiation of epithelial cells.
Conclusion: Our mouse model completely recapitulates the intestinal phenotype of human MVID, including severe diarrhoea, loss of microvilli, microvillus inclusions and accumulation of secretory granules. Our data indicate a novel mechanism for MYO5B in regulating polarity of epithelial cells, which might explain the secretory component of diarrhoea in MVID due to disturbed barrier function. We conclude that loss of MYO5B disturbs both apical and basolateral recycling of proteins and causes MVID.

P0607 SYSTEMATIC REVIEW ON FEEDING DISORDERS IN CHILDREN DIAGNOSED WITH AUTISM

G. Veereman[1], N. Fairon[1], K. Holdt Henningsen[1], N. Benahmed[1], W. Christiaens[1], M. Eyssen[1]
[1]*Belgian Health Care Knowledge Center, Brussels, Belgium*

Contact E-mail Address: gveereman@gmail.com
Introduction: Autism spectrum disorder (ASD) is a neurodevelopmental disorder diagnosed according to defined criteria set out in the DSM-5. Feeding disorders are a major concern of parents caring for children with ASD. Since recent evidence-based guidelines fail to address this issue we conducted a systematic review (SR) on the subject.
Aims & Methods: Medical databases (Medline Ovid and Pubmed, Psychinfo Ovid, Embase & Cochrane) were searched using Mesh terms and keywords referring to 'autism' and 'feeding disorders' with no time limits. All studies on children, with any study design, were included. We adhered to the PRISMA recommendations.
Results: Four SR and 17 primary studies reached our selection criteria. One SR confirmed the higher prevalence of eating disorders in ASD [1]. Two SRs described selective eating patterns [2, 3]. One meta-analysis was retrieved on treatment outcomes to improve feeding [4]. Additional primary studies were published from 1978 onwards. They reported on diagnosis (n = 1), feeding behaviour (n = 4), breastfeeding (n = 1), nutritional deficiencies (n = 5) and feeding programs (n = 6).
Conclusion: Despite their frequency, current guidelines fail to address feeding difficulties experienced by children with ASD. Recent SR focus on (behavioural) interventions to improve oral intake in autistic children. Studies on underlying physiological mechanisms, deglutative function, sensory or motor function of the upper gastrointestinal (GI) tract are lacking. Since autism is currently considered a neurodevelopmental disorder it may be advisable to explore GI function.

P0608 DIETARY MODIFICATIONS OF THE MATERNAL DIET AMONG BREASTFEEDING MOTHERS

M. Iacovou[1], G. Yelland[1], J. Barrett[1], P. Gibson[1], J. Muir[1]
[1]*Department of Gastroenterology, Monash University, Melbourne, Australia*

Contact E-mail Address: marina.iacovou@monash.edu
Introduction: Fussing and colicky infants are challenging to the breastfeeding mother and multiple actions are taken in attempt to improve infant behaviour. One apparently common technique is for mothers to adjust their own habitual diet. Changes instituted have stemmed from 'old-wives tales' and popular beliefs. A major concern of dietary change is that nutritional adequacy may be compromised. The frequency and types of manipulation used and the success of such adjustments are poorly documented.
Aims & Methods: To explore the dietary practices of breastfeeding mothers, to define the frequency of dietary change, reasons for such action, and to gauge whether they are at risk of nutritional inadequacy.
An on-line survey was developed using Qualtrics software application. Survey questions were designed to collect both quantitative and qualitative data. The survey was anonymous and volunteers were invited to participate through websites and social media such as Facebook and Twitter.
Results: Of the 1203 respondents, 1,046 (87%) completed the survey. 780 (75%) modified their usual diet while breastfeeding. The most common reasons were 'baby was unsettled' (33%), 'baby had lots of wind/gas' (29%), 'baby wasn't sleeping well' (18%), 'baby had reflux' (18%) and 'baby had colic' (11%). The most common dietary modifications were minimisation of the intake of alcohol (79%), coffee (43%), cow's milk (24%), milk chocolate (21%), and cabbage, chilli and onion (each 20%). Information was sourced from the internet (46%), maternal and child health nurses (44%), the Australian Breastfeeding Association (37%), and books and mother's groups (each 21%). Sourcing information from paediatricians was less common (9%) and 89% of respondents who had modified their diet had never seen a dietitian. 25% of respondents who had removed dairy did not replace it with other calcium-rich foods nor did they take a calcium supplement. 44% that modified their diet did not take a suggested breastfeeding multi-vitamin for when the nutrition guidelines are difficult to meet.
Conclusion: Dietary modification among breastfeeding mothers is common practice (3 out of four) and a variety of food and drink sources are avoided placing them at risk of deficiencies such as calcium. This together with the fact that the majority of information is sourced from the internet and not experts in nutrition suggest this group is at risk of nutritional inadequacies in general.

Introduction: Infantile colic is the most common complaint for which parents seek professional advice during the first months of life, and occurs in both breastfed and formula-fed infants. Mothers are often advised to avoid certain 'gas-forming' foods (e.g., onions or legumes) although the scientific evidence supporting this advice is poor. A recent placebo-controlled study of probiotics showed a mean improvement of 49 minutes over one month, in symptoms of infantile colic (cry-fuss) in both arms. Anecdotal reports of relief of infantile colic when the mother reduced dietary FODMAPs (Fermentable Oligo- Di- and Mono-saccharides And Polyols) have been received by our group. The low FODMAP diet is known to reduce bloating and abdominal pain in adults with irritable bowel syndrome. This prompted our assessment of the concept that maternal low FODMAP diet might be efficacious for infantile colic.
Aims & Methods: To perform a proof-of-concept study of the effect of a low FODMAP diet in breastfeeding mothers, on the behaviour of their infants with colic.
An open-label study of infants with colic, as defined by the Wessel Criteria, was undertaken. Mothers, who were exclusively breastfeeding, were supplied with a low FODMAP diet for seven days. Using the validated Barr diary, the behavioural patterns of infants were captured for seven days at baseline and daily during the dietary intervention. The mothers were followed for 14 days.
Results: 18 infants, aged 2-16 weeks (mean 8 weeks), were studied. The mothers were aged 29-40 y (mean 34 y), 85% of mothers with the first child. The duration of crying times reduced from mean (SD) of 142 (70) to 90 (60) min/d representing a reduction of 35% ($p = 0.0001$; paired t-test). Crying episodes reduced from 12 (5) to 8 (4) per day, a reduction of 33 % ($p = 0.0018$) and crying-fussing time combined reduced from 232 (69) to 161 (56) min/d, a reduction of 31% or 71 mins ($p = 0.0006$). In the weeks following the intervention, 16 mothers continued on a low FODMAP diet.
Conclusion: Consuming a low FODMAP diet was associated with a reduction of infantile colic that was greater than the anticipated clinical significance of >25%, as deemed by previous colic studies. Since infantile colic does spontaneously improve with time, a controlled evaluation of the low FODMAP diet in mothers is needed and mechanisms by which such an effect might occur require investigation.

Introduction: Obesity and malnutrition are diseases with increasing incidence lately, they becoming important health problems. Multiple factors proved that these two impair growth, an important role being played by inflammation, as well as by the inadequate nutritional intake. Inflammation, anorexia and weight loss are all manifestations of the circulating TNF-alfa. On the other hand, the adipocytes secrete hormones, growth factors, prostaglandins, pro-inflammatory cytokines, among which, the tumor necrosis factor (TNF) -α that has a pro-inflammatory effect.
Aims & Methods: The aim of the current study was to establish the role of TNF alfa 308 G/A gene in the determination of nutritional diseases such as obesity and malnutrition in child, and to establish the correlations between the polymorphisms of the gene TNF alfa 308 and antropometric and laboratory parameters.
Methods: We assessed 290 hospitalized children regarding TNF alfa 308 A/G polymorphisms, anthropometric parameters (mid-upper arm circumference / MUAC and tricipital skin fold thickness/TST), which we correlated with the laboratory findings (proteins). The patients were divided according to their nutritional status into three groups: control group (I) 112 children with normal nutritional status, the group of malnourished children, 100 children (II) and the group of obese children (III) 78 children.
Results: We observed that the genotype GG and GA of the TNF alfa 308 gene was more frequent in the malnourished group [($p = 0.01$, OR 1.73, 95% CI (1.28-2.36)], while the genotype GG was more frequent in the obese group ($p = 0.01$, OR 2.21, 95% CI (1.37-4.40). The G allele is also more frequent in the malnutrition group ($p = 0.02$) BMI, MUAC and TST were significantly correlated with the genotypes GG and GA of the TNF alfa 308 gene ($p = 0.001$), in malnutrition group ($p = 0.01$). The same correlation was found for the low serum albumin levels. Serum TNF alfa was correlated with the TNF alfa 308 gene polymorphism in the case of the malnourished children group for genotypes GG ($p = 0.02$) and GA ($p = 0.001$), while serum IL 6 was correlated with TNF alfa 308 gene polymorphism in case of genotype GG ($p = 0.001$).
Conclusion: TNF alfa 308 is an important parameter of inflammation, correlated with nutritional disorders. Malnutrition is more frequently encountered in children who have the GG and GA genotype of the TNF alfa 308 gene, while GG genotype is correlated with obese group inclusively with the form of severe obesity.

Introduction: Telomerase Cajal body protein 1 (TCAB1) is a stable component of the telomerase holoenzyme that plays a major role in telomere synthesis. TCAB1 missense mutations have recently been shown to cause dyskeratosis congenita by the disruption of telomerase trafficking. Whether TCAB1 mutations are associated with liver cirrhosis formation is currently unknown and the hypothesis of the present study.
Aims & Methods: The TCAB1 gene was sequenced in 144 individuals (48 patients with hepatitis C-induced cirrhosis, 48 patients with alcohol-induced cirrhosis and 48 non-cirrhotic controls). In total, 3.744 DNA sequences were analysed and compared to the wildtype TCAB1 form in order to determine the incidence of mutations. Patients with nucleotide variants within the TCAB 1 gene were screened for demographic and clinical characteristics, such as progression of disease, overall survival or tumorigenesis.
Results: We detected 9 different nucleotide variants within the TCAB1 gene, including a newly identified c.663G > A p.V221V mutation in the group of hepatitis C-induced cirrhotics (allele frequency 0.010). The frequency of single nucleotide polymorphisms in African patients was significantly increased compared to Caucasian patients (p value <0.0001). Furthermore, the group of homozygote mutation carriers in the alcohol-induced cirrhosis group was found to significantly correlate with a more rapid progression of liver cirrhosis (p value 0.0139). Survival data of this group showed a significant correlation between the presence of homozygote TCAB1 nucleotide variants and liver failure (p value 0.0352).
Conclusion: Taken together, these data provide the first experimental evidence that TCAB1 gene mutations are present in a subset of liver cirrhosis patients. Furthermore, we were able to show that TCAB1 mutations lead to an accelerated cirrhosis formation in chronic liver disease and a decreased survival of affected patients with alcohol-induced liver cirrhosis. These data provide a potential starting point for the development of new therapeutic strategies for the treatment or prevention of liver cirrhosis.

Contact E-mail Address: matthias.lohr@ki.se
Introduction: For many tumors, therapy is sparse beyond the guidelines. More treatment relevant biomarkers are known for targeted therapy. DNA analysis with next generation sequencing (NGS) is becoming a routine. However, to analyse the vast amount of data and provide concrete, evidence-based treatment recommendations is a challenge.
Aims & Methods: To demonstrate the feasibility of personalised cancer medicine by applying NGS in a quality controlled set-up together with the newly developed evidence-based software tool TreatmentMAP (CE-marked).
Results: From Oct 2013 to April 2015, 51 patients were analysed with TreatmentMAP. In 4 cases, more than one tumor was investigated. NGS was performed (WXS = 33; panel/paired = 15, panel = 3). Sequencing could be performed in all but one patient (Whole Exome; bone metastasis). Sequencing quality was insufficient for analysis in 3 cases (paired panel), leaving 47 patients. The indication was: Pancreatic = 20; Colorectal = 10; Breast = 3; CUP = 2; NSCLC = 2; and 1 case each for Adenocarcinoma, Common Bile Duct, Endometrial, Glioblastoma, Liver, Lung, Leukemia, B-Cell Lymphoma, Mantle-Cell Lymphoma, Meningioma, Multiple Myeloma, Prostatic, Sigmoid, Uveal melanoma.
In 44/47 patients, drugable targets (response biomarkers) could be identified (range 0-8; median 3). In 28/47 patients (range 0-5; median 1) biomarkers indicated lack of efficacy (e.g. KRAS mutation in CRC). In 42/47 patients, biomarkers indicated increased toxicity (range 0-7; median 2), in 14/42 patients FDA-approved biomarkers for toxicity were detected (22 biomarkers).
Of the positive biomarkers, 32 biomarkers in 20 patients indicated drugs approved in the indication, 55 biomarkers in 29 patients indicated approved drugs, and 44 biomarkers in 28 patients indicated experimental drugs (preclinical and phase II - III). Six patients have already received drugs recommended by TreatmentMAP. In 9 patients, toxicity markers explained observed toxicity during previous treatment.
Conclusion: In 93 of the evaluable patients, at least one drugable target could be identified using this evidence-based software. In less than 50% of the patients, these were approved in the indication. In 89% of the cases, a biomarker indicating increased toxicity was detected, in 20% FDA-approved. In conclusion, application of personalised csancer medicine has to take into account that many drugs approved may not be available for the required indication.

P0613 METHYLATION OF NEUROG1 IN SERUM CAN COMPLEMENT THE FECAL IMMUNOCHEMICAL TEST FOR COLORECTAL CANCER SCREENING IN FAMILY-RISK INDIVIDUALS

L. De Chiara[1], O. Otero Estévez[1], **J. Cubiella**[2], V. Hernández[3], I. Castro[2], M. Páez de la Cadena[1], F. J. Rodríguez-Berrocal[1], V. S. Martínez-Zorzano[1]
[1]*Bioquímica, Genética e Inmunología, University of Vigo, Vigo,* [2]*Aparato Digestivo, Complexo Hospitalario Universitario de Ourense, Ourense,* [3]*Aparato Digestivo, Complexo Hospitalario Universitario de Vigo, Vigo, Spain*

Contact E-mail Address: ldechiara@uvigo.es
Introduction: *NEUROG1* (Neurogenin1) is frequently found methylated in colorectal cancer (CRC) and has been included as a criteria to classify tumors as CIMP (CpG island methylator phenotype)[1-2]. Individuals with first-degree relatives with CRC are at increased risk for developing advanced neoplasia [AN; CRC and advanced adenomas (AA)][3]. Therefore, new non- invasive screening methods for this population are still necessary.
Aims & Methods: To determine the diagnostic yield of *NEUROG1* methylation for the detection of AN in asymptomatic individuals with first-degree relatives with CRC. All individuals were recruited from "Complexo Hospitalario de Ourense" and underwent a colonoscopy, a fecal immunochemical test (FIT) and a blood extraction. Methylation of *NEUROG1* in serum samples was assessed using pyrosequencing in 33 individuals with no neoplasia, 36 AA and 8 CRC cases (44 AN). The promoter region analyzed included the 12 CpG sites reported by Herbst *et al.* (2011)[4] for CRC diagnosis.
Results: Mean methylation levels for each of the 12 CpG sites analyzed were increased in individuals with AN compared to no neoplasia, though no statistically significant differences were found. The area under the curve (AUC) for discriminating AN resulted between 0.467-0.621, with the highest AUCs corresponding to CpG site 7, 8 and 9. Based on this optimal combination the AUC was 0.619 (95% CI 0.491-0.747). Given the importance of a high specificity for a screening test, a sensitivity of 27.3% was reached with a 93.9% specificity for detecting AN.
In relation to FIT (cut-off $\geq$100 ng/mL), all CRC cases were detected and 33.3% of the AA cases. Among FIT negative individuals, CpG sites 7-9 from *NEUROG1* showed an AUC of 0.620 (95% CI 0.474-0.766) for the diagnosis of AA. One-fourth (25%) of the AA not diagnosed by FIT were detected, with a 93.9% specificity (cut-off $\geq$10.6% methylation).
Conclusion: Methylation analysis of *NEUROG1* by pyrosequencing revealed that its diagnostic performance for AN may be maximized including only 3 of the 12 CpG sites (CpG sites 7-9). Based on our study, methylation of *NEUROG1* in serum seems valuable to complement FIT for the detection of AA in CRC screening.

P0614 A NOVEL SAMPLING METHOD FOR ANALYSIS OF THE HUMAN GUT MICROBIOME

J. Booth[1], **A. Llewelyn**[1], C. Collins[1]
[1]*Origin Sciences Limited, Cambridge, United Kingdom*

Contact E-mail Address: jodie.booth@originsciences.com
Introduction: The gut microbiome is the most complex bacterial community in the human body. Alterations in the composition of intestinal microbiota are associated with various disease states including inflammatory bowel disease, obesity and colon cancer.
The majority of studies of the human gut microbiome have analysed stool samples although mucosal biopsy specimens have also been used in numerous studies. In this study, we investigated the utility of OriCol™, a novel sampling device, for profiling the human gut microbiome.
Aims & Methods: This study was undertaken to compare the microbiome profile collected in human stool, rectal swab and rectal mucosa. The purpose of the study was to examine the differences and relationships in gut microbial abundances using the different sampling techniques, and to validate the degree to which the OriCol™ sampling technique can accurately replicate trends in microbial diversity using stool samples as a microbial reference.
The OriCol™ device is a simple, convenient method for sampling the rectal mucosa without the need for prior fasting or bowel preparation. Sampling can be performed by a trained healthcare professional in less than 5 minutes. The device incorporates a nitrile membrane, which after insertion into the rectum via a standard proctoscope, is inflated to make contact with the rectal mucosa. The membrane is then deflated and retracted into the device prior to removal from the patient. Upon retraction the material sampled from the rectal mucosa is retained on the inverted membrane. The device can either be stored frozen or a suitable buffer added to preserve the material for subsequent analysis.
Samples from the rectal mucosa (obtained using the OriCol™ device) and stool were obtained from 5 healthy volunteers on three discrete occasions. A single rectal swab sample was taken from each volunteer immediately before the final OriCol™ sample. The microbial community of samples was profiled via 16S V4 sequencing.
Results: OriCol™ and stool samples have comparable diversity measures, while samples taken using a rectal swab show lower diversity. Whole microbiome abundance profiles were significantly different between OriCol™ and stool samples when grouped by subject ($p < 0.001$) or sample type ($p < 0.001$). These differences were attributable to shifts in abundance rather than the presence or absence of bacteria. Significantly higher levels of Proteobacteria were observed in OriCol™ over stool. The OriCol™ device is able to capture differences between donors, but the microbial community is different to that from stool samples.
Conclusion: The OriCol™ device offers a novel, simple and convenient method for physician-led sampling of the gut microbiome represented in the rectal mucosa. Samples using the OriCol™ device contain the same spectrum of bacteria as stool samples but there are differences in the abundance of certain groups, with mucosal organisms such as Proteobacteria relatively enriched in the OriCol™ samples. We hypothesise that this may be due to the capture of bacteria closer to the mucosa by the OriCol™ device.

P0615 MINIMUM CURVILINEARITY: AN INNOVATIVE NONLINEAR MULTIVARIATE ANALYSIS REVEALS PROTON-PUMP-INHIBITOR-RELATED PATTERNS IN GASTRIC METAGENOMIC DATA

C. V. Cannistraci[1], G. Cammarota[2], G. Ianiro[2], A. Palladini[2], F. Paroni Sterbini[2], S. Bibbò[2], F. Franceschi[2], B. Posteraro[2], L. Masucci[2], G. Gasbarrini[2], M. Sanguinetti[2], A. Gasbarrini[2]
[1]*Biomedical Cybernetics Group, Biotechnology Center (BIOTEC), Technische Universität Dresden, Dresden, Germany, Dresden, Germany,* [2]*Gastroenterology and Microbiology, Catholic University, Rome, Italy*

Contact E-mail Address: kalokagathos.agon@gmail.com
Introduction: Unsupervised discovery of patterns that segregate groups of samples in omic datasets is a pivotal task that is useful in many metagenomic case-control studies. Principal Component Analysis (PCA) and many other linear multivariate methods are the first resort, routinely used for this purpose (Dinsdale et al, 2013). However, they often lack the ability to reveal complex, nonlinear data patterns.
Aims & Methods: We introduce Minimum Curvilinear Embedding (MCE) - a machine learning for nonlinear multivariate analysis (Cannistraci et al, 2010) - in order to detect complex patterns in metagenomic data. Minimum Curvilinearity (MC), the principle behind MCE, suggests that curvilinear distances between samples (e.g. case-control individuals) can be estimated as pairwise distances over their Minimum Spanning Tree (MST), constructed according to a selected norm (Euclidean, correlation, etc.) in a high-dimensional feature space (e.g. the metagenomic space). The collection of all nonlinear pairwise distances forms a distance matrix called MC-distance matrix or MC-kernel, which can be used as an input in algorithms for dimensionality reduction, classification and generally in machine learning (Cannistraci et al, 2010). In MCE, the MC-kernel can be centred or non-centred, and its singular value decomposition is used to favour a sample projection onto a two-dimensional space for visualisation and analysis. Thus, MCE is a form of nonlinear and parameter-free kernel PCA.
Results: Does proton pump inhibitor (PPI) treatment significantly modify the gastric microbiota? In order to answer this question, we collected 24 gastric biopsy samples from subjects: 12 under PPI treatment, 4 untreated *Helicobacter pylori* positve (HP+), 4 untreated *Helicobacter pylori* negative (HP-) and 2 untreated undefined. Amplicons were sequenced on a Roche 454 plataform.
Using PCA (and other linear methods) we found that our samples do not appear to differentiate according to treatment. This could be a normal conclusion that researchers would draw by applying classical multivariate analysis on case-control metagenomic datasets, such as ours, in many labs across the world. However, we decided to test whether the presence of nonlinear relations between the samples would represent a cause for the linear multivariate approach to fail. In fact, our further analysis showed that MCE can clearly separate samples according to the different conditions and treatments in cases in which PCA fails to reveal any clear structure. We were also able to use MCE to perform reverse engineering of the discriminant bacterial 'social networks' responsible for the separation between the different conditions.
Conclusion: The juxtaposition of PCA and MCE visualisations can provide a novel standard of multivariate analysis for discovering and validating significant linear/nonlinear complementary patterns in metagenomic data and, in general, in case-control omic studies.

Introduction: Extracellular vesicles (EVs) have recently emerged as mediators of intercellular communication both in normal physiological and pathological processes, including cancer. They have been shown to carry mRNAs, non-coding RNAs, proteins and even gDNA fragments harbouring specific mutations, therefore EVs in biological fluids may serve as a "liquid biopsy" of cancer. Nevertheless, controversy regarding nucleic acid (NA) location has arisen two possible scenarios: the first suggests that all NAs are selectively sorted inside EVs, while the second suggests that NAs are randomly attached to the surface of EVs.
Aims & Methods: The aim of the current study was to characterize the vesicle-enclosed and surface-bound RNA and gDNA content in EVs isolated from colorectal (SW480), breast (MDA-MB231) and lung (A549) cancer cell cultures and plasma samples from cancer patients and healthy controls (n = 12). EVs were isolated using size-exclusion chromatography and characterized by electron microscopy and Western blot analysis using specific EV markers (CD9, CD81, CD63, Alix), H3 as a marker for apoptotic bodies and GM130 as a negative control. Then, EVs were treated with RNaseI or DNaseI followed by total NA extraction from the treated and non-treated samples. NA amount was measured by Qubit and 2100 Agilent Bioanalyzer and expression levels of 5S and 28S rRNAs and selected miRNAs were quantified by RT-qPCR.
Results: Treatment of EVs with RNAse showed that 30 to 60% of EV RNA content was attached to the surface of EVs obtained from various cell cultures. Further expression analysis revealed that rRNA fragments were predominantly located on the surface of EVs, while the majority of miRNAs were enclosed within the vesicles. The total amount of RNA tended to lower in plasma-derived EVs than in cell culture-derived EVs, yet the proportion of vesicle-enclosed and surface-bound RNA was 90% vs 10%. Regarding gDNA content, we found that DNA amount varies significantly among the cell lines and 20 to 40% of DNA fragments were attached to surface of cell line-derived EVs, while plasma EVs contained 50-fold lower amounts of gDNA than EVs derived from the cell lines.
Conclusion: This study showed that miRNAs are predominantly packed inside EVs derived from cancer cell lines and patients' plasma, while rRNA and gDNA fragments are found in the vesicle-enclosed and surface-bound form. Furthermore, the NA yield tends to be lower in plasma-derived EVs than those produced by cancer cell lines suggesting that either cancer cells secrete EV-associated NAs more efficiently than normal cells or the enhanced NA secretion is an *in vitro* phenomenon. (Financed by project 625/2014)

Introduction: Loss of genetic stability seems to be one of the main pathogenic key processes appearing early in carcinogenesis of colorectal carcinomas (CRC). We used the Cytokinesis-Bloked Micronucleus Assay (CBMN) technique for detecting DNA damages. The aim of our study was to predict the presence of significant colorectal lesions by specific biomarkers detected by this method in average risk persons.
Aims & Methods: We designed a prospective study including patients undergoing diagnostic or opportunistic screening colonoscopy. A blood sample was obtained from each patient to to be analyzed by CBMN technique for specific biomarkers: presence of micronuclei (MN), nucleoplasmic bridges (NPB) and the Nuclear Division Index (NDI).
Results: 98 patients met the inclusion criteria, 57 of them assimilated to average-risk persons (age between 50-75 years, with no personal or familial CRC history). The mean age of our group was 55.36. The advanced neoplasia rate was 34.68% for the entire group. In the average-risk group 21.05% had advanced adenoma and 26.31% adenocarcinomas. MN frequeny and NPB presence were not significanty different in patients with neoplastic lesions compared to normal population or non-neoplastic colorectal lesions. NDI was significant lower in patients with adenoma or adenocarcinoma versus individuals with normal colonoscopy or non-neoplastic lesions, in the whole group but also in average-risk group (AUC ROC = 0.668, $p = 0.005$ and AUC ROC = 0.715, $p = 0.006$ respectively). For a cutt-off value of NDI = 1.8, the sensitivity in detecting any neoplasia was 97.7% for all patients and 97% for medium-risk patients. NDI was significantly lower in patients with advanced neoplasia compared with individuals with normal colonoscopy or with non significant colorectal lesions (AUC ROC = 0.636, $p = 0.029$ for all patients, AUC ROC = 0.672, $p = 0.029$ for average-risk group). For the same cut-off value of NDI of 1.8, the sensitivity in detecting advanced neoplasia was 97% for all patients and 96% for average-risk group. When predicting only carcinomas, an NDI value of < 1.8 will predict it with a sensitivity of 94.4% for all patients and 93.3% for average-risk group.
Conclusion: We found a significantly low Nuclear Division Index in patients with advanced colorectal neoplasia in average risk individuals. NDI score may have a certain value in colorectal cancer screening.

P0618 VALIDATION OF SMARTPILL WIRELESS MOTILITY CAPSULE FOR GASTROINTESTINAL TRANSIT TIME

P. M. Hellström[1], H. D. Tartera[1], A. Al-Saffar[1], M. A. Halim[1], D.-L. Webb[1], G. Lindberg[2], P. Sangfelt[1]
[1]*Medical Sciences, Uppsala University, Uppsala,* [2]*Medicine, Karolinska Institutet, Stockholm, Sweden*

Introduction: Normal values for gastrointestinal transit time were quantified in healthy Swedish volunteers using SmartPill® wireless motility capsule (WMC). This ambulatory method, permits motility recordings (transit time and luminal pressure) in real time, by 5 days, without exposing to radiation, and it possible study the response to food intake, bowel movements, normal daily activity, periods of pain and discomfort. We wanted establish WMC normal values for gastric emptying, small bowel, colon and whole gut transit. Furthermore, evaluated the stability of recordings upon repeat recordings and estimated the fidelity of naked-eye inspection of transit values vs software-aided values; and finally comparison of gastric emptying and small bowel transit as measured by video capsule endoscopy (VCE) was made.
Aims & Methods: Seventy-two healthy volunteers ingested a 260 kcl meal, and SmartPill® with 100 ml of water, after which food intake ad libitum was permitted. Data obtained from the WMC was transferred to a receiver carried; values presented were regional (gastric, small bowel, colon), and total transit time, and other group of 75 subject taked the under fasting conditions.
Results: Using the SmartPill in 72 healthy subjects we obtained the following normal values displaying a Gaussian distribution (hours): Gastric emptying time (GET) 2.87-3.38, Small bowel transit time (SBTT) 4.82-5.67, colon transit time

(CTT) 18.50-23.27, and whole gut transit time (WGTT) 27.03-32.20. The variation coefficient varied between 33 to 48% indicating a certian spread of values. The maximum GET was 6.1, Max SBTT 11.2, max CTT 54.9 and max WGTT 68.1. Comparison between software and physician evaluation we obtained a correlation of r = 0.99 for WGTT. The Bland-Altman plot analysis exhibited only one single outlier in repeated measurements after 1 and 2 weeks. The comparison of SmartPill and PillCam GET and SBTT regularly showed shorter transit times with PillCam, most likely as a result of the fasting condition with PillCam as compared with SmartPill ($P < 0.05$).

Conclusion: The SmartPill WMC gave robust data of transit times for passage through different regions of the gastrointestinal tract. Our results suggest that the SmartPill technology is able to detect transit times for passage through different regions of the gastrointestinal tract. Estimates of transit are reliable with little differences from physicians "true" estimates by visual readings. Furthermore, capsule endoscopy may not substitute for WMC for estimates of transit as done under other conditions and defined by anatomical landmarks rather than functional divides in the gut. The feasibility of the recordings as well as the useful interpretation softare makes the SmartPill a strong competitor for use in the clinical setting where its use is comparable to that of the PillCam. Swift and easy trustful values of gastric emptying, small bowel transit and colon transit values can be obtained in order to verify gastroparesis, constipation and possibly also high amplitude contractions causing painful discomfort in patients with enteric dysmotility.

Introduction: Colorectal cancer (CRC) is a common malignancy worldwide. Numerous parameters including genetic alterations, lifestyle factors as well as the composition of colonic microflora are relevant in CRC development. Tumour-specific metabolic changes progressively attract interest in the perpetuation of a malignant phenotype since they provide a chance to understand the tumour's biology.

Aims & Methods: We investigated paired samples of normal colon tissue and colorectal cancer tissue of 53 CRC patients. The samples were gained during endoscopy, thus, avoiding long ischemic time usually coming along with tumour surgery. Gas chromatography / mass spectrometry (GC/MS) was performed to analyse differences in metabolic profile of normal and tumourous tissue of CRC patients.

Results: Several differences in metabolic profile of normal and malignant transformed tissue were revealed. These included changes in energy household and cell turnover in tumorous tissue like dysregulation of tricarboxylic acid (TCA) cycle, increase of glycolysis, and augmented protein formation. Furthermore, several metabolites arising in microbial metabolism were found at heightened levels in cancer tissue.

Conclusion: In conclusion, GC/MS metabonomics revealed interesting differences in the metabolic profiling of human CRC and normal colon mucosae. Especially, the significant disparity in abundance of bacterial metabolites reflecting the importance of composition of colonic microflora in the development of CRC is worth further investigation. A better understanding of tumours biology has a great potential in the development of personalized therapeutic strategies in the treatment of this common neoplasia.

Introduction: Nearly 25% of adult population in western countries have the metabolic syndrome (MS). Hyperferritinemia (HF) is frequently present in patients with this clinical entity (dysmetabolic hyperferritinemia). The presence of mutations in the HFE gene, like the H63D/H63D mutation, may induce MS in these patients.

Aims & Methods: A Prospective study of 132 consecutive patients with HF (> 200µg / L women, > 300µg / L men) was conducted from January to December 2010. The Metabolic syndrome was defined by the presence of waist circumference ≥94cm men; ≥80 cm women. And two of the following factors: Triglycerids ≥ 150 mg/dL or treatment for this dislypemia; HDL < 40 mg/dL women, < 50 mg/dL men or treatment for this dislypemia; glucose ≥ 100 mg/dL or Type 2 diabetes; hypertension: blood pressure ≥130 mm Hg/ ≥85 mm Hg. or treatment for arterial hypertension. DNA was extracted from the blood samples and *HFE* gene analysis was performed by multiplex real-time PCR using LightCycler technology (LC 1.0). Simultaneous detection of the *HFE* C282Y, H63D and S65C mutations was carried out in a single capillary using LC-Red 640, LC-Red 705 and fluorescein-labelled hybridization probes (Tibmolbiol, Berlin, Germany). Melting curve analysis was used to distinguish wild type and mutant alleles in each case. The results were compared with a control group of blood donors from the same geographical area.

Results: In 97 from 132 patients we have all the data to determine the MS presence: 44/80 men (55%) and 10/17 women (59%) presented MS. The HFE mutations from 51/54 patients with MS were: 2 C282Y/wt (3.92%); 11 H63D/H63D (21.56%); 15 H63D/wt (29.41%); 3 C282Y/H63D (5.88%); 19 wt/wt (37.25%); 1 S65C/ wt (1.96%). The genotype frequency of the H63D/H63D mutation in MS cases was significantly higher than in controls (7) - 21.56% vs 7.76% > ($p = 0.011$); the H63D allelic frecuency was 42.15% in MS group and 31% in controls ($p = 0.027$).

Conclusion: The H63D/H63D genotype and H63D allele predispose individuals with HF to MS.

P0621 A1166C AGTR1 AND I/D ACE GENETIC POLYMORPHISMS DETERMINE REGULATION OF CHEMOKINES AND FORMATION OF THE VICIOUS CIRCLE INVOLVING ENDOTHELIAL DYSFUNCTION OF MESENTERIC VESSELS AND INTESTINAL DYSBIOSIS IN HEPATIC STEATOSIS

Introduction: Fatty liver disease or Hepatic Steatosis (HS) is frequently observed in patients with arterial hypertension (AH) as they both have common systemic pathogenesis realized through metabolic and immune mechanisms involving vascular and digestive system injury. Moreover, chronic vascular damage influences intestinal byocenosis causing further damage to liver. We hypothesized that the combination of vascular and metabolic changes may have detectable genetic background.

Aims & Methods: The aim is to evaluate the endothelial function and mesenteric vessels remodeling depending on I/D polymorphism of angiotensin-converting enzyme (ACE) gene and A1166C polymorphism of angiotensin II type 1 receptor (AGTR1) gene in patients with HS and AH.

Study included 104 patients with HS combined with AH (50 female, 54 male, age 53.2 ± 8.7). Intimae-media thickness (IMT) of abdominal aorta (AO) and other flow mediated parameters of mesenteric vessels status were evaluated by sonography. Nitric oxide (NO) and nitrite/nitrate plasma concentrations, vascular adhesive molecule (sVCAM-1) levels were defined by ELISA. ACE (I/D) and AGTR1 (A1166C) genes polymorphisms assessed with PCR.

Results: High risk of endothelial dysfunction is associated with D-allele of ACE gene ($p < 0.001$) and C-allele of AGTR1 gene ($p = 0.02$). Flow-mediated parameters of mesenteric vessels were higher in DD-genotype patients. IMT of abdominal aorta was higher in CC-genotype of AGTR1 gene ($p = 0.039$-0.01) and no dependence was found on I/D genotypes of ACE gene. sVCAM-1 level was significantly higher in D-allele of ACE gene ($p < 0.01$) than in II-genotype and not depending on A1166C polymorphism of AGTR1 gene. Nitric oxide plasma level does not depend on ACE (I/D) and AGTR1 (A1166C) genes polymorphisms. Vascular remodeling in HS patients (AO IMT enlargement for more than 0.9 mm) is associated with III-IV grades intestinal dysbiosis and 1.3-1.6 times growth of sVCAM-1 plasma levels ($p < 0.05$-0.001). AO IMT strongly positively correlates with dysbiosis severity ($r = 0.69$-0.83), presence of HS and sVCAM-1 level ($r = 0.64$-0.87) and is not dependent on arterial hypertension severity.

Conclusion: Risk contingents for endothelial dysfunction and mesenteric vessels remodeling in HS patients include DD-genotype carriers of ACE gene because of increased sVCAM-1 plasma levels and diameter of mesenteric vessels; and CC-genotype carriers of AGTR1 gene due to significant enlargement of Intimae-media thickness of abdominal aorta ($p \leq 0.02$-0.001).

P0622 NONALCOHOLIC FATTY LIVER DISEASE (NAFLD) AS POTENTIAL RISK FACTOR OF CARDIOVASCULAR DISEASE AND ONCOLOGICAL DISEASE IN DIABETIC TYPE 2 PATIENTS

D. Caroli[1], A. Nogara[2], E. Rosa-Rizzotto[1], A. Boscolo Bariga[2], F. De Lazzari[1]
[1]*Gastroenterology Unit, Padova,* [2]*Internal Medicine, Chioggia, Italy*

Introduction: NAFLD is an increasingly cause of liver damage in western countries associated with obesity, hypercaloric diet and the sedentary lifestyle. The increasingly high prevalence of NAFLD and its possible damage on several organs due to its inflammatory effects (cardiovascular risk and oncological risk) will lead to a prioritary health care problem in the next future. Validated prognostic scores for NAFLD and for cardiovascular risk in diabetics patients were respectively Fatty liver index (FLI) and UK Prospective Diabetes Study (UKPDS risk engine)

Aims & Methods: The aims of our study are to assess the real correlation between FLI and UKPDS risk with cardiovascular (CE) and oncological events (OE) in a cohort of diabetic type 2 patients, in order to identify with accurancy the best predictor. 2004 patients referred to our Diabetics Center Ambulatory and in a regular follow-up were retrospectively tested. UKPDS risk and FLI were calcolated for each patient. Data such as CE, OE,

anthropometric, biochemical and metabolic features were also collected. T test for unpaired data and Pearson Chi-squared test were performed.
Results: 304/2004 pt (15%), 211 M and 93 F, were FLI >60; in this group we observed 14 (5%) OE (7 M and 7 F) and 81 (27%) CE (64 M and 17 F). 743/2004 pt (37%), 638 M and 17 F), were FLI < 20; in this other group we observed 9 (1%) OE (6 M and 3 F) and 74 (10%) CE (47 M and 27 F). The statistical analysis showed that patients with FLI > 60 have a higher risk of OE ($p = 0.0006$) or CE ($p = 0.0001$) compared to patients FLI < 20. We identified also two peculiar profiles of cardiovascular risk, in fact male gender patients with FLI > 60 presented a significant higher risk of developing CE than female ($p < 0.05$); instead female gender patients with FLI < 20 presented a significant higher risk of developing CE than male ($p < 0.001$). No statistical significance was found between FLI > 60 +UKPDS >20 and CE ($p = 0.754$). FLI > 60 and FLI < 20 patients also significantly differed respectively for mean age 62.2 vs 68.4 y ($p = 0.02$), duration of diabetes 4.9 y vs 13.24 y ($p = 0.002$) and mean glycated hemoglobin 8.7y vs 7.9 ($p = 0.009$).
Conclusion: An early and aggressive program of follow-up and treatment could be established in diabetic type 2 patients with FLI > 60 and so with reasonable suspicion of NAFLD because this population have higher risk to develop CE and OE in comparison to FLI < 20 (or FLI negative and not suspicion of NAFLD). The simultaneous UKPDS and FLI positivity doesen't improve accuracy in predicting CE.

P0623 HIGH BODY MASS INDEXES PRESERVE BONE MINERAL DENSITIES IN PATIENTS WITH NON-ALCOHOLIC FATTY LIVER DISEASE

M. Farrugia[1], **M. Gerada**[1], J. Bonello[1], J. M. Gauci[1], R. Pullicino[2], J. Gerada[1]
[1]*Gastroenterology,* [2]*Radiology, Mater Dei Hospital, Msida, Malta*

Contact E-mail Address: jurgen.gerada@gmail.com
Introduction: The effect of non-alcoholic fatty liver disease (NAFLD) on bone mineral density (BMD) is poorly understood. NAFLD is more prevalent with higher body mass indexes (BMI).
Aims & Methods
Aim: We aimed to evaluate the effect of different classes of BMI on BMD in adult patients with NAFLD.
Methods: Adult patients diagnosed with NAFLD on liver imaging in 2013 were enrolled in the study. Patients with concomitant liver pathologies were excluded. Patient demographics were obtained from the medical notes and the BMI was calculated and classified using the WHO classification (underweight (<18.5), normal (18.5-24.9), overweight (25-29.9) and obese (≥30)). BMDs of the femur and lumbar spine were measured in all patients by dual energy X-ray absorptiometry. Age and gender-matched Z scores and T scores were calculated and analysed against the different BMI classes using the ANOVA model.
Results: 197 NAFLD patients were enrolled in the study (178 females, 90.3%; mean age 63.5, range 35-82; mean BMI 32.8, range 22-48.6). No underweight patients were present in the study. Obese patients had higher BMD T scores (-0.38 ± 1.12) of the whole femur than overweight patients (-0.82 ± 1.074) and normal BMI patients (-1.53 ± 0.89) (*p 0.001*). This was also true for the femoral neck (-0.97 ± 1.14, -1.41 ± 1.00, -1.77 ± 0.95, respectively, *p 0.007*) and lumbar spine (-0.71 ± 1.38, -1.06 ± 1.16, -1.80 ± 1.62, respectively, *p 0.017*). Likewise, obese patients had higher BMD Z scores of the whole femur (0.71 ± 1.09, *p 0.002*), femoral neck (0.59 ± 1.1, *p 0.005*) and lumbar spine (0.46 ± 1.36, *p 0.008*) compared to overweight patients (0.26 ± 1.15, 0.16 ± 1.03, 0.04 ± 1.15 respectively) and normal BMI patients (-0.25 ± 0.79, -0.25 ± 0.84, -0.65 ± 1.31 respectively). On subgroup analysis of obese patients, obese class 3 patients (BMI >40) had higher BMD T scores of the whole femur (*p 0.002*) and lumbar spine (*p 0.003*) but not of the femoral neck (*p 0.321*) when compared to obese class 2 (BMI 35-39.9) and obese class 1 (BMI 30-34.9) patients.
Conclusion: In NAFLD patients, obesity was associated with stronger bone mineralisation, demonstrating a linear relationship with increasing BMIs. NAFLD patients with normal BMI should undergo BMD to screen for osteopenia. Weight loss in NAFLD obese patients might have deleterious effects on bone health.
Disclosure of Interest: None declared

P0624 URSODEOXYCHOLIC ACID INFLUENCE ON EFFICACY AND SAFETY OF STATIN THERAPY IN PATIENTS WITH HIGH RISK OF CARDIOVASCULAR EVENTS AND NONALCOHOLIC FATTY LIVER DISEASE: THE RACURS STUDY (POST-HOC ANALYSIS)

M. Nadinskaya[1], S. Martsevich[2], N. Kutishenko[2], I. Balashov[2], O. Lerman[2]
[1]*Department of Propaedeutics, I. M. Sechenov First Moscow State Medical University,* [2]*Federal State Institution National Research Center for Preventive Medicine, Moscow, Russian Federation*

Contact E-mail Address: marianad@rambler.ru
Introduction: The RAKURS study included 62% of patients with a history of nonalcoholic fatty liver disease (NAFLD).
Aims & Methods: To assess the ursodeoxycholic acid (UDCA) influence on efficacy of statin therapy in patients with high risk of cardiovascular events (CVE) and NAFLD.
Data of case report forms of 262 patients enrolled in the RAKURS study. NAFLD group – 234 subjects – is formed based on ultrasonic data (hyperechoic appearance of hepatic parenchyma) at the moment of enrollment. It was divided into two subgroups: fatty liver (159 subjects) – patients with normal level of ALT, and nonalcoholic steatohepatitis (NASH, 75 subjects) – patients with elevated level of ALT (the median is 58.9 U/l). The fatty liver subgroup included patients significantly older than in the NASH subgroup: mean age was 61.62 ± 8.19 and 57.86 ± 8.76 years, respectively ($p < 0.05$). The NASH included more men: 65% vs 42% in the fatty liver subgroup ($p < 0.05$).
Results: Statin therapy in combination with UDCA in the fatty liver subgroup was administrated to 92%, in the NASH subgroup – to 97% of patients. The subgroups did not show any difference in terms of initial total cholesterol (TC), low-density lipoprotein cholesterol (LDL-C), and triglycerides (TG).
After 6 months of follow-up there was a significant ($p < 0.05$) reduction in TC to 4.1 mmol/l, LDL-C to 1.89 mmol/l and TG to 1.24 mmol/l in the fatty liver subgroup, and TC to 4.0 mmol/l, LDL-C to 1.9 mmol/l and TG to 1.3 mmol/l in the NASH subgroup. Changes of the above listed levels were similar in the subgroups. In the NASH subgroup there was a significant ($p < 0.05$) decrease in ALT to 30 U/l. The dynamics of alkaline phosphatase, gamma glutamine transferase, bilirubin and creatinphosphokinase remained within reference range during the whole period of the treatment.
Among the patients who were taken lipid-lowering therapy for the first time (47 subjects in the fatty liver subgroup and 24 subjects in the NASH subgroup), initial higher TC 6.47 mmol/l and TG 2.03 mmol/l were observed in the NASH subgroup vs TC 6.1 mmol/l and TG 1.19 mmol/l in the fatty liver subgroup. LDL-C was similar in the both subgroups: 3.9 mmol/l. At the end of the first month of statin therapy combined with UDCA in the fatty liver subgroup there was a decrease in TC to 5.1 mmol/l, LDL-C to 3.17 mmol/l, TG to 1.62 mmol/l; in the NASH subgroup there was a decrease in TC to 4.8 mmol/l, LDL-C to 2.72 mmol/l and TG to 1.62 mmol/l. The decrease of the above listed levels was more evident ($p < 0.05$) in the NASH subgroup. A significant positive dynamics of ALT decrease to 53.5 U/l was found in patients with NASH (initially 58.7 U/l).
Conclusion: 6-month statin therapy in combination with UDCA showed significant lipid-lowering effects in patients with high risk of CVE and NAFDL, as well as normalization of ALT in the NASH subgroup. Among the patients who previously had not taken statins in the NASH subgroup, higher levels of TC and TG were observed. The same subgroup showed more evident lipid-lowering effects than the fatty liver subgroup during the first month of the treatment.

P0625 METABOLOMIC MARKERS OF LIVER DAMAGE AND THEIR IMPLICATION IN THE ADVANCEMENT OF LIVER INJURY: FROM FATTY LIVER TO HEPATOCELLULAR CARCINOMA

M. Gaggini[1], C. Saponaro[1], C. Rosso[2], F. Carli[1], E. Buzzigoli[1], F. Filipponi[3], D. Ciociaro[1], E. Bugianesi[2], A. Gastaldelli[1]
[1]*Cardiometabolic Risk Unit, Institute of Clincal Physiology, Pisa,* [2]*Dept. of Medical Sciences, Division of Gastroenterology and Hepatology, Turin,* [3]*Hepatobiliary Surgery and Liver Transplantation, University of Pisa Medical School Hospital, Pisa, Italy*

Contact E-mail Address: melania.gaggini@alice.it
Introduction: The liver is a key organ in general metabolism and waste handling. Non alcoholic fatty liver disease (NAFLD), can progress to steatohepatitis, fibrosis and cirrhosis, and also to hepatocellular carcinoma (HCC) independently from cirrhosis. Chronic liver disease is associated with alterations in hepatic and whole body lipid metabolism caused by lipotoxicity due to elevated free fatty acid (FFA), oxidative stress and IR. Together these events play a significant role in determining the progression of liver disease.
Aims & Methods: Since circulating metabolites have been proven to be excellent markers of liver function, the aim of this work was to evaluate plasma small-molecule that could mark NAFLD and their differences in subjects with different degrees of liver damage vs. those that already developed HCC.
In 44 patients with NAFLD evaluated with biopsy, 47 patients with HCC and 21 subjects without liver disease (CT), we evaluated, by gas chromatography mass spectrometry, FFAs composition, de novo lipogenesis index (DNL = palmitic/linoleic acid), unsaturated to saturated fat ratio (PUFA/SFA), and a new index (GSG index) of liver damage calculated as glutamate/(serine+glycine). Moreover we evaluated Adipose tissue (Adipo-IR = FFA x Insulin) and peripheral (HOMA = glucose x Insulin/22.5) insulin resistance. Histology was scored according to Kleiner. APRI score (AST/platelet count), that is an index of fibrosis, was calculated in all subjects.
Results: Patients with liver disease had increased IR, especially in HCC that showed higher Adipo-IR (16.4 ± 1.7 vs 8.4 ± 0.8 vs 5.6 ± 0.9) and HOMA (8.38 ± 0.76 vs 3.21 ± 0.28 vs 2.04 ± 0.32) compared to NAFLD and CT (all $p < 0.005$). The worsening of liver disease was associated with the increase of DNL index and a decrease in PUFA/SFA ratio that was more evident in HCC than NAFLD compared to CT ($p < 0.0001$). In NAFLD, DNL index and PUFA/SFA changed proportionally to the severity of fibrosis particularly with Fibrosis score 3-4 (all $p < 0.0001$). GSG-index was increased proportionally to liver enzymes, (all $p < 0.0001$) and was higher in patients with Fibrosis score 3-4 or HCC compared to CT or no fibrosis. In all subjects, GSG, DNL and PUFA/SFA were related to Adipo-IR ($R = 0.23$;$R = 0.34$;$R = -0.38$) and HOMA ($R = 0.25$;$R = 0.43$;$R = -0.20$). Moreover, we found that the increase in APRI score in subjects with FLD and HCC was associated with adipose tissue IR and HOMA DNL index, GSG index and the PUFA/SFA ratio (all $p < 0.0001$).
Conclusion: We found several metabolomic markers of liver damage (GSG, DNL, PUFA/SFA, adipo-IR, HOMA) that mark differences in degree of liver fibrosis in NAFLD or presence of HCC, indicating metabolic dysfunction as one of the major risk factors for liver disease.

Contact E-mail Address: supers_stars@uni.de

Introduction: Multiple studies showed that Peroxisome Proliferator Activated Receptor gamma – NR1C3 (PPARG) plays an important role in various biological processes including lipid and glucose metabolism. PPARG has been implicated in the pathology of numerous diseases including obesity, diabetes, atherosclerosis, and cancer. PPARG agonists have been used in treatment of different metabolic disorders and Nonalcoholic Steatohepatitis (NASH) norm regulating glucose metabolism, decreasing steatosis, inflammation, and fibrosis. However, existing data is confusing, challenging efficacy of therapeutic use of PPARG agonists.

Aims & Methods: The aim of the study was to clarify the perspectives for individualized therapy with thiazolidinediones depending on PPARG Pro12Ala polymorphism. 249 patients with metabolic syndrome, hypertension, and dyslipidemia participated in the study. Among them 50 (20.08%) patients with NASH were selected to form study group. PPARG agonist Pioglitazone administered 30 mg daily during 50-51 weeks. Genetic polymorphism (Pro12, Pro12Ala, Ala12Ala) of PPARG gene determined by PCR. Genotypes distributions were as follows: Pro12 Pro (n = 32, 64.0%); Pro12Ala (n = 14, 28.0%); Ala12Ala (n = 4, 8.0%). Clinical examination and liver biopsies performed prior and after study.

Results: Pioglitazone improved glycemic control and glucose tolerance ($P < 0.001$), normalized liver aminotransferase levels as it decreased AST by $42.1 \pm 1.17\%$ $P = 0.014$; ALT by $57.5 \pm 1.37\%$, $P < 0.001$; decreased hepatic fat by $54.6 \pm 2.09\%$, $P < 0.001$; and increased hepatic insulin sensitivity by $48.5 \pm 1.63\%$ $P = 0.006$. Administration of pioglitazone caused improvement in histologic findings with regard to steatosis, ballooning necrosis, and inflammation. In 4 (8%) Ala12Ala patients no reliable changes were observed, except glycemic control and glucose tolerance. Reduction in fibrosis did not change significantly. Statistically insignificant weight gain and mild lower-extremity edema developed in two subjects with Pro12Ala genotype, no other side effects were observed.

Conclusion: Administration of thiazolidinediones leads to metabolic and histologic improvement in most patients with NASH. However, individual response may be affected by Pro12Ala polymorphism of PPARG gene. This study shows that carriers of Ala genotype whilst comparatively rare among NASH patients are much less sensitive to PPARG agonists' therapy. Our data partially explain the nature of failure of several thiazolidinediones use and their risk of side effects (bladder cancer or hepatitis).

Introduction: Hepatic granulomas have been reported in 2-15% of unselected liver biopsies.

Aims & Methods: The aim of our study was to evaluate the prevalence and the aetiology of granulomas in patients who underwent liver biopsy.

A retrospective review of hepatic biopsies performed in our Department between 2010 and 2015. Medical records, biochemistry tests as well as imaging and molecular studies that were relevant for the diagnosis were also reviewed.

Results: Over the study period, 1629 liver biopsies were performed. Hepatic granulomas were identified in 86 (5.3%). Of those, NASH accounted for the majority of cases (26.7%), followed by primary biliary cirrhosis (PBC) (17.4%), autoimmune hepatitis (AIH) (14%) and sarcoidosis (5.8%).

Infectious causes were less common, representing 16.5% of all cases: 4 cases of Hepatits C virus (HCV) infection, 1 case of Hepatits B virus (HBV) infection, 1 case of HBV/HCV coinfection, 1 case of Schistosomiasis, 1 case of Enterobiasis, 2 cases of Tuberculosis, 1 case of Q fever, 1 case of hepatosplenic candidiasis and 1 case of parasitic infection with no agent identified.

Two cases of drug toxicity were found, which were associated with antiretrovirals and etanercept use. Finally, 7 idiopathic cases were also reported.

Conclusion: In accordance with what has been described in previous studies, the prevalence of hepatic granulomas was 5.3%. Our study showed that NASH was the most common cause of granuloma formation, followed by PBC and AIH. Differently to what has been reported in developing countries, infectious causes represented a small fraction of hepatic granulomas in our series.

Contact E-mail Address: sofiacarvalhana@msn.com

Introduction: Serum aminotransferases are often used in screening for liver disease. However, the prevalence and causes of elevated aminotransferases have geographic variations and there are no population-based data in Portugal.

Aims & Methods

Aims: determine the prevalence and factors associated with elevated aminotransferases in the general Portuguese population.

Methods: We conducted a nationwide, population-based cross-sectional study of adults resident in mainland Portugal. Serum biochemical liver tests (AST, ALT, GGT), serological markers for hepatitis B and C, as well as metabolic risk factors and alcohol consumption were assessed. Elevated aminotransferases (AST and/or ALT) was defined in women as ≥30 IU/L and in men ≥40 IU/L. The diagnostic criteria of NAFLD included hepatic steatosis (fatty liver index (FLI) > 60), without excessive alcohol consumption (< 20g/day).

Results: From 1688 individuals studied, 50.4% were men, mean age 50.2 ± 18.3 years and mean BMI was 27.0 ± 4.9 Kg/m^2, with 40.4% overweight and 22.8% obese. Insulin resistance (HOMA-IR > = 3), hepatic steatosis (FLI > 60) and metabolic syndrome (MS) were 27%, 14% and 19%, respectively.

Prevalence of elevated aminotransferases was 10.7% (95% CI: 10.0-11.4). The probable cause of this elevation was NAFLD in 45%, excessive alcohol consumption (> 20g/day) in 9.3%, HCV in 1.7%, HBV in 0.6% and unexplained cause in 43.4%.

Patients with elevated aminotransferases were mainly men (70%), overweight/obese (81%), with insulin resistance (47%), hepatic steatosis (42.6%) and MS (38.5 %), $p < 0.05$.

There was a significant positive correlation between aminotransferases and the following variables: FLI ($r = 0.29$), NAFLD ($r = 0.18$), BMI ($r = 0.17$), HOMA-IR ($r = 0.14$), gender ($r = 0.13$), and MS ($r = 0.12$). In multivariate analysis only FLI and BMI were independent risk factors for elevated aminotransferases. No correlation was found among aminotransferases and age, smoking and physical activity.

Conclusion: The prevalence of elevated aminotransferases was 10.7%. Fatty liver and the metabolic risk factors, namely MS and obesity, were the most frequent cause of their increase. These results emphasize the need for considering metabolic risk factors in the presence of elevated aminotransferases.

Contact E-mail Address: weiyaohsieh@gmail.com

Introduction: Fatty liver has shown strong association with metabolic syndrome in previous cross-sectional studies. Fatty liver index (FLI) is an algorithm to identify fatty liver while lipid accumulation product (LAP) which represents cardiometabolic disorders is used to predict liver steatosis as well. However their predicative value of metabolic syndrome in subjects without fatty liver is still obscure.

Aims & Methods

Aims: To explore the association between LAP and FLI, and metabolic syndrome in subjects without fatty liver.

Method: We enrolled consecutive subjects who received health check-up services at the Taipei Veterans General Hospital from 2002 to 2009. Ultrasonography was applied to diagnose fatty liver. The ability of the FLI and LAP to predict metabolic syndrome was assessed by analyzing the area under the receiver operating characteristic (AUROC) curve.

Results: Among the 29,797 subjects enrolled in this study, fatty liver was diagnosed in 44.5% of the population and it had the highest association with metabolic syndrome by multivariate analysis with an odds ratio of 2.499 (95% confidence interval 2.339-2.670, $p < 0.001$). Moreover, LAP and FLI are better than other serum markers to predict metabolic syndrome (AUROC: 0.884 and 0.875, respectively). Among the 16542 subjects without fatty liver, male gender, larger body mass index, older in age, higher serum alanine aminotransferase, and higher gamma-glutamyl transferase levels were correlated with metabolic syndrome by multivariate analysis. LAP and FLI are still better than other serum markers to predict metabolic syndrome in subjects without fatty liver (AUROC: 0.871 and 0.879, respectively).

Conclusion: FLI and LAP could accurately predict metabolic syndrome among subjects without fatty liver disease in a large-scale population in Taiwan. Accordingly, non-fatty liver patients with a high FLI or LAP may need intensified lifestyle modification and counseling.

Abstract number: P0633 Table: Hepatic Lipid Peroxidation and Liver Function Tests in Mice after 24 Hours of CCl_4 Treatment.

Parameter	Saline + Olive oil	6-OHDA + Olive oil	Saline + CCl4	6-OHDA + CCl4	Phentolamine + CCl4	Nadolol + CCl4
4-HNE (μg/μg protein)	0.23 ± 0.02	0.18 ± 0.02**	0.33 ± 0.07*	0.23 ± 0.03$^{\#\#,\ \dagger\dagger}$	0.25 ± 0.01$^{\#}$	0.28 ± 0.02
ALT (IU/L)	40 ± 11	51 ± 28	15,519 ± 4,678***	7,809 ± 2,527$^{\#\#}$	7,318 ± 3,799$^{\#}$	10,830 ± 4,381

The results are presented as mean ± S.D.; * and ** Denote significant differences compared with the Saline + Olive oil group ($p < 0.05$ and 0.01, respectively); $^{\#}$ and $^{\#\#}$ Denote significant differences compared with the Saline + CCl_4group ($p < 0.05$ and 0.01, respectively)

Introduction: Mechanisms of inflammation in alcoholic liver disease (ALD) are still unclear. Th17 and regulatory T (Treg) cells are critically linked to inflammatory immune response. While Th17 lymphocytes exert pro-inflammatory effects, Treg cells are potent immune suppressors, and they may reciprocally control their function. Human Th17 differentiation is IL-1beta1, IL-6, IL-23 and IL-17A- dependent and suppressed by TGF-beta1. On the other hand TGF-beta1 enhances the differentiation of human Treg cells. To date, the Th17/Treg balance has not been explored in patients with ALD yet. Moreover, women develop more severe alcohol-associated liver injury at lesser ethanol intake and fewer years of exposure. They seem to respond stronger in comparison to males after inflammatory induction. It may result from different hormone patterns (estrogens are immune stimulators, testosterone is rather immunosuppressive).
Aims & Methods: The aim of our study was to determine an impact of the Th17 / regulatory T (Treg) cells balance and its corresponding cytokine profile on the ALD outcome. Possible gender-related differences in the alcohol-induced inflammatory response were also assessed. 147 patients with ALD were prospectively recruited, assigned to subgroups based on their gender, severity of liver dysfunction and presence of ALD complications at admission, and followed for 90 days. Peripheral blood frequencies of Th17 and Treg cells together with IL-1beta, IL-6, IL-17A, IL-23, and TGF-beta1 levels were investigated.
Flow cytometry was used to identify T cell phenotype and immunoenzymatic ELISAs for the corresponding cytokine concentration assessments. Multivariable logistic regression was applied in order to select independent predictors of advanced liver dysfunction and the disease complications.
Results: IL-17A, IL-1beta, IL-6 levels were significantly increased, while TGF-beta1 decreased in ALD patients. The imbalance with significantly higher Th17 and lower Treg frequencies was observed in non-survivors. IL-6 and TGF-beta1 levels differed in relation to the patient gender in ALD group. Concentrations of IL-6 were associated with the severity of liver dysfunction, development of ALD complications, and turned out to be the only independent immune predictor of 90-day survival in the study cohort.
Conclusion: IL-6 revealed the highest diagnostic and prognostic potential among studied immune biomarkers and was related to the fatal ALD course. Gender-related differences in immune regulation might influence the susceptibility to alcohol-associated liver injury.

Introduction: Alcohol represents the most common cause of liver cirrhosis in the Western countries. Total alcohol abstinence represents the cornerstone in the management of alcoholic cirrhosis (AC). When liver function fails to improve with abstinence, liver transplantation (LT) is the treatment of choice. However LT in patients with AC remains controversial for the risk of alcohol recidivism after LT, and the perception of AC as a "self-inflicted disease". Actually, HCV-related cirrhosis is the leading indication for LT.
Aims & Methods: The aim of this study was to evaluate the differences in terms of survival, recidivism and complications between patients who underwent LT for AC and HCV-related cirrhosis. A total of 297 patients who underwent LT at the Gemelli Hospital were retrospectively evaluated. In particular 66 (22.2%) patients underwent LT for alcoholic cirrhosis, and 52 (17.5%) patients for HCV-related cirrhosis. The survival rate was evaluated according to the Kaplan-Meier model. Recidivism for patients with AC was defined as any alcohol intake after LT. Recidivism for HCV-related cirrhosis was defined as histological evidence of chronic hepatitis C within 3 years of LT. Moreover post-surgery complications, chronic and acute rejection, onset of cancer, infectious, cardiovascular and metabolic disease was evaluated.
Results: Patients who underwent LT for AC showed a higher, however not significant, rate of survival than patients who underwent LT for HCV-related cirrhosis. Patients with HCV-related cirrhosis showed a significant higher prevalence of recidivism after LT ($p = 0.02$). Patients transplanted for AC presented a significantly higher prevalence of cancer, in particular of upper digestive tract ($p = 0.04$). No differences were found in the prevalence of cardiovascular, metabolic and infectious disease, rejection, and post-surgery complications between the two groups.
Conclusion: This study shows that our patients who underwent LT for AC have a higher survival rate and a lower recidivism rate than patients who underwent LT for HCV-related cirrhosis. No differences in terms of complications after LT were found between two groups, with the except of the higher prevalence of cancer in the AC group. These data are in line with previous literature data

Introduction: Several studies have suggested efficacy of Baclofen (BAC) at low or high dose in reducing alcohol consumption. Since March 2014, Temporary Recommendation for Use of BAC has been allowed by the French drug agency (ANSM) in this indication.
Aims & Methods: The aim of the study was to assess effectiveness and safety of BAC at 12 months in alcohol-dependent patients with or without liver cirrhosis. Between June 2010 and September 2013, 100 consecutive patients from 2 liver and alcohology units were included in this prospective open label study. Patients provided written consent before treatment initiation. BAC was orally administered at a dose of 15mg/day and weekly increased until alcohol indifference was obtained. The treatment was associated to social-psychological support and medical care.
Results: BAC was started in 100 patients (75 males, mean age 53 ± 9 years): 65 were cirrhotic and 16 had a chronic pancreatitis. After 1 year, 86 patients were still involved in the follow up, 83 were treated with BAC, 9 were lost of follow-up, 4 were dead and 1 had been transplanted. At a mean BAC dosage of 40mg/day [30–210], mean daily alcohol consumption (DAC) was reduced from 106 to 18g/day ($p < 0.001$). A decrease of the DAC > 50% was observed in 77 patients. Among them, a « low consumption » group of 64 patients was identified: 44 were completely abstinent and 20 drunk less than 30g/day. No predictive factor of response was identified. In this group, a significant improvement of consumption biomarkers was observed: decrease of mean gGT activity from 4.8N to 2N ($p < 0.001$), mean ASAT activity from 2.6N to 1.1N ($p < 0.001$) and mean erythrocyte globular volume from 100.6 to 92.8m3 and increase of mean platelets count from 171,000 to 193,000/mm3 ($p = 0.032$). In the 39 cirrhotic patients of the « low consumption » group, total bilirubin serum concentration significantly decreased from 34.2 to 19.5mmol/L ($p = 0.026$), prothrombin time increased from 69 to 77% ($p < 0.001$) and albuminemia increased from 34.2 to 37.2g/L ($p = 0.07$). Twenty patients (20%) reported minor side effects leading to a treatment withdrawal in 2 cases. No liver or renal function deterioration occurred in cirrhotic patients.
Conclusion: In our cohort, baclofen treatment associated to a global care led to a dramatic reduction of alcohol consumption. This effective treatment is well tolerated and associated with a significant improvement of consumption biomarkers and of liver function tests in cirrhotic patients.

Introduction: In addition to being the primary organ involved in redox cycling, the liver is also one of the most highly innervated tissues in mammals [1]. Although the sympathetic nervous system (SNS) is known to modulate both liver regeneration [2] and hepatic fibrosis [3], less is known regarding the role of the SNS in modulating the hepatic response to oxidative stress.
Aims & Methods: Our aim was to investigate the role of the SNS in healthy and oxidatively stressed liver parenchyma, theorizing that sympathectomized animals would be protected against oxidative stress. C57Bl/6JNarl male mice were treated with 6-hydroxydopamine hydrobromide to cause chemical sympathectomy or with either the α-adrenergic antagonist phentolamine or the β-adrenergic antagonist nadolol. Thereafter, carbon tetrachloride (CCl_4) injection was used to induce acute oxidative liver injury. Development of liver injury, oxidative stress, hepatocyte ultra-structural damage, and inflammatory responses were investigated.
Results: Sympathectomized animals were protected from acute CCl_4-induced liver injury as measured by an increase in lipid peroxidation as assessed by 4-hydroxy-2-nonenal (4-HNE) levels; elevation of serum alanine aminotransferase (ALT), lactate dehydrogenase (LDH) and alkaline phosphatase (ALP) levels; DNA oxidative damage; and morphological features of cell damage. In addition, chemical sympathectomy modulated the CCl_4-induced inflammatory response within the liver. Attenuated injury in sympathecomized mice was associated with raised heme oxygenase-1 expression. CCl_4-induced lipid peroxidation and hepatotoxicity were suppressed by administration of an α-adrenergic antagonist.
Conclusion: We conclude that the SNS provides a permissive microenvironment for hepatic oxidative stress and injury indicating the possibility that targeting the hepatic α-adrenergic signaling could be a viable strategy for improving outcomes in patients with acute hepatic injury.

Contact E-mail Address: l.nelson@ed.ac.uk

Introduction: Chlorpromazine (CPZ) is an antipsychotic that can cause severe liver injury including intrahepatic cholestasis (jaundice). Preclinical in vitro models such as rat hepatocyte couplets or primary rat and human hepatocytes sandwich cultures have been the used to analyze hepatic transport processes. Dysregulation of the hepatobiliary transporter, bile salt export pump, is now recognized as a molecular initiating event in cholestasis. However existing models, including animal models, do not accurately predict cholestasis in humans. Therefore, new methods of detecting cholestatic liver injury caused by candidate compounds under development is critical. Cholestatics can also have profound effects on tissue architecture. For example, CPZ and cyclosporine-A have recently been shown to destabilize intercellular tight junctions (TJs) via oxidative stress-mediated effects on TJ-associated cytoskeletal pericanalicular F-actin distribution in a 2D human hepatic HepaRG cell model[1-2]. HepaRG cells correctly localize hepatobiliary transporters to canalicular structures, comparable with primary human hepatocytes, and exhibit functional polarity[3].
Aims & Methods: We aimed to develop a HepaRG-based LiverBioChip, as a preclinical test system for CPZ-mediated cholestatic liver injury, using impedance-based biosensing. Differentiated HepaRGs were cultured to confluence on 8-well (8W10E+) gold micro-electrode arrays. On day 8, CPZ time-/dose-response [0-100 μM] was monitored with quantitative impedance, |Z|, measurements (180s intervals; multiple frequencies: 4-64kHz) for 24h; to detect the TJ parameter (Rb), using |Z|-spectra modeling. Correlative hepatotoxicity/ phenotypic assays were performed: i) ATP-depletion; Prestoblue (PB: live-cell viability); and i) F-actin/phalloidin fluorescent staining.
Results: Real-time |Z| monitoring showed highly-sensitive/ temporal dose-response to CPZ; with a decrease of impedance at all frequencies, indicating a global decline in cellular health. Subsequent |Z|-spectra modelling reflected significant early (1h) disruption of TJ, and the cell-substrate adhesion parameter (z-alpha), at all CPZ doses [25, 50, 100 μM]. Endpoint ATP-depletion and PB assays (24h) correlated with |Z| changes only at the lethal [100 μM] dose. Fluorescent F-actin/phalloidin staining confirmed disruption to bile canalicular- [50-100 μM CPZ] and TJ-associated hepatic structures (ZO-1 TJ protein).
Conclusion: LiverBioChip provides a continuous/ quantitative real-time indicator of hepatic TJ integrity; revealing early, dose-dependent disruption of TJs even at sub-toxic CPZ levels (25 μM). This non-invasive platform may provide mechanistic insight into effects of putative cholestatic compounds for pre-clinical drug discovery.

Introduction: Experimental and neuroimaging studies suggest a striatal dopaminergic dysfunction in alcohol dependence. Repetitive transcranial magnetic stimulation (rTMS) is a new promising treatment for substance addiction. Preliminary data in alcohol-dependent patients showed that rTMS of the dorsolateral prefrontal cortex increases dopamine release in the striatum, reducing craving.
Aims & Methods: The aim of this study is to assess DAT availability in actively drinking alcoholics before and after deep rTMS by 123I-FP-CIT SPECT, exploring changes in DAT levels and clinical parameters. We enrolled 14 untreated patients (12 M, mean age: 49 ± 10 years) with a DSM-IV diagnosis of alcohol dependence and a current alcohol drinking phase and without a major psychiatric disorder. After baseline SPECT scan, 11/14 patients were randomised to a real rTMS ($n = 5$) or a sham stimulation ($n = 6$). Each patient underwent 12 rTMS sessions for one month and a second SPECT scan was carried out at the end of treatment. Severity of alcohol dependence and craving were assessed before and after rTMS through the Alcohol Dependence Scale, Penn Alcohol Craving Scale and Obsessive Compulsive Drinking Scale. Anxiety and depression were evaluated by the State-Trait Anxiety Inventory and Zung Depression Self-Rating Scale. The alcohol Timeline Follow-back (TLFB) was used to estimate daily drinking. A ^{123}I-FP-CIT template was created with images of 20 healthy subjects (HS, 12 M, mean age: 47 ± 16 years). Patient scans were spatially normalised to the ^{123}I-FP-CIT template by SPM8. Analysis was performed using VOIs selected from a digital atlas; VOI mean activity concentration was obtained through Marsbar toolbox and Specific Binding Ratios (SBR) were calculated in the caudate nuclei and putamina.
Results: At baseline, alcoholics showed higher SBR in caudate nuclei and putamina ($p < 0.05$) in comparison with HS. An inverse correlation was found between SBR in the left caudate and anxiety levels ($p < 0.05$). After treatment, patients submitted to real rTMS had a reduction in SBR and no differences were any longer detected in comparison with HS. Conversely, patients submitted to sham stimulation showed higher SBR as compared with HS ($p < 0.05$) also at SPECT examination after treatment. When considering TLFB data, a significant reduction in alcohol intake ($p < 0.05$) was detected only in patients submitted to real rTMS.
Conclusion: Our preliminary data show that striatal DAT availability is increased in alcohol-dependent patients, supporting the assumption of a dysfunctional dopaminergic system. The finding of a SBR ''normalization'' as well as a reduction in alcohol intake after real rTMS, although obtained in a small sample, could suggest a clinical usefulness of deep rTMS.

Introduction: Tuberculosis (TB) remains a major global health problem. Anti-TB drugs have proven efficacy against TB, however, they can induce various adverse events of which hepatoxicity is the most serious. Anti-tuberculosis drug induced liver injury (ATLI) is emerging as a significant threat to TB control, though limited data is available at present. This study aims to estimate the incidence of ATLI and understand its clinical features.
Aims & Methods: This was a single-center, prospective study which consisted of cohort of TB patients who received DOTS treatment at EAMC from December 2013 to May 2014. Only 285 patients who were at least 18 years of age were included. Clinical and laboratory features of ATLI were monitored for the treatment duration.
Results: We monitored 240 TB patients, 52 were dropped from the study while 188 continued. Nine patients developed ATLI with cumulative incidence of 4.8 % (95% CI, 2.4 – 7.19%). Nausea, abdominal pain were the most frequently observed signs and symptoms. Three (33.33%) ATLI patients had severe

hepatotoxicity, 7 (77.77 %) recovered, 1 (11.11%) failed to respond to treatment with continued elevation of aminotransferases and 1 (11.11%) died as a result of ATLI.

Conclusion: For this cohort, ATLI incidence was higher compared to data from China and Canada, comparable with Hongkong, and Singapore but lower than Taiwan. Presence of comorbidities showed trend to increase ATLI, however, further analysis only showed those with liver and biliary diseases to be statistically significant. Larger cohort of patients is suggested.

Introduction: Severe Alcoholic Hepatitis (SAH) is defined by modified Maddrey's Discriminant Function (mDF) $\geq$32 and is associated with very high short-term mortality. Corticosteroids reduce mortality in SAH patients but not to the desired extent. Bovine Colostrum is a biologic, food supplement and has immunomodulatory functions (1). Its effector constituents are immunoglobulins, growth factors (Insulin Like Growth Factor 1, 2; Transforming Growth Factor Beta), Lactoferrin and Lactoperoxidase. Lactoferrin is converted to Lactoferricin B in the stomach by pepsin which is bactericidal. Immunoglobulin G (IgG) interacts with mucosa associated lymphoid tissue, to maintain a healthy mucosal barrier and prevents gram negative bacteria and endotoxins from entering the porto-systemic circulation. Decreased endotoxemia dampens the pro-inflammatory cytokine cascade (IL 1β, IL 6, α TNF). Thus hepatocyte death and development of multisystem organ failure is averted. We aimed to study the efficacy of combination therapy of Corticosteroids and Bovine colostrum in improving mDF and reducing short-termmortality in patients with SAH.

Aims & Methods: Seventeen patients with SAH were prospectively evaluated, and 10 out of these were included. Bovine Colostrum (20 grams thrice in a day for eight weeks) and Prednisolone (40 mg once a day for four weeks, tapered over next four weeks) were administered to these patients. Serum Cytokines IL6, IL8, IL10 and TNFα were measured at 0 and 8 weeks. Paired t Test was used for analyzing the data. Data are expressed as mean $\pm$ SD. Trial was registered at Clinical Trial.gov -NCT02265328.

Results: The mean age was 41.6 $\pm$ 7.9 years and 100% were males. There was a significant improvement in mDF level from 78.1 $\pm$ 14.2 at baseline to 43.6 $\pm$ 23.8 at 8 weeks; p = 0.001]. Also there was a significant change in IL6 and IL8 levels at 8 weeks (table). The survival at one month and three months was 90% and 70% respectively.

Table: Test of difference: baseline versus 8 weeks in patients with severe alcoholic hepatitis after treatment with bovine colostrum and corticosteroids.

	Paired Differences						
	Mean	Std. Deviation	Std. Error Mean	95% Confidence Interval of the Difference	T		p value
IL 8	0.09443	0.06111	0.02310	0.03791	0.01509	4.088	0.0064
IL 6	0.05014	0.02284	0.008634	0.1620	0.1119	5.808	0.0011
α –TNF	-0.0064	0.02964	0.01326	-0.04320	0.03040	0.4827	0.6545
mDF	34.714	14.829	5.605	21.000	48.429	6.194	0.001

Conclusion: In patients with SAH, treatment with combination therapy of Bovine Colostrum plus Prednisolone lead to significant improvement in the liver biological functions. The 3 month survival of 70% in this study was much better than 30% survival reported prevoiusly with the use of corticosteroids alone in SAH patients (2). Therefore, this combination could be a better option for treatment of patients with SAH. Larger randomized controlled trials are required to confirm these findings.

Contact E-mail Address: anapatriciarandrade@gmail.com

Introduction: Acute alcoholic hepatitis (AAH) is a distinct clinical entity in the spectrum of alcoholic liver disease and is associated to high short-term mortality. Different score systems have been used to assess the severity and predict the prognosis of patients with AAH.

Aims & Methods: Evaluate the ability of seven different score systems to predict 90-day mortality and analyse other potential predictors of mortality.

Retrospective analysis of patients admitted to our department due to AAH, between November 2009 and October 2014. The following score systems were analysed: Child-Pugh (CP), Maddrey discriminant function (MDF), model for end-stage liver disease (MELD), Glasgow alcoholic hepatitis score (GAHS), Age-Bilirubin-INR-Creatinine (ABIC), Lille score (LS) and CLIF consortium-organ failure score (CLIF-OF).

Results: We included 59 cases of AAH (78% men, mean age 47 $\pm$ 8 years). The mortality rate at 90 days was 22% (n = 13). Forty-nine percent of patients (n = 29) initiated therapy with corticosteroids. Only 28% (n = 8) of patients were complete responders (LS $<$ 0.16) while 38% (n = 11) were non-responders (LS $>$ 0.56). Encephalopathy (p = 0.038), ascites (p = 0.013), CP score $>$ B (p = 0.034), LS $>$ 0.56 (p = 0.002), and a higher GAHS (p = 0.009) and CLIF-OF (p $<$ 0.001) score were significantly associated with higher 90-day mortality. In multivariate analysis, CLIF-OF score was the only one independently associated with higher mortality at 90 days (OR 2.99, 95% CI: 1.63-5.50, p $<$ 0.001).

Conclusion: AAH was associated with a 90-day mortality of 22%. The CLIF-OF score was the only score significantly associated with higher mortality at 90 days, with an OR of 2.99.

Introduction: Drug-induced liver injury (DILI) is the most common cause of acute liver injury. IBD patients might have an increased risk of DILI due to long-term treatment, multiple therapies and altered nutritional status. Any liver injury during IBD treatment might further compromise treatment choices, efficacy and overall health.

Aims & Methods: First, prospectively evaluate on-treatment prevalence, severity and evolution of liver injury in IBD patients for 6 months. Second, evaluate the impact of IBD treatment with azathioprine and/or anti- TNF on the prevalence of liver injury. Third, evaluate liver injury implications for further IBD therapy. From 1/1/2014 to 1/6/2014 all IBD cases visiting a single center were included. Demographics, IBD status, IBD therapy and possible PSC were recorded. Liver blood tests were measured at three time points 3 months apart. Liver injury was defined as elevated ALT, GGT and ALP above 1.5 times the upper limit of normal (ULN). Two types of liver injury were predefined: transient elevation (once or twice) and persisting elevation (at all three time points). Severe liver injury was defined as ALT $>$ 5xULN at any time. The prevalence of hepatotoxicity was compared among 4 treatment groups (no azathioprine, no anti-TNF (1), azathioprine (AZA) solo (2), anti-TNF solo (3), and combination therapy (4). Finally, we evaluated the need for change of IBD therapy caused by liver injury.

Results: 205 IBD patients were included, with median age of 40, male/female ratio 102/103, Crohn's/UC ratio 127/78, 27% with prior GI resection, 2 cases with PSC. IBD was treated with no AZA and no anti-TNF in 40 cases, azathioprine solo in 40 cases, anti-TNF solo in 63 cases and combination therapy in 62 cases. For 6 months, transient ALT elevation was observed in 18 cases (8.78%), GGT in 21 cases (10.24%) and ALP in 5 cases (2.44%). Persisting ALT elevation was observed in 3 cases (1.46%), GGT in 3 cases (1.46%) and none of ALP. Severe liver injury was observed in 1 case (0.49%) with bilirubin $<$ ULN. The prevalence of transient liver injury among the 4 treatment groups was 5 vs. 10 vs. 12.7 vs. 9,6% for ALT and 12.5 vs. 17.5 vs. 15.9 vs. 3.2% for GGT and was not statistically different. Liver injury did not result in any change of IBD therapy.

Conclusion: Liver injury in treated IBD patients was relatively common (~10%). However, it was mostly transient, non-severe and rarely (~1.5%) persisted for 6 month. IBD therapy with azatioprine and/or anti-TNF did not increase the risk of liver injury. No changes of IBD treatment resulting from liver injury were needed.

Introduction: Alcoholic steatohepatitis (ASH) is a severe condition in the spectrum of alcoholic liver disease (ALD) that is histologically characterised by

neutrophil infiltration which correlates with mortality.[1] The underlying mechanisms of neutrophilic inflammation in the development of ALD are poorly understood and treatment options are rare.[2] Lipocalin-2 (LCN2) was originally found in granules of neutrophil granulocytes and termed neutrophil gelatinase-associated lipocalin (NGAL). Recently, it was shown that the liver is the predominant source of LCN2 during infections and that LCN2 is essential in liver homeostasis and experimental hepatic injury.[3,4]

Aims & Methods: Our aim was to investigate the role of LCN2 in the pathogenesis of ASH. Hepatic and systemic LCN2 elevation was measured in patients with histologically ensured ASH. Furthermore, 6- to 8-week-old female C57BL/6 WT and Lcn2-deficient (*Lcn2*$^{-/-}$) mice were fed a Lieber-DeCarli diet containing 5% (vol/vol) ethanol or a control diet for 2 weeks ad libitum. ASH was determined by liver-to-body-ratio, GPT-elevation, steatosis and hepatic inflammation. Adoptive transfer experiments of wild-type and *Lcn2*$^{-/-}$ neutrophils were performed to dissect the role of hepatic and neutrophil-derived LCN2 in ASH.

Results: We found a systemic and hepatic upregulation of LCN2 in patients with ASH compared to NAFLD controls, which we similarly observed in wild-type mice on a Lieber-deCarli diet. Immunocytes in hepatic tissue were the predominant source of *Lcn2* expression. *Lcn2*$^{-/-}$ mice were protected from ASH as demonstrated by diminished GPT elevation, steatosis and neutrophil infiltration. Mechanistically, we found in adoptive transfer experiments of WT and *Lcn2*$^{-/-}$ neutrophils that cell-intrinsic (rather than hepatic) LCN2 is required for neutrophilic inflammation in ASH.

Conclusion: LCN2 drives neutrophilic inflammation in ASH in a neutrophil-intrinsic manner. Our study suggests that pharmacologic neutralisation of Lcn2 blocks neutrophil migration and protects from ASH.

Introduction: Hepatic encephalopathy (HE) is a severe complication of cirrhosis which independently influences prognosis. We previously showed an increase in blood-brain barrier (BBB) permeability in cirrhotic rats with HE. The aim of the present work was to assess the effects of sodium benzoate (Bna), a drug removing ammonia through non-urea cycle pathway, and Rifaximin (RFX), a non adsorbable antibiotic, on BBB permeability in cirrhotic rats with HE.

Aims & Methods: Three groups of rats were considered: SHAM, Bile Duct Ligation (BDL), BDL + hyperammonic dietary (BDL-NH3). In each group, rats were treated by BNa or RFX. HE was assessed using neurocomportemental testing (6 minutes tail suspension test assessing the time of immobility). NH3 levels were assessed before sacrifice. BBB permeability was assessed by IV injection of a fluorochrome (Texas Red 10kDa) before transcardial washing. Brain fluorescence was estimated by fluorimetry after right hemisphere squeezing.

Results: Mean time of immobility was longer in BDL-NH3 and BDL rats than in SHAM ($p = 0.0004$). Ammonemia was significantly higher in the BDL-NH3 than in BDL rats, and higher in the BDL than in SHAM rats ($p < 0.0001$). Intra-cerebral fluorescence was significantly higher in BDL-NH3 than in BDL group, and higher in BDL than in SHAM group ($p = 0.029$) confirming the passage of the fluorochrome through the BBB. BNa treatment significantly decreased ammonemia levels and intra-cerebral fluorescence in the BDL and BDL-NH3 rats ($p < 0.04$ for all) but did not modify the mean time of immobility. On the contrary, RFX treatment did not modify ammonemia levels but significantly decreased intra-cerebral fluorescence ($p < 0.05$) and the mean time of immobility ($p = 0.0004$).

Conclusion: In cirrhotic rats displaying HE, BBB permeability is increased, through different mechanisms dependent and independent of hyperammonemia. BNa and RFX are effective in restoring BBB integrity in HE cirrhotic rats but only RFX is able to decrease HE in this model.

Introduction: ^{13}C- aminopyrine breath test (^{13}C-ABT) is a simple, sensitive tool to evaluate liver function, and its results may discriminate between patients with or without cirrhosis. Also, it was previously reported that, in patients suffering from chronic liver disease of various etiologies, ^{13}C-ABT can discriminate between those with chronic hepatitis and those with cirrhosis. It was reported that breath test can be used as a prognostic index in liver metastases even if concurrent biochemical liver tests are normal or only slightly disturbed.

Aims & Methods

The aim of this study: The aim of this study was to compare ^{13}C-ABT results between normal subjects, patients with liver cirrhosis with and without hepatocellular carcinoma in order to identify function differences between various chronic liver diseases and to evaluate different methods of expressing ^{13}C-ABT results and to maximize the information obtained from the test.

Patients and Methods: This study was carried out on 60 patients with cirrhosis and 15 normal subjects divided into three groups: group I (30 patients with liver cirrhosis), group II (30 patients with liver cirrhosis and hepatocellular carcinoma) and group III (15 healthy volunteers of matched age and sex to patient groups as a control group). ^{13}C-ABT was done to all subjects of this study.

Results: The mean aminopyrine % dose/hour after 60 minutes was significantly lower in cirrhosis group and HCC group compared to control group, and it was significantly lower in HCC group compared to cirrhosis group.
