Conclusion: Both biliary calprotectin and IL-6 levels can be used as surrogate markers of bile duct inflammation to monitor disease activity and progression. The may serve tools for assessing treatment response for medical and endoscopic therapy for PSC.

P1283 THE MOLECULES OF INTERCELLULAR ADHESION AND HIGH-SENSITIVITY C-REACTIVE PROTEIN IN PRIMARY BILIARY CIRRHOSIS

V. Sagynbaeva[1], **L. Lazebnik**[2], S. Umarova[3]
[1]*City Clinical Hospital No70, Healthcare Department of Moscow,* [2]*The Department of Outpatient Therapy, State Funded Institution of Higher Professional Education "Moscow State Medical and Dental University of A.I. Evdokimov", Moscow, Russian Federation,* [3]*Department of Therapy No1, Kyrgyz-Russian Slavic university, Medical faculty, Bishkek, Kyrgyzstan*

Contact E-mail Address: venera_32@rambler.ru

Introduction: The goal of the research is to study the role of the molecule of intercellular adhesion (sVCAM and sP-selectin) and the high-sensitivity C-reactive protein (HCRP) in the genesis of the primary biliary cirrhosis (PBC) to determine the severity of the autoimmune process and the severity of the disease.

Aims & Methods: 22 patients (22 women) with primary biliary cirrhosis (PBC) were examined. The patients' age was 38-74 years, the average age – 52.7 ± 4.0 ($M \pm \sigma$). The diagnosis was verified using data of clinical, laboratory, immunological, histological and instrumental methods of research. AMA-M2, sVCAM, sP-selectin and HCRP were determined in the patients' blood serum by enzyme-linked immunoassay using test-system «Orgentec», «Biomerica» (Germany), «Bender MedSystems» (Austria). Statistical analysis was performed using the computer program «STATISTICA 6.0», the accuracy of the obtained values was determined by Student t-test.

Results: Among the 22 patients with PBC, the level of AMA-M2 averaged 113.6 ± 11.3 IU/ml (normal <20U/ml). As the results of this research showed in PBC in active stage the levels of sVCAM and sP-selectin in the blood serum averaged 40.0 ± 7.0 and 18.6 ± 1.2 ng/ml, respectively ($p < 0.001$). In these patients the increase of the levels of sVCAM and sP-selectin was accompanied by severe cholestasis syndrome: ALP 392.9 ± 60.7 U/l, GGTP 406.1 ± 81.3 U/l and an increase in the level of the high-sensitivity C-reactive protein to 0.110 ± 0, 01mg/L (for a minimum concentration of <0.005 mg/l).

Conclusion: Thus, in primary biliary cirrhosis in active stage the increase of the level of the molecules of intercellular adhesion (sVCAM and sP-selectin) can be marked accompanied by severe cholestasis syndrome and increase in the level of the high-sensitivity C-reactive protein. The increased level of the molecules of intercellular adhesion (sVCAM and sP-selectin) and HCRP reflects the severity of the autoimmune process and the severity of the PBC.

Introduction: Early identification of ursodeoxycholic acid (UDCA) treated patients with primary biliary cirrhosis (PBC) is important, since new therapies are under active evaluation.

Aims & Methods: To assess the association between alkaline phosphatase (ALP), bilirubin and transplant-free survival in terms of absolute risk (AR) for 5- and 10-year all-cause mortality or liver transplant using the recently proposed GLOBE score, in patients with PBC.

For current analysis the GLOBE score (www.globalpbc.com) was used, a risk score comprising age, bilirubin, ALP, albumin and platelet count after one year therapy of UDCA therapy to calculate the risk of liver transplantation/death. Various scenarios were run predicting this risk at 5- and 10-year, using static values for age (55 years), platelets (250 per 10^9/L) and albumin (1.0xULN). ALP and bilirubin levels were varied from 1 time to 4 times the upper limit of normal (ULN). Change in absolute risk was calculated for increases in bilirubin and ALP, holding the other variable constant.

Results: Table 1 shows AR at 4 levels of bilirubin and ALP, and absolute change in risk when bilirubin and ALP are increased from 1x to 2x, 2x to 3x and 3x to 4x the ULN.

Conclusion: The greatest increase in risk for death/transplant was when bilirubin increased from 1x to 2x the ULN. Similarly, the highest increase in risk resulted when ALP increased from 1x to 2x the ULN. These data indicate that early treatment, reducing and maintaining ALP and bilirubin at ULN, would have the greatest benefit in terms of absolute increased transplant-free survival in PBC patients.

Disclosure of Interest: None declared

Abstract number: P1284

Absolute risk of developing a clinical endpoint (liver transplantation or death)after 5- / 10-year UDCA treatment

Alkaline phosphatase levels (xULN)	Bilirubin levels (xULN)			
	1xULN	**2xULN**	**3xULN**	**4xULN**
1xULN	12.5% / 30.3%	22.6% / 49.9%	31.3% / 63.6%	38.9% / 73.4%

Contact E-mail Address: roxanasirli@gmail.com

Introduction: Currently, validated non-invasive methods for fibrosis assessment in chronic hepatitis are transient elastography (TE) and serological tests (FibroTest-ActiTest). Virtual Touch Imaging Quantification (VTIQ) Elastography became available in the last years.

Aims & Methods: The aim of this study is to find the relevance of VTIQ for the evaluation of liver fibrosis as compared to the reference method, liver biopsy (LB).

Our retrospective study included 281 subjects (147 women and 134 men, mean age 46.3 ± 13.1); 109 with chronic hepatitis B and 172 with chronic hepatitis C, evaluated during a 4 years period. All subjects were evaluated in the same session by LB and VTIQ. LBs were assessed according to the Metavir score. Ten VTIQ measurements were made in each patient (using a Siemens Acuson S2000™ ultrasound system), and a median value was calculated, measured in meters/second. Only measurements with IQR < 30% were considered reliable (Bota et al.2013)

Results: According to the Metavir score, 2.8%(8) pts were F0; 21.7%(61) were F1; 43.4%(122) were F2; 22.4%(63) were F3 and 9.6%(27) were F4.

From the 281 subjects, VTIQ valid measurements were obtained in 278 subjects (invalid determinations in 1.2%).

A significant correlation (Spearman rho = 0.401) was found between VTIQ measurements and fibrosis ($p < 0.0001$).

The mean values of VTIQ according to fibrosis groups were: F0 1.1 ± 0.2m/s; F1 1.3 ± 0.6m/s; F2 1.5 ± 0.6m/s; F3 1.7 ± 0.7m/s; F4 2.4 ± 0.7m/s.

The performance of VTIQ for fibrosis assessment are presented in the table.

	Cut-off (m/s)	AUROC	Sensitivity (%)	Specificity (%)	+LR	-LR	PPV (%)	NPV (%)
F1	**1.14**	0.759	71,85	87,50	5,75	0,32	**99,5**	8,4
F2	1.22	0.683	67,94	63,77	1,88	0,50	85,0	39,6
F3	1.71	0.729	51,14	86,32	3,74	0,57	63,4	79,2
F4	**1.77**	0.855	80,77	82,54	4,63	0,23	32,3	**97,7**

For the calculated optimal cut-off, VTIQ had very good positive predictive value for the presence of any fibrosis (F1-F4), even if a high overlap rate was observed in pts with F0, F1 and F2. VTIQ also had a good negative predictive value for cirrhosis (table).

Conclusion: Liver stiffness evaluation by means of VTIQ can be performed in the vast majority of patients (98.8%). ARFI is an accurate method for predicting any fibrosis (PPV 99.5% for a cut-off of 1.14 m/s), and also to exclude cirrhosis (NPV 97.7% for a cut-off of 1.77 m/s).

Introduction: Non-invasive evaluation of liver fibrosis by using ultrasound based-elastographic techniques is increasingly used in the last years. Non-invasive evaluation of liver fibrosis by using ultrasound based-elastographic techniques is increasinglyused in the last years.

Aims & Methods: The aim of the present study was to assess the reproducibility of a new point shear wave elastography which uses ARFI technique – ElastPQ, as a non-invasive method for liver fibrosis evaluation.

The study included 74 consecutive subjects, with or without chronic hepathopaties and healthy volunteers. Out of 74 subjects, in 33 subjects liver stiffness was assessed by a single operator, while in 50 subjects liver stiffness was assessed by two operators in the same session.

Two operators, with experience in liver elastography, performed 10 consecutive valid elastographic measurements in the liver parenchyma, avoiding large vessels with the ElastPQ (Philips, Affinity) technique. Reliable LS measurements were defined as the median value of 10 LS measurements expressed in kPa. The intra and interobserver reproducibility of ElastPQ technology was analyzed with intraclass correlation (ICC) coefficient.

Results: The overall intraobserver agreement was better than the interobserver one: ICC 0.92 vs. ICC 0.85. A strong correlation was obtained between measurements assessed by both operators ($r = 0.86$, $p < 0.0001$) and also between measurements assed by a single operator 0.76 ($p < 0.0001$). For both intra- and interobserver reproducibility, the ICCs were similar in patients with high body mass index (BMI) ≥25 kg/m^2 vs. <25 kg/m^2 (0.90 vs. 0.93 and 0.89 vs. 0.82, respectively).

Conclusion: ElastPQ is a highly reproducible method for assessing liver fibrosis with excellent intra and interobserver agreement.

Introduction: Diffusion-weighted magnetic resonance imaging (DWI) was new non–invasive method measures the freedom of water proton diffusion in tissues which can be described by the apparent diffusion coefficient (ADC) and was recently facilitated to be used for abdominal imaging. The impact of liver fat ADC is currently unclear.

Aims & Methods: The aim of this study was to assess the impact of liver steatosis, detected by histology on ADC value of diffusion MRI for fibrosis diagnosis in patients with chronic hepatitis C (CHC) genotype 4. Three hundreds CHC patients (186 males and 114 females), aged 43.8 ± 10.1years were histologically staged for liver fibrosis by Metavir score: Activity (A0-A3), fibrosis stage (F0-F4) and steatosis stages were assessed in liver specimens. DWI of the liver was performed within 15 to 60 days after biopsy, to avoid artifacts related to early post biopsy changes using a 1.5 Tesla (T) scanner. Following coronal localizer of the abdomen, all patients underwent axial T1 weighted images (TR/TE = 600/20 ms) and axial true FISP (TR/TE = 4.3/2.1 ms) of the liver with field of view (FOV) of 25- 25 cm , section thickness of 7 mm , interslice gap of 1mm, and acquisition matrix of 256x224. ADCs were correlated with fibrosis stage, steatosis grade, using linear regression.

Results: Mean ADC value was 1.5 ± 0.3 (range 1.0-2.09). Diffusion MRI values (ADC) decreased significantly the advance of fibrosis stage from 1.95 ± 0.02 in F0; to 1.55 ± 0.02 in F1; 1.55 ± 0.02 in F2; 1.47 ± 0.02 in F3; and 1.36 ± 0.10 in F4; $p \leq 0.001$). Similar results were obtained after exclusion patients with steatosis ≥5% ($p \leq 0.001$). There were inverse weak to moderate correlations between ADC and Age (r = -0.2), body mass index (r = -0.12), severity of necroinflammatory activity (r = -0.4), stage of fibrosis (r- = -0.6) and steatosis (r = -0.14). However the multivariate linear regression analysis revealed that fibrosis is only significant independent predictor of ADC with a coefficient of determination (R^2) = 0.23.

Conclusion: The presence of steatosis detected by histology in patients with CHC G4, has no impact on ADC value of diffusion MRI for fibrosis assessment. Therefore it is unlikely to confuse the performance of diffusion MRI to evaluate hepatic fibrosis in suspected patients with steatosis.

Introduction: It is known that changes in patients with diffuse liver diseases at the vascular level are systemic in nature.

Aims & Methods: To unvestigate the state of the microcirculation in various forms of diffuse liver diseases by noninvasive laser Doppler imaging (LDI) with functional tests. 79 patients were divided into 3 group. The 1st group - patients with alcoholic liver cirrhosis (n = 45) among them 14 patients with class A, 18 patients with class B and 13 patients with class C; The 2nd group -patients with alcoholic steatohepatitis (ASH) and nonalcoholic steatohepatitis (NASH) (n = 21) ; the 3rd group - patients with viral hepatitis "C" (n = 13). The control group - 40 patients with diseases of digestive tract without liver diseases. Perfusion (P) c.u; concentration (C) – c.u , blood flow velocity (υ) mm\s in area of thenar and hypothenar were estimated by LDI. As a provocative test

was applied extended cold test. Difference between initial perfusion and after cold test (ΔP) was analyzed (%) afterwards.
Results: A significant increase in blood flow values (P -240.15 ± 1.8c.u; C-32 ,78 ± 3.3 c.u; υ -10.57 ± 5.0 mm\ s) in comparison with the control group (P -127 , 2 ± 5.6 c.u , C -64.8 ± 6.2 c.u , υ -2, 55 ± 2.5 mm\s) was observed in all cases of cirrhosis class C and 6 (33 %) patients of cirrhosis class B ($p < 0.05$). Cold test in these patients was negative ($\Delta P < 10\%$). For one year follow-up we established that in all these patients increased microcirculation parameters. 6 of them died. In all patients with liver cirrhosis class A and in 5(28%) patients with liver cirrhosis class B , in all patients with hepatitis C high degree of activity (more 400 000 ribonucleic acid (RNA) ME\ml) and in patients with NASH and ASH high degree of activity moderate increased of blood flow in the studied areas were observed (P – 188.64 ± 4.2c.u , C - 48, 67 ± 3.3 c.u , υ - 6.02 ± 5.2 mm\s). Microcirculation in patients with low viral load (RNA less 400 000 ME\ml) and patients NASH in low activity levels were comparable to the control group. Cold tests in these patients were primarily positive ($\Delta P > 15\%$). These data pointed out at conservation of microcirculation in these patient. We didn't reveal decompensation of liver disease in this case during follow-up period. In 7 (39%) patients with liver cirrhosis class B moderate increased of blood flow were observed too, but the cold test in these group was $\Delta P = 10\text{-}15\%$(intermediate value). Among these patients 3 became class A, 3 patients remained class B and 1 patient became class C while on treatment during follow-up period. The more the changes in liver were (by biopsy), the more significant changes were identified in microcirculatory blood flow ($r = 0.76$)
Conclusion: Changes in perfusion > 135 c.u; concentration < 58 c.u, speed > 5 mm/s in patients with diffuse liver diseases characterize the clinical significance of microcirculation disturbances in this pathological process. $\Delta P < 10\%$ we estimated as disturbance of reversibility of tissue microcirculation functional resources, that served as the basis for unfavourable forecasting with high possibility of decompensation development; $\Delta P > 15\%$, pointed out at lower possibility of decompensation of disease during 12 month. $\Delta P = 10\text{-}15\%$ - questionable forecasting. It takes futher medical observation.

P1289 EFFECTIVENESS AND SAFETY OF TRANSARTERIAL EMBOLIZATION IN PATIENTS WITH LIVER METASTASES OF A NEUROENDOCRINE TUMOUR

W. Verbeek[1], M. Meier[2], S. van Dijk[1], M. van Leerdam[2], W. Prevoo[3], M. Tesselaar[4]
[1]*Gastroenterology,* [2]*NKI, Amsterdam, Netherlands,* [3]*Radiology,* [4]*Medical Oncology, NKI, Amsterdam, Netherlands*

Contact E-mail Address: m.tesselaar@nki.nl
Introduction: Transarterial embolization (TAE) is an effective treatment for liver metastases from neuroendocrine tumour (NET). It reduces arterial blood flow to the tumour resulting in ischemia and necrosis. In this single centre study the effectiveness and safety of TAE was evaluated.
Aims & Methods: Patients with histological confirmed gastro-entero-pancreatic NET with liver dominant metastases were retrospectively investigated. Adverse events, tumour response, decline in symptomatic carcinoid syndrome and overall survival were evaluated.
Results: A total of 30 patients (15 male, median age 61.5 years), underwent 47 TAE procedures between 2009 and 2014. The primary NET site was ileum (n = 16; 53.3%), colon (n = 6; 20%), pancreas (n = 1; 3.3%), lung (n = 1; 3.3 %) and unknown (6; 20%). Almost all patients (97%) received octreotide treatment for symptomatic NET, prior to TAE. Twenty two patients (73.3%) were also diagnosed with extrahepatic metastases. The median time from primary metastatic NET diagnosis to first TAE was 36.5 months. After TAE procedures a transient elevated level of bilirubin, gamma GT, ASAT, ALAT and LDH was seen in all patients. Two patients had major TAE related complications. No TAE related death occurred. CT scan was performed 1 and 3 month after TAE; 80.9% of the patients had a decrease of neuroendocrine liver metastases volume. This decrease was significantly higher when liver metastatic involvement before TAE was < 50%. There was a significant decrease in chromogranin A both 1 and 3 months after TAE ($p = 0.001$ and $p = 0.017$, resp.). Of the 30 patients who had a carcinoid syndrome before TAE, 88% had a decrease in clinical symptoms at 1 month follow up and 69.6% at 3 months follow up. Sixteen patients underwent 2 or 3 TAE procedures for progression of carcinoid symptoms. The overall survival at 1-year follow up was 86.7%.
Conclusion: TAE is a relative safe treatment for liver metastasized NET which can be done multiple times within 1 patient. It reduces carcinoid syndrome in the majority of patients and shows a significant reduction in tumour marker. Radiological decrease rate is significantly higher in patients who have < 50 % liver involvement.

[3]*Department of Surgery, E-DA Hospital/ I-SHOU University, Kaohsiung, Taiwan, Province of China*

Contact E-mail Address: lincw66@gmail.com
Introduction: Hepatocellular carcinoma (HCC) is one of the most common malignancies, with an increasing incidence and is the third leading cause of cancer-related mortality in the world [1]. Most HCC patients are diagnosed at an advanced stage and have very poor prognosis and low survival. The effective biomarkers need to predict the clinical outcome of patients with HCC. Autophagy is a process through which long-lived proteins and damaged organelles are conveyed to the lysosome for removal by degradation and recycling [2,3]. Some studies have shown that autophagy plays a key role in the progression and development of cancer. But, the role of autophagy in the prognosis and metastasis of human HCC is not well unknown.
Aims & Methods
Aims: The study aims to explore the expression of markers of autophagy genes and cell proliferation using immunohistochemistry (IHC) in human HCC tissues. We also investigate the autophagy markers associated with clinicopathological characteristics and prognosis.
Methods: We retrospectively analyzed 210 patients diagnosed with HCC by histology after surgical resection at E-DA hospital/ I-Shou University, Kaohsiung, Taiwan, from 2009 to 2013. The demographic data, recurrence, and survival were collected until April 2015. The expression of autophagy-related markers (LC3, Beclin-1, Atg5, Atg7, and p62) were analyzed by IHC staining using HCC tissues and non-tumor tissues.
Results: Two hundred and ten HCC patients were collected. The average age is 59.5 years old and the rate of male is 80.9%. The rate of HBV, HCV, and Non-HBVHCV is 62%, 24%, and 14%, respectively. Median survival was 38.3 months (range 1.3-64.1 months). The positive rate of Beclin-1 was significantly lower in HCC tissues than adjacent tissues (70.5 vs. 88.5%, $P = 0.01$). In HCC, Beclin-1 expression was negatively correlated with cirrhosis background ($P = 0.04$) and Edmondson grade ($P = 0.03$). The strong positive of Beclin-1 is significantly associated with increasing the 5-year survival rates ($P = 0.02$). Univariate and multivariate Cox regression analysis revealed that Beclin-1 expression was an independent indicator for overall survival in HCC patients ($P < 0.05$).
Conclusion: Our results demonstrate that the expression of autophagy marker, Beclin-1, might be a strong prognostic factor of HCC, especially in patients underwent liver resection.

Introduction: Prolyl hydroxylase domain (PHD) deletion results in the stabilization of hypoxia inducible factor (HIF), a key compound in the cellular response following hypoxia which has been linked to cancer development. We previously showed that PHD inhibition results in an increased expression of liver progenitor cells (LPCs) which coincided with a phenotypic switch from hepatocellular carcinoma (HCC) to hepato-cholangiocarcinoma in diethylnitrosamine (DEN)-induced hepatocarcinogenesis[1,2].
Aims & Methods: In this study, we investigated if the effect of PHD2 inhibition on the expression of markers for hypoxia and LPCs occurs during the initiation and development of HCC following DEN treatment. PHD2 haplodeficient ($PHD_2^{+/-}$) and wild type (WT) mice were weekly injected with 35mg/kg DEN and euthanized after 5, 10, 15 and 17.5 weeks of DEN induction, before tumor nodules could form[1]. Livers were prelevated and analyzed for the expression of downstream targets of HIF (Vascular endothelial growth factor alpha, Vegfa and Glucose transporter 1, Glut1) and LPC markers (cytokeratin 7, CK7; cytokeratin 19, CK19; prominin1, Prom1 and epithelial cell adhesion molecule, Epcam) using qPCR and immunohistochemistry. The results were linked to neoplastic transformation of hepatocytes determined by reticulin staining. Results were significant at $p < 0.05$.
Results: Vegfa and Glut1 RNA expression were significantly upregulated after 17.5 weeks of DEN induction in WT and $PHD_2^{+/-}$ mice with a significantly higher increase for Glut1 in $PHD_2^{+/-}$ mice. Prom1 and CK19 expression followed these results with a significant increase after 17.5 weeks of DEN induction, however without differences between $PHD_2^{+/-}$ and WT mice. For CK7 and Epcam, the RNA expression did not change during early hepatocarcinogenesis. Immunohistochemistry revealed an increased CK19 immunoreactivity after 15 weeks of DEN induction compared to earlier time points in $PHD_2^{+/-}$ mice which was mostly caused by increased cytoplasmic expression in hepatocytes rather than ductular expansion. The intracellular domain of Epcam was significantly more expressed after 17.5 weeks of DEN in $PHD_2^{+/-}$ mice compared to WT mice. Neoplastic transformation was limited to some reticulin free cells after 15 and 17.5 weeks of DEN in both $PHD_2^{+/-}$ and WT mice.
Conclusion: These results show an increased expression of LPC characteristics, coinciding with augmented expression of hypoxic markers during early HCC

development. However, the effects of PHD2 haplodeficiency were limited to non-existing. Based on this and our previous reports[1,2] we conclude that induction of the hypoxic response affects the expression of LPC characteristics and tumor phenotype not in an early event but coincides with the occurrence of neoplasticity.

Introduction: Sperm-associated antigen 9 (SPAG9), a member of cancer testis (CT) antigen family, has been reported to be involved in the development of hepatocellular carcinoma (HCC), however, its post-transcriptional regulatory mechanisms have not been well understood. Since microRNAs (miRNAs) are powerful post-transcriptional regulators of gene expression. We focused on the miRNAs-mediated regulation of SPAG9. By using three publicly available algorithms (TargetScan, miRanda and PicTar), miR-141 was identified as a candidate miRNA that could target 3'-UTR of SPAG9.
Aims & Methods: The present study was aimed to investigate the role of miR-141-mediated SPAG9 regulation in the development and progression of HCC. SPAG9 and miR-141 expression levels were detected in HCC tissues and cell lines by Western blot and real-time PCR. Dual-luciferase reporter assay and Western blot were used to validate SPAG9 as a direct target gene of miR-141. Cell proliferation, apoptosis, invasion, and migration were also examined to figure out whether miR-141-mediated regulation of SPAG9 could impact on HCC progression.
Results: We observed an inverse correlation between SPAG9 and miR-141 expression in HCC tissues and cell lines. We also demonstrated that SPAG9 was a direct target gene of miR-141. The overexpression of miR-141 markedly attenuated the expression of SPAG9 via targeting a binding site located at 3'-UTR of SPAG9 mRNA. Finally, we showed that repression of SPAG9 by transfection with miR-141 mimics resulted in a significant reduction in cellular proliferation, invasion, migration and cellular motility of HCC cells, and imitating the SPAG9 knockdown effects on HCC cells. Furthermore, restoration of SPAG9 in miR-141-expressing cells was sufficient to alleviate the tumor suppressive effects of miR-141.
Conclusion: Our data suggested that the loss or suppression of miR-141 may cause aberrant overexpression of SPAG9 and promote the genesis of HCC.

P1293 T-CELL FACTOR-4 ISOFORMS PARTICIPATE IN EMT THROUGH WNT5A INDUCTION IN HUMAN LIVER CANCER CELLS

H. Koga[1,2], N. Toru[1,2], M. Abe[1,2], Y. Ikezono[1,2], F. Wada[1,2], H. Iwamoto[1,2], T. Sakaue[1,2], H. Yano[1], T. Torimura[1,2]

Introduction: The T-cell factor (TCF)-4 is a key transcriptional factor critically regulating Wnt/β-catenin signaling. Previously we identified 14 TCF-4 isoforms derived from human HCC cell lines (1). The TCF-4J and K pair have been characterized based on the presence (K) or absence (J) of a SxxSS motif, which was shown to decrease β-catenin-dependent transcriptional activity of TCF-4. TCF-4J-overexpressing HCC cells (J cells) exhibited high tumorigenic potential in contrast to TCF-4K-overexpressing cells (K cells) (2). In spite of the lower tumorigenic activity, K cells often showed morphological alteration, reminiscent of epithelial-mesenchymal transition (EMT), which is known to be involved in the non-canonical Wnt signaling pathway (Bo et al., *BMC Cancer* 2013). The finding suggested that the SxxSS motif had potential to regulate EMT through the non-canonical Wnt signaling pathway.
Aims & Methods: The aim of this study was to investigate whether the functional SxxSS motif modulated expression levels of EMT regulators and Wnt5a, a representative non-canonical Wnt ligand.
Methods: The human HCC cell line HAK-1A (Yano, et al., Hepatology 1993) was used. TCF-4K mutants (269A, 272A, and 273A) were constructed with conversion of serine (S) in the SxxSS motif to alanine (A) by site-directed mutagenesis. HAK-1A-derived stable clones overexpressing TCF-4J, K, and K-mutants (269A, 272A, and 273A cells, respectively) were established. Western blot analysis and real-time RT-PCR were employed to evaluate protein and mRNA expression levels, respectively. Sh-RNA was used to knockdown *wnt5a* gene expression. ChIP assay was performed by using SimpleChIP Enzymatic Chromatin IP Kit (Cell Signaling Technology) and specific qPCR primers for *wnt5a* gene promoter region (Qiagen).
Results: The 269A-mutant cells robustly expressed Wnt5a in both protein and mRNA levels, while empty vector-transfected cells (control), J cells, or K cells did not. Of note, Wnt5a expression was coupled with SLUG expression and EMT-like cellular morphological change. Snail was hardly expressed in the cells examined in this study. When the Wnt5a expression was specifically silenced by using sh-RNA, the expression level of SLUG was clearly decreased. The TCF-4K-mutant isoform 269A showed high affinity to the *wnt5a* promoter region.
Conclusion: The findings in this study suggest that the SxxSS motif of TCF-4 directly regulates transcription of Wnt5a, thereby modulating the expression level of the EMT-regulator SLUG in a human HCC cell line.

P1294 MICRORNA-207 CONTROLS PRP19 EXPRESSION IN HEPATOCELLULAR CARCINOMA

J.-M. Zhu[1], T.-T. Liu[1], X.-Z. Shen[1]
[1]*Department of Gastroenterology, Zhongshan Hospital of Fudan University, Shanghai, China*

Contact E-mail Address: jiminzhu@gmail.com

Introduction: microRNAs (miRNAs) are small non-coding RNA molecules of 21-24 nt that regulate the expression of numerous target genes by transcriptional inhibition or translational repression. Multiple lines of evidence suggest that miRNAs play important roles in tumor (such as, hepatocellular carcinoma (HCC)) development, progression, invasion, metastasis and prognosis. Our previous unpublished work suggested that microRNA-207 (miR-207) upregulates in HCC tissues than in normal liver tissues. Unfortunately, our understanding of the molecular mechanisms that governs its role in development, progression, invasion, metastasis and prognosis remains fragmentary.
Aims & Methods: In this study, a genome-wide miRNA microarray was used to identify differentially expressed miRNAs in HCCs patients. Next, miR-207 expression in normal liver tissues, HCC tissues and adjacent non-tumor tissues was validated, and the predictive values of miR-207 for the prognosis of HCC patients were explored using $\chi 2$ test, Student's t test, paired t test, and Mann-Whitney test. The biological roles of miR-207 and its underlying roles in HCC were also investigated in the Huh7, MHCC-97H, SMMC-7721, L02 and Hep3B cell lines.
Results: Forty-two miRNAs were differentially expressed in HCCs. Several of these miRNAs were previously found deregulated in other cancers. Additionally, the miR-207 was found upregulated in ~80% of HCCs and in all HCC-derived cell lines. Overexpressed intratumoral miR-207 was associated with poor survival rate ($P < 0.001$), and was an independent prognostic factor for overall survival rate ($P < 0.001$) in the patients with HCC. Overexpression of miR-207 in L02 cell line remarkably enhanced cell proliferation, migration, and invasion; while inhibition of miR-207 in Hep3B cell line caused the opposite effects. Further study found that miR-207 suppressed the expression of pre-Mrna processing factor 19 (Prp19) by directly binding to its 3'-untranslated region, and sensitized Hep3B cell to CDDP-induced apoptosis. Moreover, miR-207 expression levels correlated positively with Prp19 in human HCC tissues. Western blot showed that overexpression of miR-207 in L02 cell upregulates the expression of Prp19, while inhibition of miR-207 in Hep3B cell downregulates the expression of Prp19, suggesting that Prp19 might play as a oncogene in HCC.
Conclusion: Taken together, our findings suggest that miR-207 could play a role in the development of HCC, at least in part, by modulating Prp19. These findings establish a basis toward the development of therapeutic strategies aimed at blocking miR-207 in HCC.

Contact E-mail Address: filizakyuz@hotmail.com
Introduction: Hepatocellular carcinoma (HCC) is a worldwide increasing problem. Identification of prognosis is important for the management of HCC. We aimed to investigate the impact of interleukin (IL)-29, galectin-3, leptin, fibronectin and protease activated receptor-1 (PAR-1) on the prognosis of patients with HCC.
Aims & Methods: Sixty HCC patients (75% male) and 20 healthy volunteers (70% male) were enrolled in this prospective study. All demographic and clinical data were analyzed. Serum samples were obtained on the first admission before any adjuvant and metastatic treatment was given. Serum IL-29, galectin-3, leptin, fibronectin and PAR-1 were determined by using ELISA kits.
Results: All patients had cirrhosis and Child-Pugh stage were as follows: 61.5% Child A, 35.9% Child B and 2.6% Child C (61.7% HBV, 11.7% HCV, 6.7% HBV + HCV, 11.7% alcohol and 8.3% cryptogenic). Fifty-three percent of HCC patients were died in median 7.5 months. The mean age of the patients was 59.2 ± 10.2 years and 53.4 ± 8.2 years for the controls. Mean serum level of IL-29 was higher in patients with HCC than controls (32.55 ± 31 vs 11.46 ± 5.4 pg/mL, $p < 0.015$). Galectin-3 was significantly higher in HCC group (6.7 ± 4.2 vs 1.38 ± 0.79 ng/mL, $p < 0.001$). Fibronectin levels were higher in controls than HCC patients (260635 ± 60735 vs 257353 ± 63986 ng/mL, $p > 0.015$). But, mean PAR-1 and leptin levels were similar in two groups ($p > 0.05$). Total lesion diameter was related to worse survival ($p = 0.018$). Lesion diameter was positively correlated with PAR-1 levels ($p = 0.018$, $R = 0.332$). AFP levels was positively correlated with extrahepatic metastasis ($p = 0.005$, $R = 0.366$). Biomarkers were divided in 2 groups according to median levels. In log rank analysis, they don't have any effect on survival ($p > 0.05$).
Conclusion: IL-29 and galectin-3 were significantly higher in HCC patients. Although, they can be a diagnostic marker for HCC, they had no prognostic value in HCC patients.

Contact E-mail Address: amrfouly@yahoo.com
Introduction: Hepatocellular carcinoma (HCC) is a common cancer that typically occurs in the presence of liver cirrhosis. It is considered a global problem because of its dramatically increasing incidence. More than 90% of patients have non resectable tumor at first diagnosis. While sorafenib is the currents treatment standard for advanced stage hepatocellular carcinoma (HCC), radioembolization with Yttrium-90 microspheres (Y90-TARE) is a novel transarterial approach for patients with advanced HCC. Because there are multiple patient and treatment related variables within advanced stage HCCs that should be considered for treatment selection, we aimed to analyse a number of clinical and biochemical parameter in relation to survival after TARE which are currently not part of the guidelines (for example aspartate amino transferase, AST and C-reactive protein, CRP).
Aims & Methods: Between 11/2010 and 3/2014, 202 patients with unresectable hepatocellular carcinoma were included in this prospective study. Yttrium-90 glass microspheres radiotherapy was performed in a lobar fashion via the right or left hepatic artery. In bilobar HCC, right and left liver lobe were treated within 4-6 weeks intervals. The mean radiation dose was 118 (+/-23) Gy per single treatment. Median survival time was considered as primary endpoint with further subgroup analysis within unilobar and bilobar HCCs.
Results: Among 202 patients with advanced HCC treated by 334 sessions of Y-90-TARE (mean 1.5 sessions/patient), unilobar advanced HCC was present in 85(42%) patients and bilobar advanced HCC in 117 (58%). In unilobar HCC, baseline serum AST level and CRP in combination were found to be important predictors for survival. In normal AST & CRP (found in 36/85 patients; 42%) median survival was 20.1 months (95CI:14.5-25.6); in high AST & normal CRP (3/85; 4%) was 15.3 months (95CI:10.5-19.8); in normal AST and high CRP (38/85; 45%) was 9.0 months (95CI:5.2-12.7); and in high both AST & CRP (8/85; 9%) was 1.9 months (95CI:0.0-5.2) which showed significantly reduced survival probability ($p < 0.0001$).
In bilobar HCC, multivariant analysis showed that BCLC stage and abdominal ascites had significant impact on long term survival. Median survival time in bilobar HCC in Child A patients without ascites (71/117; 60%) was 18.4 months (95CI:13.4-23.3) in BCLC-B with normal CRP (24/117; 21%) compared to 11.1 months (95CI:4.7-13.7) in patients with elevated CRP (11/117; 10%); and was 8.5 months (95CI:5.4-11.7) in BCLC-C with normal CRP (17/117; 15%) versus 5.8 months (95CI:3.8-7.7) in patients with elevated CRP (19/117; 16%), ($p < 0.01$).
Conclusion: It seems that unilobar and bilobar HCC distribution is valuable predictor for survival in advanced HCC, which is not part of current HCC staging systems. Also serum AST and CRP could have a significant role as biochemical predictors for longer survival time.

P1297 GEOEPIDEMIOLOGY OF HEPATOCELLULAR CARCINOMA (HCC) IN THE ISLAND OF CRETE. A POSSIBLE ROLE OF PESTICIDES

D. Sifaki-Pistola[1], A. Voumvouraki[2], D. Samonakis[2], M. Koulentaki[2], N. Papiamonis[2], **E. Kouroumalis**[2]
[1]*Social Medicine,* [2]*Gastroenterology, University of Crete Medical School, Heraklion, Greece*

Contact E-mail Address: kouroum@med.uoc.gr
Introduction: Geoepidemiological data of HCC are lacking in Greece. The island of Crete has a genetically homogeneous population with minimal immigration and therefore is suitable for such studies attempting to identify a possible contribution of environmental factors in HCC.
Aims & Methods: We used a data base of HCC patients constructed over the past 20 years in our Unit, the reference center for liver disease in the island. Similar data bases for chronic HCV and HBV were also used. All patients had a histological confirmation of diagnosis. Recorded data included gender, date and place of birth and place of residence for the last 15 years. The geographic area of the study comprised the four prefectures of the island of Crete. Population statistics from 1980-2010 were obtained from the Hellenic Statistical Authority. 316 HCC patients , 633 HCV and 392 HBV patients were included in the study. Time-spatial methods were applied in Gis – ArcMap 10 software. A spatial statistical test that measures spatial autocorrelation (Moran's index) was applied at a confidence level of 95%, in order to detect any possible significant difference between the spatial distribution to place of residence. Density maps with the spatial clusters configuring the prevalence of the disease of all provinces in the island were created. Kriging Interpolation method was applied, to produce a prediction map of HCC in Crete.
Results: HCV is present in pockets of high prevalence while HBV is more uniformly distributed. HCC is more prevalent in Eastern Crete. A significant spatial autocorrelation between HCC and either HCV (Moran' $I = 0.78$, $p < 0.001$) or HBV (Moran' $I = 0.87$, $p < 0.001$) was found as expected. However there is a discrepancy in the South East of Crete, where a higher prevalence of HCC than expected from the dispersion of HCV and HBV was observed. Prediction maps also identified this area as the main source of future HCC cases. This is an area where extensive use of pesticides in large green houses is widely practiced.
Conclusion: 1) HCC is mostly found in Eastern Crete and is broadly associated with the dispersion of chronic HCV and more so with Chronic HBV.
2) In an area with widespread use of pesticides a higher than expected spatial distribution of HCC was detected.

P1298 MEANINGFUL REDUCTION OF HEPATOCELLULAR CARCINOMA RISK IN PATIENTS WITH CHRONIC HEPATITIS C WHO RECEIVED PEGILE INTERFERON PLUS RIBAVIRIN THERAPY: TWO TERTIARY CENTER EXPERIENCE

G. Sirin[1], O. Sentürk[2], A. Celebi[2], H. Yılmaz[2], M. Sezikli[1], S. Hulagu[2]
[1]*Gastroenterology, Derince Education and Research Hospital,* [2]*Gastroenterology, Kocaeli University, Kocaeli, Turkey*

Contact E-mail Address: gsirin@live.com
Introduction: Antiviral therapy may eradicate hepatitis C viral replication, but its long-term effect on the reduction of hepatocellular carcinoma (HCC) still ambiguous.
Aims & Methods: We aimed to evaluate the predictors of sustained virological response (SVR) and appraise the efficacy in decreasing HCC in chronic hepatitis C patients.
We enrolled 312 anti-HCV-positive patients who were treated with pegile interferon plus ribavirin (PR) for 12 months who admitted to Kocaeli University and Derince Education and Research Hospital. All of the patients were older than 18 years old and seronegative for HBs Ag. These patients were followed after dual therapy to the date of HCC diagnosis, death, or the end of 2014, whichever came first. The Cox's proportional hazards model was utilized to estimate the adjusted hazard ratio and 95% confidence interval associated with HCC by comparing patients with SVR or non-SVR.
Results: The mean age of the patients was 58.2 years, 162 (51.9%) were males, 298 (95.5%) were infected by HCV genotype 1, and 45 (14.4%) had cirrhosis at start of the study. There were 194 (62.2%) patients experienced SVR after received treatment. Lower HCV viral load, serum levels of total bilirubin and high platelet count were independent predictors of achieving SVR. During the 5 years of post-treatment follow-up period, 14 newly-diagnosed HCC cases (5 with SVR and 9 with non-SVR) were observed. The estimated 5-year HCC risk was 2.57% for patients with SVR and 7.6% for those with non-SVR, respectively. The cumulative risk of HCC was significantly higher for the non-SVR patients than the SVR patients ($p < 0.001$). Patients with old ages, male gender, and low levels of albumin had an increased incidence of HCC. After adjustment for the potential confounders, the patients who did not achieve SVR had 3.2 folds (95% confidence interval: 1.40-6.24) risk of developing HCC during the follow-up period.
Conclusion: Patients with chronic hepatitis C who received pegile interferon plus ribavirin therapy who achieved SVR is associated with a substantial reduction of HCC risk. Therefore chronic hepatitis C patients should be encouraged to receive antiviral therapy as early as possible and even as in young age as possible.

P1299 TRANSARTERIAL CHEMOEMBOLISATION IN THE TREATMENT OF INTERMEDIATE-STAGE HEPATOCELLULAR CARCINOMA; STUDY OF FACTORS PREDICTIVE OF SURVIVAL. CLINICAL EXPERIENCE IN A SINGLE CENTRE IN SPAIN

I. Ortiz[1], A. del Val[1], J. M. Tenías[2], E. Lonjedo[3], F. Delgado[3], V. J. Morales[1], E. Moreno-Osset[1]
[1]*Digestive Diseases, Hospital Dr. Peset,* [2]*Family and Community Medicine Teaching Unit, EVES,* [3]*Radiology, Hospital Dr. Peset, Valencia, Spain*

Contact E-mail Address: ortizpolo.inmaculada@gmail.com
Introduction: Transarterial chemoembolisation (TACE) is currently the treatment of choice for hepatocellular carcinoma (HCC) in the Barcelona-Clinic Liver Cancer (BCLC) classification intermediate stage. Although it is the most widely used therapy, many aspects remain to be clarified, primary among them being identifying the best candidates within the broad and heterogeneous group of patients the intermediate stage covers. The aim of this study was to determine overall survival after TACE and identify the factors predictive of survival.
Aims & Methods: From May 2002 to June 2010, all patients diagnosed with intermediate-stage HCC were included prospectively to receive treatment with conventional TACE plus adriamycin and lipiodol. Further treatment sessions were given if persistence of the tumour was detected on radiological follow-up with dynamic imaging tests (''on-demand strategy''). In each case, TACE was indicated after assessment by a multidisciplinary committee. The treatment was discontinued if tumour progression, vascular invasion, extrahepatic spread or worsening of liver function were observed during follow-up. Clinical, analytical and radiological variables were obtained for all cases. Survival was estimated using the KaplanMeyer method and prognostic factors analysed using the Cox regression model.
Results: A total of 123 patients were included. Mean age was 70.58 years. Objective response was obtained in 35.7% of the cases. The most common complication was post-embolisation syndrome (33.3%). Treatment-related mortality was 3.3%. Median overall survival was 29.2 months. In the multivariate analysis using the Cox regression model, age over 65 ($p = 0.02$), functional status 0 ($p < 0.001$), tumour size less than 5 cm ($p = 0.016$), objective response ($p = 0.003$) and re-embolisation ($p = 0.001$) were significant independent prognostic factors associated with longer survival. The actuarial survival at 1, 2, 3 and 4 years was 81%, 59%, 42% and 26% respectively.

Prognostic factors	**HR (IC95%)**	p
Age	0.963 (0.933 – 0.994)	0.020
Functional status	2,24 (1.45 – 3.44)	<0.001
Tumour size	1.76 (1.11 – 2.79)	0.016
Objective response	2.18 (1.30 – 3.64)	0.003
Re-embolisation	0.51 (0.33 – 0.77)	0.001

Conclusion: The patients surviving longest were aged over 65, with good performance status and HCC less than 5 cm in diameter, who had radiological objective response after therapy and underwent at least two sessions of TACE through the ''on-demand'' strategy. The results of this study may help improve selection of the patients with intermediate-stage HCC who will obtain greater benefit in terms of survival.

P1300 LONG-TERM SURVIVAL RESULT OF PATIENTS WITH HEPATOCELLULAR CARCINOMA TREATED WITH TRANS-ARTERIAL CHEMOEMBOLIZATION USING DRUG- LOADED MICROSPHERES

K. D. Thai[1], T. T. Nguyen[1], B. H. Mai[1]
[1]*Department of Hepato-Gastroenterology, 108 Hospital, Ha Noi, Vietnam*

Contact E-mail Address: kythaitrung@gmail.com
Introduction: Trans-arterial chemoembolization with drug-loaded microspheres (drug-eluting bead TACE) is a modified chemoembolization technique that has been reported in many clinical trials giving better tumour control and less side effects than conventional TACE. However, its advantage in term of long-term survival for HCC patients is still needed more evaluation. This is the first report in Vietnam on long-term results of DEB-TACE for HCC patients.
Aims & Methods
Aims: to evaluate the long-term result of HCC patients treated with TACE using doxorubicin-loaded micropheres, and to identify some prognostic factors predicting post-procedural survival.
Methods: A prospective non-randomized controlled study was done on 105 HCC patients (mean tumor size: 7.8 ±2.5mm) undergoing TACE with drug-loaded beads at 108 Military Central Hospital, from June 2011 to February 2015. We used 1 or 2 from 3 different sizes of DC-Beads (100-300μm, 300-500μm and 500-700μm) loaded with 50-150mg doxorubicin in a procedural session. Patients were followed-up for every 2-3 months after treatment. In cases of HCC remain or recurrence, patients would be treated with additional DEB-TACE or RFA/PEIT according to tumour characteristics (based on CT or MR imaging) and patient condition. Survival was canculated from the date of first TACE, using Kaplan Meier estimations. *Log-rank test* was used to analyse the differences in the mean survival time and the 1-year, 2-year and 3-year overall survival rates of subgroups according to prognostic factors.
Results: 105 HCC patients underwent totally 198 TACE procedures. The mean time of follow-up was 19.8 months. The mean overall survival time of all patients was 28 months (95%CI:24-31). The cumulative survival rates at 1-year, 2-year and 3-year follow-up were 72.4%; 55.2% and 41.3% respectively. Predictors for long-term survival were: Serum AFP, tumour morphology (single nodule or multinodules, mass or diffuse type), tumor size (smaller or larger than 8cm), grade of tumour cell differentiation, vascular invasion, Child Pugh class, Okuda and Barcelona Clinic Liver Cancer staging.
Conclusion: DC-Bead TACE is an effective treatment for HCC. However, the clinical outcome still depends on several prognostic factors.

Lanzara", Gastroenterology Unit, Second University of Naples, Naples, Italy*

Contact E-mail Address: maria.guarino86@gmail.com
Introduction: Every year hepatocellular carcinoma (HCC) develops in about 3–4% of cirrhotic patients. The squamous cell carcinoma antigen (SCCA) has been found elevated in liver cancer specimens by immunohistochemistry, and detected in complex with IgM (SCCA-IgM) in serum of patients with HCC. The aim of this study was to evaluate the ability of serological SCCA-IgM levels to predict the efficacy of HCC therapy.
Aims & Methods: From April 2012 to April 2014, 216 patients with a new diagnosis of HCC were enrolled in a prospective study. The diagnosis of HCC was made according to the AASLD 2010 guidelines. The patients were staged and treated according to BCLC Staging System; in particular, BCLC stage A and B were treated with loco-regional therapy, and BCLC stage C were treated with Sorafenib. Response to therapy was evaluated with imaging techniques, according to the mRECIST criteria. Serum SCCA-IgM levels were determined by the Elisa Hepa-IC kit (Xeptagen SpA, Venezia, Italy) at basal time (T_0) and after one month of treatment (T_1). The quantization of the complex SCCA-IgM was expressed in Arbitrary Units (AU/mL).
Results: At the time of diagnosis, SCCA-IgM was reactive in 168/216 patients (78%), mean ± SD: 274.4 ± 263.2 AU/mL. At baseline and one month into therapy, SCCA-IgM levels were significantly lower in the patients that responded positively to therapy, compared to those who had a negative response (median values at T_0: 125.9 AU/mL [C.I. 50-187.9] vs. 165.1 AU/mL [C.I. 117.3-209.9]; median values at T_1: 113.4 AU/mL [C.I 50-195] vs. 170.6 AU/mL [C.I. 111.7-344.2]) (Mann Whitney U Test $p < 0.05$). Also, the difference in the marker serum levels between T_1 and T_0 (T_1-T_0)(DSCCA-IgM) was significantly different between positive and negative responders (Mann Whitney U Test $p < 0.05$).
Conclusion: These results suggest that the determination of SCCA-IgM complex may be helpful in predicting the response to therapy in patients with HCC.

P1302 ADHERENCE TO EASL-EORTC CLINICAL GUIDELINES FOR THE MANAGEMENT OF HEPATOCELLULAR CARCINOMA IN FIELD PRACTICE: RESULTS FROM THE ITALICA DATABASE

R. Sacco[1], A. Romano[1], M. Bertini[1], G. Federici[1], M. Bertoni[1], S. Metrangolo[1], G. Parisi[1], V. Mismas[1], E. Tumino[1], G. Bresci[1], on behalf of for ITA.LI.CA. Group
[1]*Gastroenterology, Pisa University Hospital, Pisa, Italy*

Contact E-mail Address: saccorodolfo@hotmail.com
Introduction: Data on adherence to joint guidelines for the management of hepatocellular carcinoma (HCC) published in 2012 by the European Association for the Study of the Liver (EASL) and the European Organization for Research and Treatment of Cancer (EORTC) are lacking.
Aims & Methods: We retrospectively evaluated the adherence to EASL-EORTC guidelines in field-practice, using data from HCC patients registered in the Nation-wide Italian database ITA.LI.CA. and diagnosed from 2012. The ITA.LI.CA. database contains data of 5428 HCC patients treated at 18 Italian Centers. Patients were stratified according to Child-Pugh (CP) and and the Barcelona Clinic Liver Cancer (BCLC) classifications. We investigated the adherence to surveillance, diagnosis, and first-line treatment recommendations.
Results: In ITALICA, 600 patients were diagnosed of HCC since 2012 (466 males; mean ± SD age 67.4 ± 10.9 years; 277(46.2%) CP-A and 163(27.2%) CP-B; 44(8%) BCLC-0, 193(35.1%) BCLC-A, 93(16.9%) BCLC-B, 172(31.3%) BCLC-C, 48(8.7%) BCLC-D). Overall, 317(55.2%) were diagnosed during a surveillance program. Of them, 231(57.9%) were cirrhotic (median surveillance duration: 6 months). Four-hundred-ninety-six (85.3%, 449 cirrhotic) patients were diagnosed applying a radiological, 80(13.7%) a histological, and 6(1%) a cytological criterion. Five (9.7%) patients in BCLC stage 0 with CP A, and single nodules underwent tumour resection; 3(1.4%) patients in BCLC-A received liver transplantation, and 83(43.1%) received radiofrequency ablation or Percutaneous Ethanol Injection. Intermediate HCC-stage patients (BCLC-B) receiving TACE were 45(47.9%), and advanced-stage patients (BCLC-C) receiving sorafenib were 38(21.9%). Palliative care was provided to terminal stage patients (BCLC-D) in 31(64.3%) cases.

Conclusion: The overall adherence in a ''real-world'' practice to EASL-EORTC guidelines was low, particularly in patients with early stage HCC. Difficulties in patients staging and the high prevalence of older patients with relevant co-morbidities may partially explain these findings. Strategies to help improve adherence to international guidelines for HCC in field-practice and new scoring criteria are required.

P1303 EFFICACY OF SORAFENIB IN PATIENTS WITH INTERMEDIATE-STAGE HEPATOCELLULAR CARCINOMA: RESULTS FROM THE ITA.LI.CA. DATABASE

R. Sacco[1], A. Romano[1], M. Bertini[1], G. Federici[1], M. Bertoni[1], S. Metrangolo[1], G. Parisi[1], V. Mismas[1], E. Tumino[1], G. Bresci[1], on behalf of for ITA.LI.CA. Group
[1]*Gastroenterology, Pisa University Hospital, Pisa, Italy*

Contact E-mail Address: saccorodolfo@hotmail.com
Introduction: Sorafenib represents the elective treatment for patients affected from advanced-stage (BCLC-C according to the Barcelona Clinic of Liver Cancer classification) HCC; this molecule is also recommended in patients with intermediate-stage (BCLC-B) disease who have failed or are not eligible to transareterial chemoembolization (TACE). However, further information on the use of sorafenib in patients with BCLC-C HCC is warranted.
Aims & Methods: This study analyses the efficacy of sorafenib in patients with BCLC-B HCC, with respect to those with BCLC-C disease, in the Nation-wide Italian database ITA.LI.CA.
The ITA.LI.CA. database contains data of 5428 HCC patients treated at 18 Italian Centers. All patients with either BCLC stage B or C and who received sorafenib were considered. Overall survival (OS), time to progression (TTP), and disease control rate (DCR) were evaluated. Safety considerations were also performed.
Results: A total of 243 patients were included. Of these, 61 were in BCLC-B stage (29 received ≥1 TACE prior to sorafenib) and 182 in BCLC-C. In the overall population, median TTP was 8 months (95%CI 6-9), median OS was 13 months (95%CI 10-15.5), and DCR was 28.3% (complete response, CR = 1.6%; partial response, PR = 8.9%; stable disease, SD = 17.8%). Patients in BCLC-B stage had a median TTP of 10 months (95%CI 6-14), a median OS of 19 months (95%CI 12.5-26.5), and a DCR of 39.1% (CR = 2.4%; PR = 9.8%; SD = 26.8%), whereas patients in BCLC-C stage had a median TTP of 7 months (95%CI 6-8), a median OS of 11 months (95%CI 10-15.5), and a DCR of 25.3% (CR = 1.3%; PR = 8.7%; SD = 15.3%). The safety profile of sorafenib was similar in the two sub-populations.
Conclusion: These ''field-practice'' findings suggest that the administration of sorafenib in BCLC-B patients with HCC may be effective and is not associated with any new safety warning.

Contact E-mail Address: shakershaltout2@yahoo.com
Introduction: Hepatocellular carcinoma (HCC) has many curative choices which in some circumstances are equal to or even better than surgery. These strategies for treatment of HCC may induce certain local effects which trigger distinct immunological responses that may have a systemic impact on the natural history of the tumour itself. These responses are validated through the measurement of specific immune cells in the systemic circulation.
Aims & Methods: In this study, we tried to observe and analyze the immunological changes that accompany and follow HCC ablation by different procedures of radiological intervention and compare our results with the literature. This study was conducted on 50patients diagnosed with HCC who were referred to Tropical Medicine Department at Mansoura University Hospital, Egypt and 20 healthy volunteers as a control. The therapeutic strategy was selected according to the tumor stage and general condition. RFA was performed for 12 cases, PEI for 13, MWA for12 and TACE for 13 cases. All Patients were subjected to full history taking, clinical examination, liver function tests, serum alpha fetoprotein, abdominal ultrasonography, triphasic abdominal computerized tomography and lymphocyte subset assay by flow cytometry 1 day before, and 3 weeks after the treatment.
Results: In the RFA group, CD4+ cells and CD4/CD8 ratio remarkably increased after treatment ($P < 0.001$), and the CD8+ cells significantly decreased ($P < 0.002$) with concomitant increase in the CD4+/CD8+ ratio ($P < 0.001$). **In the PEI group**, CD4+ cells markedly increased after treatment ($P < 0.001$), but there were no significant differences in CD8+ cells and CD4/CD8 ratio. **In the MWA group**, CD4+ cells markedly increased after treatment ($P < 0.001$), with increase in CD4/CD8 ratio ($P < 0.007$) but there were no significant differences in CD8+ cells. **In the TACE group**, the CD4+ cells and CD4/CD8 ratio dramatically decreased after treatment ($P < 0.001$), and the CD8+ cells increased significantly ($P < 0.001$).
Conclusion: Our study has proved the presence of a relationship between the immunity and the different modes of therapy in HCC patients and demonstrated a positive attitude towards increasing the immune cells following the ablation technique.

P1306 VESSEL-EMBRACING RADIOFREQUENCY ABLATION RESULTS IN GOOD COMPLETE TUMOR ERADICATION AND LOW LOCAL RECURRENCE RATE FOR TREATING HEPATOCELLULAR CARCINOMA ABUTTING MAJOR VESSELS

W.-Y. Lee[1], C.-W. Shih[2], T.-K. Tseng[3], P.-H. Chen[4]

Introduction: In treating hepatocellular carcinoma (HCC), heat sink effect (HSE) may result in incomplete radiofrequency ablation (RFA) and increased local recurrence rate. On the other hand, the HSE may protect the vital vessels, e.g.portal veins (PV), hepatic veins (HV) or infereior vena cava, embraced within the RFA area from thrombosis destruction, therefore, the safety margin can be maximized without sacrificing the vital vessels.
Aims & Methods: To study the complete eradication efficiency and local recurrence rate of vessel-embracing RFA (VE-RFA) by multi-tined temperature-control probe.
Material and Methods: VE-RFA is defined that during RFA the probe tines embrace certain major inflow PV or outflow HV within the optimal safety margin. From Jan 2011 to Jan 2014, nine HCC cases (9 VE-RFA treated tumors) were retrospectively compared with nine BCLC stage A-matched cases (10 nonVE-RFA treated tumors) at the same interval. The monopolar multi-tined probe (AngioDynamic) was used and the heating protocol and end-point were defined according to the manufacture's guide. Safety margin indices (SMI) was defined as: (final tine extension width – maximal tumor width) / maximal tumor width). SMI was maintained > 0.5 for each RFA procedure in both groups, under the purpose to optimize the safety margin according to the tumor size. The time ratio (TR) was defined as the heating time ratio to the manufacturers' reference time for a complete RFA procedure. The higher the TR indicated the stronger the HSE. The mean RFA time ratios of both patient groups were compared , as well as the 1-year local recurrence rates. The tumor sizes are 3.02±0.65 cm and 2.89±0.58 cm in VE-RFA and RFA group, respectively ($P = 0.65$). The SMI is 0.68±0.31 vs 0.91±0.27 ($p = 0.102$) in VE-RFA and RFA group, respectively.
Results: (1) the resultant TR is 1.34± 0.47 vs 0.99 ± 0.33 ($p = 0.033 < 0.05$) in group VE-RFA and group non-VE-RFA, respectively, for a complete heating procedure with a complete eradication defined by 2-week post-RFA CT. The data indicates marked HSE in VE-RFA group than in nonVE-RFA group (2) A positive correlation exists between the vessel diameter and the HSE. That is, the slopes of the diameter-TR regression lines are positive for both HVs and PVs. (0.115 and 0.042 , respectively) (3) The HSE (increase of TR) from increase of outflow HV diameter is 2.7 times that from increase of the inflow PV diameter. (4) Provided SMI at the value > 0.5, the local recurrence rate are low in both groups, 0/9 vs 2/ 10 ($p = 0.17$) in group VE-RFA and group non-VE-RFA, respectively, at the end of 1-year follow up, with no statistical significance.
Conclusion: Given pre-conditions of SMI > 0.5 , VE-RFA by multitined monopolar probe overcome HSE , yields good complete tumor eradication and low local recurrence rate for HCC encasing or abutting major hepatic veins or portal veins. The HSE is influenced at least by two factors, i.e. the type of veins and the diameter of veins. Presumably, the HVs yield more HSE than the PVs.

P1307 TUMOR VASCULARITY ON IMAGES WELL REPRESENTS THE BIOLOGICAL MALIGNANCY OF INTRAHEPATIC CHOLANGIOCARCINOMA INCLUDING THE NODAL STATUS COMPARED WITH THE TUMOR SIZE

Y. Yamamoto[1], M. A. Turkoglu[1], T. Sugiura[1], Y. Okamura[1], T. Ito[1], R. Ashida[1], T. Miyata[1], S. Uemura[1], Y. Nakanuma[2], K. Uesaka[1]

Contact E-mail Address: yamayu-1@koto.kpu-m.ac.jp
Introduction: Recently, several authors [1] advocated that lymph node (LN) dissection is not necessary in patients with intrahepatic cholangiocarcinoma (ICC) without nodal metastases. However, preoperative imaging studies do not indicate the exact nodal status in cases of hepatobiliary cancers. Surgeons sometimes utilize the tumor size as an absolute determinant of the indication for LN dissection of ICC. On the other hand, some authors have recently emphasized that the vascularity of ICC is strongly associated with the incidence of LN metastasis or survival. However, the relationships between the tumor size or vascularity of ICC and various histopathological factors have not yet been clearly investigated.

Aims & Methods: Seventy patients with mass-forming dominant ICC underwent hepatectomy between 2003 and 2013 were included in the subsequent analysis. Using the late arterial phase CT, we calculated the CT ratio as the CT value of the tumor divided by the CT value of the non-tumorous liver parenchyma. We examined the relationships between clinicopathological and immunohistological factors of ICC and the tumor size or vascularity. A hepatic progenitor cell and biliary marker (neural cell adhesion molecule (NCAM)) and large bile duct marker (S100P) were examined as immunohistochemical marker.
Results: The cumulative 5-year overall survival rate and median survival time were 43.3% and 44.3 months, respectively. Lymph node (LN) metastasis was found in 19 patients. A receiver operating characteristics (ROC) analysis revealed that there were no correlations between the tumor size and lymphatic invasion (AUC = 0.499, p = 0.986), perineural invasion (AUC = 0.435, p = 0.419), LN metastasis (AUC = 0.658, p = 0.658), reactivity for NCAM (AUC = 0.394, p = 0.128) or S100P (AUC = 0.439, p = 0.372) or mucin secretion (AUC = 0.605, p = 0.162), whereas there were significant correlations between the tumor vascularity of ICC and lymphatic invasion (AUC = 0.768, $p < 0.001$), perineural invasion (AUC = 0.668, p = 0.038), LN metastasis (AUC = 0.748, p = 0.001), reactivity for NCAM (AUC = 0.674, p = 0.012) or S100P (AUC = 0.713, p = 0.003) or mucin secretion (AUC = 0.743, $p < 0.001$). A Cox proportional hazards analysis identified LN metastasis (p = 0.012) and perineural invasion (p = 0.017) as independent predictors of survival. Logistic regression analysis revealed that CT ratio of < 0.94 and macroscopic mass-forming and periductal infiltration were independently associated with the incidence of LN metastasis.
Conclusion: Important prognostic factors of ICC, such as LN metastasis or perineural invasion, are not associated with the tumor size, but rather the vascularity of the tumor. Even for small tumors, surgeons should presume of the risk of LN metastasis and/or lymphatic or perineural invasion in patients with hypovascular ICC. In order to properly assess the presence of LN metastasis, it is important to consider the vascularity of the ICC lesion and the presence of macroscopic periductal infiltration with mass-forming ICC.

P1308 RISK FACTORS ASSOCIATED WITH CAVERNOUS TRANSFORMATION OF THE PORTAL VEIN: A CASE-CONTROL STUDY

M. Nadinskaya[1], O. Borisov[1], V. Ivashkin[1]
[1]*The Department for Propaedeutics in Internal Medicine, I.M.Sechenov First Moscow State Medical University, Moscow, Russian Federation*

Contact E-mail Address: marianad@rambler.ru

Introduction: Cavernous transformation of the portal vein (CTPV) may develop as a consequence of portal vein thrombosis (PVT). Both systemic and local factors have an influence on the process of thrombogenesis. In Russia, no case-control studies aimed to assess CTPV development risk factors were conducted so far.
Aims & Methods: To evaluate the association between the development of CTPV and PVT risk factors.
Study design: Case-control study. 38 patients (16 males and 22 females, mean age 44.8 ± 14.8) with the diagnosis of CTPV on contrast-enhanced MSCT and/or Doppler ultrasonography were included in the "CTPV" group. The "Controls" group was composed of 49 age and sex-matched healthy individuals who had no CTPV. Systemic and local factors were assessed in both groups. Systemic factors included: hyperhomocysteinemia (HHcy); protein S (PS), protein C (PC) and antithrombin III (ATIII) deficiency; antiphospholipid syndrome (APS); myeloproliferative diseases (MPDs); polymorphisms in genes related to coagulation: prothrombin [FII G20210A], factor V Leiden [FVL], coagulation factor VII [FVII Arg353Gln G > A], methylenetetrahydrofolate reductase [MTHFR C677T], beta-fibrinogen [FGB beta G455A], glycoprotein Ib (platelet) alpha polypeptide [GP1BA c. -5T > C], integrin alpha-2 [ITGA2 C807T], platelet glycoprotein [ITGB3 (GPIIIa) Leu59Pro T > C], methionine synthase reductase [MTRR A66G], plasminogen activator inhibitor [PAI-1 4G/5G], P-selectin glycoprotein ligand-1 [SELPLG Met62Iso G > A], Janus kinase-2 [JAK2 V617F G > T].
Results: Local factors were found in 14 (37%) patients. A statistically significant association was established between CTPV and omphalitis and umbilical sepsis (p = 0.01), while no significant results were obtained for other local factors (abdominal infections, liver cirrhosis, abdominal surgery). Significant differences between "CTPV" and "Controls" were found for MPDs (p = 0.001), JAK2 V617F (p = 0.02), PS and PC deficiency (p = 0.02), No significant differences were established for APS, ATIII deficiency and HHcy.
No significant differences between two groups were found when studying allele distribution of the following genes related to coagulation: FII G20210A (Odds Ratio [OR] 3.4; 95% Confidence Interval [CI] 0.3 to 39.6), FVL (p = 0.4), FGB beta G455A (OR 0.7; CI 0.3 to 2.1), FVII Arg353Gln (OR 0.6; CI 0.2 to 2.1), MTHFR C677T (OR 0.7; CI 0.3 to 1.8), MTRR A66G (OR 1.4; CI 0.3 to 6.1), GP1BA c. -5T > C (OR 0.9; CI 0.3 to 2.6), ITGB3 (GPIIIa) Leu59Pro (OR 1.3; CI 0.4 to 4.0), SELPLG Met62Iso (OR 0.4; CI 0.1 to 2.3), ITGA2 C807T (OR 0.8; CI 0.3 to 2.2).
The differences between the patients and controls in the frequency of 4G allele carriers, and 5G/5G homozygotes of PAI-1 lay close to the border of statistical significance (p = 0.07; OR 3.9; CI 0.8 to 18.9).
Conclusion: This study established an association between CTPV and following risk factors: omphalitis and umbilical sepsis; MPDs, PS and PC deficiency, JAK2 V617F. No significant differences were found for abdominal infections, liver cirrhosis, abdominal surgery, APS, ATIII deficiency, HHcy and polymorphisms in genes related to coagulation. The obtained results for PAI-1 gene lie in close proximity to statistical significance. Investigations with a larger group of participants are required to specify the role of genes related to coagulation in the development of CTPV.

Introduction: The usefulness of diffusion-weighted magnetic resonance imaging (MRI) in gastrointestinal cancer has been reported. In this study, we examined the true positive rate of differentiation between benign and malignant elevated lesions of the gallbladder on diffusion-weighted MRI compared with pathological diagnosis, and assessed the usefulness.
Aims & Methods: The subjects were 59 patients who underwent diffusion-weighted MRI for gallbladder polyps or gallbladder cancer and who underwent resection from October 2009 to December 2013. We defined high intensity at high b values with low intensity on ADC maps as diffusion suppression, and an indication of cancer on diffusion-weighted MRI. We compared the findings with those of pathological diagnosis in all 59 cases. Then we classified the cases into the following 3 groups: (1) suspected gallbladder polyp group, 16 cases, (2) suspected early gallbladder cancer group, 22 cases, (3) suspected advanced cancer group, 21 cases. We examined the true positive rate of diffusion-weighted MRI for each group.
Results: The true positive rate, sensitivity, and specificity were 88.1%, 93.5%, and 82.1%, respectively, overall, (1) 87.5%, x%, and 87.5%, respectively, in the suspected gallbladder polyp group, (2) 86.4%, 86.7%, and 85.7%, respectively, in the suspected early cancer group, and (3) 90.5%, 60.0%, and 100%, respectively, in the suspected advanced cancer group.
Diffusion-weighted MRI showed high true positive rates. There were two false-negative cases in group (2), both consisting of intramucosal cancer in part of the lesion 20 mm or less in diameter. There were four false-positive cases; two cases in group (2), both consisting of adenoma 10 mm in diameter, and two cases in group (3), both consisting of xanthogranuloma.
Conclusion: Diffusion-weighted MRI was useful for differentiation between benign and malignant elevated lesions of the gallbladder.

Introduction: Endoscopic papillectomy (EP) offers a minimally invasive method for lesions of the ampulla of Vater as an alternative option to surgery. This study aimed to evaluate the results of EP performed for ampullary neoplasms at a single center.
Aims & Methods: From January 2005 to October 2014, 19 patients diagnosed with ampullary tumor were treated with EP. The cases were analysed retrospectively. At least 4 biopsies were taken in all patients before EP procedure. Histologic diagnosis was adenoma in all cases. EP was performed for ampullary lesions without endoscopic or histopathological findings of malignancy. Duodenoscope and hot snare were used for papillectomy. After EP, we placed a pancreatic stent randomly in 5 of 19 patients (26%).
Results: 19 patients (13 men and 6 women; median age 65.1 years, range 28-82) were enrolled. The median follow-up period was 36 months (range 14-68 months). Out of 19 patient, 18 were non-familial adenomatous polyposis (FAP) cases and one patient was with FAP. The papillary lesions ranged from 9 to 32 mm in size. Histopathological examination of the resected specimens revealed nonspecific changes in 1 patient (5%), low-grade dysplasia in 9 (48%), high-grade dysplasia in 5 (26%) and carcinoma in 4 (21%). Pancreatitis occurred in one of the patients (20%) with pancreatic stent. Pancreatitis developed in 3 cases of the group without pancreatic stent (21%) ($p > 0.05$). No mortality was seen and morbidity occured in 31.5 % of the patients, including pancreatitis in 4 (21.5%), bleeding in 1 (5%), biliary complications in 1 (5%). No perforation and papillary stenosis were observed. The mean hospital stay was 2.7 days (range 1-15 days). The resection was en bloc in 11 patients (58%) and the piecemeal technique was carried out in 8 cases (42%). Treatment was accepted inadequate in 4 patients diagnosed with adenocarcinoma (11%) because of submucosal invasion. These patients were undergone pancreatoduodenectomy. During the follow-up, these 4 patients died due to complications of

adenocarcinoma or surgery within 1 year. No recurrence of tumor was observed in the other 15 cases. Eventually, EP was considered to be curative in 78.9% of all patients.
Conclusion: EP has lower morbidity and mortality rates than surgical procedures. EP is also an important staging approach and a safe, effective and technically applicable treatment option for lesions of the ampulla of Vater as well. It should be taken into consideration as the first-line treatment option for tumors of the ampulla of Vater without intraductal invasion. Further studies including much more patients are needed to decide whether pancreatic stenting is necessary.

P1311 RECURRENCE OF AMPULLARY ADENOMAS AFTER ENDOSCOPIC PAPILLECTOMY

S. M. Park[1], **K. B. Kim**[1], T. Jung[1], H. Jeong[1], H. Lee[1], J. K. Lim[1], J.-H. Han[1], H. B. Chae[1], S. J. Youn[1]
[1]*Internal Medicine, Chungbuk National University Hospital, Cheongju, Korea, Republic Of*

Contact E-mail Address: smpark@chungbuk.ac.kr
Introduction: Endoscopic papillectomy has been regarded as a safe and effective treatment for ampullary tumors. However, recurrence after complete resection was frequently observed.
Aims & Methods: The aim of the present study was to analyze the recurrence rate and management after endoscopic papillectomy. Twenty patients with papillary mass who had undergone endoscopic papillectomy over a 10-year period were reviewed (16 male, 4 female; mean age 63 years). Endoscopic papillectomy was performed for both benign and premalignant ampullary tumors. Surveillance after the procedure was performed at 3 and 9 months and then each year afterwards with lateral scopy. The mean duration of the follow-up was 26 months (range: 6-79 months). Pathological diagnosis, follow-up, long-term outcomes were reviewed.
Results: Pathologic diagnoses were low-grade dysplasia (n = 11), high-grade dysplasia (n = 3), adenomyoma (n = 3), inflammatory lesion (n = 2), and paraganglioma (n = 1). Complete resection was achieved in 18 cases (90%); two cases with incomplete resection were treated with surgical ampullectomy in the case with high-grade dysplasia and endoscopic ablation with electrocautery in the other patient with low-grade dysplasia. Three sporadic cases and one familial colonic polyposis recurred during the follow-up at 16, 18, 24, and 36 months. All cases revealed low-grade dysplasia by surveillance biopsies and they were treated with electrocautery. During the follow-up period (mean 14 months; range, 6-26 months) after the 2nd treatment, recurrence was not observed.
Conclusion: Recurrence occurred frequently in ampullary adenomas after complete resection. However, these cases can be safely treated with electrocautery. Careful surveillance is needed after endoscopic treatment for ampullary adenomas.

P1312 ENDOSCOPIC METALLIC STENT PLACEMENT FOR UNRESECTABLE MALIGNANT BILIARY STRICTURE USING A BALLOON ENTEROSCOPE IN PATIENTS WITH SURGICALLY ALTERED GASTROINTESTINAL ANATOMY

T. Ogawa[1], K. Ito[1], S. Koshita[1], Y. Kanno[1], K. Masu[1], Y. Noda[1]
[1]*Department of Gastroenterology, Sendai City Medical Center, Sendai, Japan*

Contact E-mail Address: t-ogawa@openhp.or.jp
Introduction: Recently, reports on endoscopic retrograde cholangiography using a single- (SBE) or double-balloon enteroscope (DBE) in patients with surgically altered gastrointestinal anatomy have been increasing. However, there have been few studies on endoscopic metallic stent (MS) placement in patients with surgically altered gastrointestinal anatomy.
Aims & Methods: The aim of this study was to investigate the efficacy and safety of endoscopic MS placement for unresectable malignant biliary stricture using a short SBE or DBE in patients with surgically altered gastrointestinal anatomy. Between July 2010 and July 2014, 11 patients with unresectable malignant biliary stricture and surgically altered gastrointestinal anatomy (mean age, 76 yrs.; 5 males, 6 females) in whom endoscopic MS placement using a short SBE (1520 mm working length, 3.2 mm working channel) or a DBE (1520 mm working length, 2.8 mm working channel) had been attempted were included in this study. Main outcome measurements were technical success, clinical success, early complications (within three days after MS placement), late complications, and stent patency. Clinical success was defined as a decrease of total bilirubin level to a normal level or less than half of the initial bilirubin level. Complications were according to consensus criteria.
Results: Five patients had lymph node metastasis from gastric cancer, 4 had pancreatic cancer, 1 had bile duct cancer, and 1 had gallbladder cancer. The gastrointestinal reconstruction methods which had been performed were Roux-en Y reconstruction in 6 patients, hepaticojejunostomy in 4 (pancreatoduodenectomy in 2, total pancreatectomy in 1, and choledochectomy in 1), and BillrothIIreconstruction in 1. Reaching the papilla or the choledochojejunostomy site was successful in 91% (10/11). Endoscopic MS placement was successful in all patients except in one in whom the papilla could not be reached. Clinical success was obtained in all patients (10/10). Mean procedure time was 76 minutes. Early complication occurred in one patient (mild pancreatitis). In a mean follow-up period of 113 days, late complication occurred in one patient (stent occlusion). Mean stent patency was 252 days.
Conclusion: Endoscopic MS placement for unresectable malignant biliary stricture using a short SBE or DBE in patients with surgically altered gastrointestinal anatomy had high technical and clinical success rates with an acceptable complication rate.

Contact E-mail Address: voigtlaender.torsten@mh-hannover.de
Introduction: Patients with primary sclerosing cholangitis (PSC) are at high risk for the development of cholangiocarcinoma (CC). Analysis of micro ribonucleic acid (MiRNA) patterns is an evolving research field in biliary pathophysiology with potential value in diagnosis and therapy.
Aims & Methods: Our aim was to evaluate miRNA patterns in serum and bile of patients with PSC and/or CC. Serum and bile from consecutive patients with PSC (n = 40 (serum), n = 52 (bile)), CC (n = 31 (serum), n = 19 (bile)) and patients with CC complicating PSC (PSC/CC) (n = 12 (bile)) were analyzed in a cross-sectional study between 2009 and 2012. The miRNA levels in serum and bile were determined with global miRNA profiling and subsequent miRNA-specific polymerase chain reaction-mediated validation.
Results: Serum analysis revealed significant differences for miR-1281 ($p = 0.001$), miR-126 ($p = 0.001$), miR-26a ($p = 0.001$), miR-30b ($p = 0.001$) and miR-122 ($p = 0.034$) between patients with PSC and patients with CC. MiR-412 ($p = 0.001$), miR-640 ($p = 0.001$), miR-1537 ($p = 0.003$) and miR-3189 ($p = 0.001$) were significantly different between patients with PSC and PSC/CC in bile.
Conclusion: Patients with PSC and/or CC have distinct miRNA profiles in serum and bile. Furthermore, miRNA concentrations are different in bile of patients with CC on top of PSC indicating the potential diagnostic value of these miRNAs.
Disclosure of Interest: None declared

P1314 THE IMPLICATION OF ANOMALOUS UNION OF PANCREATICOBILIARY DUCT IN PATIENTS WITH BILIARY TRACT CANCERS: COMMUNITY-BASED, SINGLE-CENTER EXPERIENCE IN KOREA

Y.-S. Moon[1], M. S. Kim[1], J. W. Lee[1], T. O. Kim[1], J. H. Park[1], S. Y. Yang[1], J. H. Choi[1]
[1]*Inje University Haeundae Paik Hospital, Busan, Korea, Republic Of*

Contact E-mail Address: ymoon@paik.ac.kr
Introduction: Anomalous union of pancreaticobiliary duct (AUPBD) is characterized as long common channel of the pancreaticobiliary junction. AUPBD is well known as pathogenesis of choledochal cyst, and is associated with various biliary tract cancers. The aim of this study was to see the incidence of AUPBD in Korean patients undergoing endoscopic retrograde cholangiopancreatography (ERCP) and to elucidate its association with biliary tract cancers.
Aims & Methods: Seven hundred twenty eight patients underwent ERCP according to indications between March 2010 and May 2014 at Inje University Haeundae Paik Hospital, secondary, community-based medical center. ERCP was performed by one experienced endoscopist. Four hundred forty two biliary tract cancer patients were retrospectively reviewed during same period at the hospital.
Results: During that period, AUPBD was detected in 11 patients. Ten (1.37%) patients were via ERCP, and 1 case was additionally from the review of imaging in biliary tract cancers. The mean length of the common channel was 14.9 mm with a range of 6 to 20 mm. There are 7 patients of biliary tract cancer with AUPBD. Four patients are gallbladder (GB) cancer and 3 patients are bile duct cancer. The incidence of malignancy in APBDU was 63.6%. Bile duct dilatation was found in one case of GB cancer group and 1 bile duct cancer. Higher incidence of cancer was observed in bile duct dilatation group (100%, 1 GB cancer and 1 CBD cancer), compared to no dilatation group (56%). Four cases showed AUPBD on ERCP but no biliary tract cancer. On review of 442 biliary tract cancer patients, there were 127 patients with GB cancer (28.3%) and bile duct cancer 315 (72.1%). In 442 biliary tract cancers, only 7 patients were associated with AUPBD (1.6%). Patients of GB cancer with AUPBD were 3 patients. The lesions were located at fundus in 2 patients and one was in body. Patients of bile duct cancer with AUPBD were four. The location of bile duct cancer were 1 proximal, 1 middle, 1 distal portion and 1 cystic duct. In four patients with AUPBD without biliary tract cancer, these patients were diagnosed with computed tomography, ERCP and magnetic resonance cholangiopancreatography. Three patients were diagnosed as acute cholecystitis and one patient was diagnosed only as AUPBD without biliary disease by regular check-up.
Conclusion: AUPBD is a rare congenital anomaly which is related to biliary tract cancers. The rate of biliary malignancies is extremely high in AUPBD patients of Korea, especially in dilated bile duct cases. In terms of biliary tract cancers, the incidence of AUPBD is still low, but we are careful to delineate it.

P1315 IS EXTENDED RESECTION FOR ADVANCED GALLBLADDER CANCER JUSTIFIED?

Y. Yamamoto[1], T. Sugiura[1], Y. Okamura[1], T. Ito[1], R. Ashida[1], S. Uemura[1], T. Miyata[1], K. Uesaka[1]
[1]*Division of Hepato-Biliary-Pancreatic Surgery, Shizuoka Cancer Center, Shizuoka, Japan*

Contact E-mail Address: yamayu-1@koto.kpu-m.ac.jp
Introduction: The clinical impact of extended resection for advanced gallbladder cancer remains unclear.
Aims & Methods: A total of 96 patients underwent resection for Stage II, III, or IV gallbladder cancer between 2003 and 2012. Of these, 29 patients who underwent major hepatectomy (major Hx group; resecting two or more sections) were enrolled in this study. Moreover, resection was not undertaken after laparotomy in 15 patients (unresectable group) between 2003 and 2012 because they had unsuspected distant metastasis. Of these, 12 patients underwent non-surgical treatments: three patient received chemotherapy with gemcitabine, three patients received S-1 + cisplatin, five patients received gemcitabine + cisplatin, and one patient received irinotecan + cisplatin. Surgical results of the major Hx group were examined, and overall survival (OS) between the major Hx group and the unresectable group were compared in this study.
Results: In the major Hx group, 23 patients underwent right hemihepatectomy, two patients underwent central bisectionectomy, three patients underwent right hepatic trisectionectomy, and one patient underwent left hepatic trisectionectomy. Twenty-five patients underwent extrahepatic bile duct resection, nine patients underwent portal vein resection and reconstruction (PVR group) and nine patients underwent combined pancreatoduodenectomy (major HPD group). There was no in-hospital mortality in the major Hx group. The OS in the major Hx group was significantly better than that in the unresectable group (median survival time (MST) 17.7 vs. 11.4 months, 5-year OS; 26.3% vs. 0.0%, $p = 0.004$). Especially, the OS in patients with Stage III ($n = 15$, MST 29.8 months, 5-year OS 31.6%) and Stage IVa ($n = 9$, MST 17.6 months, 5-year OS 29.6%) were significantly better than that in the unresectable group ($p = 0.008$, 0.025), however, the OS in patients with Stage IVb ($n = 4$, MST 13.6 months, 5-year OS 0.0%) was comparable with that in the unresectable group ($p = 0.995$). Cox proportional hazard analysis revealed that only lymph node metastasis ($p = 0.032$) was independent prognostic factor of survival in the major Hx group, however, the OS in patients with lymph node metastasis ($n = 20$, MST 16.3 months, 5-year OS 10.0%) was better than that in the unresectable group ($p = 0.062$). The OS in the PVR group ($n = 9$, MST 17.6 months, 5-year OS 33.3%) was comparable with that in the non-PVR group ($n = 20$, MST 21.5 months, 5-year OS 26.2%, $p = 0.817$), and the OS in the PVR group was better than that in the unresectable group ($p = 0.054$). Overall morbidity in the major HPD group ($n = 9$) was significantly higher than that in non-PD group ($n = 20$, 89% vs. 40%, $p = 0.014$) The OS was comparable between the major HPD group and non-PD group (5-year OS; 34.6% vs. 21.1%, MST; 29.8 months vs. 17.2 months, $p = 0.565$), and the OS in the major HPD group was significantly better than that in the unresectable group ($p = 0.017$).
Conclusion: In the patients with Stage III or IVA gallbladder cancer, aggressive major Hx, including major HPD or combined PVR, may be justified for otherwise unresectable tumors. However, the surgical indications for major Hx in the patients with bulky lymph node metastasis should be carefully evaluated due to the poor prognosis after surgery. On the other hand, Stage IVB gallbladder cancer should be treated as systemic disease.

P1316 PLATELET SECRETION OF CXCL4 REGULATES NEUTROPHIL RECRUITMENT AND TISSUE INJURY IN ACUTE SEVERE PANCREATITIS

M. Merza[1], R. Hwaiz[1], S. Regner[1], **H. Thorlacius**[1]
[1]*Department of Clinical Sciences, Section of Surgery, Skåne University Hospital, Lund University, Malmö, Sweden*

Contact E-mail Address: henrik.thorlacius@med.lu.se
Introduction: Platelets are known to play an important role in acute pancreatitis via promotion of neutrophil accumulation although mechanisms behind platelet-dependent accumulation of neutrophils in the pancreas remain elusive. Platelets contain a wide-spectrum of different pro-inflammatory compounds, such as chemokines. CXCL4 (platelet factor 4) is one of the most abundant chemokine in platelets and we hypothesized that CXCL4 might be involved in platelet-dependent accumulation of neutrophils in the pancreas.
Aims & Methods: The aim of this study was to examine the role of CXCL4 in acute pancreatitis. Pancreatitis was provoked by infusion of taurocholate into the pancreatic duct in C57BL/6 mice. Animals were treated with an antibody against CXCL4 or platelets prior to induction of pancreatitis. Plasma and lung levels of CXCL4, CXCL2 and IL-6 were determined by use of ELISA. Flow cytometry was used to examine surface expression of Mac-1 on neutrophils. Plasma was obtained from healthy individuals (controls) and patients with severe acute pancreatitis.
Results: Challenge with taurocholate increased plasma levels of CXCL4 and depletion of platelets markedly reduced plasma levels of CXCL4, indicating that circulating levels of CXCL4 are mainly derived from platelets in acute pancreatitis. Inhibition of CXCL4 reduced taurocholate-induced neutrophil recruitment, IL-6 secretion, edema formation, amylase release and tissue damage in the pancreas. However, immunoneutralization of CXCL4 had no effect on CXCL2-evoked neutrophil expression of Mac-1 or chemotaxis in vitro, suggesting an indirect effect of CXCL4 on neutrophil recruitment in acute pancreatitis. Targeting CXCL4 significantly attenuated plasma and lung levels of CXCL2, which is a potent neutrophil chemoattractant and inhibition of the CXCL2 receptor attenuated neutrophil infiltration and tissue damage in the inflamed pancreas. Patients with severe acute pancreatitis had significantly increased plasma levels of CXCL4 compared to healthy controls.
Conclusion: These results suggest that platelet-derived CXCL4 is a potent stimulator of neutrophil accumulation in acute pancreatitis and that this is mediated via generation of CXCL2 in the inflamed pancreas. We conclude that CXCL4 plays an important role pancreatic inflammation and that targeting CXCL4 might be a useful way to ameliorate pathological inflammation and tissue damage in acute pancreatitis.

P1317 AFMK, METABOLITE OF MELATONIN, ATTENUATES ACUTE PANCREATITIS BY ACTIVATION OF CELLULAR ANTIOXIDATIVE MECHANISMS

J. M. Jaworek[1], J. Szklarczyk[1], M. Kot[1], J. Bonior[1], M. Góralska[1], U. Czech[1], P. Pierzchalski[1], A. Leja-Szpak[1], K. Nawrot-Porabka[1]
[1]*Department of Medical Physiology, Faculty of Health Sciences Jagiellonian University Collegium Medicum, Krakow, Poland, Krakow, Poland*

Contact E-mail Address: jolanta.jaworek@uj.edu.pl
Introduction: Melatonin is well known as antioxidant and pancreatic protector, but the effect of melatonin metabolite: N^1-acetyl-N^2-formyl-^{5}methoxykynuramine (AFMK) on acute pancreatitis was unknown.
Aims & Methods: To assess the effects of AFMK on caerulein-induced pancreatitis (AP) in the rats and on the level of an antioxidant enzyme glutathione peroxidase (GPx) and tumor necrosis factor alpha (TNF alpha) in AR42J pancreatic acinar cells.
AP was induced by subcutaneous caerulein infusion (25 microgr/kg). AFMK (5, 10 or 20 mg/kg) was given intraperitonealy to the rats 30 min prior to the induction of AP. Lipid peroxidation products (MDA + 4HNE) and the activity of GPx were measured in pancreatic tissue. Blood samples were taken for evaluation of amylase and TNF alpha concentrations. GPx, and TNF alpha were determined by Western blot in AR42J cells subjected to AFMK (10^{-12}, 10^{-10}, 10^{-8} M) without or with addition of caerulein (10^{-8}M).
Results: AP was confirmed by histological examination and by increases of amylase and TNF alpha blood levels (by 800% and 300%, respectively). Pancreatic MDA + 4HNE was increased by 300%, whereas GPx activity was reduced by 50% in AP rats. AFMK significantly diminished histological manifestations of AP, decreased amylase and TNFalpha blood concentrations, reduced MDA + 4HNE and augmented GPx in the pancreas of AP rats. In AR42J cells AFMK alone or combined with caerulein markedly increased protein signals for GPx, and reduced that for TNFalpha.
Conclusion: AFMK significantly attenuated acute pancreatitis. This could be related to antioxidative effect of this substance and possibly, to the modulation of TNF alpha production.

Contact E-mail Address: stephan.haas@karolinska.se
Introduction: Acute pancreatitis (AP) ranges from a mild localized inflammation to a severe systemic disease with high mortality. Inflammation leads to production of free radicals, which in turn contributes to worsening of the inflammatory response. Repeated injections of the cholecystokinin analogue cerulein, which induces oxidative stress and AP, is one of the most frequently used *in vivo* models of AP. Numerous diagnostic and prognostic markers of acute pancreatitis have been evaluated over the years, but there is still a lack of specific markers of AP and an early marker which can reliably predict mortality.
Aims & Methods: The overall aim of this study was to identify and evaluate potential diagnostic and prognostic markers of AP.
AP was induced through 9 hourly injections of cerulein in C57/Bl6J-mice. Control mice were injected with sodium chloride. RNA from pancreatic tissue collected one hour post the last injection, was analyzed by microarray. Altered expression of selected genes was confirmed by real-time PCR from two separate experiments.
AR42J-cells (as a substitute for primary acinar cells) were stimulated with cerulein and the expression of selected genes was evaluated by real-time PCR. In order to investigate the role of oxidative stress, we treated the cells with the antioxidant N-acetylcystein (NAC) at the time of cerulein-stimulation. Blood from AP and control mice collected one hour post the last injection was processed and serum protein levels of the most promising gene, regulator of calcineurin 1 (Rcan1), was measured by ELISA.
Results: 2038 genes out of more than 16000 genes were identified as differentially expressed between mice with cerulein-induced AP and control mice. Altered expression of Rcan1, Lcn2, Srxn1, Rtn4, Sesn2, Plaur and Epha2 in murine pancreatic tissue was confirmed.
The stress regulated genes Rcan1 and Sesn2 were further studied. Their expression was significantly increased in cerulein-stimulated AR42J-cells, but this was

blocked by NAC. Rcan1 serum levels was significantly higher in mice with AP mice compared to controls.
Conclusion: Rcan1 expression is highly increased in a well-established mouse model of AP. Rcan1 is regulated by oxidative stress. Clinical studies are warranted to determine whether RCAN1 can serve as a prognostic marker in patients with AP.

Contact E-mail Address: vinciane.rebours@bjn.aphp.fr
Introduction: Obesity is a well-known risk factor for pancreatitis. Mechanisms involved are multiple: pro-inflammatory cytokines induced by the adipose tissue, insulin resistance and hyperinsulinism, especially. Pancreatic stellate cells are activated and increase the extra cellular matrix synthesis. Bariatric surgery is one of the more efficient treatments of morbid obesity.
Aims & Methods
Aim: To assess pancreatic endocrine and exocrine lesions in obese rats (high-fat diet, HFD) and to analyze consequences of bariatric surgery on these lesions.
Methods: 30 male Wistar rats were included: obese (after 4 months HFD) or non obese (ND, normal diet). A part of HFD rats underwent bariatric surgery: by pass (BP) or sleeve gastrectomy (SG). Four groups were constituted: Gr1, HFD (n = 8); Gr2, HFD-BP (n = 11); Gr3 HFD-SG (n = 5); Gr4, ND (n = 8). After rat sacrifice (J14 or J40 after surgery), weight, % of weight loss and glycoregulation were analyzed. Each entire pancreas specimen was analyzed by pathological exam: number of adipocytes islets, fibrosis, acino-ductal metaplasia, abnormality of Langerhans islets (HHF: hypertrophy, hypervascularisation, fibrosis), and hemosiderin deposition in intra acinar or endocrine location.
Results: A first comparison between HFD and ND rats showed an increase of HHF and hemosiderin deposition in HFD rats ($p = 0.0012$ and $p = 0.0078$, respectively). The increase of the weight in HFD rats was associated with abnormalities of the glycoregulation ($r = 0.44$, $p = 0.08$).
In the all-4 groups, HHF lesions were associated with hemosiderin deposition ($r = 0.88$, $p < 0.0001$).
A second analyze was performed in HFD rats after bariatric surgery. In operated rats, it was observed a decrease of 1/ number of HHF lesions ($p = 0.001$), 2/ hemosiderin deposition ($p = 0.0006$) and 3/ amount of adipocytes ($p = 0.01$). This decrease was more important in HFD-By Pass compared to HFD-Sleeve Gastrectomy. In HFD-BP rats, HHF lesions and hemosiderin deposition were associated with acino-ductal metaplasia lesions ($p = 0.08$ et $p = 0.02$). The number of acino-ductal metaplasia lesions was higher in rats with higher weight before sacrifice ($p = 0.03$). Moreover, number of HHF lesions was associated with a decreased glycemia after by-pass procedure ($r = -0.76$, $p = 0.02$) but with an increased glycemia after sleeve gastrectomy ($r = 0.95$, $p = 0.05$).
Conclusion: Pancreas specimens of obese rats show pancreatitis lesions (acino-ductal metaplasia, fibrosis) in acinar location and in the endocrine-exocrine interface. Abundant hemosiderin deposition confirmed the angiogenesis process and the vascular lesions associated with the activation of the pancreatic stellate cells and the fibrogenesis.
Bariatric surgery, and the by pass procedure especially, allows decreasing pathological pancreatic lesions in obese rats and reversing the pancreatitis process in an early manner.

P1320 KYNURENIC ACID AND ITS NOVEL ANALOGUE SZR-72 DIMINISH THE SEVERITY OF EXPERIMENTAL ACUTE NECROTIZING PANCREATITIS IN RATS

Z. Balla[1], B. Kui[1], E. S. Kormányos[1], B. Iványi[2], L. Vécsei[3], F. Fülöp[4], T. Takács[1], P. Hegyi[1], Z. Rakonczay Jr[1]
[1]*First Department of Medicine,* [2]*Department of Pathology,* [3]*Department of Neurology,* [4]*Institute of Pharmaceutical Chemistry, University of Szeged, Hungary, Szeged, Hungary*

Contact E-mail Address: ballazs@freemail.hu
Introduction: The pathogenesis of acute pancreatitis (AP) is not well understood and the disease has no specific therapy. There is evidence that the blood brain barrier (BBB) permeable L-kynurenic acid (KYN) analogue SZR-72 has immune modulatory roles in several inflammatory diseases.
Aims & Methods: We investigated the effects of KYN and SZR-72 on experimental AP.
In the AP groups, male SPRD rats were injected intraperitoneally (i.p.) with 3 g/kg L-ornithine 1 hour after the administration of physiological saline (PS) (n = 6-8) or 30-300 mg/kg SZR-72 (n = 6-8) or KYN (n = 6-8). Control animals were injected i.p. with PS instead of L-ornithine or 30-300 mg/kg SZR-72 or KYN (n = 6-8). Animals were sacrificed at 24 hours. Laboratory [serum amylase-, pancreatic myeloperoxidase activity, pancreatic dry/wet weight ratio] and histological parameters were measured to evaluate disease severity.
Results: The injection of rats with L-ornithine significantly increased the measured laboratory and histological parameters vs. the control groups. The administration of 30-300 mg/kg SZR-72 or KYN did not influence the examined parameters in the control groups. Pre-treatment of AP rats with 30 mg/kg SZR-72 or KYN did not have affect on disease severity. However, all measured laboratory and histological parameters were significantly reduced in AP animals in response to treatment with 300 mg/kg SZR-72 or KYN.
Conclusion: Our experiments demonstrated that SZR-72 and KYN have a dose-dependent protective effect on L-ornithine-induced AP. Since KYN is non BBB permeable and both KYN and SZR-72 exerted a beneficial effect on AP severity, this beneficial effect seems to peripheral. Further investigations are needed to determine the mechanism of SZR-72 action.
This study was supported by OTKA, TÁMOP and MTA.

P1321 PREVENTING POST-ERCP PANCREATITIS (PEP): THE ROLE OF PROPHYLACTIC PANCREATIC DUCT STENTING IN THE RECTAL NSAID ERA

N. L.-H. Bekkali[1], S. Murray[1], D. Joshi[1], G. J. Johnson[1], M. H. Chapaman[1], S. P. Pereira[1], G. J. M. Webster[1]
[1]*HPB, UCLH, London, United Kingdom*

Contact E-mail Address: noor.bekkali@uclh.nhs.uk
Introduction: Pancreatitis is an important complication following ERCP. Rectal NSAIDs at ERCP is now the standard of care to reduce the risk of PEP. They are particularly effective in those patients where prophylactic pancreatic stenting has failed. Pancreatic duct (PD) stenting also reduces the risk of PEP in high risk patients but failed PD stenting carries reported PEP rates (up to 35%).
Aims & Methods: To assess whether prophylactic pancreatic stenting is still justified in the rectal NSAID era.
We retrospectively evaluated the use of pancreatic stents in a UK tertiary referral centre between January 2013 & December 2014 in whom rectal NSAIDs were used universally. Prophylactic PD stenting was attempted in those patients with predicted high risk of PEP (e.g. SOD, multiple pancreatic cannulation).
Electronic records were reviewed for indication of pancreatic stenting, successful placement and complications. Patients were contacted by telephone where hospital records were insufficient.
Results: A total of 1361 ERCPs were conducted during the study period. Pancreatic stenting was attempted in 250 cases (18%) and was successful in 235 patients (94%). Prophylactic pancreatic stenting failed in 14 patients (5.6%). Only one patient from this group (1/14 = 7%) developed PEP, and had both sphincter of Oddi dysfunction (SOD) and a contra-indication to NSAIDs. Sixty-one per cent (153/250), of successfully placed pancreatic stents were inserted prophylactically, in whom 12% (19/153) developed PEP. The majority (79%, 15/19) of these patients had SOD, where pancreatic sphincterotomy was also performed in 40% (6/15). The relative risk for PEP between those successfully stented and those where stenting failed was 0.5 (p = ns). NSAID use was contraindicated in 22 patients (9%, 22/250) due to allergy or renal impairment, of whom two (9%) developed PEP.
Conclusion: The rate of PEP in high-risk patients receiving PD stents was similar to previous studies. Of note, PEP rates in failed stenting were surprisingly low (7%). This might reflect NSAID use, and questions the necessity of PD stenting in the NSAID era.

P1322 THE USE OF ALLOPURINOL AS A PROPHYLAXIS FOR POST ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY (ERCP) PANCREATITIS

R. M. Elwakil[1], A. A. Ibrahim[1], E. F. Barakat[1], H. T. Salem[1], A. H. Elgazzar[1], M. M. Hussein[1]
[1]*Tropical Medicine, Faculty of Medicine, Ain Shams University, Cairo, Egypt*

Contact E-mail Address: elwakilreda@gmail.com
Introduction: Pancreatitis is the most serious ERCP complication. Many trials were conducted to reduce the frequency and severity of post ERCP pancreatitis. The efficacy of allopurinol and other antioxidants were studied in prevention of post ERCP pancreatitis.
Aims & Methods: The aim of this study was to prospectively evaluate the use of allopurinol in the prevention of post – ERCP pancreatitis. One hundred consecutive patients of both sexes, their age ranged from 20-70 years, who were indicated for ERCP, whatever the etiology, in Ain Shams Specialized Hospital during the period from January 2011 to December 2014 were recruited. The subjects were divided into **Group 1:** 50 patients who received allopurinol tablets before the ERCP procedure (300 mg 15 hours before the procedure and another dose of 300mg of allopurinol 3 hours before the procedure) **(Study group). Group 2:** 50 patients who were subjected to ERCP without allopurinol prophylaxis **(Control group).** Both groups were matched together as regards age, sex, clinical picture before ERCP, comorbidities, ERCP procedures and ERCP findings. The patients were followed up for the 24 hours after the procedure clinically for detection of abdominal pain and manifestations of any other complications. Laboratory investigations including CBC, ALT, AST, serum amylase and serum lipase were evaluated. Radiological confirmation of cases suspected to have pancreatitis was done.
Results: Pancreatitis was diagnosed in 4 patients (4%) who belonged to the control group. However, there was no statistically significant difference between both groups. Post-ERCP Elevation of ALT was statistically significantly higher in group2 than in group 1 (94 vs. 127 U, $p < \mathbf{0.001}$). Asymptomatic elevation of serum amylase was present in 19 patients (38%) from group 1 and 46 patients (92%) from group 2 with statisticaly significant difference between both groups (median 102 vs .610U $p < \mathbf{0.001}$). Female gender, younger age, precut needle sphincterotomy, unintended pancreatic duct cannulation and injection appeared to be significant risk factors for post-ERCP pancreatitis.
Conclusion: Allopurinol tablets 300mg orally (15 hours, and 3 hours before ERCP) reduced post-ERCP pancreatitis, asymptomatic hyperamylesemia, vomiting, hospitalization, and elevation of ALT.

P1323 GALLSTONE AND ALCOHOLIC PANCREATITIS – EVALUATION OF ATLANTA AND DETERMINANT-BASED CLASSIFICATION SCORES

S. R. Fernandes[1], P. Santos[1], J. Carvalho[1], M. Moura[1], T. Antunes[1], J. Velosa[1]
[1]*Gastrenterologia e Hepatologia, Hospital Santa Maria - Centro Hospitalar Lisboa Norte, Lisboa, Portugal*

Contact E-mail Address: samuelrmfernandes@gmail.com
Introduction: Gallstones and alcohol represent the most common causes of acute pancreatitis. Classification scores have not been evaluated separately for these two entities.
Aims & Methods: To evaluate the performance of 1992 Atlanta (AT1992), Revised Atlanta (AT2012) and Determinant-based-classification (DBC) in several outcomes in patients with gallstone and alcoholic pancreatitis. Retrospective study including admissions between January 2003 and September 2014 in a single tertiary referral center. Demographics, mortality, admission to intensive care unit (ICU) and need for interventional procedures were considered outcomes. Statistical analysis was performed using SPSS v21.0.
Results: 358 patients (59.2% male) were included, 59.2% with gallstone pancreatitis. Age at admission was lower in alcoholic pancreatitis (47.1 ± 12.8 versus 72.6 ± 14.1 years, $p < 0.001$). Persistent organ failure (16.5% versus 6.6%, $p = 0.007$), ICU admission (43.0% versus 22.6%, $p < 0.001$) and mortality (8.5% versus 2.2%, $p = 0.016$) were higher in gallstone pancreatitis. There was no difference in the need for interventions or duration of hospitalization. DBC showed higher accuracy in predicting mortality in both alcoholic and gallstone pancreatitis (AUC 0.90 and 0.87, $p < 0.001$), while AT2012 was significant only for gallstone pancreatitis (AUC 0.761 and 0.873, $p > 0.05$ and $p < 0.001$). AT1992 could not predict mortality in either situation. DBC fared better in predicting ICU admission (AUC 0.80 and 0.84 versus 0.76 and 0.77 versus 0.68 and 0.7, $p < 0.001$) and in the need of interventions (0.85 and 0.90 versus 0.73 and 0.76 versus 0.62 and 0.69, $p < 0.001$).
Conclusion: Alcoholic and gallstone pancreatitis are separate entities. DBC was superior in predicting all clinical outcomes especially in patients with alcoholic pancreatitis.

P1324 ATLANTA, REVISED ATLANTA AND DETERMINANT-BASED CLASSIFICATION – APPLICATION IN A COHORT OF PORTUGUESE PATIENTS WITH ACUTE PANCREATITIS

S. R. Fernandes[1], J. Carvalho[1], P. Santos[1], M. Moura[1], T. Antunes[1], J. Velosa[1]
[1]*Gastrenterologia e Hepatologia, Hospital Santa Maria - Centro Hospitalar Lisboa Norte, Lisboa, Portugal*

Contact E-mail Address: Samuelrmfernandes@gmail.com
Introduction: Acute pancreatitis represents a complex and potential fatal disease whose clinical course may be highly variable. Over the years, several classification systems have been developed in order to predict disease severity. These scores have not been previously validated for the Portuguese population.
Aims & Methods: To evaluate the accuracy of 1992 Atlanta (AT1992), Revised Atlanta (AT2012) and Determinant-based-classification (DBC) scores in predicting severe clinical outcomes in Portuguese patients with acute pancreatitis. Retrospective study including admissions between January 2003 and September 2014 in a tertiary referral center. Clinical outcomes included mortality, admission to intensive care unit (ICU), need for interventional procedure and total and ICU length of stay. Statistical analysis was performed with STATA v13.0 and SPSS v21.0.
Results: 525 patients (59% male) were included. Mean age at admission was 56.4 ± 19.1 years. Most common etiologies included gallstones (38.7%), alcohol (26.1%) and idiopathic (17.9%). During hospitalization 23.0% developed organ failure (in 46.3% persistent) and 5.9% were deceased. In all classification scores higher grades of severity were associated with worse outcomes. Overall, DBC was superior to AT2012 and AT1992 in predicting need for interventions (AUC 0.88 versus 0.78 versus 0.70, $p < 0.001$), admission to ICU (AUC 0.81 versus 0.80 versus 0.75, $p < 0.001$) and mortality (AUC 0.91 versus 0.89 versus 0.69, $p < 0.001$). All scores performed similarly in evaluating total and ICU length of stay.
Conclusion: Recent classification scores performed better in all clinical outcomes and showed higher accuracy in predicting severe acute pancreatitis. Our data supports their use for Portuguese patients with acute pancreatitis.
Disclosure of Interest: None declared

P1325 TRENDS OF HOSPITALIZATION FOR ACUTE AND CHRONIC PANCREATITIS IN A PORTUGUESE MAJOR REFERRAL CENTER

S. R. Fernandes[1], J. Carvalho[1], T. Antunes[1], J. Velosa[1]
[1]*Gastrenterologia e Hepatologia, Hospital Santa Maria - Centro Hospitalar Lisboa Norte, Lisboa, Portugal*

Contact E-mail Address: samuelrmfernandes@gmail.com
Introduction: The incidence of acute and chronic pancreatitis has risen over the last decades. No study has specifically addressed hospitalization and mortality in Portuguese patients with acute and chronic pancreatitis.
Aims & Methods: To evaluate the trends in hospitalization and mortality in acute and chronic pancreatitis in a Portuguese tertiary referral center. Retrospective study including hospital admissions between 6/1988 and 3/2014 in a single center. Statistical analysis was performed using SPSSv21.0.
Results: During the study period, there were 4699 and 1338 admissions respectively for acute and chronic pancreatitis corresponding to 3807 and 831 patients. There was an annual growth in hospitalizations in both acute (25.1%) and chronic pancreatitis (23.1%). Women were more commonly admitted with acute pancreatitis (2462 versus 2237) the reverse being true for chronic pancreatitis (326 versus 1012). Age was similar between patients with acute and chronic pancreatitis (67.9 ± 19.0 and 64.9 ± 15.2). 7.3% with acute and 4.9% with chronic pancreatitis required admission to intensive care units (ICUs). Overall, mortality was higher in chronic pancreatitis (8.8% versus 14.2%, $p < 0.05$) and in patients admitted to ICUs (43.4% and 22.9% respectively for acute and chronic pancreatitis). There was a trend towards decreased mortality in acute pancreatitis (15.2% versus 5.1%, $p < 0.05$). Older age at admission but not the number of hospitalizations predicted in-hospital mortality ($p < 0.001$).
Conclusion: Admissions for acute and chronic pancreatitis have increased over the last 25 years. Although mortality remains high it has decreased over time. Age remains an important predictor of mortality.

P1326 WHAT IS THE NATURAL HISTORY OF FLUID COLLECTIONS IN ACUTE PANCREATITIS?

S. Campos[1], D. Gomes[1], A. Oliveira[1], F. Portela[1], C. Sofia[1]
[1]*Centro Hospitalar Universitário de Coimbra, Coimbra, Portugal*

Contact E-mail Address: saratcampos@gmail.com
Introduction: The recently revised Atlanta criteria changed the perspective on the fluid collection (FC) in the context of acute pancreatitis (AP) and the natural history of these reclassified collections is not yet defined.
Aims & Methods
Aim: Evaluate the natural history of fluid collections in acute pancreatitis.
We retrospectively evaluated all patients admitted to a Gastroenterology department of a tertiary hospital between January-2012 and December-2014 with the diagnosis of AP complicated by FC.
Results: Of the 491 patients admitted with AP (466 interstitial edematous AP - IEP, 27 necrotizing AP - NP), 55 (12%) developed FC. This subgroup: male sex-67%; mean age-59 years; mean number of days with symptoms prior to admission 1.83; etiology lithiasic-26% / ethanolic-26% / hypertriglyceridemia-3.7% / post-ERCP-9.3% / idiopathic-35%; moderately severe-59%.
Thirty IEP developed peripancreatic fluid collections (PPFC), 13 (43%) evolved to pseudocysts, 3 of which were infected. Regarding NP, 25 complicated: 11 acute necrotic collections acute (ANC), 54% evolving into walled-off necrosis (WON); 14 FC without evidence of necrosis. Two ANC and the WON became infected.
During follow-up, there was spontaneous resolution in: 40% > pseudocysts (minimum detected time of resolution- 57 days) and 46% > ANC. Fifteen patients required drainage, mostly because of FC infection: percutaneous-10 (success-30%), endoscopic necrosectomy-4 CNA/WON (success-25%), surgical-9 (4 in PPFC/pseudocysts infected; 5 with infected CNA/WON previously submitted to necrosectomy in, including the cases of radiological and/or endoscopic failure; success-33%). A patient suspected of having a pseudocyst underwent cephalic duodenopancreatectomy, revealing a intraductal mucinous papillary neoplasm. We documented 10 deaths: 40% with infected necrotic collections, 60% submitted to surgery, 80% during the AP hospitalization.
Conclusion: The FC following AP are relatively frequent events in our clinical practice. The PPFC evolved, in about half the cases, into pseudocysts that, in a considerable percentage of the cases, were resolved. In the context of a NP, most developed FC. The ANC solved in nearly 50% of cases. However, evolving into WON, the prognosis becomes reserved, for the high morbidity and mortality rates that are associated, despite the interventions performed.

P1327 SELECTIVE UTILIZATION OF ERCP AND ENDOSCOPIC ULTRASOUND FOR GALLSTONE PANCREATITIS WITH THE ABSENCE OF CHOLEDOCHOLITHIASIS ON MULTIDETECTOR COMPUTED TOMOGRAPHY

S. M. Park[1], J. G. Park[1], K. B. Kim[1], J.-H. Han[1], H. B. Chae[1], **S. J. Youn**[1]
[1]*Internal Medicine, Chungbuk National University Hospital, Cheongju, Korea, Republic Of*

Contact E-mail Address: smpark@chungbuk.ac.kr
Introduction: Endoscopic ultrasound (EUS) is an accurate diagnostic tool to detect common bile duct (CBD) stones that could not be otherwise detected by multidetector computed tomography.
Aims & Methods: This study aimed to evaluate the necessity for performing endoscopic retrograde cholangiopancreatography (ERCP) in the patients with gallstone pancreatitis when sludge was revealed in the CBD by EUS. Consecutive forty-one patients (M:F, mean age, 57 ± 18 years) with the suspicion of gallstone pancreatitis and no evidence of CBD stones by MDCT underwent EUS within 24 hours after admission. Early ERCP (within 72 hours after EUS) was performed in the patients with CBD stones or sludge by EUS findings, as well as the patients showing clinical deterioration. The patients' medical records were retrospectively analyzed based on clinical symptoms, biochemical data, and hospital courses.
Results: EUS revealed CBD stones, sludge, and none in 13 (31.0%), 7(17%), and 25 (51.3%) patients, respectively. ERCP was performed in 20 patients with CBD stones or sludge and 3 patients with clinical deterioration. CBD stones were revealed by ERCP in 11 out of 13 cases. However, sludge was revealed in 3 out of 7 and 3 patients with aggravated cases. All patients were improved and hospital days did not differ between the two conditions (with or without ERCP). However, 2 patients showed major complications including perforation and bleeding and improved after conservative management.
Conclusion: Fifty percent of the patients with sludge by EUS showed no evidence of CBD lesions by ERCP. Therefore, ERCP in the patients with sludge

and stable clinical course are not necessary. Further studies are needed to determine proper timing of EUS in gallstone pancreatitis.

P1328 CLINICAL OUTCOMES OF ENDOSCOPIC PANCREATIC SPHINCTEROTOMY COMBINED PANCREATIC DUCT STENT IN PATIENTS WITH ACUTE RECURRENT PANCREATITIS CAUSED BY BILIARY MICROLITHIASIS

Y.-H. Huang[1], P.-T. Chen[1], H. Chang[1], W. Yao[1], K. Li[1]
[1]*Peking University Third Hospital, Beijing, China*

Contact E-mail Address: huangyonghui@medmail.com.cn
Introduction: To investigate the feasibility of EPS combined pancreatic duct stent for acute recurrent pancreatitis caused by biliary microlithiasis.
Aims & Methods: The 52 patients of ARP (2 or more attacks of AP) from 2005 to 2014 were diagnosed biliary microlithiasis by ERCP, bile microscopy or IDUS and all underwent EST or EPS. All the patients were under follow-up after endoscopic therapy to observe the recurrence and incidence of complication. Compare the rate of recurrence, incidence of the early and late complication, the time of hospitalized and costs between two groups. Compare the known risk factors of post EST late complication such as the diameter of the CBD, papillary diverticulum, and history of the gallbladder surgery between patients with long-term complication and without.
Results: 52 patients (male 28, female 24) suffered from frequent episodes of acute pancreatitis from 2 to more than 20 times. All the patients were non-randomly divided into 2 groups according to the endoscopic therapy: 28 cases in EST group (with or without EPBD or ENBD) and 24 cases in EPS group (with or without pancreatic stent). There were 9 cases PEP after the endoscopic therapy (3 in EST group, 6 in EPS group, $P = 0.322$). The mean time of hospitalization in EST group was 7 days, while it was 5 days in EPS group ($P = 0.040$). The mean costs was 18648.20 yuan each patient in EST group and 15642.65 yuan in EPS group ($P = 0.013$). During the follow up (mean 64 months, range 3-118 months), there were 5 patients occurred pancreatitis recurrence, 3 in EST group, 2 in EPS group, the treatment efficiency in EST group and EPS group is 89.3% and 91.7% respectively ($P = 1.000$ with chi-square test and $P = 0.888$ with Log-rank test). The incidence of long-term complication is 32.1% in EST group and 8.3% in EPS group ($P = 0.046$ with chi-square test and $P = 0.388$ with Log-rank test). The P value of the diameter of the CBD, papillary diverticulum, and history of the gallbladder surgery to the incidence of long-term complication is 0.929, 0.838, 0.921 respectively.
Conclusion: EPS has equivalent treatment efficiency to EST through blocking the pathophysiology progress of microlithiasis inducing pancreatitis episodes. At the same time, EPS save the function of biliary sphincter so that decrease the risk of long-term complication, and pancreatic stent is efficient to prevent PEP. In summary, EPS combined with pancreatic stent is more suitable to the treatment of acute recurrent pancreatitis caused by biliary microlithiasis.

Introduction: Chronic pancreatitis (CP) can lead to development of pancreatic exocrine insufficiency (PEI).
Some CP patients are not adequately monitored. Consequently diagnosis of complications such as PEI may be delayed, resulting in postponement of specific treatment.
Aims & Methods: To evaluate nutritional status, quality of life(QoL) and PEI in CP patients without adequate follow-up.
Cross-sectional multicenter study involving 11 hospitals. CP patients without follow-up by gastroenterologist in the last two years were included. A complete medical exam including laboratory and EORTC-QoL-c30 questionnaire were performed to evaluate CP and complications. PEI status was determined by fecal elastase-1 concentration in stools (FE).
Results: 56% smokers, 52% regular alcohol consumers). Mean time (95%CI) from diagnosis to the inclusion in the study was 7.2(5.3-9.3) years.
25.5% of the patients indicated their overall health and their QoL was 1-2 (7 points scales, 1-very poor, 7-excellent).
FE analysis was available in 37 patients: 20(54.0%) had FE < 200 mcg/g, and 17(45.9 %) were considered to suffer from severe PEI (FE < 100mcg//g).
Analytical parameters out of range and clinically significant were: albumin, RBP, lipids, glucose, HbA1C, LDL, magnesium, vitamins K, A, D, E, B12; and prothrombin time.
Statistical significant differences between nonePEI (n = 17) PEI patients (n = 20) were observed at (median [Q1, Q3]): glucose (102.0 [90.0,116.0]177.5 [113.0,224.5]), HbA1C (5.5 [5.4,6.0] 7.0 [6.4,8.0]) and Vitamin E (14.3 [13.0,15.6] 10.1 [6.6,13.0]).
Conclusion: Unmonitored CP-patients suffering from PEI have impaired nutritional status and low QoL. Closer monitoring is needed for these patients.

Contact E-mail Address: emmanuel.coronel@uchospitals.edu
Introduction: Von Hippel Lindau (VHL) syndrome is an autosomal dominant genetic disorder that has a high penetrance and wide phenotypic expression. Close to 60 percent of patients with VHL show pancreatic involvement. An animal study has shown that the VHL gene can regulate endocrine function but this phenomenon has not been described in humans. There are only a few case reports that describe the relationship between VHL and exocrine pancreatic insufficiency. The aim of our study is to describe pancreatic findings (by imaging) and to correlate with the presence of exocrine and / or endocrine function in a group of patients with this genetic disorder.
Aims & Methods: We performed a retrospective electronic medical record review of patients with VHL seen in our Pancreatic Disease Center. We collected the following information: age, sex, gender, genetic mutation, characteristics of organ involvement, pancreatic imaging findings and degree of cyst involvement, clinical evidence of exocrine pancreatic insufficiency (EPI) (the frequency of bowel movements, weight loss, steatorrhea, gas, post prandial abdominal distention), fecal elastase-1 measurement and evidence of endocrine insufficiency (HbA1c).
Results: A total of 13 patients were identified. Nine patients were women and four were men. The median age of our patient group was 37 (19-70). Of these 13 patients, eleven had a documented genetic mutation. Eleven patients had a strong family history of VHL. One was a sporadic mutation. Simple pancreatic cystic lesions were present in eight. In this group, six patients had complete cystic replacement of the pancreas, the median age was 46.5 (23-56), two patients had significant duodenal compression causing gastric outlet obstruction requiring laparoscopic gastrojejunostomy. Three had symptoms suggestive of EPI (all with complete cystic replacement of the pancreas) and two had a fecal elastase measured consistent with severe pancreatic exocrine insufficiency (less than 50 and 88 with normal being > 200). One patient provided an inadequate sample. Pancreatic enzyme replacement therapy was started with marked improvement in symptoms including weight gain. In addition, three patients with complete cystic replacement of the pancreas were screened for EPI, two had a normal fecal elastase and one provided an inadequate sample. Among the three patients with symptomatic EPI, all had a HbA1c measured and two were newly diagnosed with type 3c diabetes (HbA1c 6.8 and 8.1). Four patients had lesions in the pancreas highly suggestive of pancreatic neuroendocrine tumors (PNETs) and one had a lesion suggestive of a serous cystadenoma.
Conclusion: Complete cystic replacement of the pancreas is common in patients with VHL. Particular attention must be made for the early diagnosis of exocrine and endocrine pancreatic insufficiency, both of which were newly diagnosed in our small cohort. Guidelines for screening and management of pancreatic involvement in patients with VHL are needed to improve and standardize quality of care.
Disclosure of Interest: None declared

P1331 OBSERVATIONAL, PROSPECTIVE, SINGLE-CENTER STUDY TO EVALUATE THE DIAGNOSTIC YIELD OF THE DYNAMIC EUS, EUS-ELASTOGRAPHY AND ENDOSCOPIC PANCREATIC FUNCTION TEST (EPFT) FOR THE DIAGNOSIS OF EARLY CHRONIC PANCREATITIS (CP)

J. E. Domínguez-Munoz[1,2], J. Lariño-Noia[1,2], A. Álvarez-Castro[1,2], L. Nieto-García[2], B. Lindvkist[3], J. Iglesias-Garcia[1,2]
[1]*University Hospital of Santiago de Compostela,* [2]*Foundation for Research in Digestive Diseases, Santiago de Compostela, Spain,* [3]*Institute of Medicine, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Germany*

Contact E-mail Address: info@fienad.org
Introduction: Early diagnosis of CP is hindered by the limited accuracy of diagnostic methods. EUS and the endoscopic pancreatic function test (ePFT) are the most sensitive morphological and functional method respectively in this setting. EUS-elastography allows for evaluating the degree of pancreatic fibrosis in CP, and the dynamic evaluation of the main pancreatic duct (MPD) after i.v. secretin provides with additional dynamic information. We developed a multimodal EUS-based approach for pancreatic evaluation by integrating these four methods.
Aims & Methods: Aim of our study was to evaluate the concordance among the different data obtained by this EUS-based multimodal test in patients with suspected early CP.
Methods: A prospective, observational study was designed. Patients with clinically suspected CP and 3-4 EUS criteria of the disease at EUS were included after informed consent. For the multimodal test, EUS was performed under deep

sedation with the Pentax EG-3270UK linear scope, attached to the HI-VISION Ascendus. Quantitative elastography was performed in the head, body and tail of the pancreas and the mean strain ratio (SR) was considered as the final result (normal SR < 2.25). After that, secretin (0.2 μg/kg) was given intravenously and duodenal fluid was collected at 15, 30 and 45 minutes thereafter for bicarbonate quantification (normal peak > 80 mEq/L). Diameter of the MPD was measured by EUS at 5, 10, 25 and 40 min after secretin stimulation. A maximal dilatation of the MPD of at least 50% from basal was considered as normal. A descriptive analysis was performed.
Results: 29 patients (mean age 39.8 years, range 18-65, 16 male) were included. The EUS-based multimodal procedure was feasible in 28 cases (19 with 3 EUS criteria and 9 with 4 EUS criteria of CP respectively). Elastography (SR) was abnormally high in all 28 patients. Peak bicarbonate concentration was abnormally low in 24 (85.7%) patients. Dynamic dilatation of the MPD after secretin was reduced in 21 (75%) cases. In addition to showing 3-4 criteria of CP at EUS, 20 patients (71.4%) had all three additional parameters abnormal (elastography, bicarbonate concentration and dynamic dilatation of the MPD) and strongly supported the diagnosis of CP. Five patients (17.9%) had two parameters abnormal (elastography and bicarbonate in one, and elastography and MPD distensibility in 4) and three patients (10.7%) had only the elastography abnormal. There were 2 complications related to the procedure: Mild acute pancreatitis and pulmonary aspiration related to deep sedation.
Conclusion: The multimodal EUS-based pancreatic evaluation including B-mode EUS, elastography, ePFT and dynamic evaluation of the MPD after secretin stimulation provides with relevant dynamic morphological and functional information of the pancreas supporting the diagnosis of early CP.

P1332 IMPACT OF PANCREATIC EXOCRINE INSUFFICIENCY (PEI) ON THE MORTALITY RATE OF CHRONIC PANCREATITIS (CP): A RETROSPECTIVE EVALUATION OF A SINGLE-CENTER PROSPECTIVE DATABASE

N. Vallejo-Senra[1,2], **J. Iglesias-García**[1,2], J. Lariño-Noia[1,2], J. E. Domínguez-Munoz[1,2]
[1]*University Hospital of Santiago de Compostela,* [2]*Foundation for Research in Digestive Diseases, Santiago de Compostela, Spain*

Contact E-mail Address: info@fienad.org
Introduction: Prevalence of CP is increasing in last years mainly due to the improvement of diagnosing technologies. EPI, defined as the inability of the exocrine pancreas to perform a normal digestive function, is the leading consequence of CP. Little is known about the mortality in patients with CP, and there is no data about the mortality in patients with CP and EPI.
Aims & Methods: We aimed to assess the risk of death in patients with CP with and without EPI.
Methods: We performed a retrospective analysis of a prospectively collected database of patients with CP under follow-up in our Pancreas Unit. Diagnosis of CP and EPI was based on EUS and C13-MTG breath test respectively. Mortality rate and causes of death were compared between patients with and without EPI. Statical analysis was performed using the chi-square test and T-student test.
Results: A total of 480 patients were analyzed (77.5% men), with a median age of 53 years (range 15-88) during a median follow-up of 5.3 years (IC95% 4.2-6.4). Prevalence of EPI was 21.8% (105 patients), 82.7% men, with a median age of 54 years (range 15-83). Patients without EPI (375, 78.2%), had a median age of 53 years (range 19-88), and 75.7% were men. The main etiology was alcohol and/or smoking (63.3%). There were a total of 41 deaths (17.1‰ /year). The main cause of death was cancer (n = 16) of lung (n = 4), pharynx or larynx origin (n = 3), cholangiocarcinoma (n = 2), prostate (n = 2), and others. Six patients developed pancreatic cancer during follow-up, but only 1 patient died for this reason. Pancreatic cancer was diagnosed at early stage in the remaining 5 patients and are considered to be cured. Other causes of death were infectious disease (10 cases, 5 from biliary origin), liver cirrhosis (n = 4), cardiovacular disease (n = 4), and others (n = 7). The number of deaths among the EPI group was 18 (34.3 ‰/year), in contrast with the non-EPI group (23 cases, 12.3‰/year, $p < 0.001$), with median ages of 57 (IC95% 52-65) and 63 years (IC95% 58-66), respectively ($p < 0.05$). Causes of death were similar in patients with and without EPI. Median time between diagnosis of CP and death was (5.1 [IC95% 3.3-5.3] and 6.2 years [IC95% 4.8-8.4] in patients with and without EPI). Etiology of CP in patients who died was alcohol and/or tobacco in all cases except one (CFTR mutation).
Conclusion: Annual mortality rate in patients with CP in our cohort was 17.1‰ /year. Patients with CP die at a young age. Mortality rate is markedly higher in patients with CP and EPI than in those without EPI. Most deaths are related to alcohol and/or tobacco abuse. Surveillance of these patients may be a good strategy to prevent death from pancreatic cancer.

P1333 LONG-TERM FOLLOW-UP AND NATURAL HISTORY OF TROPICAL PANCREATITIS

K. T. Shenoy[1], K. B. Leena[2]
[1]*Gastroenterology, Sree Gokulam Medical College and Research Foundation, Venjaramoodu,* [2]*Senior Research Manager, Population Health and Research Institute, Trivandrum, India*

Contact E-mail Address: drktshenoy@gmail.com
Introduction: Tropical pancreatitis has high morbidity and long-term complications. To study the natural history and occurance of malignancy, we followed a prospective cohort in S India.
Aims & Methods
Aims: To evaluate the long-term sequele and complications in Tropical pancreatitis and to estimate the survival in associated malignancy.
Methods: In this prospective study, we studied 1480 subjects with tropical pancreatitits in a tertiary referral centre attached to Trivandrum Medical college in S India recruited between January 1980 and March 2006 and followed up till March 2015. At each follow up visit, data were collected for any complications. C T scan, MRI and MRCP were carried out and mortality and morbidity were assessed. Univariate analysis, Cox Proportional Hazard regression and Kaplan Meir Survival curves were plotted and analysed.
Results: Of the 1480 sujects, 96% had cacific pancreatitis. Mean follow up was 9.3 years and median was 5-3 (range 1-33 years). 164 subjects developed pancreatic malignancy. Age in those with malignacy was 45 ± 12.4 years and 34.2 ± 12.08 in those without malignancy. 12 had pancreatic ascites and 8 had pancreatic absess. 38 percent in the malignancy group had hepatic/ distant metastasis and were inoperable. The relative risk of mortality for: age over 50 was 4.97 (95% CI 3.7-6.67); for smoking 1.39 (95% CI 1.01-1.89). KM survival probability were 0.55 (95% CI 0.42-0.66) at 3 months; 0.24 at 6 months and 0.13 at 9 months. Duration of diabetes and abdominal pain didnot affect survival.
Conclusion: Pancreatic malignacy developed in 11% of subjects with tropical pancreatitis on long-term follow-up and has increase chance of metastatsis and high mortality.

Contact E-mail Address: kovacheva_mila@abv.bg
Introduction: Deficiency of fat-soluble vitamins such as vitamin D (VD) is present in chronic pancreatitis (CP), reccurent pancreatitis (RP) and after pancreatic surgery (PS) but little is known for it extent.
Aims & Methods: To determine the prevalence of VD deficiency in patients with CP, RP and after PS and to assess its relationship to the severity of morphological imaging data. Study encompassed 78 patients (40 male, 38 female), mean aged 52 years (range 20-84y), who consented to participate; 49 patients suffered from CP, 21 patients – from RP, 8 patients underwent PS. Alcohol abuse was the most common aetiology (40 patients), 19 patients had chole- or choledoholithiasis, and 19 patients were with other etiology. Patients were divided into four groups (gr.) according to imaging morphological data based on Cambridge classification for CT/MRCP (grade I-IV): 18 in gr. I, 20 in gr.II; 21 in gr.III , and 19 in gr.IV; 39 patients were with proven pancreatic exocrine insufficiency (PEI). Exocrine function was evaluated using the secretin-enhanced MRCP, with ^{13}C mixed triglycerides breath test (cut-off at 29%) and faecal elastase-1 (normal > 200 μg/g). Determination of 25-hydroxyvitamin D (25OHD, sum of $25OHD_3$ and $25OHD_2$) was performed by a validated, DEQAS certified ID-LC-MS/MS method with accuracy and precision within 7.5% and linearity range 3.0-300.0 nmol/L. VD status was assessed as deficiency (25OHD < 25 nmol/L), severe insufficiency (25–50 nmol/L), mild insufficiency (50–80 nmol/L), and sufficiency (> 80 nmol/L). Statistical analysis was performed with SPSS v15 package.
Results: Total 25OHD for all patients was 38.9 ± 25.7 nmol/L (range 3.8–105.7 nmol/L); 30 patients (38.5%) had deficiency; profound insufficiency was found in 28.2% of patients; another 26.9 % were with mild insufficiency, and only 5 patients (6.4%) were in sufficiency status. Mean 25OHD in the morphological groups was as follows: gr.I: 58.0 ± 22.0 nmol/L, gr.II 49.6 ± 21.2 nmol/L, gr.III 30.0 ± 24.4 nmol/L and gr.IV 23.4 ± 20.0 nmol/L. VD status worsened with severity of morphological changes - deficiency, severe insufficiency, and mild insufficiency being respectively 11%, 22% and 67% (gr. I), 10%, 50% and 40% (gr.II), 62%, 24% and 14% (gr.III), and 68%, 16% and 16% (gr.IV). There was a statistically significant difference in VD status between gr.I and III, $p < 0.01$; gr.I and IV, $p < 0.001$; gr.II and III, $p < 0.05$; and gr.II and IV, $p < 0.01$. Lowest 25OHD levels (14.7 ± 6.1 nmol/L) were registered in patients with most severe imaging data (Cambridge III and IV) regardless of season or cause. VD status was lower in patients with proven PEI compared to without PEI, $p < 0.05$. VD status was lower in patients with alcohol aetiology, in females and in older patients > 50y but this is not statistically significant. There was no significant seasonal difference in VD status within groups.

Conclusion: Most of our patients with or without PEI were with vitamin D deficiency and insufficiency and there was a strong relationship between 25OHD levels and severity of morphological imaging changes.

P1335 CHANGES OF IMMUNE SYSTEM AND CYTOKINE LEVELS IN PATIENTS WITH CHRONIC PANCREATITIS

O. Krylova[1]
[1]*SI "Institute of gastroenterology of NAMS of Ukraine", Dnepropetrovsk, Ukraine*

Contact E-mail Address: lenkr@bk.ru
Introduction: According to the present point of view, there is an important complex of exogenous and endogenous etiological factors in development of chronic pancreatitis (CP): toxic-metabolic, immune, genetic, nutritional and many others, and that's why this disease is considered polyetiological.
Aims & Methods: To examine the state of the immune system and cytokine levels in patients with various forms of CP. There were examined of 210 patients with various forms of CP - I group - obstructive (26 patients), II - calculous (56) III – chronic inflammatory pancreatitis (78), IV - CP complicated by pseudocyst (50). Subpopulations of lymphocytes was determined using monoclonal antibodies (standard method NIH USA). Changes of levels of immunoglobulin classes IgA, IgM, IgG in the serum was determined by radial immunodiffusion Mancini. Study of proinflammatory and profibrotic cytokines TNF-α, IL-10, REG-1 α, TGF- β1, the concentration of lactoferrin was carried out by ELISA.
Results: Chronic inflammation with CP is accompanied by dysfunction of immune system: reduction of T-lymphocytes (CD3+), T-helper cells (CD4+), increase of level of citotoxic T-cels (CD8+), the phagocytic activity of neutrophils, activation of humoral immunity in all patients by the level of the CIC and B-cell markers (CD19+). The level of immune disorders increases with prolonged duration of disease. At the same time cytokine regulation of immune cells is disturbed, that is manifested by increased levels Lithostathine-1-alpha (REG-1α) 8.7 times (much more than in patients of III and IV groups ($p < 0.001$), and lactoferrin 18.7 times (much more than in patients of I and II groups ($p < 0.001$). The level of proinflammatory cytokines (TNF-α) was significantly higher in patients of II and IV groups ($p < 0.001$), the content of TGF-β1 - in patients of II and III ($p < 0.001$). For all patients it was characteristical decrease in the level of apoptosis protein receptor CD95 ($p < 0.01$).
In determining the relationship between markers of stone formation it was found that calcification of duct / pancreatic of parenchyma detected at the level of the coefficient of calcification (REG 1 α / lactoferrin) of less than 0.5. At the level of the coefficient of 0.5-1.0 - high probability of stone formation, and a value of 1.5 and above it - is low.
Identified markers of progression CP: coefficient calcification (REG 1α / lactoferrin) 0.5-1.0; translocation DNAase I from the cytoplasm to the nucleus of acinar cells; activation of collagen (reduction ratio oxyproline/ Glucuronic acid 0.5 below), increase in fibrosis activators (TGF-β1, TNF-a), intensification of lipid peroxidation (MDA).
Conclusion: All patients with CP were had violation of regulatory, proliferation and activation functions of the immune system, which leads to frustration in the cytokine level of immunity and, consequently, the deepening of the inflammatory and fibrotic process.

P1336 HIGH PREVALENCE OF EXOCRINE PANCREATIC INSUFFICIENCY IN 1105 SWEDISH PATIENTS WITH GASTROINTESTINAL SYMPTOMS

S. Haas[1], A. Hedström[1], M. Löhr[1]
[1]*Center for Digestive Diseases, Karolinska University Hospital, Stockholm, Sweden*

Contact E-mail Address: stephan.haas@ki.se
Introduction: With age, there is a physiological decline of organ function. For the pancreas this could be demonstrated histologically in a autopsy study[1] and also in an epidemiological study[2]. The aim of this study was to determine the exocrine pancreatic function in a cohort of patients with clinical symptoms of pancreatic insufficiency (eg, abdominal pain, diarrhea, bloating) which, however, had no previously diagnosed pancreatic pathology.
Aims & Methods: District physicians and gastroenterologists were offered to perform a fecal elastase-1 test in those patients who had gastrointestinal symptoms that could indicate exocrine pancreatic insufficiency (EPI) (abdominal pain, bloating, diarrhea). Patients had no known pancreatic disorders.
Results: 1105 F-elastase (FE-1) tests were performed by a standard ELISA (ScheBo Biotech®). The referring doctors received the test result and were offered counseling by phone. The results showed that 208/1105 (18.4%) had exocrine pancreatic insufficiency (EPI) (<200 μg/g) and 8.3% had even FE 1 <100 μg/g. The EPI-frequency increased with age: 8.3% for less than 30 years and 29% in the group older than 80 years. The results confirmed our interim analysis from 2014. In a separate group of patients with diabetes mellitus (n = 89; 80% IDDM), which was tested regardless of clinical manifestation, the frequency of EPI has also been significantly higher and 7.9% showed an FE-1 < 100 μg/g.
Conclusion: Consistent with previous studies, we were able to identify a high EPI frequency in patients who have some type of gastrointestinal symptoms. The prevalence of EPI was markedly increasing with age.

Introduction: Malnutrition is one of the most important consequences in chronic pancreatitis and it correlates with risk of complications and mortality. Its early assessment with serum nutritional markers together with imaging and anthropometric data provide better decisions regard to enzym replacement therapy.
Aims & Methods: Evaluation of the potential role of prealbumin (preAlb) and retinol binding protein (RBP) as screening tools for malnutrition in patients with chronic pancreatitis (CP), recurrent pancreatitis and after pancreatic surgery and their correlation with morphological changes based on CT/MRCP data. Serum samples of 80 patients (41 male, 39 female) at mean age 52 (20-84) were collected in our centre for the period February 2014 – April 2015. 49 patients had CP, 22 patients – recurrent pancreatitis, 9 patients underwent pancreatic surgery. Alcohol was the most common aetiology being the cause in 41 patients (51.3%), 19 patients had chole- and choledoholithiasis and 20 patients were with other etiology. Exocrine function was evaluated using the secretin-enhanced MRCP, ^{13}C mixed triglycerides breath test (cut-off 29%) and faecal elastase-1 (normal >200 μg/g). 39 patients were with pancreatic exocrine insufficiency (PEI) and 41 without. We divided patients according to imaging morphological data based on Cambridge classification for CT/MRCP (grade I–IV) in group (gr.) I-19, II-20; III-22; IV-19 patients. Serum preAlb and RBP levels were measured by immunonephelometry assay. In addition to clinical information, BMI, imaging data, preAlb and RBP were assessed and other proteins: albumin and CRP. The statistical analysis was performed via SPSS version 15.
Results: Mean ± SD in common group: PreAlb for all patients was 0.2001 ±0.1016g/L, and RBP- 0.0384 ±0.0289; 40% of patients (7% of Cambridge grade I) had both preAlb and RBP below reference limits; 52% of patients were with preAlb under 0.2 g/L (mean 0.1309) with following distribution in Cambridge groups: I- 26%; II- 50%; III- 62% and IV- 75%. RBP under 0.03 g/L was found in 46.25% of patients (mean 0.0286) with following distribution in Cambridge gr. I- 26%; II- 50%; III- 52% and IV- 50%. PreAlb mean for patients with proven PEI was 0.1875 vs. 0.2120 in those without PEI, and for RBP 0.0368 vs. 0.0401. Based on clinical data and BMI the estimated sensitivity and specificity for malnutrition detection of preAlb are 68.85% (95% CI 55.71% to 80.10%) and 73.68 with positive predictive value 89.36%. The sensitivity and specificity of RBP in the group are 57.14% and 79.17% respectively with a positive predictive value of 86.49%. When comparing the data for prealbumin and RBP with imaging morphological data we found statistically significant correlation. It is for preAlb between gr. I and gr. III, $p < 0.05$; between gr. I and gr. IV, $p < 0.01$; as well between groups with mild imaging changes (both I and II) and groups with severe imaging changes (III and IV), $p < 0.05$. Similar were data regard to the RBP ($p < 0.001$).
Conclusion: Prealbumin and RBP tests are easy to perform and reliable tools in combination with imaging data and BMI for screening of malnutrition in patients with CP.

P1338 IMAGING MODALITIES IN CHRONIC PANCREATITIS: A SYSTEMATIC REVIEW AND META-ANALYSIS

Y. Issa[1], M. Kempeneers[1], H. V. Santvoort[1], S. Bipat[2], M. Boermeester[1]
[1]*Surgery,* [2]*Radiology, AMC, Amsterdam, Netherlands*

Contact E-mail Address: y.issa@amc.uva.nl
Introduction: Chronic pancreatitis (CP) is an inflammatory disease of the pancreas, which often is accompanied with severe pain and impaired endocrine and exocrine pancreatic function. Imaging modalities are indispensable for the diagnosis and the treatment of CP. The most frequent used imaging modalities are endoscopic retrograde cholangiopancreatography (ERCP), abdominal ultrasonography (US), endoscopic ultrasonography (EUS), magnetic resonance imaging (MRI) or computed tomography (CT). Aim of this study was to give diagnostic accuracy summary estimates for imaging modalities for CP.

Aims & Methods: A broad systematic search was performed in Cochrane Library, MEDLINE, EMBASE and CINAHL databases for studies evaluating imaging modalities for CP. The search included terms for chronic pancreatitis, MRI, CT, EUS, ERCP and US. The inclusion criteria were: one or more imaging modality was evaluated in patients with CP (≥5 patients), the imaging technique was compared with a reference standard, and enough data was reported to extract the number of true-positive, true-negative, false-positive, and false-negative results. We excluded studies that reported other imaging techniques than mentioned above, or imaging techniques used for treatment, reviews, case-reports, and book chapters. All search hits were evaluated for eligibility by two reviewers. The Quality Assessment of Diagnostic Accuracy Studies - 2 (QUADAS-2) tool was used to assess the methodological quality of the included studies. Bivariate random-effects modeling was used to obtain summary estimates of sensitivity and specificity (I2 > 25%).
Results: A total of 7641 titles and abstracts were screened for eligibility. For 220 studies, the full text was retrieved, of which 45 studies fulfilled the inclusion criteria, with evaluation of 3629 patients. Sensitivity of ERCP 82% (95% CI: 76% > 87%) was significant higher than the sensitivity of US 67% (95% CI: 53% > 78%) (p = 0.018). The sensitivity of EUS 82% (95% CI: 71% > 90%), MRI 78% (95% CI: 69% > 85%) and CT 75% (95% CI: 66% > 83%) did not differ significantly. There were also no significant differences in specificity for the CT 91% (95% CI: 81% > 96%), MRI 96% (95% CI: 90% > 98%), EUS 91% (95% CI: 83% > 95%), ERCP 94% (95% CI: 87% > 98%) and US 98% (95% CI: 89% > 100%).
Conclusion: The ERCP and EUS have the highest diagnostic accuracy of all the imaging modalities in detection of CP, followed by the CT and MRI. The US had the lowest diagnostic accuracy.
Disclosure of Interest: None declared

P1339 COMPARISON OF DIFFERENT CLASSIFICATION TOOLS FOR THE DIAGNOSIS OF CHRONIC PANCREATITIS

Y. Issa[1], U. Ahmed Ali[1,2], S. van Dieren[1], H. van Santvoort[1], M. A. Boermeester[1]
[1]*Surgery, AMC, Amsterdam,* [2]*Surgery, UMCU, Utrecht, Netherlands*

Contact E-mail Address: issayama@gmail.com
Introduction: Several classification tools for the diagnosis of chronic pancreatitis (CP) are used in daily practice and in clinical research. There are, however, no studies describing and comparing the differences between the classification tools. The aim of this study was to compare the Mannheim, Büchler and Luneburg classification tools for CP.
Aims & Methods: A retrospective analysis of a prospectively collected multicentre patient cohort including 669 patients with a first episode of acute pancreatitis was performed. The patients were retrospectively followed-up for a median period of 5 years, through medical records and patient's questionnaires. We evaluated and compared the Mannheim, Büchler and Lüneburg classification tools for 1) the diagnosis of CP; 2) the influence of each criteria (subtracting or adding) within the classification tool on the total number of diagnosed patients; 3) the agreement (Kappa) of the different classification tools; 4) the estimated sensitivity, specificity, positive predictive value and negative predictive values for each classification tool with Bayesian latent-class analysis.
Results: The median follow-up period of the patients was 57 months (IQR 42-70). 1) CP was diagnosed in 50 (7%), 60 (9%), 59 (9%), 61 (9%) and 46 (7%) of 669 patients by the Mannheim definite, Mannheim propable, Lüneburg, Büchler and the treating physician, respectively. 2) Adding or subtracting of the following criteria led to significant changes in the total number of diagnosis of CP: abdominal pain, recurrent pancreatitis, moderate to marked ductal lesions, endocrine and exocrine insufficiency, pancreatic calcifications and pancreatic pseudocysts. 3) The overall agreement between the Mannheim, Büchler and Lüneburg was substantial (Kappa 0.75, ranging 0.69 – 0.79). The agreement between the different classification tools and the diagnosis made by the physician was moderate (Kappa 0.60, ranging 0.52 – 0.71). 4) The Büchler score had the highest sensitivity (94%), followed by the Mannheim (87%) and the Lüneburg tool (81%). The specificity ranged from 97% to 99%, with the positive predictive value ranging from 72% (Lüneburg) to 92% (Mannheim).
Conclusion: Differences between the total number of diagnosis of CP by the classification tools can be mainly attributed to whether abdominal pain or recurrent pancreatitis, exocrine and endocrine pancreatic insufficiency, pancreatic calcifications, moderate to marked ductal lesions and pancreatic pseudocysts are included in the classification tools. A combination of these criteria in a modified classification tool may lead to a higher diagnostic accuracy for the diagnosis of CP. The overall agreement between the classification tools was substantial.

P1340 CHRONIC PANCREATITIS: WHERE DO WE STAND? AN INTERNATIONAL MULTIDISCIPLINARY SURVEY AND CASE VIGNETTE STUDY

Y. Issa[1], H. van Santvoort[1], P. Fockens[2], M. Besselink[1], T. Bollen[3], M. J. Bruno[4], M. A. Boermeester[1]
[1]*Surgery,* [2]*Gastroenterology, AMC, Amsterdam,* [3]*Radiology, St Antonius Ziekenhuis, Nieuwegein,* [4]*Gastroenterology, Erasmus MC, Rotterdam, Netherlands*

Contact E-mail Address: issayama@gmail.com
Introduction: There is very little insight into factors associated with the decision making of surgeons and gastroenterologist in different aspects of diagnoses and treatment of chronic pancreatitis (CP). The aim of the study was to gain more insight into the current opinion and clinical decision making of international expert pancreatologists regarding the diagnosis and treatment of CP.
Aims & Methods: An online survey and clinical case vignettes regarding the diagnosis and treatment of CP was send by e-mail to members of the International Hepato-Pancreato-Biliary Association, American Pancreatic Association, European Pancreatic Club, European Society of Gastrointestinal Endoscopy and the Dutch Pancreatitis Study Group. The survey consisted of several short questions regarding the use of imaging modalities and classification tools in the diagnosis of CP. Furthermore, the use of surgery, endoscopy and extracorporeal shock wave lithotripsy (ESWL) in the treatment of CP. This survey was proceeded by questions and statements regarding several controversial and clinical cases of CP.
Results: A total of 288 pancreatologists, 56% surgeons and 44% gastroenterologists, participated with the survey. The majority (54%) was registered as a specialist for over 10 years and 77% worked at an academic center in Europe (59%), North-America (16%) or Asia (15%). 52% of the specialists did not use any classification tool for the diagnosis of CP, the rest used either the Mayo Clinic (28%), Mannheim (25%), or Büchler (25%) tools. Overall, computed tomography was the most preferred imaging modality to asses an enlarged pancreatic head (59%), pancreatic pseudocyst (55%), pancreatic calcifications (75%) and peripancreatic fat infiltration (68%). Magnetic resonance imaging was preferred when evaluating main pancreatic duct abnormalities (60%). The majority (59%) of the gastroenterologists indicated to use ESWL the treatment of CP. Total pancreatectomy with auto-island transplantation (TP-AIT) was significantly more often performed in North-America, compared to other continents (p < 0.001). TP-AIT was most preferred treatment in patients with parenchymal calcifications, without dilatation of the main pancreatic duct (PD) (27%) and in patients with refractory pain despite maximal medical, endoscopic and surgical treatment (21%). Distal pancreatectomy (57%) or endoscopic + ESWL (39%) were the preferred treatments of a solitary stone in the PD of the pancreatic tail. In patients with casting stones over the entire PD, 59% preferred an operation (Frey) versus 41% endoscopic + ESWL, as was the case in patients with an enlarged pancreatic head, 58% preferred an operative treatment (PPPD) versus 42% endoscopy.
Conclusion: In most clinical cases there was no consensus regarding the preferred treatment, with variance between surgery or endoscopy/ESWL. The diversity of clinical and morphological presentation of CP and lack of evidence based guidelines and studies, demonstrate that the clinical decision making is for most part still based on local expertise, beliefs and disbeliefs. The treatment should be performed in a multidisciplinary team in an expert center.

P1341 ADVANCES IN HIGH RESOLUTION CROSS SECTIONAL IMAGING AND THE RISING PREVALENCE OF PANCREATIC CYSTS OVER THE PAST DECADE

M. Moris[1], M. Bridges[2], R. Pooley[2], M. Raimondo[1], T. Woodward[1], J. Stauffer[3], H. Asbun[3], M. Wallace[1]
[1]*Gastroenterology,* [2]*Radiology,* [3]*General Surgery, Mayo Clinic, Jacksonville, United States*

Contact E-mail Address: Wallace.Michael@mayo.edu
Introduction: Increasingly, pancreatic cystic lesions (PCLs) are being discovered incidentally in patients who undergo cross-sectional imaging. It has been suggested that this increase is a direct result of the development of more sophisticated imaging techniques, but only limited data are available on the real prevalence of PCLs.
Aims & Methods: To determine the PCL prevalence in patients undergoing magnetic resonance imaging (MRI) for non-pancreatic indications on successive MR systems. Also, to compare prevalence based on the demographic and comorbidity features of the patients.
All consecutive abdominal MRIs performed between January and February from 2005 to 2014 were listed. Clinical charts were chronologically reviewed to identify the first 50 suitable candidates of each year. Exclusion criteria were: positive history of pancreatic disease including cysts, pancreatic symptoms, pancreatic indication of the study or previous abdominal MRIs. Once selected, each study was reviewed by an expert pancreatic MRI radiologist.
Results: 1962 patients were reviewed to find 500 suitable candidates. Overall, 208 patients(41.6%) had a non-reported incidental cyst. The proposed diagnosis was uncertain in 128 cases(62%), followed by an IPMN in 72 patients(35%). Extrapancreatic cysts were found in 70% of the patients and were strongly associated with PCLs. The univariate logistic regression showed a strong relationship between PCLs and age (p < 0.0001), diabetes mellitus (DM) (p = 0.001) and personal history of a previous cancer (p = 0.01) (specifically, non-melanoma skin cancer [p = 0.03] and hepatocellular carcinoma [p = 0.02]). The multivariable model showed a strong association between the type of hardware and software and PCLs (p < 0.0001) with newer versions corresponding with increased numbers of detected PCLs. Although PCLs occurred with greater frequency in the higher field strength MRIs, it was not significantly associated (p = 0.10). However, the small number of 3T MRIs limited the ability to test with sufficient power.
Table 1: Association between MRI technical features and diagnosis of PCLs

		Univariate analysis		Multivariate analysis

Hardware platform*		Overall test 0.0002		Overall test <0.0001	
Symphony (2001)	30.3	1.00	–	1.00	–

(continued)

Table 1: Continued

Variable	% with PCL	Univariate analysis OR (95% CI)	P value	Multivariate analysis OR (95% CI)	P value
Sonata (2001)	23.1	0.7 (0.3-1.6)	0.37	1.0 (0.4-2.5)	0.98
Espree (2004)	48.4	2.2 (1.2-3.9)	0.012	2.7 (1.3-5.4)	0.005
Avanto (2006)/ Aera (2013)¤	49.0	2.2 (1.4-3.4)	0.0004	3.0 (1.8-5.0)	<0.0001
Skyra (2010)	56.3	3.0 (1.4-6.4)	0.006	3.9 (1.6-9.2)	0.002
Software		Overall test <0.0001		Overall test <0.0001	
VA	29.0	1.00	–	1.00	–
VB	49.1	2.4 (1.6-3.5)	<0.0001	3.0 (1.9-4.7)	<0.0001
VD	51.4	2.6 (1.3-5.3)	0.009	3.1 (1.4-6.8)	0.006

*Install date included with platform model. Skyra is 3T other platforms are 1.5T¤These 2 versions, technically similar, were merged due to small sample size

Conclusion: Our study demonstrates the relationship between the higher trend of incidental PCLs observed in recent years and the improvements in the technical features of MRIs. Also, we confirmed the association between older age, DM and PCLs. In addition, we postulate that a history of non-pancreatic neoplasms and extrapancreatic cysts may have an influence on the presence of PCLs

Contact E-mail Address: Wallace.Michael@mayo.edu
Introduction: Intraductal papillary mucinous neoplasms (IPMNs) are increasingly diagnosed with a variable natural history. Given their malignant potential, intensive surveillance programs are recommended. However, it is unclear whether all patients benefit from this strategy
Aims & Methods: To calculate the frequency of malignant transformation in an long-term observational IPMN cohort. Also, to describe the demographic, clinical and imaging features associated with malignancy.
A longitudinal IPMN registry was created involving five centers in Europe and the United States. Patients with a clinical suspicion of IPMN were included. Data regarding demographics, symptoms, imaging tests and surgical procedures were collected. Only patients with a follow-up greater than 1 year and with incident malignant cases (diagnosed 3 months after the initial visit) were analyzed. Malignancy was defined as surgically-confirmed high-grade dysplasia or invasive cancer. The demographic, clinical and imaging features of the malignant group were compared with the rest of the cohort in both the initial and the last visit
Results: A total of 495 patients seen between 1999 and 2014 were included, with a median follow-up of 3 years. The median age was 67 with a female predominance (65%). 89% of the cohort had a branch duct involvement. There was a median number of 1 cyst per patient (median size of 15mm). Overall, 19 patients were diagnosed with malignancy with a time until diagnosis ranging from 3 months to 11 years. The incidence of malignancy was 7 cases per 1000-persons-year with a bimodal distribution corresponding to the intervals 3-36 and 54-66 months. An isolated case was diagnosed after 11years of follow-up. No differences between groups were seen regarding age, gender or BMI. Cyst size, main/mixed duct involvement and the presence of symptoms, concretely steatorrhea and diabetes mellitus, were significantly associated with malignancy during the entire follow-up.
Table 1: Study variables significantly associated with malignancy

VARIABLE	INITIAL VISIT			FINAL VISIT		
Malignancy (%)	Control (%)	P value	Malignancy (%)	Control (%)	P value	
Cyst size	16	451	0.003*	13	344	<0.001*
Mean (mm) ± SD	27.7 ± 16.0	17.5 ± 12.4	32.2 ± 10.1	17.2 ± 10.4		
Duct involvement	19	469	<0.001¥	15	370	0.001¤
Main/Mixed duct	9 (47.4%)	43 (9.2%)	6 (40.0%)	30 (8.2%)		
Branch duct	10 (52.6%)	426 (90.8%)	9 (60.0%)	340 (91.9%)		
Mass-nodule	19	472	0.14¤	16	429	<0.001¥
Yes	3 (15.8%)	31 (6.6%)	5 (31.3%)	14 (3.2%)		
Symptoms	19	473	<0.001¤	17	463	<0.001¥
Yes	15 (79.0%)	167 (35.3%)	8 (47.1%)	45 (9.7%)		
Steatorrhea	19	476	0.03¤	19	476	0.04¤
Yes	17 (89.5%)	470 (98.7%)	1 (5.3%)	0 (0%)		
Diabetes mellitus	19	476	<0.001¥	19	476	<0.001¥
Yes	7 (36.8%)	50 (10.5%)	6 (31.6%)	33 (6.9%)		

*Wilcoxon rank-sum test, ¥Chi-square test, ¤Fisher's exact test

Conclusion: Malignant transformation of IPMNs tends to occur in the first 6 years since diagnosis. Late malignant transformations are rare, although the risk is still present. The cyst size, main/mixed duct involvement and pancreas-specific symptoms are good predictors of malignancy.

Introduction: Distinguishing benign from potentially malignant pancreatic cystic lesions has important prognostic and therapeutic implications. Diagnosis is achieved through a combination of history, imaging, biochemical, endoultrasonographic (EUS) and cyst aspirate (CA) analysis. We evaluated the accuracy of suspicious and high risk variables identified at EUS and CA analysis to predict premalignant or malignant histopathology confirmed at surgery.
Aims & Methods: Patients who underwent EUS prior to surgery were selected. Data on age, sex, cyst location, suspicious (S) or high risk (HR) EUS or CA features, diagnosis (grouped as benign vs premalignant/malignant) at EUS (EUS-D), post CA analysis (CA-D) and combined EUS and CA analysis (EUS&CA-D) were collected. These were compared with final histological diagnosis (H-D) from surgery. High-risk (HR) variables were defined as C4/C5 diagnosis or carcinoma embryonic antigen (CEA) >192ng/ml on CA, and cyst size >30mm, PD dilatation >10mm, mural nodules or mixed solid/cystic components at EUS Suspicious (S) variables included HR features or mucin, C3 diagnosis or amylase >1000 U/L on CA, and pancreatic duct (PD) dilatation or cyst wall thickening on EUS. Variables were assigned a score of 1 when present, and combined with either EUS-D (EUS-D-S or EUS-D-HR) or CA-D (CA-DS or CS-D-HR). A single positive variable defined positivity in groups. EUS and CA outcomes were then evaluated to identify the sensitivity, specificity, area under the ROC curve (AUC) and likelihood ratio (LR) to predict H-D.
Results: 38 patients were identified (mean age 60.4 years, range 19-81; 52.6% female). Histology identified benign (18.5%; retention cysts, accessory spleen, chronic pancreatitis, hydatid, serous cystic neoplasm), premalignant (60.5%; intraductal papillary mucinous neoplasm (IPMN), mucinous cystadenoma, solid pseudopapillary tumour) or malignant disease (21.1%; adenocarcinoma, adenosquamous carcinoma, neuroendocrine tumour). Analysis (AUC and LR) ranked by AUC confirmed EUS-D-S significantly predicted H-D (0.81, p = 0.022; 5.87) with a sensitivity and specificity of 83.7% and 85.7% respectively. This was followed by EUS-D-HR (0.68; 4.29; p = 0.187), CS-D-HR (0.64; 1.83; p = 0.306), EUS&CA-D-HR (0.62; 1.81; p = 0.374) and CS-D-S (0.52; 1.04; p = 0.89). EUS&CA-D-S did not predict H-D (0.5; 1.16; p = 1.0).
Conclusion: EUS can accurately predict final H-D in patients cystic pancreatic lesions with excellent sensitivity and specificity when modelled appropriately. Interestingly, the accuracy of this method diminished when combined with CA variables.

Introduction: Previously, we presented an association between the expression of the transcription factor CUX1, metastatic behaviour and poor differentiation in human insulinomas. CUX1 mediated tumor-promoting functions via enhancing proliferation, resistance to apoptosis and angiogenesis *in-vitro*. In patients with non-functioning pancreatic neuroendocrine tumors (PNETs), the role of CUX1 has to be elucidated. In these patients, chemotherapy is recommended as first-line therapy in metastatic disease. However, biomarkers in this setting are still lacking. Therefore we assessed the role of CUX1 and proteins involved in the metabolism of cytotoxic chemotherapy in patients with metastatic PNETs.
Aims & Methods: We analysed expression of CUX1, O6-methylguanine-DNA methyltransferase (MGMT), thymidylate synthase (TS) and dihydropyrimidine dehydrogenase (DPD) via immunohistochemistry in 34 out of 93 PNET patients treated with streptozocin (STZ)-based regimens and dacarbacine (DTIC). To further assess the functional role of CUX1, profiling of DNA damage-, proliferation- and apoptosis-associated genes was performed in CUX1-modulated BON1 cells. Genes regulated on mRNA level were validated via immunoblotting. Statistical evaluation was performed with cox regression, log-rank test and Fisher's exact test.

Results: The mPFS (progression-free survival) in this cohort receiving chemotherapy was 11 months. 80% of the patients progressed within 24 months. A predefined CUX1 immunoreactivity score (IRS) higher than 8 was significantly associated with shorter PFS in this patient cohort. Functionally, CUX1 affects caspases and DAPK1 as mediators of resistance mechanisms to cytotoxic drugs. In contrast, established drug metabolism markers such as MGMT and DPD had no predictive value. Interestingly, decreased TS expression was linked to reduced PFS in patients receiving cytotoxic chemotherapy.
Conclusion: We identified the transcription factor CUX1 and TS as modulator of responsiveness to chemotherapy and potential novel biomarker in patients with PNETs.

Introduction: Optimal preoperative diagnosis of pancreatic cysts improves decision making. In premalignant pancreatic cysts, surgery prevents malignant progression. However, the natural history of pancreatic cysts is not well characterized and cysts with dysplasia do not always develop invasive malignancy. Therefore, it is unclear in which patients the benefits of surgery outweigh the risks.
Aims & Methods: We aimed to determine the accuracy of the preoperative diagnosis in patients with pancreatic cysts who underwent resection and to evaluate the proportion of patients in whom surgery was retrospectively justified. From our prospective database (2006-present) of patients with pancreatic cysts, we extracted patients who underwent pancreatic surgery. The decision for surgical treatment was made in our multidisciplinary pancreatic and hepatobiliary meeting based on the international guidelines (Tanaka et. al 2012 and Del Chiaro et al. 2013). Surgery was considered justified for malignancy and symptomatic pancreatic cysts (i.e. recurrent pancreatitis, weight loss or abdominal pain likely caused by the cyst). Cysts with high-grade (HG) dysplasia or invasive malignancy were considered malignant.
Results: From the 113 patients who underwent resection, data were incomplete for 3 patients. Therefore 110 patients were included in our analysis (median age 62.5 years (IQR 48.75-71), 58% female). Patients underwent surgery median 3 months (IQR 2-6) after identification of the cyst. Only 11 patients (10%) were referred for surgery during initial follow-up because of suspicion of malignancy (8%) or symptoms (2%). Preoperative classification of the type of cyst was correct in 71% of patients and in 86% of patients the correct differentiation between benign and (pre)malignant was made.
In hindsight, surgery was justified in 46% of patients: resection of a neoplastic pancreatic cyst with invasive malignancy (22%) or HG dysplasia (5%), pancreatic malignancy (7%), solid pseudopapillary neoplasm (4%), neuroendocrine tumour (2%), acinar cell carcinoma (1%), sarcoma of the stomach (1%) or a symptomatic cyst (5%). In the remaining 54% of patients surgery could be seen as overtreatment: resection of a premalignant cyst without HG dysplasia or invasive malignancy in 42% and of a pancreatic cyst with no malignant potential in 13%.
Conclusion: In most patients with pancreatic cysts preoperative differentiation between benign and (pre)malignant is correct. Nevertheless, when following the current guidelines, overtreatment is inevitable.

Introduction: The diagnostic dilemma of imaging-based resectability assessment in pancreatic cancer is illustrated by the facts that 1) a tumor that has been considered resectable still carries the risk of understaged disease due to diagnostic inaccuracy, 2) determining the resectability of a tumor cannot rule out rapid tumor progress or incipient dissemination once the diagnosis has been made. Comprising a significant fraction of the patients' overall survival, a prolonged delay from onset of symptoms to diagnosis and treatment may even imply an increased risk for unanticipated progression from resectable to unresectable disease at laparotomy (UDP). In contrast to tumor size (TS) and vascular involvement (VI) at diagnostic imaging, the ''window of opportunity'', i.e. time interval from imaging to resection (IR) represents a risk factor for UDP that may be may be potentially controllable.
Aims & Methods: To evaluate the IR interval together with vascular involvement (VI) and tumor size (TS) as potential risk factors for UDP. Patients with histologically confirmed PC planned for curative-intent resection from 2008-2014 were identified from a prospectively maintained database. IR, TS, and VI were recorded. Their impact on UDP was evaluated using univariate and multivariate regression. Risk estimates were approximated as hazard ratios (HR).
Results: Median IR was 43 days. Of 349 PC patients planned for resection, 82 had UDP (resectability rate 86.5%). The UDP risk increased significantly for IR $\geq$ 33 days (26.2% vs 13.5%; HR 2.270; $p = 0.021$) and TS > 30 mm (28.6% vs 10.5%; HR 2.732; $p < 0.001$). Major VI significantly increased the UDP risk in univariate (37.9% vs 20.6%, HR 2.423; $p = 0.007$) but did not contribute to the prediction model in multivariate analysis ($p = 0.411$), in contrast to IR ($p = 0.029$) and TS ($p < 0.001$), which were independent UDP risk factors. UDP confirmed <33 days after imaging was significantly associated with a prolonged disease-specific survival (15.4 vs 6.7 months, $p = 0.019$).
Conclusion: Determining a low-stage pancreatic cancer at diagnostic imaging cannot rule out rapid tumor progress to advanced-stage or incipient dissemination once the diagnosis has been made. Operation within 33 days after diagnostic imaging may halve the risk of unanticipated tumor progression at laparotomy. The results underscore the need of efficiency and streamlining in the management of pancreatic cancer at all stages of medical care.

P1347 PAIN AS A PREDICTOR OF SURVIVAL IN PATIENTS WITH PANCREATIC DUCTAL ADENOCARCINOMA – A SYSTEMATIC REVIEW AND META-ANALYSIS

S. Schorn[1], C. Schneider[1], I. Demir[1], H. Friess[1], G. O. Ceyhan[1]
[1]*Surgery, Klinikum Rechts der Isar der TU München, München, Germany*

Contact E-mail Address: stephan.schorn@tum.de
Introduction: Neuropathic, abdominal pain occurs in the majority of patients with pancreatic ductal adenocarcinoma (PCa). Serveral studies could clearly demonstrate that the severity and frequency of pain correlates with pathohistological characteristics of PCa. Nevertheless a consensus of the clinical value of pain as predictor of abdominal pain hasn't been reached yet.
Aims & Methods
Aims: Investigation of pain as a prognostic tool in patients with PCa.
Methods: For this purpose PRISMA-Guidelines were used to perform systematic review and meta-analysis. By screening the databases of Scopus, Pubmed, The Cochrane library and Google Scholar for the terms ''pain'', ''survival'', ''recurrence'', ''pancreatic ductal adenocarcinoma'' and ''pancreatic cancer relevant papers were extracted and included in systematic review.
Results: A total of 4000 studies could be identified analyzing the influence of pain in PCa. After exclusion of irrelevant paper 38 studies could be identified meeting all predefined inclusion criteria for systematic review. 7 univariate hazard ratios (HR) and 2 univariate odds ratios (OR) could be included in the meta-analysis, identifying pain as a strong prognostic factor on OS (HR 1.63, CI: 1.18-2.24, $p = 0.003$; OR 2.69, CI: 1.56-4.62; $p = 0.0004$). Furthermore, by pooling multivariate HR, pain was revealed to be also an independent factor on OS (HR 1.55, CI: 1.29-1.87, $p < 0.00001$).
Conclusion: This is the first systematic review and meta-analysis investigating the impact of pain on OS in patients with PCa.
Here, we could clearly identify pain as a negative predictor of patients' outcome. Therefore, abdominal pain in patients suffering from PCa should receive increased attention due to its high clinical relevance.

Introduction: Nationwide series on outcome and predictors of survival after distal pancreatectomy (DP) for pancreatic ductal adenocarcinoma (PDAC) are lacking.
Aims & Methods: Adults who underwent DP for PDAC in 17 Dutch pancreatic centers between January 2005 and September 2013 were analyzed retrospectively. Patients were excluded when histopathological diagnosis was not PDAC or when data was lacking. Primary outcome was survival. Predictors of survival were identified using a Cox regression model.
Results: In total, 761 consecutive patients were identified, 620 patients were excluded, because of non-PDAC histopathology (n = 616) or lack of data (n = 4). Therefore, 141 patients (45% (n = 63) male, mean age 64 years (SD10)) were included. Multivisceral resection was performed in 43 patients (30%) and laparoscopic resection in 7 patients (5%). A major (Clavien-Dindo score III or higher) complication occurred in 33% of patients. Mean tumor size was 44mm (SD23) and histopathological examination showed 70 R0 resections (50%). 90-day mortality was 6%. Overall, 63 patients (45%) received adjuvant chemotherapy. Median survival was 17.0 months (IQR 13.0-21.0) with a median follow-up of 17 months (IQR 8-29). One-, three- and five-year cumulative survival were 64%, 29% and 22%, respectively. Independent predictors of poor postoperative survival were R1/R2 resection (HR 1.63 (95% CI 1.09-2.43)), pT3/pT4 stage (HR 1.92 (95% CI 1.28-2.86)) and not receiving adjuvant chemotherapy (HR 1.59 (95% CI 1.06-2.38)).
Conclusion: This nationwide series identified several independent predictors of survival after DP for PDAC. Further studies should assess to what extent improved surgical technique, patient selection and use of adjuvant chemotherapy improve survival.

Introduction: The differential diagnosis of pancreatic solid lesions remains challenging. The aim of this study was to investigate the usefulness of contrast-enhanced endoscopic ultrasonography (CE-EUS) in differentiating pancreatic cancer (PC) from other pathological lesions. In addition, to examine what histology CE-EUS images reflected, the images were compared with histology in PC with resection.
Aims & Methods: CE-EUS was performed for patients with a pancreatic solid lesion consecutively. Tumors were classified into three vascular patterns (hypervascular, isovascular, and hypovascular) at two time phases (early phase and late images). The correlations between vascular patterns, and histology of tumors or immunostaining of resected PC tissues were examined.
Results: Total 147 patients underwent CE-EUS. The final diagnoses were PC (n = 109), inflammatory mass (n = 11), autoimmune pancreatitis (n = 9), neuroendocrine tumor (n = 8) and others. In late phase image, 104 of 109 PCs showed hypovascular pattern, which diagnosed PC with sensitivity and specificity of 94% and 71%, respectively. Of 28 PCs with surgery, 10 presented isovascular, while 18 hypovascular in early phase image. Histology of early isovascular PCs was more likely to be differentiated than that of early hypovascular PCs. (iso; 6 well- and 4 moderately-differentiated, hypo; 3 well-, 15 moderately-, and 1 poorly-differentiated) ($P = 0.028$). Immunostaining revealed that hypovascular area in early phase image reflected heterogeneous prevalence of tumor cells with fibrous tissue, necrosis, and few vessels. Therefore, in our experience of 61 EUS-FNA procedures, all 8 cases in which diagnosis was not possible from the obtained sample exhibited the early hypovascular pattern ($P = 0.02$).
Conclusion: CE-EUS could be useful for differential diagnosis in solid pancreatic lesions, histological differentiation of PCs and diagnostic value of EUS-FNA.

Introduction: Gastric endoscopic submucosal dissection (G-ESD) has been accepted as a minimally invasive treatment modality of a defined subgroup of patients with early gastric cancer. It is less invasive than surgery and provides the same long-term survival. Nevertheless, in countries with low incidence of gastric cancer, quality of G- ESD remains an important issue. The purpose of this study is to evaluate short-term results of G-ESD in a single European institution.
Aims & Methods: All patients treated by G-ESD in our center between November 2011 and October 2014 were included. G-ESD was indicated according to expanded criteria of the Japanese Gastric Cancer Association. G-ESD was performed by using either Flush-knife, IT-knife 2 and Dual-knife. G-ESD was indicated only for lesions being considered manageable with regard to the endoscopists experience. The 30-day mortality, *En bloc* resection, R0 resection, curative resection and complications were considered as short-term results.
Results: Among 25 patients, 14 (56%) were males and 11(44%) were females. Mean age was 71.5 (range 40-90) years. The mean lesion size was 20 (range 5-66) mm. From a total of 25 lesions, the location was as follows: antrum 15(60%), angulus 3(12%), body 3(12%), subcardia 3(12%), cardia 1(4%). Lesion morphology according to Paris classification was: 0-Is 7(28%), 0-IIa 10(40%), 0-IIb 1(4%), 0II-a + IIc 5(20%) and 0II-a + III 1(4%) and 1(4%) remaining lesion was subepithelial. The final histology was neoplastic in 20(80%), of them LGIEN in 3(12%), HGIEN in 5(20%), T1m carcinoma in 5(20%), T1sm1 carcinoma in 3(12%), T1sm2 and sm3 2(8%) and neuroendocrine tumour in 2(8%). Remaining 5(20%) lesions were non- neoplastic, of them hyperplastic 3(12%), intestinal metaplasia 1(4%) and ectopic pancreas 1(4%). Results of the forceps biopsy corresponded to final histology in 14(56%) of cases. The 30-day mortality was none. In the cases of neoplastic lesions, *En bloc*, R0 and curative resection was achieved in 17(85%), 17(85%) and 16(80%) respectively. Perforation and delayed bleeding occurred in 2(8%) and 0(0%) of all cases respectively.
Conclusion: Gastric endoscopic submucosal dissection may be considered feasible and safe treatment even in a country with low incidence of gastric cancer. The curative resection was achieved in 80% and perforation occurred in 8% of the cases.

Introduction: The over-the-scope clip system, OTSC (Ovesco Endoscopy, Tübingen, Germany) is an advanced clipping device developed for closure of luminal gastrointestinal (GI) defects.
Aims & Methods: The aim was to evaluate the clinical outcomes of patients treated with the OTSC.
This is an observational, open-label, retrospective, single-arm case series conducted at a tertiary care endoscopy unit. This study involved 116 clip applications in 90 patients (median age 57 years [range 25-86], 31 women) with endoluminal GI defects from fistulae and anastomotic dehiscence to peptic ulcer bleeding and stent anchoring.
Results: A total of 116 clips were applied in 90 patients. The range of indications included gastrointestinal bleeding (n = 21), gastrocutaneous fistulas (n = 17), tracheo-oesophageal and/or oesophagopleural fistulae (n = 20), gastrocutaneous fistulae (n = 24), resection of submucosal tumor (n = 16), stent fixation (n = 10), and perforation closure (n = 8). The deployment success rate for the OTSC device was 97.4% (113 out of 116 applications). The clinical success rate was 84.4% (98 of 116 applications). The clinical success was highest in gastrocutaneous fistulae (95.2%), peptic ulcer bleeding (95.2%), stent anchoring (90%), and closure of perforation (85.7%), whereas the clinical success for TE fistulae was lowest (50%). Complications related to the application of the clipping device included minor bleeding (n = 2). There were no further complications related to endoscopy or sedation.
Conclusion: To our knowledge, this is the largest single-center experience using the OTSC system. The OTSC system is a useful device in a variety primary and iatrogenically-induced endoluminal GI tract disorders including leaks, GI bleeding and stent anchoring, even in very old and frail patients. The success rates for GI bleeding, closure of gastrocutaneous fistulae, endoscopic resection and stent fixation are high (>90%), whereas the success rates for tracheoesophageal fistulae closure is lower (50%).

P1353 EXTREME ENDOSCOPY: A NEW PARADIGM IN INTERVENTIONAL ENDOSCOPY

P. T. Kröner[1,2], I. Jovanovic[1], M. C. Phillips[3], K. R. Kyanam Kabir Baig[1], S. P. Sugandha[1], K. Mönkemüller[1]
[1]*Basil I. Hirschowitz Endoscopic Center of Excellence, Gastroenterology, University of Alabama at Birmingham, Birmingham,* [2]*Internal Medicine, Mt. Sinai St. Luke's Roosevelt Hospital, New York,* [3]*Department of Anesthesiology, University of Alabama at Birmingham, Birmingham, United States*

Contact E-mail Address: klaus1@uab.edu

Introduction: Extreme endoscopy is a new discipline in interventional GI endoscopy. Previous data on extreme endoscopy comes from case reports.

Aims & Methods: The aim was to report on the feasibility and outcomes of extreme endoscopy.

Observational, retrospective study conducted at a tertiary care hospital during an 18-month period. All procedures were performed under general anesthesia. Extreme endoscopy comprises five key components: (i) use of multiple scopes or dual endoscope technique; (ii) use of various types of overtubes (OT), (iii) utilization of modified devices, (iv) use of fluoroscopy and, (v) necessity of utilizing a tool box with: wire cutter, glue, tape, foam (Endosponge). Single- or double balloon enteroscopy (SBE, DBE) (n = 215) and DBE or SBE ERCP (n = 85) were not defined as extreme endoscopy, unless the technique was utilized to perform a) endoscopic re-anastomosis of disrupted GI tract; b) PATENT (percutaneous assisted transprosthetic endoscopic therapy); c) SBE- or DBE-rendezvous-ERCP; d) endoluminal stenting, e) removal of migrated SEMS from the small bowel. Additional exclusions: endoscopic submucosal dissection (ESD) or peroral endoscopic myotomy (POEM) cases (n = 45) and pancreatic necrosectomies (n = 28). Success was defined as resolution of the primary luminal problem.

Results: 65 patients (29 female, 36 male, median age 62.5 years, age range 21-81) with various types of complex primary, secondary or post-surgical anatomy endoluminal GI defects that underwent 85 procedures were studied. In 23 patients (35%) previous surgical, endoscopic or radiologic attempts at solving the problem had failed. In 13 patients (20%) there were no other interventional treatment options available. Interventions performed: PATENT (n = 3), endoscopic re-anastomosis of the disrupted or perforated GI tract (n = 6), Endosponge placement for drainage of huge cavities (n = 3), OT-assisted removal of mesh (n = 2), OT-assisted removal of migrated lap bands (n = 3), OT-assisted SEMS placement of the small bowel and/or colon (n = 31), combined closure of fistula or perforation and placement of direct endoscopic jejunostomy (n = 7), SBE- or DBE ERCP with exchange of scope for slim cholangioscope to perform elecrohydraulic lithotripsy (EHL) (n = 8), rendezvous-DBE ERCP to place SEMS into the bile duct (n = 4) or to place plastic stents percutaneously under direct endoscopic view (n = 2), OT-assisted endoscopy allowing for ERCP or PEG placement in patients with esophageal stenosis (n = 4). The technical success was 87.8%. The mean procedure time was 35 minutes (range 45 min to 4 hours). There were no major adverse events associated with the procedures.

Conclusion: This is the largest study reporting on extreme endoscopy. Albeit time consuming, extreme endoscopic interventions lead to a resolution or remediation of complex endoluminal disorders in the majority of patients. It appears that extreme endoscopy may provide hope for patients in whom no other choices exist. Now multi-center studies in this topic are warranted.

Contact E-mail Address: pedronunesml@gmail.com

Introduction: In the stomach, the correlation between white light endoscopy (WLE) and histology in the diagnosis of gastric premalignant conditions is considered low. In reference centres, virtual chromoendoscopy with Narrow-Band Imaging (NBI) has been associated to the identification of these lesions with high accuracy.

Aims & Methods

Aim: To evaluate the diagnostic validity of high resolution endoscopy with and without NBI in the diagnosis of gastric premalignant conditions.

Methods: A multicentre prospective study (5 tertiary centres in 5 countries: Portugal, Italy, Romania, United Kingdom and United States of America) involving the systematic use of high-resolution scopes with imaging registry with and without NBI in a centralized informatics platform available online. All users used the same NBI classification. Endoscopic biopsies were obtained systematically and histological result was considered the diagnostic gold standard.

Results: A total of 226 patients and 1076 images and biopsies were included. The indication for endoscopy was symptoms (83%) and surveillance (17%). The final per-patient diagnoses were as follows: normal mucosa (42%), intestinal metaplasia only in the antrum or corpus (37%) and extensive intestinal metaplasia (21%) with an additional 22 lesions with dysplasia in 19 patients being diagnosed. With NBI the validity per biopsy was 11% higher than WLE (93% vs 82%, $p < 0.001$), with no difference in the identification of *Helicobacter pylori* gastritis (75% vs 74%). NBI sensitivity for dysplasia was 91% (vs 78% WLE, $p < 0.001$) with a negative likelihood ratio of 0.1. NBI specificity for intestinal metaplasia was 97% (vs 99% WLE) with a positive likelihood ratio of 34.8, with a superior sensitivity when compared to WLE (88% vs 57%, $p < 0.001$).

Conclusion: For the first time, diverse centres using a single classification show that use of NBI in real-time demonstrates a high concordance with the histological results and is superior to conventional endoscopy. The global diagnostic accuracy superior to 90% suggests that routine use of NBI may allow guided instead of random biopsy samples during gastroscopy.

Introduction: Despite significant advances in diagnosis and treatment, the prognosis of esophageal squamous cell carcinoma (ESCC) remains poor highlighting the importance of early detection. Although white light (WL) upper endoscopy can be used for screening of the esophagus, it has limited sensitivity for early stage disease. Thus, development of new promising near-infrared (NIR) optical imaging combined with targeted fluorescent nanoprobes to improve the diagnostic capabilities of upper GI endoscopy for early detection of ESCC is an urgent need.

Aims & Methods: The aim of this study was to develop a method for the detection of esophagus neoplasms using near-infrared imaging with a RGD-modified nanoprobes Cy5.5-PAMAM-PEG-c(RGDfk)(PC-PEG-RGD). The targeted nanoprobe PC-PEG-RGD and the control non-targeted nanoprobe Cy5.5-PAMAM-PEG (PC-PEG) were characterized by hydrogen nuclear magnetic resonance spectroscopy, fourier transform infrared spectroscopy, ultraviolet spectrometry and fluorescence spectrometry. The toxicity of nanoprobes to esophageal squamous cancer cells TE-1 were researched by MTT method. The targeting effects of PC-PEG-RGD and PC-PEG to TE-1 cells were studied by confocal microscopy imaging and flow cytometry. The 4-NQO induced esophageal cancer model was imaged for NIR signal after the injection of nanoprobes for 24 hours. Target to background ratios (TBR) were compared for both WL and NIR imaging. The paresence of tumor was confirmed by histology and the integrin-β3 expression was observed by immunohistochemical staining.

Results: The molar ratio of PAMAM/PEG/c(RGDfk) in PC-PEG-RGD was measured as 10/14/1. The presence of Cy5.5 was also confirmed by the absorption peak at 675nm and the emission peek at 700nm in the ultraviolet spectra and fluorescence spectra, respectively, for both targeted and non-targeted nanoprobes. The IC_{50} values of PAMAM, PC-PEG and PC-PEG-RGD were 2.04μM, 1.35μM and 1.70μM, respectively. The mean Cy5.5 fluorescence intensity of TE-1 cells with 0.1μM nanoprobes were 2625.00 ± 476.60 (non-targeted, 2 hours), 22485.00 ± 698.61 (targeted, 2 hours), 3670.25 ± 247.89(non-targeted, 24 hours) and 49203.75 ± 818.94 (non-targeted, 24 hours). The difference between different groups had statistical signigicance. The attachment of PC-PEG-RGD on the cell membrane when the TE-1 cells were treated with this nanoprobe for 24 hours at 37°C was demonstrated in vitro confocal fluorescence microscopic imaging. NIR imaging shows the targeted nanoprobe PC-PEG-RGD enhanced the local esophageal neoplasms fluorescence intensity significantly. And the location of tumor tissue intetrin-β expression was correspond to the place of near-infrared fluorescence in confocal fluorescence microscopic imaging.

Conclusion: The targeted RGD-modified PAMAM with novel imaging devices has the potential to improve esophageal neoplasms detection by fluorescently highlighting tumorous regions.

P1356 HIGH-DEFINITION (HD) ENDOSCOPY BUT NOT I-SCAN SIGNIFICANTLY INCREASES THE DETECTION OF MARKERS OF COELIAC DISEASE: A MULTICENTRE UK STUDY

P. D. Mooney[1], M. Kurien[1], M. Burden[1], N. Patel[2], S. Wong[1], J. Teare[2], D. Sanders[1]
[1]*Academic Department of Gastroenterology, Royal Hallamshire Hospital, Sheffield,* [2]*Gastroenterology, St Mary's Hospital, Imperial College, London, United Kingdom*

Introduction: Coeliac disease (CD) remains underdiagnosed. Many patients with CD have undergone a previous endoscopy where the opportunity to make a diagnosis was missed. Clinicians may rely on endoscopic markers of CD to guide biopsy but they lack sensitivity. A routine duodenal biopsy approach may solve this problem but it is expensive. Methods to improve the macroscopic detection of CD at endoscopy to guide biopsy would seem advantageous. I-Scan, a digital enhancement technique, has shown promising results. However, only one, single-centre study has been performed. This was an uncontrolled, unblinded trial in high prevalence population (35% CD). We aimed to assess the utility of I-Scan in a lower prevalence population in a randomised controlled trial.
Aims & Methods: Patients from 2 UK hospitals (Royal Hallamshire Hospital, Sheffield and St. Mary's Hospital, London) were randomized into 2 groups: Group 1 standard HD white light endoscopy (WLE) and Group 2 WLE plus I-Scan. These patients were compared to a standard non-HD WLE control group, Group 3. The presence of endoscopic markers of CD, scalloping, mosaic pattern, nodularity, loss of duodenal folds or increased vascularity was noted throughout the duodenum. All patients received at least 4 duodenal biopsies. Coeliac serology was performed concurrently. Macroscopic markers of CD are compared to villous atrophy (VA) on histology as the gold standard.
Results: 700 patients (63% female, mean age 51.7) were recruited (201 into Group 1, 199 in Group 2 and 300 into Group 3). In total 130 (18.5%) new diagnoses of CD were made (19 in Group 1, 22 in Group 2 and 89 in Group 3). In new CD cases, endoscopic markers of CD were seen in 80.5% in the HD groups compared to 41.6% in Group 3 ($p < 0.0001$).
In Group 2, I-Scan appeared to enhance changes in 18% of new CD cases. However there was no significant difference in sensitivity between Group 1 (89.5%) and Group 2 (72.7%) ($p = 0.2$). Full sensitivity and specificity analysis is shown in table 1.
The severity of VA was analysed for missed cases. There was no significant difference in the distribution of VA severity across the 3 groups ($p = 0.6$). The use of HD and I-scan did not prevent total VA being missed.
Table 1: Analysis of the 3 interventions

	Sensitivity	Specificity	PPV	NPV
Group 1	89.5 (65.5 - 98.2)	92.9 (87.8 - 96.0)	56.7 (37.7 - 74.0)	98.8 (95.4 - 99.8)
Group 2	72.7 (49.6 - 88.4)	84.8 (78.5 - 89.6)	37.2 (23.4 - 53.3)	96.2 (91.5 - 98.4)
Group 3	41.6 (31.4 - 52.5)	98.1 (94.9 - 99.4)	90.2 (75.9 - 96.8)	79.9 (74.4 - 84.5)

Conclusion: HD endoscopy significantly increases the detection of the endoscopic markers of CD ($p < 0.0001$). However although I-scan appears to enhance the changes of VA it does not significantly increase the detection of markers ($p = 0.2$).

Contact E-mail Address: petebasford@hotmail.com

Introduction: Despite advances in endoscope technology there is still a significant miss rate of neoplastic lesions during gastroscopy. Mucosal views during gastroscopy are frequently impaired by residual bubbles and mucus.
Aims & Methods: We conducted a randomised controlled trial in 126 patients attending for routine outpatient gastroscopy. Trial ref: EudraCT Number 2013-001097-24. Subjects were randomised in a 1:1:1 ratio to receive a pre-procedure drink of water, Simeticone and n-acetylcysteine (Group A), water alone (Group B) or no preparation (Group C). Study endoscopists were blinded to group allocation. 4 digital images were taken at pre-defined locations during the procedure – lower oesophagus, upper body, antrum & fundus. Images were then collated and rated for mucosal visibility (MV) using a 4 point scale (1 = best, 4 = worst) by 4 separate experienced endoscopists who were also blinded to group allocation. The primary outcome measure was mean mucosal visibility score. Secondary outcome measures were total procedure duration and volume of fluid flush required during the procedure to achieve adequate mucosal views.
Results

Group	A - Simeticone/ NAC	B – Water	C – no preparation
Mean Mucosal Visibility (MV) Score (range 1-4)	1.35	2.11	2.21
Mean Procedure duration (sec)	309	352	334
Mean Volume of flush (ml)	2.0	31.5	39.2

Results are shown in table 1. There were no significant differences between groups in age, gender or indication for endoscopy. The mean MV score for group A was significantly better than for group B and group C ($p < 0.001$ for both comparisons). There was no significant difference in mean MV score between groups B and C ($p = 0.541$). Interobserver agreement of MV scores was good (mean kappa 0.464).
Mean volume of flush required during gastroscopy to achieve adequate mucosal views was significantly lower in group A than group B ($p = 0.001$) and group C ($P < 0.001$). There was no significant difference in mean flush volume between groups B & C ($p = 0.583$). Procedure duration did not differ significantly between any groups.
Subgroup analysis of MV scores at each location demonstrated significantly better mucosal visibility in group A compared to group B and group C at all locations ($p < 0.0025$ for all comparisons).
There were no adverse events related to the trial medication.
Conclusion: A pre-procedure drink containing Simeticone and n-acetylcysteine significantly improves mucosal visibility during routine gastroscopy. It also significantly reduces the need for flushes during the procedure to achieve adequate views. This may improve detection of early neoplasia and other pathology during gastroscopy. Subanalysis of separate locations demonstrates significant benefit in both the lower oesophagus as well as stomach, demonstrating potential benefit in Barrett's oesophagus surveillance procedures.

P1358 CLINICAL IMPACT OF ENDOSCOPIC RADIAL INCISION FOR ESOPHAGOGASTRIC ANASTOMOTIC STRICTURE: A PRELIMINARY PROSPECTIVE STUDY

P.-H. Zhou[1], Z. Zhang[1]
[1]*Endoscopy Center and Endoscopy Research Institute, Zhongshan Hospital, Fudan University, Shanghai, China*

Contact E-mail Address: zhou.pinghong@zs-hospital.sh.cn
Introduction: Benign esophagogastric anastomotic stricture after surgery seriously affects the quality of life of the patients, especially for patients with refractory dysphagia symptom after several traditional dilations. However, there is little promising endoscopic techniques which is safe, effective and easy to learn. Therefore, we performed a new endoscopic therapy, endoscopic radial incision (ERI) in order to improve the prognosis of benign esophagogastric anastomotic stricture.
Aims & Methods: We performed ERI for patients suffered from esophagogastric anastomotic stricture and evaluated the safety, efficacy and operating time of this procedure. A total of 17 patients with esophagogastric anastomotic stricture after surgery, as diagnosed by esophagogastroduodenoscopy and a dysphagia score ≥ 3 were prospectively included. The primary outcome was symptom relief during follow-up. Secondary outcomes were procedure-related parameters and adverse events.
Results: Each patient was successfully received one-time ERI. The average time for ERI procedure was 10 minutes (range 4–20 minutes). Esophageal perforation occurred in one case and was successfully managed with conservative treatments. During a mean follow-up period of 9 months (range: 2-18 months), the mean dysphagia score decreased from a mean of 3.11(range 3-4) to 0.9(range 0-2) after ERI ($P < 0.001$).
Conclusion: ERI seems to be a safe and effective therapeutic method for benign esophagogastric anastomotic stricture after surgery.

P1359 OUT OF HOURS BLEEDER SERVICE - THE LEICESTER EXPERIENCE OVER TEN-YEARS

R. D. Ramiah[1], D. Lim[1], P. Wurm[1]
[1]*Gastroenterology, University Hospitals of Leicester, Leicester, United Kingdom*

Contact E-mail Address: rekha.ramiah@uhl-tr.nhs.uk

Introduction: University Hospitals of Leicester (UHL) NHS Trust has been offering a comprehensive out of hour (OOH) endoscopy service for almost 10 years. Following our publication in *Frontline Gastroenterology*[1] reviewing our OOH data from inception of the service in 2006 to 2010, we felt it important to review the evolution of the service.

In the wake of rising demands we introduced a Consultant-led and Registrar supported weekday in-reach service in 2013, with a morning visit to the acute medical units and a daily in-patient emergency list. Our study looked at the effect of this on OOH endoscopy volume, call outs and therapeutic interventions.

Aims & Methods: To compare our data with our previous data set we analysed 6 month periods of OOH data from each year [2011-15]. Activity was collated by reviewing endoscopy reports [Unisoft reporting tool), separate OOH record books and daily spreadsheet activity returns. We looked at indication and timing of procedures, endoscopic findings, interventions and outcomes.

Results

"Appropriate" Indications	"Inappropriate" Indications
Haematemesis	Dysphagia
Haematemesis + Melaena	Nausea + Vomiting
Melaena	Weight loss
Liver disease + evidence of bleed	Diarrhoea
Liver disease +drop in Haemoglobin	Anaemia
Dysphagia + Haematemesis	Abdominal pain
Intermittent rectal bleeding	Constipation
Overt rectal bleeding	Dyspepsia and previous peptic ulcer
Bloody diarrhoea	IBD assessment

640 procedures were performed during the study period. The introduction of an in-reach service initially resulted in reduced daytime weekend activity but one-year later weekend activity was back to baseline. Although there was an apparent increase in 'true OOH calls', i.e. 5pm until 9 am over our 5 year period the absolute numbers remain small and are in fact not different from our previous study with approximately one emergency procedure per week. There was a 15.9% rise in appropriate referrals as per UHL criteria (see above table).

Endoscopic findings of varices and variceal bleeding increased by approximately 3.5-fold. There was also a 3.5-fold increase in the proportion of endoscopies employing combination therapy and the use of adrenaline injection mono-therapy halved, a reflection of complaince with recently published National Institute for Health and Care Excellance (NICE) guidance[2]. The number of patients requiring emergency laparotomy or arterial embolisation remained very small [2-4 cases per 6 month interval].

Conclusion: The total number of procedures has reduced compared to 2006-2010[1]. This is likely to be the result of better education, change in referral pathways and working patterns. The increase of patients presenting with variceal bleeding appears to reflect a nationwide trend. We observed a decrease in the use of adrenaline mono-therapy and concurrent increase in combination therapy for non-variceal upper gastrointestinal bleeds. Provision of an inreach service and daily in-patient endoscopy list has not affected our overall in-patient endoscopy volume in the study period intervals. Gastroenterology units need to review and re-invent their in-patient and OOH work pattern on a regular basis to address the increasing demands on inpatient endoscopy services.

ENDOSCOPY AND IMAGING III - HALL 7

P1360 DIAGNOSIS OF INVASION DEPTH OF EARLY ESOPHAGEAL CANCER BY JAPANESE CLASSIFICATION OF MAGNIFYING ENDOSCOPY FOR SUPERFICIAL SQUAMOUS CELL CARCINOMA (RETROSPECTIVE SINGLE CENTER STUDY)

R. Nakamura[1], T. Omori[2], H. Kawakubo[1], T. Takahashi[1], N. Wada[1], H. Takeuchi[1], Y. Kitagawa[1]
[1]*Keio University School of Medicine, Tokyo,* [2]*Kawasaki Municipal Ida hospital, Kawasaki, Japan*

Contact E-mail Address: rieko-na@cam.hi-ho.ne.jp

Introduction: Recently, the Japan esophageal society constructed a new classification. This classification was intended to be simple and easily applicable in general clinical practice. But the true accuracy of diagnosis is under consideration.

Aims & Methods

Aim: To investigate the accuracy of diagnostic criteria based on Japanese classification of magnifying endoscopy for surficial esophageal squamous cell carcinoma (SESCC), the examination by magnifying endoscopy of each SESCC cases was reviewed according to the classifications. Furthermore, in misdiagnosis cases, the causes of misdiagnosis were investigated.

Cases and Methods: Between April 2011 and December 2012, the cases of SESCC undergone endoscopic submucosal dissection (ESD) at Department of Surgery, Keio University School of medicine were extracted and only the cases with appropriate evaluation by magnifying endoscopy before the endoscopic treatment were included and the findings of magnifying endoscopy were reviewed as detail. The endoscopic diagnoses of cancer invasion depth by diagnostic criteria based on Japanese classification of magnifying endoscopy for SESCC and the final histopathological diagnoses of resected cancer lesions were compared. The accuracy rate was calculated according to classifications of magnifying endoscopy and the causes of misdiagnoses cases were investigated.

Results: 90 cases were reviewed in detail. According to classifications of magnifying endoscopy, 71 cases are classified to B1, 16 cases B2, and 3 cases B3. Accuracy rates of diagnoses of tumor depth were 91.5% of B1 (65 cases), 56.2% of B2 (9 cases), and 100% of B3 (3 cases).The causes of misdiagnoses according to classifications of magnifying endoscopy were investigated. B1 cases: The causes of difficulty of diagnoses were considered to be surficial normal epithelia or cornification covered on cancer mucosa by endoscopic findings. Compared endoscopic findings and histopathological findings, very small deepest cancer invasion area or normal epithelia covered on deepest invasion cancer area leaded to misdiagnoses of cancer vessels. B2 cases: The causes of difficulty of diagnoses by endoscopic findings were considered as follows; to be large cancer making impossible to examine whole cancer lesions in detail which was cause of misdiagnoses of cancer vessels in deepest cancer invasion area, to have change of cancer vessels by inflammation, and to be diagnosed as more advanced lesions by the cancer form.

Conclusion: The accuracy of diagnosis of SESCC invasion depth using the diagnostic criteria based on Japanese classification of magnifying endoscopy for SESCC was over 90% of accuracy rate in B1 cases, while about 50% in B2 cases. In B1 cases, when the deepest cancer invasion area was very small or surface of cancer lesion was covered by normal epithelia, the diagnosis of cancer invasion depth was difficult, while the consistency of B1 vessels and depth of cancer invasion was high in the area that cancer vessels could be diagnosed. In B2 cases, the cancer lesion was often large which caused inadequate examination or modified surficial vessels leaded to be difficult to diagnose depth of cancer invasion. So that, the consistency of B2 vessels and histopathological cancer invasion depth was not so high in the result.

P1361 OUTCOMES OF PERCUTANEOUS ENDOSCOPIC GASTROSTOMY IN PEDIATRIC AGE WITH A PEXIES TRIANGULATION SYSTEM

R. Jijón Crespín[1], M. Navalón Rubio[1], F. Alberca De Las Parras[1], J. Egea Valenzuela[1], J. Alvarez Higueras[1], A. Ono Ono[1], M. Muñoz Tornero[1], G. Antón Ródenas[1], E. Estrella Diez[1], E. Navarro Noguera[1], E. Sánchez Velasco[1], A. Pereñíguez[1], G. Carrilero Zaragoza[1], L. F. Carballo Alvarez[1]

Contact E-mail Address: roxannajijon@gmail.com

Introduction: The percutaneous endoscopic gastrostomy (PEG) is the method of choice for the establishment of gastrostomies in pediatric patients. This procedure can be performed as a direct technique or a thread pulling method. However, there are little data about gastropexy technique in children to date.

Aims & Methods: The aim of this analysis is to report the experience of PEG placements by pexias triangulation system in pediatric patients. All consecutive pediatric patients who underwent a PEG by pexies from 2010 to 2014 were reviewed. Clinical and demographic variables as age, weight, indications (emergency or deferred), complications, need for endoscopy and time tracking were collected. In 18 cases it was placed a button through the expansion system.

Results: Nineteen cases (12 female, mean age: 6.3, range: 7 months-13 yr): 18 cases of PEG and 1 case of direct jejunostomy were collected. The minimum weight was 5.7 kg (7 patients weighing less than 15 kg).

The indications for PEG were as follows: encephalopathy (n = 9, 50%), malnutrition (n = 7) (2 secondary to cystic fibrosis, 1 neurofibromatosis, 1 heart disease, 1 methylmalonic acidemia and 2 neoplasms), dysphagia due to refractory esophageal stenosis (n = 1), myopathy (n = 1) and suction-swallowing disorder prolonged in patients with distal arthrogryposis (n = 1).

There was only one (5.2%) procedure-related emergency complication (intestinal perforation) in a patient with a history of multiple abdominal surgery and surgical gastrostomy presenting with a gastric prolapse. We detected procedure-related deferred complications in 3 cases (all with encephalopathy): episodes of irritability and apnea at 18 hrs after the start of enteral nutrition (n = 1) and vomits (n = 2). All were self-limiting after stopping nutrition and subsequent restart. Direct jejunostomy as a single incident peristoma losses was resolved by replacing the probe button and managing nutrition ball 30 cms beyond the stoma. None of the patients required new endoscopy or sedation to spare because all allowed implemented a low profile device. The mean follow-up was 2 months.

Conclusion: Percutaneous endoscopic gastrostomy with a pexies triangulation system is a recently developed technique using a three-suture to pexy the stomach to the abdominal wall. This device allows direct implantation of a button during the endoscopic procedure and reasonable security rates according to our data. It may avoid the need of a second endoscopy for the PEG tube removal.

Contact E-mail Address: samuelrmfernandes@gmail.com
Introduction: Boerhaave's syndrome (BS) is a rare and potentially fatal condition due to spontaneous rupture of the esophagus, usually following intense effort of vomiting or retching. Surgical repair or exclusion of the esophagus in combination with pleural drainage and broad-spectrum antibiotics is usually recommended. Despite early recognition and treatment, mortality remains high. Recently, endoscopic management has been advocated in selected cases.
Aims & Methods: We report our experience managing BS with a primarily endoscopic approach using self-expandable covered metallic stents (SEMS). Patients presenting with BS between 8/2010 and 12/2013 were studied.
Results: We included 5 male patients with BS. The mean age was 47.4 ± 19.6 years. Etiologies included food impaction with bolus of meat, retching due to alcohol withdrawal and pill impaction in distal esophageal stricture secondary to eosinophilic esophagitis. CT findings included pneumomediastinum in 4 patients and air in the hepatic parenchyma and gastric wall in 1 patient. All patients received broad spectrum antibiotics. Additionally, drainage of purulent pleural effusions was performed in 3 patients. One patient required mechanical ventilation due to type 1 respiratory failure. The median (IQR) time to emergency endoscopy was 35(3.5-516) hours. SEMS were successfully placed in all patients and effectively excluded the perforations. SEMS used included partially covered Ultraflex® 70/100 x 23/28 mm (n = 2), partially covered Hanarostent® 60/100 x 20/26 mm, fully covered Hanarostent® 100/140 x 20/26 mm and fully covered Wallflex® 120 x 18/25 mm. The median (IQR) time to resumption of oral feeding was 3.0(54-162) days. There were no complications and patients were discharged after a median (IQR) of 16(7-44.5) days. The median (IQR) time until removal of SEMS was 8(5.5-66.5) weeks.
Conclusion: Our case series included patients with 3 different etiologies of Boerhaave's syndrome. In our opinion, emergency placement of SEMS provided an effective and minimally invasive alternative to conventional surgical management. Other potential benefits of interventional endoscopy included shortened hospital stay and faster resumption of oral feeding.

Introduction: Gastric subepithelial tumors represent a diagnostic and therapeutic challenge, given the histologic heterogeneity and potential malignant behavior.
Aims & Methods: To evaluate the interest, efficiency and safety of endoscopic resection for subepithelial gastric lesions, especially of size < 20 mm. We realized a single-center retrospective study in a tertiary care center of 34 patients with subepithelial gastric lesions who underwent a preoperative diagnosis by EUS ± FNA and an endoscopic resection.
Results: A total of 34 lesions (4 GIST, 4 leiomyoma, 6 neuroendocrine tumors (NETs), 6 pancreatic rest, 7 focal inflammatory tissue, 2 lipoma, 1 well differentiated focal signet ring cells carcinoma, 1 schwannoma, 1 benign fibroid tumor, 1 hamartoma, 1 eosinophilic granuloma). Mean histological size was 18.5 mm. Concordance between EUS ± FNA evaluation and final histological diagnosis was 50%. 9 EMR, 19 ESD and 6 Hybrid Resection were performed. 94.1% lesions were resected in one piece. Complete histological and definitive resection, with a follow up of 6 months, was obtained in 91.2%. A vertical resection was insufficient in 4 cases. The GIST needs a complementary surgical resection and the NETs was successfully treated by a new ESD session. There were only one severe adverse event (2.9%); 1 pneumoperitoneum with ESD, 3 bleeding with 1 ESD and 2 EMR, always treated conservatively or endoscopically.
Conclusion: Endoscopic resection is safe and should be the procedure of choice for both diagnosis and definitive resection for subepithelial gastric lesions of size under 20 mm.

P1364 EFFICACY OF A NEW HEMOSTATIC FORCEPS (FD-Y0007) DURING GASTRIC ENDOSCOPIC SUBMUCOSAL DISSECTION (ESD): A PROSPECTIVE RANDOMIZED CONTROLLED TRIAL

S. Tanaka[1], T. Toyonaga[1], Y. Morita[2], T. Ishida[2], T. Azuma[2]
[1]*Endoscopy,* [2]*Gastroenterology, Kobe university Hospital, Kobe, Japan*

Contact E-mail Address: tanakas@med.kobe-u.ac.jp
Introduction: Endoscopic submucosal dissection (ESD) is widely accepted as a standard treatment for early gastric cancer. One challenging aspect of ESD is hemostasis. It is often difficult to control pulsatile bleeding from arterioles or bleeding from raw surfaces deep in the submucosal layer. We developed a new hemostatic forceps with a large cup and a rotation function (FD-Y0007) with the aim of achieving more effective hemostasis.
Aims & Methods: The objective of this study was to investigate the hemostatic ability of the FD-Y0007 during gastric ESD. This study was a prospective randomized controlled trial, which was conducted at a cancer referral center. Fifty-nine (59) patients who were scheduled to undergo ESD for a total of 66 gastric neoplasms (median tumor size of 16 mm) were enrolled and randomly assigned to either the Coagrasper or the FD-Y0007, which was used for hemostasis throughout the case. The procedures were performed by 4 endoscopists. The main outcome measure was the time required to obtain hemostasis, which was measured for the first episode of bleeding during each case.
Results: Hemostasis time for the first bleeding episode during ESD was 45 seconds (range 11 - 230) for the Coagrasper vs. 15 seconds (range 9 - 56) for the FD-Y0007 ($p < 0.001$). When all episodes of bleeding were 32 (range 7-230) second in Coagrasper vs. 14 (range 5-235) second in FD-Y0007 ($p < 0.001$). The rate of number of grasping attempts required for hemostasis was ≤ 2 in the Coagrasper was 59% and that in the FD-Y0007 was 89% ($p < 0.001$). The operation time (54 minutes vs. 45 minutes), rate of en bloc resection (96% vs. 100%), and number of adverse events (perforation; 3.2% vs. 6.9% and bleeding; 0% vs.0%) were not significantly different between the two groups. In addition, the FD-Y0007 demonstrated more effective hemostatic ability than the Coagrasper independent of tumor location or bleeding pattern.
Conclusion: Compared to the Coagrasper, the FD-Y0007 efficiently reduces the hemostatic time during gastric ESD with no increase in adverse events.

Contact E-mail Address: jeremiejacques@gmail.com
Introduction: Gastroparesis is defined as a syndrome of objectively delayed gastric emptying in the absence of mechanical obstruction and cardinal symptoms (early satiety, postprandial fullness, nausea, vomiting). Gastric emptying scintigraphy is considered as a standard for diagnosis of gastroparesis. Manometric studies of patients with gastroparesis show prolonged periods of increased pyloric tone and phasic contractions, a phenomenon termed as "pylorospasm". Endoscopic therapies of pylorospasm have emerged with recently the development of per-oral endoscopic pylorotomy (POP) by analogy to POEM in achalasia. We explore the effect of POP on gastric-emptying in normal pigs.
Aims & Methods: A first gastric emptying scintigraphy of a semi-solid meal labelled with 15 MBq Tc99m-DTPA was performed in 4 large white pigs (25.5 +/- 2.9 kgs) under a light sedation with intravenous propofol beginned 15 minutes after a premedication with intramuscular ketamine. The semi-solid meal

Abstract number: P1362. Table 1: Characteristics, type of stent used and outcomes of the patients

Patient	Sex/ Age	Symptoms	Etiology	Type/dimensionsof Stent (mm)	Time from onset	Pleural drainage	TT discharge	TT removal
1	M/72	Epigastric pain, hematemesis, dyspnea	Food impaction with meat bolus	Ultraflex®, partially covered metallic stent23/28 x 70/100	72hours	Yes	9 days	5 weeks
2	M/48	Thoracalgia, hematemesis	Alcohol withdrawal	Ultraflex® partiallycovered metallic stent 23/28 x 70/100	24hours	Yes	6 days	6 weeks
3	M/18	Epigastric pain, vomiting, hematemesis	Eosinophilic esophagitis	Hanarostent®, partially covered metallic stent20/26 x 60/100	<12hours	No	5 days	8 weeks
4	M/55	Epigastric pain, vomiting, dyspnea	Alcohol withdrawal	Hanarostent®, covered metallic stent20/26 x 100/140	39 days	Yes	54 days	9 weeks
5	M/44	Epigastric pain, vomiting	Alcohol withdrawal	Wallflex®, covered metallic stent 18/25x120	<12hours	No	16 days	31 mths

(M=male; TT = time to)

was administered after initiation of the sedation using a large nasogastric feeding tube.
Between 2 to 5 days after, an endoscopic pylorotomy (POP) was performed on anesthetised pigs (intravenous propofol and sufentanyl) with an hybridknife type T (Erbe Medical, Germany) according to the previous reported technique: mucosal entrance in the antrum at the greater curvature 3 to 5 cm proximal to the pyloric opening; submucosal tunnel dissection; endoscopic pyloromyotomy and closure with endoscopic hemoclips.
After 7 days of follow-up a second gastric emptying scintigraphy was performed according to the above mentionned protocol to evaluate the effect of the POP on the gastric emptying of normal pigs.
Results: POP: Mean duration of the procedure was 55 (+/- 4) minutes. All cases were completely performed under air insufflation. No bleeding occured per-procedure or post-procedure. Only one perforation for the first case occured during the myotomy phase but without any clinical significance during the 7 days of follow up before the second gastric emptying scintigraphy.
Gastric emptying scintigraphy: The post-POP gastric emptyning was 2.22 fold faster than the pre-POP gastric emptying with statistical significance: T 1/2 post-POP = 84.5 (+/-) 35.7 min vs T 1/2 pre-POP = 188.4 (+/- 87.3) min; $p = 0.029$.
Conclusion: Per-oral endoscopic pyloromyotomy is safe and accelerate gastric emptying of a factor of 2 in healthy pigs. A study is ongoing on a model of gastroparesis in pigs which have previously been treated by a troncular vagotomy and a pilot human study will begin at the end of the year to confirm this promising results. Just like POEM in achalasie, POP may become the standard treatment of gastroparesis.

P1366 ACUTE UPPER GI BLEEDING (AUGIB) OUTCOMES IN A 24/7 TERTIARY CENTRE, MUCH NEEDED TOPICAL DISCUSSION IN AN ERA OF TOPICAL HAEMOSTATIC ENDOSCOPIC TREATMENT

S. Chandrapalan[1], A. Ramakrishnan[1]
[1]*Gastroenterology, University Hospital of North Midlands Nhs Trust, Newcastle Under Lyme, United Kingdom*

Contact E-mail Address: arulraas@yahoo.com

Introduction: Despite highly successful endoscopic treatment[1], acute upper gastrointestinal bleeding (AUGIB) rebleeding rate of 13% and mortality of 10% remains a key concern[2]. Topical haemostatic therapy is evolving in Non variceal Gastrointestinal bleed (NVGIB) management and registry data[3] suggest that it is non inferior to current standard endoscopic treatment.
Aims & Methods: Our hospital is a tertiary centre with 24/7 endoscopy/interventional radiology/surgery facilities but falls in most deprived quintile of deprivation. We reviewed our 24/7 AUGIB services to look at NVGIB rebleeding/mortality outcomes and to evaluate the service need for topical haemostatic therapy. We performed a retrospective study over a 12 month period from September 2012 to August 2013. We searched Hospitals Episode Statistics (HES) for haematemesis, melaena or unspecified gastrointestinal haemorrhage codes and collected demographics, endoscopy data and outcomes from electronic records.
Results: There were 500 patients with a mean age of 66.4. Male: Female - 291:209. Rebleeding rate was 6%; mortality 10.8% and 1% required radiological/surgical interventions. Non Variceal accounted for 69% (344), variceal 9% (44) and no cause for bleeding 22% (112). NVGIB endoscopy findings were - 15% duodenal ulcer, 8% gastric ulcer, 33% Oesophagitis/Gastritis/Duodenitis, 7% others, 4% malignancy, 2% oesophageal ulcer.
Conclusion: Our audit shows that 24/7 AUGIB service in a tertiary centre can provide highly successful endoscopic treatment in preventing rebleeding (6% compared to 13% national data[2]) but does not improve mortality. The reason for non improvement in mortality is unsurprising[1] but compared to national data, slight increase could be multifactorial and we feel it is related to the deprivation score[4]. Currently, we see the role of topical haemostatic therapy in 24/7 tertiary centres to be in select population and does not require change of protocols from dual endoscopic treatment.

P1367 ENDOSCOPIC ANTERIOR FUNDOPLICATION WITH THE MEDIGUS ULTRASONIC SURGICAL ENDOSTAPLER (MUSE^{TM}): RESULTS FROM AN EX-VIVO SIMULATION TRIAL TO ASSESS THE EFFICACY OF THE PROCEDURE BY COMPARING STAPLING POSITION AND GASTRIC YIELD PRESSURES

T.-G. Gweon[1], K. Matthes[1]
[1]*Gastroenterology, Harvard Medical School, Boston, United States*

Contact E-mail Address: gweontae@naver.com

Introduction: GERD is the result of lower esophageal sphincter (LES) dysfunction caused by inappropriate transient LES relaxation or diminution of resting basal pressure. Recently, the Medigus Ultrasonic Surgical Endostapler (MUSE^{TM}, Medigus, Omer, Israel), a combined video- and ultrasound-guided transoral surgical stapler, has been FDA-cleared and CE-cleared for endoscopic anterior fundoplication.
Aims & Methods: Aim of this study is to determine the ideal position of the staples in relation to the gastroesophageal junction (GEJ) in a validated simulation model. MUSE procedures were performed in the EASIE-R simulator (Endosim LLC, Hudson, MA) using fresh ex-vivo porcine stomachs. As a surrogate for LES function, the gastric yield pressure (GYP) was determined by inserting an 18-Gauge cannula into the stomach lumen, which was connected to a pressure transducer. The stomach was gradually filled with methylene-blue dyed normal saline using a roller pump. The GYP was determined by detection of reflux of the methylene-dyed water in the esophagus with a gastroscope positioned above the GEJ. Four different techniques were compared by varying the distance of stapling location from the GEJ and the angle between the staples in the horizontal plane. Group A: 2 staples each at 3cm distance, angle 180 degrees; Group B: 2 staples at 3cm, angle 90 degrees; Group C: 2 staples at 4cm; angle 180 degrees; Group D: 3 staples at 3cm; 90 degrees between each staple (180 degrees total).
Results: We performed 10 MUSE procedures in each group. Baseline GYP before the procedure was 0 mmHg in all groups. Mean GYPs (±SD) after the procedure were as follows: Group A 16.9 ± 8.7; Group B 8.1 ± 7.9; Group C 12.2 ± 9.4; Group D 22.7 ± 13.3. Comparisons of each group was done using the student *t* test and were as follows:

Comparison	p-value
Group A vs Group B	0.03
Group A vs Group C	0.26
Group A vs Group D	0.26
Group B vs Group C	0.31
Group B vs Group D	0.01
Group C vs Group D	0.06

Conclusion: We observed significant differences in GYP among the tested 4 groups. Based on our results, we recommend the placement of 3 staples at 3 cm distance from the GEJ with an angle of 90 degrees between each staple position (1st and 2nd; 2nd and 3rd), which resulted in the most efficient LES valve mechanism. Limitations of this study are the small sample size and the use of an ex-vivo model with lack of intrinsic LES pressure.

Contact E-mail Address: tmorimo@juntendo.ac.jp

Introduction: Hemostatic forceps is increasingly used acute upper gastrointestinal bleeding (UGIB) to achieve hemostasis as it has become readily available for Endoscopic mucosal dissection (ESD). Hot biopsy forceps (Radial Jaw^{TM} 4 Hot Biopsy Forceps, Boston Scientific, Marlborough, MA, USA) is particularly useful in hot biopsy forceps polypectomy and achieving hemostasis in ESD. We previously reported the efficiency and safety of hot biopsy forceps for ablation of gastric antral vascular ectasia[1]. Besides, in recent days it has also been used for cold polypectomy during colonoscopy[2].
Aims & Methods: The aim of the current study was to evaluate the efficacy of achieving hemostasis for non-variceal UGIB using hot biopsy forceps. A total of 188 cases were evaluated retrospectively between January 2009 and December 2014. We divided the cases into two groups, and compared the hemostasis, re-bleeding rate, and clinical background. Group A consisted of 141 cases where endoscopic hemostasis with hot biopsy forceps for acute UGIB was performed. Group B consisted of 47 cases where hemostasis was achieved with the other conventional endoscopic methods. Endoscopic treatment for UGIB was performed when cases presented with active spurting and oozing (Forrest classification Ia and Ib), and visible non-bleeding vessel (Forrest classification IIa).
Results: Clinical characteristics among groups (A/B) were male: female [89:52/39:15], average age [70.0 ± 14.5/67.9 ± 14.9] years, use of anti-coagulant agents [27.7%/21.3%], and non-steroidal anti-inflammatory drug use was [12.8%/8.5%]. The average of Hemoglobin (Hb) level was [8.4 ± 2.8/9.2 ± 2.7], and Blood urea nitrogen (BUN) / Creatinine (Cr) ratio was [45.5 ± 20.0/48.9 ± 30.0]. There were no statistically significant differences between the two groups in hemostatic rate [99.3%/100%], and re-bleeding rate [2.9%/2.1%].
Conclusion: Our use of hot biopsy forceps in active UGIB shows this method is equivalent to conventional endoscopic methods in achieving hemostasis. This method is easy, cost-effective and doesn't require special preparations or ability. Further prospective studies can confirm our finding.

P1369 THE DIAGNOSTIC PERFORMANCE OF CONVENTIONAL ENDOSCOPY FOR DIAGNOSING SUBMUCOSAL INVASION BY EARLY GASTRIC CANCERS: THE "NON-EXTENSION SIGN" AS A SIMPLE DIAGNOSTIC MARKER

T. Nagahama[1], K. Yao[2], K. Imamura[3], A. Iwashita[4], T. Kojima[3]
[1]*Gastroenterology, Fukuoka University Chikushi Hospital, Fukuoka,* [2]*Endoscopy,* [3]*Gastroenterology,* [4]*Pathology, Fukuoka University Chikushi Hospital, Chikushino-city, Japan*

Contact E-mail Address: nagahamagogo@gmail.com

Introduction: Differentiation between mucosal (M) or microinvasive submucosal (SM1: less than 500 micrometer) and invasive submucosal (SM2: 500 micrometer and over) cancer, as an indicator of the depth of invasion, is an important determinant of the method of treatment of early gastric cancer (EGC). Therefore, the present study sought to determine the ability and the inter-observer agreement of conventional endoscopy (CE) to diagnose SM2 cancer using only ''non-extension sign'' under unified viewing methods.
Aims & Methods: This study examined consecutive cancerous lesions detected in successive patients who underwent CE prior to either endoscopic or surgical resection at this hospital between January 2006 and December 2013.
EGCs were diagnosed according to invasion depth as M-SM1 or SM2. Each endoscopic examination was performed by a single independent endoscopist, with the diagnoses recorded in a database immediately following each procedure. SM2 cancer was diagnosed when one of two criteria is fulfilled according to the CE findings [1]: (I) massive elevation; or (II) mucosal convergence with elevation. These non-extension signes findings relate to the increased thickness and rigidity caused by massive submucosal invasion by the cancer. When the gastric wall is strongly extended by endoscopic insufflation of a large volume of air, the SM2 invasive area can be seen as a trapezoid protrusion. So this ''non-extension sign'' was assessed only when the entire stomach wall is strongly distended.
In terms of the endoscopic diagnostic criterion, lesions that were positive for the ''non-extension sign'' were classified as SM2 cancers, and those negative for the ''non-extension sign'' were classified as M-SM1 cancers. The histopathological findings were used as the gold standard.
Results: We examined a total of 981 lesions from 822 patients. There were 127 true positive lesions, 824 true negative, 11 false positive, and 19 false negative. This yielded a sensitivity of 87.0% (95% CI 81.5-92.4%), specificity of 98.6% (95% CI 97.9-99.4%), positive predictive value of 92.0% (95% CI 87.5-96.5%), negative predictive value of 97.8% (95% CI 96.7-98.7%), and diagnostic accuracy of 96.9% (95% CI 95.8-98.0%). The values of inter-observer variation for diagnosing submucosal invasion by EGC using ''non-extension sign'' was 0.839 (excellent agreement [2]) between 2 endoscopists.
Conclusion: In the present study, the ''non-extension sign'', detectable using CE, is a straightforward and effective means for accurately determining the suitability of minimally-invasive endoscopic treatment.

Contact E-mail Address: ohki.takeshi@twmu.ac.jp

Introduction: Endoscopic cell sheet transplantation to prevent a stricture after esophageal endoscopic submucosal dissection (ESD) was developed in our university hospital. Cell sheet was harvested by each patient's own oral mucosal tissue. Isolated epithelial cells from the oral mucosal tissue were cultured for 16 days using culture dishes with intelligent temperature-responsive surface. We were able to get transplantable epithelial cell sheets by reducing temperature without protein enzyme. Then, the autologous cell sheets were endoscopically transplanted onto the bed of the esophageal ulcer after ESD. We reported the result of regenerative medical clinical research on *Gastroenterology* in 2012.
Aims & Methods: The aim of our study is feasibility of cell sheet transplantation in other institutes. We educated endoscopic cell sheet transplantation by animal examinations before the clinical research and directly taught in each 10 cases from 2011 at Karolinska Institute in Sweden and Nagasaki University.
Results: Selected medical staff at Karolinska Institute in Sweden received training from us on this technology. They, then, adapted the techniques to their clinical studies, which focused on Barrett's esophagus with high-grade dysplasia. Ten patients participated in the study and results were collected. Currently, the Institute is preparing for the randomized control study.
Nagasaki University conducted a study to determine the possibility of transferring collected oral mucosal tissue to the cell processing center at our university by air. Many variables, such as temperature, humidity, vibration, were taken into considerations. Cells collected from 10 subjects were transported to us successfully.
Conclusion: This is the first successful model on cell sheet transplantation for the prevention of stricture. We hope that this technology will be widely used around the world in the future.

Introduction: Observing an X-ray monitor and an endoscopic monitor is necessary for fluoroscopy-guided therapeutic endoscopic procedures such as ERCP. However it is difficult to view the two monitors simultaneously. A see-through head-mounted display (SHD, Moverio BT-100; Seiko Epson Corp., Azumino, Japan) was developed for viewing moving images projected 20–30 cm in front of the eyes. The images do not obstruct the surrounding view.
Aims & Methods: The aim of this study was to evaluate the utility of SHD for clinical use. We conducted two experiments. Experiment 1 verified the non-inferiority of SHD-guided endoscopic procedures to normal monitor-guided endoscopic procedures. Subjects were three doctors and one nurse; the nurse had no endoscopy experience. The times necessary to conduct a series of endoscopic observation procedures and head movements during observations were compared between normal monitors and SHD. Endoscopy was performed by insertion through the esophagus. The stomach to the duodenal papilla and the stomach interior were observed. Each subject performed two runs of observations using each monitoring method. The shortest time was used as the procedure time. The head movement was measured using the inertial measurement unit of the SHD. Examination 2 used the gastrostomy model as the model to perform endoscopic procedures while observing multiple monitors. Subjects were four doctors with gastrostomy experience. They performed two runs of the procedure

using each monitoring method to compare the procedural times and head movements.
Results: Experiment 1) The median of the procedure time of four subjects was 51.5 s (range 48–69 s) by normal monitoring, and 53 s (range 46–76 s) by SHD. None of the four subjects, including the nurse, showed even slight up and down or left and right shifting of the head position. Experiment 2) The median procedure time of the four subjects was 36 s (range 26–41 s) by normal monitoring, and 32 s (range 25–41 s) by SHD. Regarding head movement, all subjects exhibited up and down or left and right shifting of the head position by normal monitoring every time their eyes moved between the monitor and the gastrostomy site, although all subjects were able to perform the procedure while exhibiting almost no head position shift using SHD.
Conclusion: When guided by SHD, the procedure performance was not inferior to that of normal monitor-guided endoscopic procedures. Additionally, it was possible to perform procedures during which multiple monitors were observed simultaneously without shifting the head position, suggesting the possibility of its usefulness for therapeutic endoscopy where an X-ray monitor is also used.

P1372 SINGLE CLIP VERSUS MULTI-FIRING CLIP DEVICE FOR CLOSURE OF SUBMUCOSAL ENTRANCE AFTER PER-ORAL ENDOSCOPIC MYOTOMY (POEM)

T. Verlaan[1], F. Ponds[2], A. Bredenoord[1], P. Fockens[1]
[1]*Gastroenterology & Hepatology, Academic Medical Center,* [2]*Gastroenterology & Hepatology, Academic Medical Center Amsterdam, Amsterdam, Netherlands*

Contact E-mail Address: t.verlaan@amc.uva.nl
Introduction: Per Oral Endoscopic Myotomy (POEM) is an alternative treatment for achalasia. With this technique an esophageal myotomy is completely performed endoscopically. After the myotomy the 2-3 cm long entry site of the submucosal tunnel is closed with endoscopic clips. After placement of each clip a next clip has to be introduced through the working channel of the endoscope. A new endoscopic clip system has recently been introduced (Clipmaster3, Medwork, Germany). With this system it is possible to place up to 3 consecutive clips without having to reload and therefore could reduce closure time.
Aims & Methods: We performed a prospective study with this new multi-firing device looking at efficacy, safety and ease of use. Moreover, closure using Clipmaster3 was compared to closure with standard endoscopic clips. Patients diagnosed with achalasia who underwent POEM were prospectively studied. Both physician and endoscopy nurse were trained to use Clipmaster3 prior to the first procedure. The following variables were collected for both groups: sex, age, achalasia subtype based on high-resolution manometry, disease duration, length of the mucosal incision, successful closure, closure time of the mucosal incision, number of clips used for successful closure, unsuccessfully placed clips, adverse events and postoperative stay. Handling of the Clipmaster3 was evaluated by both endoscopist and endoscopy nurse by means of a VAS score (0 = impossible, 10 = very easy).
Results: Twelve POEM closures with Clipmaster3 were compared to 24 standard-POEM procedures based on the same physician and assisting endoscopy nurse for all procedures. Data of the procedures were compared in a 1:2 manner. The Clipmaster3 and the standard group did not differ in sex distribution, age (42 yrs [29-49] vs 41 yrs [34-54] p 0.379) and type of achalasia (p 0.181). Median disease duration differed between groups, 24 months [10-66] for Clipmaster3 vs 2 months [1-32] (p 0.018) for standard closure. Length of the mucosal incision did not differ between groups (25.0 mm [20-30] vs 20.0 mm [20-30], p 1.0). Successful closure could be performed in all patients in both groups. Closure time did not differ between the groups (622 s [438-909] vs 598.5 s [488-664] p 0.72). The number of clips that were placed to achieve successful closure did not differ (9 vs 8). The proportion of all used clips that was either displaced or discarded was larger for Clipmaster (8.8%) compared to standard closure (2.0%, p 0.00782). The number of adverse events did not differ between groups (n = 3, 25.0% vs n = 6, 25.0%). In none of the patients leakage of water-soluble contrast was seen during X-swallow at day 1. Postoperative stay was 1 day for all patients. In both groups there was no readmission or mortality. VAS score for ease of handling of the Clipmaster3 for closure did not differ between the endoscopist and endoscopy nurse and was 7 ([6-8][6-9]) out of 10.
Conclusion: This study demonstrates that Clipmaster3 for closure of the mucosal incision after POEM was safe and feasible in all patients. Compared to standard endoscopic clips Clipmaster3 was not associated with reduced closure time as was hypothesized. Compared to standard closure, more clips of Clipmaster3 were displaced or discarded to achieve successful closure. A training effect cannot be excluded as cause of these results.

P1373 ENDOSCOPIC TREATMENT FOR SUPERFICIAL BARRETT'S ESOPHAGEAL ADENOCARCINOMA: UTILITY OF MAGNIFYING NBI ENDOSCOPY AND NEGATIVE BIOPSY AROUND THE LESION FOR DIAGNOSIS OF ITS EXTENT

T. Shimizu[1], J. Fujisaki[1], M. Omae[1]
[1]*Department of Gastroenterology, The Cancer Institute Hospital Of JFCR, Tokyo, Japan*

Contact E-mail Address: tomoki.shimizu@jfcr.or.jp
Introduction: Treatment strategies for superficial Barrett's esophageal adenocarcinoma(s-BEA) and high-grade dysplasia differ substantially between Japan and Western countries. In Japan, targeting biopsy and endoscopic submucosal dissection (ESD) is favored, but sometimes horizontal extent is a difficult issue. In our hospital, horizontal margin is diagnosed in all cases by narrow-band imaging magnifying endoscopy (NBI-ME) before ESD, and recently, negative biopsies around the lesion is actively taken for confirm horizontal margin.
Aims & Methods: This study aimed to investigate the utility of NBI-ME and negative biopsies. The subjects comprised 67 lesions in 63 cases with pathologically defined s-BEA (SSBE, 56; LSBE, 7) that were endoscopically resected (ESD/EMR) in our hospital in December 2014 or before. The horizontal extent was diagnosed preoperatively in all cases by NBI-ME based on the presence or absence of a demarcation line and irregularity of the surface patterns and vascular patterns. Then, a horizontal margin-negative rate was compared between two groups: Group A, biopsy from 0 to 3 peripheral points (22 lesions in 18 cases); and Group B, biopsy from 4 peripheral points or more (45 lesions in 45 cases). Lesions with at least one of the findings of double-layered lamina muscularis mucosae, esophageal glands, and squamous cell islets detected by postoperative pathology were defined as Barrett's esophageal adenocarcinoma and subjected to analysis.
Results: Overall, the horizontal margin-negative rate was 97.0% (65/67 lesions). It was 96.5% (55/57 lesions) and 100% (10/10 lesions) with the background of SSBE and LSBE, respectively. All were negative in Group B, while it was 90.9% (20/22 lesions) in Group A in 2 of which development under the squamous epithelium was observed. Pearson's chi-square test revealed a significant difference between two groups with a p value at 0.040.
Conclusion: In diagnosis of the horizontal extent of s-BEA, NBI-ME and negative biopsies were useful. Negative biopsies from at least 4 points can be necessary to prevent misdiagnosis of the horizontal extent.

P1374 UTILITY OF MAGNIFYING ENDOSCOPY WITH NARROW-BAND IMAGING IN THE DIFFERENTIAL DIAGNOSIS OF SUPERFICIAL-ELEVATED TYPE GASTRIC EPITHELIAL NEOPLASMS BY NON-EXPERTS

T. Kojima[1], T. Nagahama[2], K. Yao[1], T. Matsui[2], A. Iwashita[3]

Contact E-mail Address: toshiki55imari@yahoo.co.jp
Introduction: Magnifying narrow-band imaging (M-NBI) has been reported to be superior to conventional white-light imaging (C-WLI) in its ability to differentially diagnose gastric cancers and adenomas [1]. However, these results have been achieved when examinations are performed by experts. The diagnostic ability of non-experts with fewer years of experience has not been reported.
Aims & Methods: This study investigated the diagnostic abilities of experts and non-experts when using C-WLI and M-NBI to distinguish superficial-elevated type gastric epithelial neoplasms as cancer or adenomas. Among consecutive patients with a gastric epithelial neoplasm who underwent endoscopic resection at our hospital between 2006 and 2011, this study included 1) superficial-elevated type lesions, 2) lesions evaluated preoperatively by both C-WLI and M-NBI, and 3) lesions that were histopathologically examined. Cases of resected lesions with a histopathological diagnosis of cancer or adenoma were reviewed in random order by two endoscopists (expert: endoscopic experience 20 years, magnified endoscopic experience 8 years; non-expert: endoscopic experience 7 years, magnified endoscopic experience 3 years). These endoscopists, who were unaware of the diagnosis, were asked to distinguish these lesions as cancer or adenoma based on the following criteria. The diagnosis by C-WLI was based on lesion color [1]. Lesions that appeared red compared to the background mucosa were diagnosed as cancer. Non-red lesions (same color or discolored compared to background mucosa) were diagnosed as adenomas. The VS classification system (VSCS), proposed by Yao et al, was used as the diagnostic criteria for M-NBI. The resected lesions were classified, based on their histopathological findings as the gold standard, into low-grade adenoma (LGA) and early cancer/high-grade adenoma (EC/HGA). Diagnostic sensitivity and specificity for EC/HGA based on C-WLI and M-NBI, when performed by an expert and non-expert, were compared. McNemar's test was used for statistical comparison between the two groups. The level of statistical significance was $p < 0.05$.
Results: There were 147 superficial-elevated type gastric epithelial neoplasms (LGA group 48; EC/HGA group 99). As for the sensitivity (95% Cl) of C-WLI vs. M-NBI in Expert, 68.6% (59.5-77.8) vs. 93.9% (89.2-98.6), the specificity were 89.5% (80.9-98.2) vs. 87.5% (78.1-96.8). In expert, M-NBI significantly had higher sensitivity than C-WLI. As for the sensitivity of C-WLI vs. M-NBI in non-expert, 67.6% (89.2-98.6) vs. 89.9% (83.9-95.8), the specificity were 84.3% (71.7-96.9) vs. 70.8% (57.9-83.6). In non-expert, M-NBI significantly had higher sensitivity than C-WLI as well as expert.
Conclusion: The diagnostic sensitivity of M-NBI using the VSCS is superior to the diagnostic sensitivity of C-WLI in the differential diagnosis of superficial-elevated type gastric epithelial neoplasms as cancer or adenoma. M-NBI had similar diagnostic ability when performed by an expert and a non-expert.

Contact E-mail Address: toshi_urao@yahoo.co.jp
Introduction: Endoscopic submucosal dissection (ESD) can be used for successful en bloc resection of early stage gastrointestinal tumors including large lesions. However, this requires an effective submucosal (SM) injection agent that is safer and more effective. We previously reported on the effectiveness of carbon dioxide (CO_2) as a SM injection agent during ESD procedure[1)]. CO_2 was filled into a 50ml syringe and then injected by hand into the SM layer which resulted in physical dissection of that layer. However, additional injection solution was necessary for maintaining the SM cushion based on previous feasibility study[2)]. Hence, we developed a high pressure CO_2 SM injection (HPCSI) technique to facilitate ESD.
Aims & Methods: The aim of this preclinical study was to assess the feasibility of this novel technique in a live pig model. Twelve domestic female pigs of about 30 kg underwent gastric ESD in two groups. Two different areas of artificial lesions measuring 3×3 cm were marked with soft coagulation in each of the six pigs. HPCOSI system consisted of a prototype electrosurgical knife which has the gas emitting lumen at the tip of the sheath with a CO_2 insufflation regulator connected to a CO_2 bottle. By alternate allocation, circumferential incision using a prototype electrosurgical knife of HPCSI, followed by SM dissection using HPCSI was performed (HPCSI group). Large vessels in the SM layer were coagulated using the tip of a knife. In the other group, conventional ESD was performed following SM injection of normal saline solution. All procedures were performed by one of two endoscopists. The area of the resected pieces was calculated by using the formula for calculating the area of a circle: (Area = Pi × radius^2) SM dissection speed was calculated by dividing the area of the resected piece in relation to the total dissection time (speed = area/time). Second look gastroscopy was performed on day 3. The thickness of submucosal layer in the resected specimens and the degree of inflammation (score: 1 to 3) around ESD-induced ulcer were evaluated histopahologically between two groups by an independent pathologist in a blind fashion.
Results: All procedure achieved en bloc resection. SM dissection speed was significant faster in the HPCSI group than the control group (8.1 ± 3.7 vs. 4.8 ± 2.2 cm^2/sec, $p = 0.017$). No perforation occurred and one delayed bleeding occurred in the control group. Second look gastroscopy did not observe any necrotic changes of gastric mucosa around ESD-induced ulcers. There were no statistically significant differences of the thickness of submucosal layer (270.8 ± 125.6 vs. 431.3 ± 107.0 μm, $p = 0.17$) and the inflammation score (1.8 ± 0.8 vs. 1.6 ± 0.5 μm, $p = 0.45$), respectively.
Conclusion: A novel HPCSI technique may represent advancement in safe and effective SM dissection procedure. The value of this technique for clinical use awaits further study.

P1376 THE EFFICACY OF ON DEMAND LIQUID SIMETHICONE IN IMPROVING ENDOSCOPIC VISIBILITY DURING UPPER GASTRO-INTESTINAL ENDOSCOPY (UGIE): A PROSPECTIVE RANDOMIZED PLACEBO CONTROL STUDY

V. Sharma[1], G. Gandhi[2]
[1]*Gastroenterology, Manipal Hospital, Jaipur, A unit of Manipal group of Hospitals and Institutions, Jaipur,* [2]*Gastroenterology, Medipulse Hospiral, Jodhpur, India*

Contact E-mail Address: vijaysadashiv@gmail.com
Introduction: Intraluminal foam and bubbles can hamper endoscopic visibility, potentially missing lesions and extending time of procedure. Simethicone is a defoaming agent which decreases surface tension, leading to coalescing of foam and bubbles. Simethicone is not absorbed from gastrointestinal tract and is not attached to other drugs, rarely has adverse effects. Previous studies reported that the addition of simethicone with bowel preparation before performing colonoscopy and small bowel capsule endoscopy is useful by increasing endoscopic visibility, diagnostic accuracy and endoscopist satisfaction. Nevertheless, there have been limited data on its usefulness in UGI endoscopy on demand basis.
Aims & Methods: To evaluate the effectiveness of liquid simethicone washing on enhancing endoscopic visibility in patients undergoing UGI endoscopy.
Randomized prospective placebo-controlled trial, adults aged 18-60 years undergoing elective UGIE included. Exclusion criteria were nasogastric tube insertion, stenosis and retention in upper digestive tract, history of gastric surgery, cardiac and coronary artery diseases within 6 weeks, uncontrolled pulmonary diseases, pregnancy, thrombocytopenia (platelet less than 20,000/mm3), coagulopathy (INR over 2.5), non co-operative and history of simethicone use within 2 weeks. Study group was given adjunctive simethicone washing, 3 ml of liquid simethicone (120 mg) in 50 ml of water and placebo group was given 50 ml of plain water. Grading system of Mc Nally used for severity of foam and bubbles as following: grade 1 (no foam, bubbles), 2 (minimal), 3 (moderate) or 4 (abundant, obscuring of mucosal surface) at stomach or duodenum. The mean value of Mc Nally scores at the stomach and was compared.
Results: A total of 144 patients were prospectively enrolled to the present study. Seven patients were excluded due to non co-oprtiveness (n = 3), NG tube feeding (n = 1), gastric surgery (n = 2), asnd recent myocardial infarction one patient. Finally 137 patients were randomized into two groups: 71 patients were given adjunctive simethicone washing, and 66 patients received placebo. Both groups were comparable on demographic and clinic parameters. In simethicone group reduction of mean value of foam and bubbles scores wass better (2.4 vs 3.8, $p < 0.001$). Endoscopist satisfaction was graded by self-rated endoscopic visibility scale as very good, good, fair, bad, very bad (30 %vs 5%, 40% vs 5%, 25% vs 30%, 5%vs 45% and 0%vs 15%). The results revealed that simethicone enhanced endoscopist satisfaction significantly by showing higher proportion of very good and good endoscopic visibility scale in this group compared to placebo (72.0% vs. 13.4%, $p < 0.001$).
Conclusion: Using on demand simethicone during UGIE, enhances endoscopic visibility, increases endoscopist satisfaction. Further studies required to prove its benefit for small lesion detection.

P1377 SINGLE-CENTRE CLINICAL EXPERIENCE OF HEMOSPRAY ENDOTHERAPY IN PATIENTS WITH ACUTE UPPER GASTROINTESTINAL BLEEDING

E. Dhesi[1], **V. Lam**[1], K. Tang[1], S. Mann[1], Y. Sharifi[1], M. Carpani[1], K. Besherdas[1], N. Van Someren[1], S. Musa[1], A. Alisa[1]
[1]*Barnet & Chase Farm Hospitals, Royal Free London NHS Foundation Trust, London, United Kingdom*

Contact E-mail Address: endip.dhesi@nhs.net
Introduction: Acute upper gastrointestinal bleeding (AUGIB) is a common medical emergency associated with a hospital mortality of 10%. Therapeutic endoscopy with conventional combined injection and mechanical application is the recognised 1st-line intervention to achieve haemostasis. However, 5-10 % of patients experience recurrence of bleeding after initial endoscopic haemostasis. Hemospray (TC-325; Cook Medical, Winston-Salem, USA) endotherapy is now becoming widely available as a novel agent to augment hemostatic efficacy.
We report on the 'real-life' single-centre experience in the UK, of the efficacy and safety of Hemospray in the management of AUGIB.
Aims & Methods: A single-centre retrospective analysis of all patients treated with Hemospray from September 2013 -April 2015 was performed. Case notes were reviewed and data collected including demographics, Rockall score, endoscopic modality, length of hospital stay, repeat procedures and transfusion requirements.
Results: 58 patients (42 male) with a mean age of 64.7 years (range 26-92) were treated with Hemospray at endoscopy. The indications for endoscopy were melaena (29, 50 %), profound anaemia (16, 28 %), haematemesis (6, 10%), oesophagogastric varices (5, 8.6%), dysphagia (1, 1.7%), dyspepsia (1, 1.7%). The mean pre-endoscopy Rockall score was 3 (range 0-7), post-endoscopy Rockall score 5 (range 1-10).
Hemospray was applied as the single modality in 16 cases (2 oesophageal tumours, 4 gastric tumours, 4 peptic ulcers, 1 peptic stricture, 1 Dieulafoy lesion, 1 unidentified D2 bleeding source). Adjunctive modality occurred in 31 cases (54.8% following variceal band ligation as the primary modality). 11 cases required rescue therapy (10 peptic ulcers, 1 polyp bleeding).
Successful haemostasis with Hemospray was achieved for all but one patient (98.3%). This patient (Dieulafoy lesion with Hemospray as solitary modality) required repeat endoscopic dual therapy (adrenaline/clips). 2 cases of bleeding DU required Hemospray despite radiologic embolization of oozing visible vessels.
No procedural complications during and immediately post-application were reported. There were no treatment-related adverse events. There was one in-patient death, not attributable to AUGIB/endoscopy. The mean length of hospital stay was 12 days (range 1-51).
Conclusion: Our experience confirms Hemospray to be an effective endoscopic modality for achieving successful haemostasis in the vast majority of cases of AUGIB, when used as single, adjunctive, or rescue endotherapy, for a wide-range of causes for AUGIB. Our 'real-life' single-centre UK experience supports Hemospray for all major causes of AUGIB; a modality that is easy to apply, and safe to use.

P1378 ENDOSCOPIC UNROOFING PROVIDES HISTOLOGY OF SMALL GASTRIC SUBEPITHELIAL TUMORS AND MAY ALSO LEAD TO TUMOR REMISSION IN MANY CASES: A RETROSPECTIVE STUDY INCLUDING FOLLOW-UP

W. Dolak[1], F. Wrba[2], B. Tribl[1], M. Schöniger-Hekele[1], M. Trauner[1], A. Püspök[1]
[1]*Gastroenterology and Hepatology,* [2]*Pathology, Medical University of Vienna, Vienna, Austria*

Contact E-mail Address: werner.dolak@meduniwien.ac.at
Introduction: Accurate diagnosis of small gastric subepithelial tumors (SETs) is essential in order to assess their malignant potential. Endoscopic unroofing by conventional snare or needle knife has been reported to yield sufficient tissue samples for histological evaluation including immunohistochemical staining.
Aims & Methods: We aimed to evaluate endoscopic unroofing in patients with small gastric SETs regarding its safety and diagnostic accuracy as well as a

potential therapeutic effect of this technique over time. In the context of a retrospective analysis, we identified patients who underwent endoscopic unroofing of small SETs of the stomach at our department. Demographic data, indication for intervention, safety of the procedure and follow-up were assessed.

Results: Between 2003 and 2012 a total of 14 patients (7 male, 7 female, median age 70 years, range 51-95 years) underwent endoscopic unroofing of 14 SETs with a mean diameter of 26 ± 13mm at endosonography. Indications were histology sampling for risk stratification (9 cases) and treatment of symptoms including bleeding or abdominal pain in patients unfit for surgical resection (5 cases). Unroofing was performed with a standard polypectomy snare and technically successful in all but one case where the cutting failed due to the big diameter (30mm) of the SET. Bleeding was the only adverse event (in 4 cases) and could always be managed by clip application and argon plasma coagulation, respectively. Histological assessment revealed mostly gastrointestinal stromal tumor (GIST) (8 cases, all of which were low risk GISTs) and one case each of leiomyoma, fibroid polyp, glomus tumor and ectopic pancreas. In one case, the specimen was not diagnostic. Histology proved complete resection of the glomus tumor, all other lesions were partly resected. Endoscopic follow-up including endosonograghy was available for 10 patients over a median time span of 8 months (range 2-81 months). Of these patients, 8 cases (6 with GIST, 1 with leiomyoma, 1 with glomus tumor) showed a complete and 2 cases (both with GIST) a partial remission of their SET over time. Until now, 1 patient with partial remission underwent surgical resection due to an increase in size of his GIST, the patient with the fibroid polyp died from an unrelated cause.

Conclusion: Unroofing of small gastric SETs is a safe procedure that showed a high diagnostic yield. In our study, this technique led to a complete remission of the SET in a majority of patients (in 62% of patients with successful unroofing), including also 6 GIST cases. For patients with gastric SETs who are unfit for surgical resection, endoscopic unroofing might be a safe and effective diagnostic and therapeutic strategy that deserves further investigation.

Contact E-mail Address: wolfgang.kreisel@uniklinik-freiburg.de

Introduction: Lichen planus is a common disease. According to various epidemiological data up to 0.5% of the population is affected. Its pathogenesis is unexplained, but an autoimmune component is highly probable. Histopathology shows a band-like predominantly T-lymphocytic inflammation at the dermo-epidermal junction with interface dermatitis. Main manifestations are skin and oral mucosa, less frequently genital mucosa. There are only few case reports and case series about an involvement of the esophagus.

Aims & Methods: In order to investigate the frequency of an esophageal involvement patients with lichen planus who were treated in our dermatological outpatient clinic were invited to undergo an esophago-gastro-duodenoscopy at the interdisciplinary endoscopical unit. Most patients were examined by one gastroenterologist (WK). The following criteria were regarded as visible macroscopical signs of esophageal lichen planus: Friability or sloughing of the mucosa, whitish areas, mucosal tears, stenosis as late sequelae. Histological criteria were (in analogy to dermal lesions): mainly lymphocytic infiltration, denudation of the epithelium, deposits of fibrinogen and/or IgG along the basement membrane in immunofluorescence.

Results: In 8/24 patients with skin and/or oral lichen planus macroscopical and histological criteria for esophageal involvement were fulfilled. in further 4 patients we found histological lesions in the esophagus. In 4/8 patients with macroscopical lesions dysphagia was the leading symptom. One patients had a scarring stenosis that required endoscopical dilatation. 3 of these 8 patients did not indicate any esophageal symptoms. Esophageal involvement of lichen planus responded well to therapy with systemic and/or local therapy with corticosteroids. However, in patients with severe dysphagia systemic corticosteroid therapy seems to be necessary for induction of symptomatic remission.

Conclusion: Even if our patients cannot be regarded as an unselected cohort, these data suggest that esophageal involvement in lichen planus is more frequent than anticipated. Surprisingly severe lesions can be found not only in patients with dysphagia but also in asymptomatic patients. Our data also suggest that endoscopic and histological criteria for esophageal involvement should be better defined, in particular the differential diagnosis to mucous membrane pemphigoid may be challenging. Currently there is no standard therapy. In patients presenting with dysphagia dermatological diseases must be considered. Vice versa in patients with skin involvement in lichen planus possible esophageal involvement should be investigated, to prevent stenosis as long-term consequence.

P1380 A NOVEL ENDOSCOPIC SUTURING DEVICE FACILITATES ENDOSCOPIC SUBMUCOSAL DISSECTION, AND DECREASE THE COMPLICATIONS

Y. Liu[1], M. Min[1]
[1]*Gastroenterology, Hospital 307 of Chinese PLA, Beijing, China*

Contact E-mail Address: 13911798288@163.com

Introduction: Endoscopic submucosal dissection (ESD) of early-stage gastrointestinal cancer improves the rate of successful en bloc resection, but it is associated with serious complications, such as bleeding and perforation. The common endoscopic suturing devices are almost expensive and based on special equipment. We designed a novel suturing device that is cheap and suitable for conventional endoscopy. Using the new device, we reported the pulley method to facilitate ESD procedures and the closure of large mucosal defects after ESD.

Aims & Methods: Fifteen patients with early-stage gastrointestinal cancers or adenomas larger than 20 mm were enrolled. The pulley method with standard clips and suturing device was used to provide traction to improve visualization of the dissection plane during ESD. The large mucosal defects post-ESD were completely closed with the novel suturing device. All operations were completed using the common single-channel endoscopy.

Results: Pulley-ESD followed by endoscopic suturing of the mucosal defects was performed in 15 patients (mean age, 64 years, 3 lesions in esophagus, 8 lesions in the stomach, 4 lesions in the colon) over a period of 10 months. All lesions (100%) were removed en bloc. No perforation or emergent surgery was noted. There were no immediate or delayed adverse events in any of the study patients. The process of pulley method was successfully completed in all patients, and the mean operating time was 10 ± 3min. Closure of post-ESD defects with the novel suturing device was technically feasible and fast (mean closure time, 10 ± 5min per patient).

Conclusion: The novel suturing device is technically feasible and fast. It can significantly facilitate en bloc ESD and decrease the complications during and post ESD.

P1381 CLINICAL OUTCOME OF ENDOSCOPIC SUBMUCOSAL DISSECTION FOR SUPERFICIAL DUODENAL NEOPLASM IN 60 LESIONS

Y. Ochiai[1], T. Akimoto[1], S. Sagara[1], T. Maehata[1], A. Fujimoto[1], R. Nakamura[1], T. Nishizawa[1], O. Goto[1], T. Uraoka[1], N. Yahagi[1]

Introduction: Superficial duodenal neoplasm is a rare disease. Recently, the improvement of endoscopic technologies has been suggested to lead to better recognition of duodenal adenoma and early cancer. Radical resection techniques such as pancreaticoduodenectomy should be avoided if possible when treating non-invasive duodenal cancer or adenoma because they cause more serious postoperative dysfunction in the duodenum than in other parts of the gastrointestinal tract. The advantage of ESD over EMR is the higher rate of en bloc resection. However, ESD is technically more difficult than ESD for lesions of other parts of the GI tract. In this study, we conducted consecutive duodenal ESD and evaluated its safety and efficacy.

Aims & Methods: Between July 2010 and December 2014, superficial duodenal neoplasm in 60 lesions was treated with ESD at our institution. The ESD procedure was carried out using a Dual Knife and/or Hook Knife through a gastroscope with waterjet functions and a CO2 insufflation system. A soft transparent hood was attached to the gastroscope tip. In most cases we performed under general anaesthesia. Data were collected and evaluated in terms of the clinical outcome.

Results: The mean tumor size was 26.5 mm in diameter (range: 2-75 mm). The en bloc resection rate was 98%. The complete en bloc resection rate was 85%.

The mean procedure time was 93.4 min. Histopathologically, there were 27 lesions of adenocarcinoma and 33 adenomas. There were 11 cases of complications (9 cases of perforation and 2 cases of delayed bleeding). Only one case with perforation required surgery; the others were managed endoscopically. Both cases with delayed bleeding were managed endoscopically. No patient died from any associated complications or duodenal neoplasm. Incomplete en bloc resection was observed in 9 cases in our institution. The estimated median follow-up period was 767 days (range 120–1436 days). Local recurrence occurred in one case. It was well controlled by hotbiopsy and argon plasma coagulation.
Conclusion: On the basis of our results, although ESD is apparently much more reliable than EMR, it should be performed only by experienced experts at advanced high-volume centers since duodenal ESD is technically demanding and risky compared with ESD in any other part of the GI tract.

P1382 USEFULNESS AND SAFETY OF ENDOSCOPIC SUBMUCOSAL DISSECTION USING A GRASPING-TYPE SCISSORS FORCEPS FOR THE REMOVAL OF EARLY GASTRIC CANCERS

Y. Kondo[1], N. Ogasawara[1], K. Adachi[1], H. Noda[1], Y. Ito[1], S. Izawa[1], M. Ebi[1], Y. Funaki[1], M. Sasaki[1], K. Kasugai[1]
[1]*Gastroenterology, Aichi Medical University School of Medicine, Nagakute, Japan*

Contact E-mail Address: konty37@yahoo.co.jp
Introduction: Endoscopic submucosal dissection (ESD) with conventional knife devices was been developed to improve the rate of successful en bloc resection. However, ESD using knife device is technically difficult and carries a high risk of perforation and bleeding, and thus requires skillful techniques. Conventional devices for submucosal incision such as the IT knife and needle knife merely bring the knife in contact with the submucosal tissue and cutting is performed using an electrosurgical current. These cutting methods without fixing the knife to the target have a potential risk of incomplete resections or major complications due to unexpected incision due to pulsation or respiratory movement. To resolve the problems related to ESD using a conventional knife device, the grasping-type scissors forceps (GSF) was developed. This study compared ESD using the GSF and ESD using the knife in terms of tumor size, en bloc resection rates, duration of the ESD procedure relative to tumor size and location, and complication rates.
Aims & Methods: Forty-two patients with early gastric cancers (EGCs) between April 2014 and February 2015 underwent ESD using the knife devices (knife group), and thirty-three patients with EGCs between April 2014 and February 2015 also underwent ESD using the GSF (GSF group). The clinical results were then retrospectively compared between the two groups.
Results: The mean duration of ESD for resected lesions of <20 mm in diameter was shorter in the GSF group than in the knife group ($p < 0.05$). On the other hand the mean duration of the procedure for resected lesions of >20 mm did not significantly differ between the two groups. The mean duration of ESD was not also associated with tumor locations between the two groups. In the knife group, complications comprised perforations in 2 patients (4.8%) and delayed bleeding that required endoscopic treatment in 3 patients (7.1%). However, there was no patient with complications in the GSF group. Although the number of complications tended to be lower for ESD with GSF, the differences did not reach the level of statistical significance. The curative en bloc resection rate in the GSF group was 100 % in tumors of <20 mm and 96.5 % in tumors of ≥ 20 mm. On the other hand the curative en bloc resection rate in the knife group was 100 % in tumors of <20 mm and 94.7 % in tumors ≥ 20 mm. There was no significant difference in the rate of curative en bloc resection between the two groups.
Conclusion: ESD using GSF was technically simpler and thus less time-consuming regardless of the location of lesions, especially when lesions of <20 mm in size. ESD using GSF was considered safe, and it can be universally applied to conventional ESD.

Contact E-mail Address: yosy29april@gmail.com
Introduction: To prevent bleeding during endoscopic submucosal dissection (ESD) is an important subject to perform ESD smoothly and safely. We have so far reported the way to decrease bleeding during ESD on the basis of submucosal vessel structures, and the vessel sealing method by soft coagulation mode (E7, 100W, VIO300D) with Flush Knife BT. On the other hand, reports about dissection and vessel sealing using forced coagulation mode with low electric output have recently been seen. Based on these suggestions, we introduced a novel vessel sealing method using forced coagulation mode with low electric output (E1, 10W).
Aims & Methods: The aim of this study is to compare the efficiency of vessel sealing using soft coagulation mode (S method) or forced coagulation mode with low electric output (F method) during ESD. Eight cases each for S method and F method were retrospectively reviewed. ESD was performed by a single operator who has more than 4000 ESD experiences before. None of the patients took any antiplatelet or anticoagulation medicine. The procedures were carried out as follows; 1) submucosal layer tissue surrounding a blood vessel was isolated, 2) both sides of the isolated vessel were cramped with the tip of the Flush Knife BT and coagulated in each coagulation mode until the blood vessels turned white, 3) the blood vessel was cut utilizing the forced coagulation mode (E3, 50W). The frequency of cramps until the vessels turned white, time between the start and finish of coagulation, and the bleeding after cutting the vessels in both method groups were recorded and they were compared statistically.
Results: The total numbers of precoagulated vessels in each group were 55 (S method) and 134 (F method). The average frequency of vessel cramps were 2.4 and 2.19 times ($p = 0.156$), the median time of coagulation were 10 and 9 seconds ($p = 0.490$), and the rate of bleeding were 31% (17/55) and 13% (17/134) ($p = 0.0031$) respectively. Most bleeding could be stopped by forced coagulation mode (E3, 50W), and the number of bleeding which needed hemostasis forceps were 1.8% (1/55) and 2.2% (3/134) ($p = 1.000$) respectively.
Conclusion: The vessel sealing using forced coagulation with low electric output less causes bleeding after precoagulation compared to that with soft coagulation mode. Considering that it takes about 20 seconds only to replace devices if we use hemostasis forceps to precogulate the vessels, this new vessel sealing method seems to be a less time consuming and efficient with low bleeding rate.

P1384 ADVANTAGE OF MAGNIFYING ENDOSCOPY WITH NARROW-BAND IMAGING FOR DETERMINING THE HORIZONTAL EXTENT OF EARLY GASTRIC CANCER OVER CHROMOENDOSCOPY, IN TERMS OF DECREASING THE SPECIMEN AREA

Y. Kitagawa[1], T. Suzuki[1], T. Hara[1], T. Yamaguchi[2]
[1]*Endoscopy,* [2]*Gastroenterology, Chiba Cancer Center, Chiba, Japan*

Contact E-mail Address: yk19820924@yahoo.co.jp
Introduction: Previous study has shown that wide resected specimen is significant factor of delayed bleeding after endoscopic submucosal dissection (ESD) for early gastric cancer (EGC) [1]. Thus, it is required to determine the horizontal extent of EGC with horizontal margin-negative and to decrease the specimen area. The standard method for determining demarcation line is standard endoscopy with dye spraying – chromoendoscopy (CE), with previous study confirming its usefulness. In recent years, the development of magnifying endoscopy with narrow-barrow imaging (M-NBI) has taken advantage of determining a clear demarcation line over CE. While successful delineation was defined that cancerous tissue was limited within the markings, no reports exist regarding the advantage of M-NBI in terms of decreasing the specimen area.
Aims & Methods: The aim of this study is to demonstrate the usefulness of M-NBI for determining the horizontal extent of EGC compared to CE, in terms of the specimen area. Between April 2012 and March 2014, ESD for solitary EGC was carried out at Chiba Cancer Center in a total of 230 consecutive lesions diagnosed by using M-NBI (M-NBI group) which met the following criteria: (?) the predominant histological type was differentiated; and (?) en bloc resection was achieved. As a control group (CE group), we selected 195 consecutive lesions between April 2007 and March 2008, which were diagnosed by using CE and met the same criteria. When the lesion showed clear margins, the periphery of the lesion was marked by electrocoagulation. On the other hand, when the lesions demonstrated unclear margins, we took multiple biopsy samples. Then we put markings, after confirming the histological findings. After the ESD, the extent of the carcinoma was reconstructed on macroscopic photograph according to histological findings. We calculated length from the carcinoma margin to the lateral margin at the short and long axis ($= a + b + c + d$ as shown in Figure 1), and compared it between M-NBI group and CE group.
Results: Differences in clinical and histological characteristics between the two groups were not significant. The horizontal margin-positive with M-NBI group and CE group were observed in 1 of 230 (0.4%) versus 2 of 195 (1.0%), respectively, with no significant difference. The frequency of taking biopsy samples with M-NBI group and CE group were 22 of 230 (9.6%) versus 63 of 195 (32.3%), respectively, with the latter significantly higher. The median length ($= a + b + c + d$) of M-NBI group and CE group were 38mm versus 41.5mm, respectively, with the former significantly shorter. In relation to different macroscopic types, those were 41mm versus 44.5mm for the flat and depressed type, respectively, showing significant difference. In relation to tumor size, those were 37.5mm versus 44mm for that >20mm, respectively, showing significant difference.
Conclusion: M-NBI took advantage of determining the horizontal extent of EGC over CE, and made a contribution to decrease specimen area in size.

P1385 THE INCIDENCE OF SYNCHRONOUS AND METACHRONOUS GASTRIC CANCER AFTER ENDOSCOPIC RESECTION OF EARLY GASTRIC CANCER ACCORDING TO THE DEGREE OF DIFFERENTIATION OF THE PRIMARY GASTRIC CANCER

Y. W. Chang[1], J. Byun[1], J.-W. Kim[1], J. Y. Jang[1]
[1]*Gastroenterology, Kyung Hee University Hospital, Seoul, Korea, Republic Of*

Contact E-mail Address: cywgi@chollian.net
Introduction: Endoscopic resection (ER) is widely used as a standard treatment for early gastric cancer (EGC) these days. However, gastric cancer can develop synchronously or metachronously after ER treatment.
Aims & Methods: The aims of this study were to investigate the predictors of recurrence of EGC after ER, especially regarding to the degree of the differentiation of primary gastric cancer. We enrolled a total of 293 patients who met the

extended criteria for ER and underwent this procedure from January 2007 to December 2012 at Kyung Hee University Hospital in Seoul, Korea. And, we retrospectively analyzed baseline characteristics and clinicopathological information about primary gastric cancer. Patients were classified into two groups, the differentiated group and the undifferentiated group. Annually, we followed up the patients with esophagogastroduodenoscopy (EGD) after ER. We excluded the patients whose follow up period was less than 6 months after ER. Synchronous gastric cancer (SGC) and metachronous gastric cancer (MGC) were counted in each group and then performed analysis which factor can influence the development of gastric cancer.
Results: Of the 293 patients, SGC developed in 41 patients (15.2%) in the differentiated group and only one patients (4.2%) in the undifferentiated group ($p = 0.221$). MGC developed in 19 patients (7.1%) in the differentiated group and none in the undifferentiated group ($p = 0.382$). Intestinal metaplasia was seen in 91.5 % of the patients in the differentiated group and 58.3 % of the patients in the undifferentiated group ($p = 0.001$). Although age was the only significant predictor of SGC in both univariate ($p = 0.047$) and multivariate analysis (OR 3.193; $p = 0.010$), it did not show significance in occurrence of MGC. Alcohol showed significant difference between the non-metachronous group and the metachronous group with *p*-value 0.036 in univariate analysis, but failed to show significant result in multivariate analysis ($p = 0.077$). Other factors including sex, smoking, *Helicobacter pylori* infection and baseline gastric mucosal atrophy did not show any statistical significance.
Conclusion: Differentiated type of gastric cancer may be a predictor of occurrence of SGC and MGC because of its high portion of intestinal metaplasia. We should consider the degree of differentiation of primary cancer, age and history of alcohol consumption together with scheduled follow-up EGD after ER. Furthermore, large scale, prospective, long-term follow-up study will be needed to validate our results.

Contact E-mail Address: yshimizu@med.hokudai.ac.jp
Introduction: We demonstrated the usefulness of a simplified narrow-band imaging (NBI) classification of surface patterns in Barrett's esophagus (BE) using high-definition magnification endoscopy with NBI (HDME-NBI) (Kato M, et al. *UEGW* 2014). It is, however, unclear whether this classification is useful for beginners. We conducted this study to validate the interpretation of the NBI classification among beginners.
Aims & Methods: A total of 248 HDME-NBI images from non-dysplastic and flat-type dysplastic areas in patients with BE were retrieved and randomized for review by eight beginners (four students and four fellows). All beginners took the 1st exam before receiving the lecture about the classification, the 2nd immediately after the lecture, and the 3rd six weeks after the lecture. The primary endpoint was observer agreement of NBI surface patterns and predicted histology (dysplasia vs. non-dysplasia), and the secondary endpoint was the classification-based diagnostic accuracy values.
Results: The overall inter-observer agreements were substantial for mucosal pattern ($\kappa = 0.65$) and predicted histology (0.61) and moderate for vascular pattern (0.56) in the 2nd. The overall intra-observer agreements were all substantial for mucosal pattern (0.73), vascular pattern (0.74) and predicted histology (0.78) between the 2nd and 3rd exams. The mean values of sensitivity, specificity and overall accuracy for all beginners in the 2nd exam were 88%, 90.2% and 89.7%, respectively.
Conclusion: The simplified NBI classification seems to be easily understandable and reliable and to have high diagnostic accuracy for beginners.

Introduction: Endoscopic submucosal dissection (ESD) was initially developed in Japan for the resection of early stage gastric cancers.
Aims & Methods: To determine the feasibility and effectiveness of endoscopic submucosal dissection (ESD) for treating early gastric cancer (EGC) in the remnant stomach of patients after gastrectomy.
From January, 2008 to December, 2013, we investigated 36 patients undergoing ESD for EGC in the remnant stomach in Endoscopy Center, Zhongshan Hospital, Fudan University. Pre- and postoperative conditions and long-term follow-up of these patients were evaluated.
Results: Both the success rate and the complete resection were 100%. The median maximum diameter of the tumor size was 1.5 (range 0.6-4.5) cm. During the ESD process, two bleeding cases were treated successfully by endoscopic hemostasis. The average operation time was 40 (10~80) min. The delayed hemorrhage was happened in 2 cases within 1-3 days after operation, and were also treated successfully by endoscopic hemostasis. There was no perforation or delayed perforation. Twelve cases were diagnosed as mild-moderate dysplasia, 7 cases were high grade intraepithelial neoplasia, 16 cases were hyperplastic polyps, and 1 case was signet ring cell carcinomawhich was at the T1 stage and the patient underwent operation for resecting gastric stump and lymph node dissection at 7 days after ESD. The postoperative follow-up was lost. The curative resections rate achieved 92.7%. The median follow-up of the remaining 35 patients was 36 (6~78) months with no discomfort and recurrence.
Conclusion: Although ESD for EGC in the remnant stomach is a time-consuming procedure and requires advanced techniques compared with ESD in normal stomach. ESD performed by endoscopists with sufficient experience appears to be feasible and effective.

P1388 ENDOSCOPIC ENUCLEATION OF UPPER GASTROINTESTINAL SUBMUCOSAL TUMORS ORIGINATING FROM MUSCULARIS PROPRIA

G. Ren[1], Y. Pan[1], L. Zhang[1], R. Huang[1], **Z. Liu**[1], X. Guo[1], K. Wu[1]
[1]*Xijing Hospital of Digestive Diseases, Xi'an, China*

Contact E-mail Address: liuzhiguo@fmmu.edu.cn
Introduction: Submucosal tumors (SMT) originating from muscularis propria of upper gastrointestinal tract is challenging to remove by conventional endoscopic submucosal dissection (cESD) method due to high perforation rate. Proper closure of mucosal defect is essential to prevent perforation related complications. Metallic clip is the most common method to close perforation. However, the failure rate is high since the size of mucosal defect is usually large. Endoscopic enucleation (EN) has been proposed previously to preserve mucosa and facility clip closure, but comparative studies had been scarce.
Aims & Methods: The purpose of this study was to compare endoscopic enucleation to cESD in clarifying its safety and efficacy in treating submucosal tumor. In this retrospective, single-center study, endoscopic enucleation was attempted in 35 patients (12 male, mean 54.3 ± 11.6 years) with submucosal tumor of esophagus (11) or stomach (24) from Mar 2010 to Mar 2013, and thirty-five submucosal tumors from 35 patients (13 male, mean 50.4 ± 11.3 years) removed by cESD were included as control. All lesions was removed by using needle-tip HybridKnife and insulated-tip knife**.** Mucosal defect closure rate and time were observed.
Results: The median size of the submucosal tumor was 18.0 mm (12.0-25.0 mm) in EN group compared to 25.0 mm (12.0-30.0 mm) in cESD group ($p = 0.260$). A total of 49 cases (23 cases in EN group, 26 cases in cESD group, $p = 0.434$) were originating from deep muscularis propria. All tumors were successfully removed in EN group, while one patient in cESD group was transferred to emergency surgery due to unsuccessful closure of perforation (100% vs. 97.1%, $p = 0.310$). The en bloc rate was 97.1% in EN group compared to 82.9% in cESD group ($p = .046$). Perforation rate was 22.9% in EN group compared to 31.4% in cESD group ($p = .612$), and clip closure was attempted in 33 and 20 cases, respectively. Satisfactory closure was achieved in 32 patients (97.0%) in EN group compared to 9 patients (45.0%) in cESD group ($p < 0.001$). Twelve patients with unsatisfactory closure were treated conservatively by extending fasting time and gastric tube drainage. The median procedure time was 28.0 min (20.0-38.0 min) in EN group compared to 57.0 min (33.0-79.0 min) in cESD group ($p < 0.001$). The median mucosal closure time was 6.0 min (4.0-9.0 min) in EN group compared to 11.0 min (7.0-24.5 min) in cESD group ($p = .001$). Twenty-four hours after the procedure, Oral intake was resumed in patients without perforation. Endoscopy one month later revealed complete healing of the iatrogenic ulcer in 32 cases of EN group and 14 cases of cESD group, and all iatrogenic ulcer was completely healed two month later. No recurrence of tumor has been observed during follow-up.
Conclusion: Both EN and cESD were safe and effective to remove submucosal tumors originating from muscularis propria of upper gastrointestinal tract, but EN had more satisfactory mucosal closure and appears to be less time consuming compared to cESD.

P1389 IRON DEFICIENCY WITHOUT ANAEMIA IN ASYMPTOMATIC PATIENTS: ARE WE DOING ENOUGH

M. U. Saleem[1], U. F. Dar[2], H. Taha[1], I. Qaisar[3]
[1]*Gastroentrology, The James Cook University Hospital, Middlesbrough, United Kingdom,* [2]*Infectious diseases, Institue of Public Health ,* [3]*Mayo Hospital, Lahore, Pakistan*

Contact E-mail Address: dr.usman77@gmail.com
Introduction: Iron deficiency (ID) without anemia determined by low ferritin levels, is a common phenomenon.[1] There is controversy and little evidence in regards to the diagnostic cascade in these asymptomatic patients at risk of gastrointestinal (GI) malignancy.[2,3] Current guidelines for this group lack consensus and available evidence is quite old.[4-6]
Aims & Methods: This study was planned primarily to evaluate current practices at our hospital to see how thoroughly patients have been investigated and

determine whether or not the current set of investigations are enough to identify all the potential causes of iron deficiency, especially GI malignancy. We identified asymptomatic patients with ID but without anaemia from our local database. Men and post-menopausal women with age over 50 years and without prior diagnosis of any cause of ID were included. Patients were labeled to have ID if serum ferritin was low (less than 15mg/dl) with a normal haemoglobin level (Hb > 115mg/dl). Proportion of patients screened for coeliac disease (CD) was also calculated. Data was analyzed to find out new cases of CD and colorectal carcinoma.

Results: Clinical notes of 444 patients were analyzed and only 76 patients (15.09%) met the eligibility criteria, having a median age 66.5 ± 9.4 years. Fifty two patients (68.4%) were male. Screening for CD was carried out in 29 (38.2%) patients. All the patients had upper GI endoscopy done. Only 23 patients (30.3%) had undergone either colonoscopy or CT colonogram. None of the patients were found to have upper gastrointestinal malignancy. Two new cases of celiac disease (2.9%) and one new case of colorectal malignancy (1.4%) were diagnosed. GI inflammation or ulceration was diagnosed in 32 (42.1%) patients.

Conclusion: We may conclude that all men and post-menopausal women with evidence of iron deficiency but without anemia should be investigated exactly in the same way as we investigate patients with iron deficiency anaemia. Special emphasis on lower gastrointestinal endoscopy if no significant cause of anaemia is found on upper GI endoscopy.

Contact E-mail Address: msseo.md@gmail.com

Introduction: Endoscopic Submucosal Dissection (ESD) enables en bloc resection of large colorectal neoplasia. However, because of the technical difficulty in colorectal ESD, en bloc resection cannot be achieved in all ESD cases. The aim of our study is to compare the outcomes between en bloc ESD and piecemeal ESD and to identify the risk factors of piecemeal ESD for colorectal neoplasia.

Aims & Methods: We reviewed the medical records of patients who underwent ESD for colorectal epithelial neoplasia, between January 2005 and April 2014 in Asan Medical Center. Patients who did not undergo follow-up endoscopy or who needed subsequent surgery and/or chemoradiation were excluded from the analysis. We analyzed complication, histologically complete resection, and recurrence rate between en bloc ESD cases and piecemeal ESD cases.

Results: Among a total of 494 patients who underwent ESD for colorectal epithelial neoplasia, en bloc ESD and piecemeal ESD were performed in 426 (86.2%) cases and in 68 (13.8%) cases, respectively. The mean tumor size was not different between en bloc ESD (32.4 ± 16.4 mm) and piecemeal ESD group (31.9 ± 10.8 mm) (p = 0.738). The proportion of adenoma, mucosal adenoacrarcinoma and submucosal adenocarcinoma was not statistically different between two groups. Histologically complete resection was more frequent in the en bloc ESD group compared with the piecemeal ESD group (80.5% vs. 61.8%, respectively; p = 0.001). The overall local recurrence rate was 1.6% (8/494). The local recurrence rate was higher in the piecemeal ESD group than in the en bloc ESD group (5.9% vs. 0.9%; p = 0.015). In univariate analysis, piecemeal ESD (OR = 6.59, 95% CI 1.61-27.03; p = 0.015), tumor size ≥35 mm (OR = 13.74, 95% CI 1.68-112.65; p = 0.003), histologically incomplete resection (OR = 6.12, 95% CI 1.44-26.04; p = 0.015), and moderate experienced endoscopist who had performed between 100 and 200 ESD cases (OR = 10.63, 95% CI 2.11-53.41; p = 0.002) were associated with local recurrence after ESD. There was no difference in perforation rate and delayed bleeding between the two groups. Piecemeal ESD was associated with sessile tumor (OR = 1.81, 95% CI 1.04-3.16; p = 0.035), hybrid ESD method (OR = 35.71, 95% CI 18.18-71.43), intraprocedural bleeding (OR = 3.55, 95% CI 1.63-7.69; p = 0.002) in the univariate analysis. Level of endoscopists' experience in ESD was not associated with piecemeal ESD. Multivariate analysis revealed that hybrid ESD (OR = 36.09, 95% CI 18.09-71.99; p < 0.001) and intraprocedural bleeding (OR = 3.71, 95% CI 1.26-10.93; p = 0.017) were independent risk factors of piecemeal ESD.

Table 1: local recurrence of en bloc and piecemeal ESD

	En bloc ESD (n = 426)	Piecemeal ESD (n = 68)	p value
Number of follow up endoscopy	1.9 ± 1.2	2.1 ± 1.3	0.154
Median follow up (IQR), months	15.5 (12.3 - 30.7)	13.7 (6.9 - 33.5)	0.278
Local recurrence	4 (0.9)	4 (5.9)	0.015

Conclusion: Local recurrence was significantly frequent in piecemeal ESD compared with en bloc ESD. Hybrid ESD technique and intraprocedural bleeding were independent risk factors for piecemeal ESD.

P1391 PSYCHOMOTOR AND COGNITIVE EFFECTS OF A 15 MINUTE INHALATION OF METHOXYFLURANE IN HEALTHY VOLUNTEERS: IMPLICATION FOR POST-COLONOSCOPY CARE

N. Q. Nguyen[1], J. E. Burgess[1], L. Toscano[1], T. L. Debreceni[1]
[1]*Department of Gastroenterology & Hepatology, Royal Adelaide Hospital, Adelaide, Australia*

Introduction: In addition to its use in ambulance services, portable inhaled methoxyflurane (Penthrox®, 3ml) has been successfully used as a form of patient-controlled analgesia for colonoscopy in both unselected and high-risk patients (Nguyen *et al* 2013, Nguyen *et al* 2015). More importantly, the use of Penthrox® for colonoscopy has been shown to be safe, cost effective and allowed earlier discharge due its lack of sedation. It remains unclear, however, whether it is safe for patients to drive and/or return to work after short-term Penthrox® inhalation.

Aims & Methods: The aim is to evaluate the psychomotor and cognitive effects of 15 minutes inhalation of Penthrox® in adult healthy volunteers. Each of the 50 healthy volunteers, age from 18 to 80 years, were studied on 2 occasions with either Penthrox® or placebo (normal saline with methoxyflurane odor) in a randomized, double-blind fashion. On each occasion, the subject's psychomotor function was examined before, immediately after, and at 30, 60, 120, 180 and 240 min after completion of a 15-min inhalation of the studied drug. Psychomotor and cognitive performance was evaluated by validated Digit Symbol Substitution Test (DSST), auditory reaction time (ART) test, eye-hand coordination (EHC) test trail making test (TMT) and logical reasoning test (LRT).

Results: Compared to placebo, a 15-min Penthrox® inhalation led to an immediate modest impairment of DSST (P < 0.001), ART (P < 0.001), EHC (P < 0.01), TMT (P = 0.02) and LRT (P = 0.04). In all subjects, the performance of all five tests normalized by 30 minutes after inhalation, and was comparable to that of placebo. Although increasing age associated with a deterioration in the performance of all five psychomotor tests, the effects of Penthrox® remained similar and were comparable amongst all age groups.

Conclusion: In all age groups, a 15 minute inhalation of methoxyflurane induces an acute but very short-lasting impairment of psychomotor and cognitive performance, which returns to normal within 30 minutes after inhalation. These findings indicate that subjects who use inhaled Penthrox® for colonoscopy can safely return to tasks that require high psychomotor skills such as driving and work on the same day.

P1392 THE AER-O-SCOPE COLONOSCOPE SYSTEM IS SAFE AND EFFECTIVE FOR COLONOSCOPY IN HUMANS

N. Gluck[1], A. Melhem[2], Z. Halpern[1], K. Mergener[3], S. Goldfarb[4], E. Santo[2]
[1]*Research Center for Digestive and Liver Diseases, Department of Gastroenterology,* [2]*Gastroenterology, Sourasky Medical Center, Tel-Aviv, Israel,* [3]*Digestive Health Specialists, Tacoma, United States,* [4]*GI View Ltd., Ramat-Gan, Israel*

Contact E-mail Address: nathang@tlvmc.gov.il

Introduction: The self-propelled, disposable Aer-O-Scope Colonoscope (AOS) with 360° view is designed to enhance visualization as well as minimize risk for perforation and infection transmission, while shortening operator training time associated with conventional colonoscopy (CC).

Aims & Methods: We evaluated AOS safety and efficacy for cecal intubation. Prospective patients presenting for colorectal cancer screening underwent AOS immediately followed by CC. Initial patients necessary for AOS operators to achieve proficiency made up the "training cohort". Subsequent enrolled patients made up the "study cohort".

AOS colonoscopy was performed to the cecum, where anatomic landmarks were photographed and mucosal suction-marks placed. During AOS withdrawal, polyps were recorded and similarly marked. At second-pass (using CC), any potential mucosal damage and suction-marks from the AOS, as well as polyps, were recorded.

Main endpoints included: 1) AOS cecal intubation rates, confirmed by anatomic landmarks and residual marks seen at subsequent CC. 2) Frequency and severity of adverse events and mucosal damage with AOS. Secondary endpoints were: 1) Subjective procedure-proficiency, evaluated by the operator based on the training cohort 2) Documenting pathologies visualized with AOS.

Results: 56/58 enrolled patients completed the study. Proficiency with AOS was attained after 8-10 procedures. Cecal intubation was successful in 98.2% (55/56 subjects, 95%CI 90.4-99.9%), including 100% (95%CI 90.7-100%) of the study cohort and 94.4% (95%CI 72.7-99.9%) of the training cohort. No mucosal damage or adverse events were reported. AOS detected 87.5% of polyps seen in tandem CC, including all polyps > 5 mm.
Conclusion: AOS was highly successful, simple to use and safe in attaining complete colonoscopy (cecal intubation).

P1393 ONE-YEAR FOLLOW-UP COLONOSCOPY AFTER CURATIVE RESECTION OF COLORECTAL CANCER: IS IT WORTHWHILE?

N. Panigadi[1], L. Pereyra[1], M. Bun[1], A. Canelas[1], R. A. Gonzalez[1], M. Omodeo[1], E. Gomez[1], J. M. Mella[1], C. Fischer[1], P. Luna[1], N. Rotholtz[1], S. C. Pedreira[1], D. Cimmino[1], L. Boerr[1]
[1]*Hospital Aleman, Buenos Aires, Argentina*

Contact E-mail Address: guinipa@gmail.com
Introduction: Colonoscopic follow-up after colorectal cancer resection (CRC) is recommended to screen for metachronous neoplasia. Although a one-year interval has been suggested, guidelines vary in the timing recommendation for the first investigation
Aims & Methods
Aim: To determine the prevalence of, and risk factor for metachronousneoplasia after curative resection of colorectal cancer among patients undergoing one year follow-up colonoscopy.
Methods: The baseline clinical and colonoscopic data and follow-up details of patients who had a one-year follow-up colonoscopy after curative colorectal resection between January 2004 and October 2014 in a teaching hospital were analyzed. Metachronous colonic lesion was defined as the presence of adenomas, advanced neoplastic lesions (ANL) (>75% villous component, high-grade dysplasia or size > 10mm) or CRC occurring after 12 month of the indexcolonoscopy. Univariate and multivariate analyses were performed to identify risk factors for metachronous adenoma, ANL and CRC. Risk was expressed in odds ratio (OR) with its corresponding 95% confidence intervals (CI).
Results: A total of 143 patients who underwent surveillance colonoscopy between 12 and 18 months after index colonoscopy, were included. The median age was 64(30-90) years and 55% were male. The prevalence of metachronousadenomas and ANL was 28/143(15%) and 7/143(4%) respectively. No metachronous CRC was found. Among the clinical and colonoscopic baseline characteristics the presence of synchronous adenoma (OR 4.2 CI 1.7 – 10.78, p0.001) and ANL (OR 3.21 CI 1.21 – 7.74, p 0.013) were independently associated with presence of metachronous adenomas on one-year follow-up colonoscopy. Presence of ANL on index colonoscopy was the only independentpredictor of metachronous ANL on one-year follow-up colonoscopy.
Conclusion: We found a relatively low prevalence of metachronous ANL and no CRC on one-year follow-up colonoscopy after curative resection of colorectal cancer. However patients with adenomas and ANL at baseline colonoscopy showed a higher risk of presenting metachronous colonic neoplasia, and therefore may benefit from this endoscopic interval.

Introduction: Endoscopic resection of dysplastic lesions in colitis (UC) has been controversial. En bloc resection of the lesion is preferable to allow precise pathologic assessment and minimize recurrence. Endoscopic Submucosal Dissection (ESD) offers this possibility but the comprehensive submucosal fibrosis from long term inflammation may increases the procedural risks and reduces complete resection.
Aims & Methods: In order to assess technical feasibility, multicentres experiences in ESD for UC dysplasia were retrospectively reviewed. Submucosal (sm) condition, namely fibrosis and fat deposition were carefully scored.
Results: Total 26 dysplastic lesions were enrolled (18 UK and 8 Japan). Patient mean age was 62 (49-86) and mean UC duration was 17 years (12-30). Macroscopically lesions were classified into IIa 2, IIa + IIb 6, IIa + IIc 1, Is 2, Is+IIa 2, LST-G 8 and LST-NG 5. Median size was 28.0mm (range5-68mm). They were located in rectum (18) including 4 lesions extended over dentate line , RS (3), SC (4) and on pouch anastomosis (1). Sm fibrosis was observed in all cases (mild 10, mod 11, severe 5) and fat deposition was observed in 9 cases (fat deposition only upper sm 5, whole sm 4).
Enbloc resection was possible in 23/26 cases. Failure of enbloc resection was due to patient intolerance (2), severe fibrosis (1) and extensive fat deposition (1). One patient had delayed bleeding on day3 post procedure. R0 resection was confirmed in 17 cases. Histology showed T1 cancer (2), high-grade dysplasia (6), low-grade dysplasia (17) and regenerative atypia (1). Three patients received panproctocolectomy afterwards. At the first follow up one patient had tiny recurrence (3 mm) which was further treated endoscopically. Hence no recurrence was observed in all patient (n = 16) who had further follow up within median 31 months (3-60).
Conclusion: ESD was feasible for UC dyplasia without an increase rate of complications. However, submucosal fibrosis and fat deposition were frequently observed which contributed to technical complexity. Due to lesions' subtlety, extra wider margin was warranted in order to achieve R0 resection.

P1395 OPTICAL DIAGNOSIS OF DIMINUTIVE COLON POLYPS: EXPERIENCED ENDOSCOPISTS BASELINE PERFORMANCE IS NO DIFFERENT TO MEDICAL STUDENTS - A CLEAR TRAINING PATHWAY IS REQUIRED

P. J. Basford[1], J. Brown[2], S. Cooper[2], B. Higgins[3], P. Bhandari[1]
[1]*Gastroenterology, Portsmouth Hospitals NHS Trust,* [2]*Pharmacy and Biomedical Science,* [3]*Mathematics, University of Portsmouth, Portsmouth, United Kingdom*

Contact E-mail Address: petebasford@hotmail.com
Introduction: Accurate optical diagnosis of diminutive colon polyps (DCPs) has been identified as a key goal for advanced endoscopic imaging techniques by the ASGE and ESGE. In-vivo studies show differences in performance between expert and non-expert endoscopists. Training and accreditation pathways for optical diagnosis of DCPs have yet to be established.
Aims & Methods: We aimed to compare the baseline optical diagnosis skills for characterising DCPs of 3 groups with varying experience of colonoscopy, and assess the impact of a novel web-based training module. Participant groups comprised Medical Students (n = 7, 0-5 colonoscopies observed), Gastroenterology Trainees (n = 7, median 120 colonoscopies performed) and Consultants (n = 7, median 3000 colonoscopies performed).
Participants undertook a test module comprising 90 randomised images of diminutive colonic polyps viewed with high definition white light (30), Pentax i-Scan image enhancement (30) and 0.2% indigocarmine chromoendoscopy (30) for which histology was predicted (adenomatous vs hyperplastic). Confidence ratings were also assigned to all predictions. Results were compared to known histopathology.
2 expert endoscopists validated the test module and obtained 86.7% accuracy. Participants then completed an interactive web-based training module before repeating the test module.
Results: Overall accuracy did not differ significantly between the three groups prior to the training module (P = 0.322) or following the training module (p = 0.708). Overall accuracy improved significantly following the training module for all 3 groups. However it remained below that of the 2 expert endoscopists (P < 0.02 for all 3 comparisons).
No significant difference in mean accuracy between the three modalities (HDWL/i-Scan/Chromo) was found pre-training. Post-training mean accuracy for WL and IC images was significantly higher than for i-Scan images (P = 0.002 & P < 0.001).
Mean kappa values and the proportion of high confidence predictions increased significantly for all 3 groups following the training module (Pre training MS/Trainees/Cons 0.106/0.298/0.216, post training 0.472/0.541/0.371). The proportion of high confidence predictions also increased significantly for all 3 groups following the training module.
Conclusion: Baseline optical diagnosis skills amongst experienced endoscopists are no higher than medical students or trainees. It appears that optical diagnosis is a specific skill which cannot be gained through experience of colonoscopy alone.
A brief web-based training intervention produces significant improvement but overall accuracy levels remain below that required to replace histopathology and hence formal training pathways need to be established and incorporated into gastroenterology training programmes.
In this study HDWL imaging was at least as accurate as advanced endoscopic imaging and chromoendoscoy before and after training.
Disclosure of Interest: None declared

Abstract number: P1395

Group	Medical Students				Trainees				Consultants			
Modality	HDWL	i-Scan	Chromo	Overall	HDWL	i-Scan	Chromo	Overall	HDWL	i-Scan	Chromo	Overall

Post-Training	73.3%	63.3%	71.0%	69.2%	71.9%	66.7%	74.8%	71.1%	73.3%	65.2%	75.2%	71.3%

P1396 DEFINING THE OPTIMAL I-SCAN SETTINGS FOR SMALL COLONIC POLYP CHARACTERISATION – RESULTS FROM A LARGE PROSPECTIVE SERIES

P. J. Basford[1], G. Longcroft-Wheaton[1], P. Bhandari[1]
[1]*Gastroenterology, Portsmouth Hospitals NHS Trust, Portsmouth, United Kingdom*

Contact E-mail Address: petebasford@hotmail.com

Introduction: Characterisation of small colonic polyps has been identified as a key goal for advanced imaging modalities by the ASGE and ESGE. Pentax i-Scan is an endoscopic digital contrast technology which has been shown to be accurate tool for characterising small colonic polyps in-vivo. I-Scan combines features which accentuate dark-light borders (surface & contrast enhancement, SE/CE) and suppression of red light whist enhancing blue/green light (tone enhancement, TE). The optimal settings for use of i-Scan in the colon have yet to be determined.

Aims & Methods: High-quality digital images of 100 small colonic polyps were recorded as part of a prospective study (NCT 01761279). Images of each polyp were recorded in 3 i-Scan modes: i-Scan 1 (SE/CE), i-Scan 2 (TE) & i-Scan 3 (SE/CE/TE). Randomised images were viewed by 2 blinded endoscopists who rated visibility of diagnostic features predicted polyp histology (neoplastic vs non-neoplastic).

Results: The proportion of adenomas rated as having visible pericryptal vessels were 59%, 81% and 82% for i-Scan 1, 2 & 3 respectively. The differences between i-Scan 1 and 2 ($P = 0.001$) and i-Scan 1 and 3 ($P < 0.001$) were statistically significant.

The difference in proportion of adenomas with no visible surface pattern between i-Scan 1 and 2 was statistically significant (26% vs 8%, $P = 0.001$), as was the difference between i-Scan 1 and 3 (26% vs 9%, $P = 0.003$). There was no significant difference between i-Scan 2 and 3 (8% vs 9%, $P = 1.00$).

Mean sensitivity for adenomatous histology between the two endoscopists was 69% for polyps viewed with i-Scan 1. Compared to i-Scan 1 assessments sensitivity was significantly higher with i-Scan 2 (86%, $P = 0.006$ for comparison), and with i-Scan 3 (87%, $P = 0.003$ for comparison). There was no significant difference in sensitivity between i-Scan 2 and i-Scan 3 assessments (86% vs 87%, $P = 1.000$).

No significant differences in specificity were found between the 3 i-Scan modes (i-Scan 1 vs i-Scan 2 $P = 0.828$, i-Scan 1 vs i-Scan 3 $P = 1.000$, i-Scan 1 vs i-Scan 3 $P = 1.000$).

Overall accuracy increased from 79% with i-Scan 1 to 86.5% with i-Scan 2 and 87.5% with i-Scan 3. There was no significant difference in overall accuracy between i-Scan 1 and i-Scan 2 ($P = 0.063$) or i-Scan 2 and i-Scan 3 ($P = 0.882$). However there was a significant difference between i-Scan 1 and i-Scan 3 assessments ($P = 0.032$).

	i-Scan 1 (SE + CE)	i-Scan 2 (TE)	i-Scan 3 (SE + CE + TE)
Sensitivity	69/100 (69%)	86/100 (86%)	87/100 (87%)
Specificity	89/100 (89%)	87/100 (87%)	88/100 (88%)
Accuracy	158/200 (79%)	173/200 (86.5%)	175/200 (87.5%)

Conclusion: Tone enhancement appears to be the most effective component of the i-Scan system for accurate small colonic polyp characterisation, with no additional benefit from the addition of surface/contrast enhancement.

P1397 COMPARISON OF DIATHERMY SNARE AND COLD SNARE POLYPECTOMY IN SMALL AND DIMINUTIVE ADENOMATOUS POLYPS WITH REGARDS TO COMPLETENESS OF RESECTION

P. Jeschek[1], E. Waldmann[1], I. Gessl[1], D. Sallinger[1], M. Ferlitsch[1]
[1]*Gastroenterology and Hepatology, Medical University of Vienna, Vienna, Austria*

Contact E-mail Address: philip.jeschek@meduniwien.ac.at

Introduction: The proper choice of polypectomy instrument and resection method is crucial regarding completeness of resection. To our knowledge, to date no study compared hot and cold snare regarding completeness of resection.

Aims & Methods: We analyzed data from the Austrian colorectal cancer screening program which was provided by participating endoscopists using a standardized form, between 2012 and 2015. In order to accurately attribute histologic findings regarding completeness of resection, exclusively procedures with resection of only one adenomatous polyp, reporting details on snare resection type, were analyzed.

Results: An overall of 1383 resections of diminutive and small polyps were analyzed.

Within the group of diminutive polyps (< 5mm, $n = 388$), resection was graded complete in 81.6% when using hot snare (HS) versus 81.2% (RR 0.99; $p = 0.91$) when using cold snare (CS). In an equal share of polypectomies completeness was graded as uncertain (HS 17.2% vs. CS 17.4%; RR 1.01; $p = 0.96$). Complete resection clearly could not be achieved in 1.2% in the HS groups vs. 1.4% in the CS group (RR 1.21; $p = 0.79$).

As for small polyps (5-10mm, $n = 995$), resection was graded complete in 87.5% when using hot snare (HS) vs. 92.4% (RR 1.06; $p = 0.037$) when using cold snare (CS). Completeness of resection was graded as uncertain in 10.7% in the HS group versus 6.8% in the CS group (RR 0.64; $p = 0.07$), while complete resection clearly failed in 1.7% in the HS groups vs. 0.8% in the CS group (RR 0.46; $p = 0.45$).

Conclusion: With regards to completeness of resection in polypectomy of diminutive adenomatous polyps, HS and CS performed equally well. As for polypectomy of small adenomatous polyps, a higher rate of complete resection might be achieved when using CS.

P1398 COLORECTAL ESD AND MANAGEMENT OF PERFORATION BY SECOND GENERATION MASTER ROBOTIC PLATFORM IN ANIMAL MODEL

P. W. Chiu[1], L. Phee[2], K. Y. Ho[3]
[1]*Chow Yuk Ho Technology Center for Innovative Medicine, The Chinese University of Hong Kong, Hong Kong, Hong Kong,* [2]*School of Mechanical & Aerospace Engineering, Nanyang Technological University,* [3]*Department of Medicine, National University of Singapore, Singapore, Singapore*

Contact E-mail Address: philipchiu@surgery.cuhk.edu.hk

Introduction: Our group previously reported a multicenter clinical trial on the safety and efficacy of Master and Slave Transluminal Endoscopic Robot (MASTER) for performance of gastric endoscopic submucosal dissection (ESD) in 5 patients with early gastric neoplasia [1]. The first prototype of MASTER is limited by the inability to exchange the robotic arms, as well as incapability to move the endoscope independent of the arms [2]. The second prototype was developed to address these issues.

Aims & Methods: The second-generation prototype of MASTER was developed with additional degrees of freedom from the robotic arms, the ability to exchange the two arms during dissection, as well as an independent platform to allow separate movement of the endoscope. With the improvement, a standardized protocol for performance of Robotic endoscopic ESD was commenced. The performance of colonic ESD using new MASTER system with the standardized protocol was tested in an ex-vivo porcine model as well as a live porcine model. Moreover, the management of perforation after ESD using the MASTER robotic platform was also examined.

Results: This is a preclinical experiment on three procedures conducted by 2nd generation MASTER. The first procedure was the performance of ESD for resection of a 5 x 5cm imaginary lesion in ex-vivo porcine model. After submucosal injection, mucosal incision was performed using the diathermy hook of one robotic arm at the proximal mucosa. The mucosal was then grasped with the second arm and further mucosal incision was performed around the lesion. Submucosal dissection was performed with clear exposure through adequate retraction of the mucosa. After complete submucosal dissection, the remaining mucosal attachment was resected. The same technique was applied for performance of MASTER robotic rectal ESD in live pig model. The procedure was successful with the specimen size of 30 x 30mm and the operative time was 53 minutes. After the procedure, an artificial perforation was created using the needle knife. The perforation was first grasper by the robotic arm at one edge, pulled laterally to reduce its size thereby minimizing gas leakage, and allowing targeted clip closure. The perforation was successfully closed by endoclip.

Conclusion: The second generation of MASTER robotic system allowed intuitive manipulation, dissection as well as clear endoscopic view for performance of colorectal ESD. The robotic arm also allowed grasping of the perforation to facilitate closure with endoclips.

Introduction: The prevention of colorectal cancer (CRC) by colonoscopy is attributed to the identification and removal of adenomas. A significant number of adenomas are missed during Standard Colonoscopy (SC), e.g., due to polyps hidden behind colon folds and flexures. The newly developed G-EYE™ Endoscope (SMART Medical Systems Ltd, Ra'anana, Israel) combines a forward viewing endoscope with an integral, reusable balloon at its bending section. During withdrawal of the G-EYE™ Endoscope, the balloon is partially inflated, allowing for the flattening of colon folds, centralization of the optical image, and

reduction in bowel slippage, thus providing enhanced visualization of the colon and increased detection of polyps and adenomas.
Aims & Methods: The aim of this study is to compare the adenoma detection rate (ADR) of G-EYE^{TM} high definition (HD) colonoscopy with that of standard HD colonoscopy. From May 2014 to April 2015, patients (age > 50) referred to colonoscopy for screening, surveillance, following positive fecal occult blood test (FOBT), or due to change of bowel habits, were randomized to either SC group or G-EYE^{TM} group. The G-EYE^{TM} Endoscope was based on the same instrument as the conventional HD-colonoscope.
Results: 360 subjects were enrolled to the study, of which 177 subjects were randomized to the SC group and 183 subjects were randomized to the G-EYE^{TM} group. The ADR, adenoma per patient, number of advanced adenomas and large-size adenomas for each group are presented in Table 1. Compared with conventional colonoscopy, G-EYE^{TM} colonoscopy increased ADR by 58%. Special attention should be given to 55% and 56% increase in number of advanced adenomas and large-size adenomas, respectively. Procedural times were similar between the two groups.
Table 1: Results summary

	SC	G-EYE	% increase
ADR	31%	49%	58%
Adenoma per patient	0.48	0.89	85%
Advanced adenomas	22	34	55%
Large adenomas (≥10mm)	16	25	56%

Conclusion: Our study has shown that the G-EYE^{TM} endoscope has a substantially higher ADR, compared to SC, which is considered to be one of the indicators for quality in colonoscopy. Moreover, the G–EYE^{TM} endoscope is able to detect not only small and diminutive adenomas but also a larger number of advanced and large size adenomas. It is therefore concluded that the G-EYE^{TM} has the potential to reduce colonoscopic miss rates and reduce interval cancer incidents.

Introduction: Electrocautery may induce deep thermal injury with transmural necrosis of the bowel, named coagulation syndrome (CS). Prevention of CS is important to avoid unnecessary surgical procedures given the increasing number of endoscopic resections performed every year. To date we do not have any approved endoscopic treatment to avoid the development of CS.
Aims & Methods: The aims of this study were to assess the efficacy of a newly developed hydrogel (patent pending) to prevent CS and to verify experimentally the safety of this treatment procedure.
Colonic microperforation secondary to thermal injury was obtained according to our rat model (1). Lesions were performed in 24 male Sprague-Dawley rats (400-450 g) under general anesthesia. Animals were randomized to receive on of the following sprayed treatments (8-rats each) onto the lesions, as a shield (Endoscopic Shielding Technique or EST): saline control (SC), sodium hyaluronic acid sodium salt 1% w/w (comparative example) and the developed hydrogel (product). Rats underwent endoscopic follow-up at 48h and 1 week. TNF-a plasma levels were determined at 48h. All survival animals were sacrificed after 7 days and ulcers sites were macroscopically and histopathologically evaluated.
Results: Animals treated with product obtained the best results in comparison with control and comparative groups, avoiding mortality (0% vs 50% and 25%; $p = 0.038$), and avoiding or reducing the risk of perforation at 7 days (0% vs 100% and 33.3%; $p = 0.02$); respectively. Mucosal healing rate (percentage of mucosal restoration) at 7 days was significantly higher with product (70% vs 30.3% and 47.2%; $p = 0.003$). Physiological healing (absence of submucosal fibrosis) was significantly higher with product (6 of 8 animals, 75%) than in saline (0 of 4 animals, 0%) and hyaluronic acid (4 of 6 animals, 66.6%) ($p = 0.02$). TNF-α levels were significantly lower with product and hyaluronic acid than in control group (344.5 ± 28.2 and 338.1 ± 17.2 vs 627.58 ± 52; $p < 0.05$).
Conclusion: Our study has demonstrated that the application of this newly hydrogel in a rat model of colon microperforation is able to prevent CS.

P1401 PROBE-BASED CONFOCAL LASER ENDOMICROSCOPY (PCLE) FOR ANGIOGENESIS EVALUATION IN LOCALLY ADVANCED RECTAL AND GASTRIC CANCERS

R. Cannizzaro[1], E. Orzes[1], P. Spessotto[2], S. Maiero[1], M. Mongiat[2], V. De Re[3], V. Canzonieri[4], M. Fornasarig[1]
[1]*SOC Gastroenterology,* [2]*Experimental Oncology,* [3]*Bioproteomic Core Facility/BIT,* [4]*Pathology, Centro Riferimento Oncologico, Aviano, Italy*

Contact E-mail Address: rcannizzaro@cro.it
Introduction: Probe-based Confocal Laser Endomicroscopy (pCLE) is an innovative endoscopic technique that allows taking high resolution images of the mucosa, facilitating the identification of cellular and subcellular microstructures allowing an evaluation of the microvasculature during endoscopic examination. Angiogenesis is a hallmark of cancer development inducing the formation of new vasculature to support its growth.
Aims & Methods: The aim of our study was to evaluate tumor neoangiogenesis through pCLE imaging in locally advanced gastric and rectal cancer patients, before and after neoadjuvant radio-chemotherapy (RT/CT).
68 consecutive patients affected by Rectal Cancer (RC, 17F, 51M mean age: 64 years) and 23 consecutive patients with Gastric Cancer (GC, 6F, 17 M mean age: 65 years) underwent endoscopy with pCLE-GastroFlex UHD probe (Mauna Kea Technologies) and i.v. fluorescein infusion in order to evaluate intratumoral vascularization and to evaluate the efficiency of blood flow. After RT/CT treatment, 32 RC (25M, 7F) and 5 GC (1F, 4M) patients were revaluated using pCLE; neoangiogenesis was evaluated according to Cannizzaro-Spessotto (CS) scale, assigning one point to each of the following features: tortuous vessels, large vessels, leakage and defective flux.
Results: 19 out of 32 (59.4%) RC and 2 out of 5 (40%) GC patients showed an improvement of angiogenesis index, while in the remaining 13 RC (40.6%) and 3 GC (60%) there were no changes of the vascular architecture following the treatment. There was a significant difference ($p = 0.00$) in neoangiogenesis CS scores between RC pre- (median CS score: 3.0) and post-RT/CT (median CS score: 2.0), while there's not difference ($p > 0.05$) between GC patients pre- (median CS score: 2.0) and post-therapy (median CS score: 2.0).
Conclusion: Our data show a better reactivation of vessels' morphology and functions in RC patients, with an improvement of angiogenesis index. In GC patients median angiogenesis index remained unmodified, without positive changes in vascular morphology, probably due to the presence of fibrosis. The results of our work demonstrate that pCLE technique is suitable to evaluate the alterations of the intratumoral microvasculature and reveal a functional improvement of vasculature in post-therapy RC patients. It may constitute a innovative approach in order to identify subjects that respond to the therapy, improving the outcome of the patients.

P1402 LARGE LOW RECTAL VS. HIGH RECTAL POLYPS: OUTCOME DATA FROM A LARGE PROSPECTIVE SERIES

R. Bhattacharyya[1], F. J. Q. Chedgy[1,1], K. Kandiah[1], G. Longcroft-Wheaton[1], F. Thursby-Pelham[1], P. Bhandari[1]
[1]*Gastroenterology, Queen Alexandra Hospital, Portsmouth, Portsmouth, United Kingdom*

Contact E-mail Address: rupam.bhattacharyya@gmail.com
Introduction: Low rectal polyps are considered to be more challenging to resect than high rectal polyps.
Aims & Methods: We aim to compare the safety, feasibility and outcomes of endoscopic resection of low rectal polyps (originating within 5cm of dentate line) versus the mid to high rectal polyps. Cohort study of patients referred to our centre. All patients who had endoscopic resection (EMR or Knife assisted resection) of rectal polyps over 20mm in size from 2009 to July 2014 were included. All procedures were performed by a single experienced endoscopist. Benign LST-G type lesions were resected by conventional EMR technique but polyps close to dentate line, those with scarring, and flat LST-NG type lesions were resected either by full ESD or Knife assisted resection technique.
Results: 181 polyps resected in 179 patients. Average patient age 71 years. Mean polyp size 50mm (range 20-170mm). Mean patient follow up 3 years. Referrals were due to large polyp size, proximity to dentate line, growth on haemorrhoidal bed, more than 50% circumference involvement or scarring due to previously failed EMR attempts. Polyp characteristics: 61 (33.7%) > 50mm, 34 (18.8%) scarred, 109 (60.2%) high rectum, 72 (39.8%) low rectum.
110/181(60.8%) were resected by ESD and 71/181(39.2%) by EMR. 60/181(33.2%) were resected en bloc. Histology showed 8(4.4%) cancers, 27(15%) HGD and 146(80.5%) LGD/non dysplastic lesions. There was no significant difference between high and low rectal lesions.

Follow up was available for 158. Endoscopic cure rate: 147/158(93%). Of these 124/147(84%) required 1 attempt, 17/147(11.5%) required 2 and 6/147(4.5%) required more than 2 attempts to achieve complete cure. Recurrence/residual polyp after first attempt was seen in 30/158 (19%) of patients. Univariate analysis showed that recurrence was significantly linked to size > 50mm, piecemeal resection, low rectal lesions and the presence of scarring (table).
The complication rate was 14/181(7.7%) which were all managed conservatively. There was 1(0.5%) significant intraprocedural bleed. There were 7(3.9%) delayed bleeds (2 needing transfusion), 1(0.5%) post polypectomy syndrome and 5(2.7%) cases of exposed muscle fibres which were clipped during the procedure with no further sequelae. There were no factors significantly predictive of complications.
Table 1: Factors associated with recurrence

	SIZE		RESECTION TYPE		SITE		SCARRING	
RECURRENCE30/158 (19%)	≤50mm	>50mm	En bloc	Piecemeal	High rectum	Low rectum	Yes	No
13/108 (12%)	17/50 (34%)	3/57 (5.2%)	27/101 (26.7%)	13/93 (14%)	17/65 (26.1%)	11/28 (39.3%)	19/130 (14.6%)	
p = 0.001		p = 0.001		p = 0.05		p = 0.003		

Conclusion: Rectal polyps referred for resection are generally very large in size (mean 50mm). It is safe and feasible to resect very low rectal polyps around the dentate line. The outcome data shows no difference in complication rates between low and high rectal polyps. Given the large sizes and rectal location, the low cancer rate reflects our careful lesion selection. Recurrence after the first attempt at endoscopic resection is higher in low rectal polyps and those with large size and scarring. However, repeat attempts can achieve complete clearance.

P1403 WHAT IS THE TRUE IMPACT OF IATROGENIC PERFORATIONS DURING COLONOSCOPY?

S. Campos[1], P. Amaro[1], F. Portela[1], C. Sofia[1]
[1]*Gastroenterology, Centro Hospitalar Universitário de Coimbra, Coimbra, Portugal*

Contact E-mail Address: saratcampos@gmail.com
Introduction: Colonoscopy is the gold standard exam to diagnose and treat colorectal lesions. It is a safe procedure, though the risk of iatrogenic injuries, including perforations, is not negligible. Traditionally, surgery was the first-line therapy in these cases. However, experience in endoscopic closure of perforations and the marketing of devices for this exact purpose have increased, thus making endoscopy a therapeutic option.
Aims & Methods
Objective: Evaluation of the perforations occurred during colonoscopy, their characteristics, treatment and prognosis.
Methods: A retrospective study of all patients with perforations secondary to colonoscopy treated in a tertiary hospital between 01-January-2006 and 01-Oct-2014. Analysis of demographic, endoscopic, radiological and therapeutic data.
Results: We identified 53 cases of perforation, 20 in colonoscopies performed in non-hospital environment (therapeutic-45%) and only with a surgical resolution. The 33 perforations occurred inhospital represent 0.12% of all colonoscopies carried out (n = 21.481). Patients: Male sex-56%; average age-71 years; colic diverticulosis-10%; prior abdominopelvic surgery-31%. Procedures: elective-93%; under sedation-21%; poor bowel preparation-56%; resident participation-35% (resident as the first performer-10 cases). Perforations: rectosigmoid location-35%; average lesions diameter-35mm; diagnosis during the procedure-51%. Treatment of perforations occurred in our unit (73% > therapeutic colonoscopies): 2-conservative, 12-endoscopic (10 successfully), 21-surgical (including the 2 cases with endoscopic approach failure). Comparing the endoscopic treatment (n = 10, G1) versus surgery (n = 22; G2): perforation size- 9mm (G1) / 28mm (G2); perforation location- 7/10 in rectum (G1), 5/21 in rectum and 5/21 transverse colon (G2); no differences in complications or mortality at 30 days.
Conclusion: Perforations in colonoscopy are rare in our clinical practice. Endoscopic closure was effective, though limited to perforations found during the procedure. The mortality is relatively low and this approach does not worsen it. An additional effort is necessary in order to detect perforations during colonoscopy.

P1404 WATER EXCHANGE IS SUPERIOR TO OTHER METHODS, ENHANCING ADENOMA AND HYPERPLASTIC POLYP DETECTION IN MALE SCREENING PATIENTS

S. Cadoni[1], M. Liggi[1], P. Gallittu[1], D. Mura[1], E. Murru[2], F. W. Leung[3]
[1]*P.O. S. Barbara, Iglesias (CI),* [2]*Preventive Medicine, Screening Center, Carbonia (CI), Italy,* [3]*Veteran Affairs, Sepulveda, and UCLA, Los Angeles, United States*

Contact E-mail Address: cadonisergio@gmail.com
Introduction: Patients may develop interval cancers (IC) after colonoscopy. High adenoma detection rate (ADR) is associated with reduced risks of IC, both in incidence and mortality. ICs, partly due to missed lesions, occur predominantly in the proximal colon (cecum to splenic flexure). There is only limited confirmation of the reproducibility of an increase in lesion detection by water exchange (WE, removal of water predominantly during insertion) seen largely in male colon cancer screening patients in U.S. studies [1-4]. In a mixed cohort of male European patients undergoing mainly diagnostic colonoscopy we confirmed these findings [DDW 2015 abstract #2144377].
Aims & Methods: The reproducibility of such observations in 50-70 year old Italian males undergoing first-time on-demand sedation screening colonoscopy was evaluated in a review (01.02.2012 to 31.12.2014) of a prospectively generated database. Split-dose bowel preparation was used to clean the colon. Insertion techniques: air insufflation (AI), water immersion (WI, removal of water predominantly during withdrawal) and WE. Primary outcome measure: overall ADR. Secondary outcome measures: proximal colon ADR, bowel preparation scores and real-time maximum insertion pain.
Results: 379 males were analysed (WE = 121; WI = 125; AI = 133). Demographics, cecal intubation rates, insertion and withdrawal times (around 13.4') were comparable in all study groups. Table 1 shows that **compared to AI**, **WE** achieved significantly higher overall and proximal colon ADR, and decreased the need for sedation. **WE (vs WI and AI)** achieved significantly higher Boston Bowel Preparation Scale scores and lowest real-time maximum insertion pain. Limitations: single-centre, unblinded study. The lack of significance in overall ADR of WE vs WI may be a type II error. Strengths: largest sample size compared with all previous reports.
Conclusion: As in male U.S. Veterans, WE is superior to air insufflation in enhancing overall and proximal colon ADR and in decreasing the need for sedation in male Italian patients undergoing screening colonoscopy. WE is superior to all the other techniques in enhancing colon cleanliness and minimizing insertion pain. Confirmation of these significant impacts in screening cases is important. WE, with the highest adenoma yield, may be relevant in addressing the issue of IC due to missed lesions. WE, with the lowest discomfort and decreased need for sedation, lessens patients' burden.

of our study was to assess the detection rate of colorectal lesions by comparing colonoscopy with the systematic mapping of proximal colon and white light colonoscopy.
Aims & Methods: In one institution, 222 asymptomatic patients (mean age 50.5) participated in study of screening colonoscopy, performed by a single endoscopist using colonoscope CF HQ190 (Olympus Medical Systems). Informed consents were obtained in all cases. Patients were excluded if the bowel preparation was inadequate, if they had an earlier diagnosed colorectal neoplasia or inflammation, or if they were receiving anticoagulant medication. Patients received intravenous propofol prior to intubation of the colonoscope. Complete colonoscopy was performed in 222 (100%) cases.
A conventional examination was performed in 98 patients. A further 124 patients were examined with the systematic mapping of cecum and ascending colon. Totally were performed at least 23 pictures for each patient: appendicular orifice, area proximal to ileocecal valve, overall view of cecum and four-quadrant pictures under each fold of ascending colon. All lesions identified during screening colonoscopy in both groups were removed completely. The two groups were similar with regard to age and gender. Mann-Whitney U Tests were used to determine differences between groups.
Results: There was not anything complications after colonoscopy. Results of colorectal lesions detection are shown in Table, the difference between two groups was insignificant (p value more than 0.05).

	Adenoma detection rate	Proximal adenoma detection rate	Proximal adenoma per patient	Patients with serrated polyp
Conventional colonoscopy	42%	32%	0.60	20%
Systematic mapping	42.7%	35.5%	0.59	23.4%

Conclusion: The results of our study show that there is not significant difference between conventional colonoscopy and systematic mapping for single colonoscopist. Multicenter study should be performed for evaluation of this approach of screening colonoscopy.
Disclosure of Interest: None declared

P1406 SCREENING COLONOSCOPY WITH INDIGO CARMINE DYEING: A BLUE CAP IS A SIGNIFICANT SIGN FOR SESSILE SERRATED POLYPS

S. Mouzyka[1]
[1]*Endoscopy, OLYMED Clinical GastroCentrum, Kiev, Ukraine*

Contact E-mail Address: mouzyka-sv@yandex.ru
Introduction: Sessile serrated polyps (SSP) are precancerous lesions, but they are often inconspicuous during screening colonoscopy. A mucous cap was described earlier as endoscopic marker for SSP detection. But, in case if mucus is not stained with bile, the visualization of SSP keeps very difficult. The aim of our study was to assess the effectiveness of a blue cap for the detection of SSP after dyeing colon mucosa by indigo carmine solution.
Aims & Methods: In one institution, 222 asymptomatic patients (mean age 50.5) participated in study of screening colonoscopy, performed by a single endoscopist using colonoscope CF HQ190 (Olympus Medical Systems). Informed consents were obtained in all cases. Patients were excluded if the bowel preparation was inadequate, if they had an earlier diagnosed colorectal neoplasia or inflammation, or if they were receiving anticoagulant medication. Patients received intravenous propofol prior to intubation of the colonoscope. Complete colonoscopy was performed in 222 (100%) cases. Totally 105 sessile lesions were detected and stained using 0.2% indigo carmine solution. All lesions and surrounding mucosa were washed actively using "water jet". Residual liquid was removed, after those endoscopic features were evaluated. In case if indigo carmine remains on lesions surface, a blue cap sign was considered. All lesions were removed endoscopically. Results of pathology examinations were compared with endoscopic features. The results of chromoendoscopy were unknown for pathologist.
Results: There was not anything complications after colonoscopy. All 76 lesions, which have had a blue cap sign, were classified pathologically as SSP. Sensitivity and specificity for detection of SSP were 93.9% and 100% respectively. There are no cases of adenocarcinoma in all patients.
Conclusion: The results of our study show that chromocolonoscopy with indigo carmine remains the effective method for differentiation of sessile colorectal lesions. A blue cap is a significant sign for endoscopic diagnosis of SSP.

P1407 DIAGNOSTIC CHARACTERISTICS OF DEPRESSED TYPE COLORECTAL NEOPLASMS IN MAGNIFYING CHROMOENDOSCOPY AND ENDOCYTOSCOPY

S.-E. Kudo[1], Y. Shakuo[1], S. Matsudaira[1], K. Ichimasa[1], Y. Fukami[1], K. Kato[1], Y. Kouyama[1], H. Oikawa[1], T. Hisayuki[1], Y. J. Kimura[1], Y. Mori[1], M. Misawa[1], T. Kudo[1], K. Kodama[1], K. Wakamura[1], T. Hayashi[1], A. Katagiri[1], H. Miyachi[1], T. Baba[1], E. Hidaka[1], F. Ishida[1]
[1]*Digestive Disease Center, Northern Yokohama Hospital, Yokohama city, Japan*

Contact E-mail Address: kudos@med.showa-u.ac.jp
Introduction: Colorectal cancers are generally recognized to develop from"polyps". This "adenoma-carcinoma sequence" theory has been in the mainstream of development of colorectal cancers. But recently the existence of many depressed-type cancers has been revealed, which are considered to emerge directly from normal epithelium, not through the adenomatous stage. This theory is called "de novo" pathway. Now, it is possible to presume the histology of colorectal lesions using magnifying endoscopy (pit pattern classification) and endocytoscopy (EC). We can observe not only the structural atypia but also the cellular atypia in living colorectal lesions. The aim is to clarify the diagnostic characteristics of depressed-type colorectal neoplasms, demonstrating the validity of pit pattern diagnosis and EC classification.
Aims & Methods: A total of 23725 colorectal neoplasms excluding advanced cancers were resected endoscopically or surgically in our unit from April 2001 to November 2014. Of these, 15404 lesions were low-grade dysplasia, 5003 were high-grade dysplasia and 1000 were submucosally invasive (T1) carcinomas. According to the developmental morphology classification, they were divided into 3 types: depressed, flat and protruded type. We investigated the rate of T1 carcinomas and the characteristics of depressed-type neoplasms concerning pit pattern and EC classification.
Results: The rate of T1 carcinomas in depressed-type lesions reached to 63.7%, meanwhile that in flat-type and protruded-type lesions was 4.1% and 3.1%, respectively. Within less than 5mm in diameter, that was 10.2%, 0% and 0.06%, respectively. Most (88.3% and 91.2%) of the flat-type and protruded-type lesions showed typeIII_L or IV pit pattern corresponding to adenomas, whereas 94.5% of the depressed-type lesions were characterized by type III_S, $?_I$ or $?_N$ pit pattern corresponding to carcinomas. As for endocytoscopy, most of the flat-and protruded-type lesions showed EC2 corresponding to adenomas. In contrast, the depressed-type lesions were observed as EC3a (24.4%) and EC3b (73.2%) corresponding to invasive carcinomas.
Conclusion: This study revealed the diagnostic characteristics of depressed-type lesions. They show typically typeIII_S,$?_I$ or V_N pit patterns in magnifying endoscopy and type EC3a or EC3b in endocytoscopy. These lesions tend to invade the submucosal layer even when they are small. Therefore, it is important to consider deeply and examine the developmental morphology of colorectal neoplasms.

P1408 DO ADJUVANTS REALLY ADD TO THE EFFICACY OF SPLIT-DOSE POLYETHYLENE GLYCOL-BASED BOWEL PREPARATIONS? A META-ANALYSIS OF RANDOMIZED CONTROLLED TRIALS

S. Restellini[1], O. Kherad[2], M. Martel[3], C. Ménard[4], A. N. Barkun[3]

Introduction: Polyethylene glycol (PEG) bowel preparations are safe and effective but require the consumption of large volumes of fluid, with relative low associated adherence. Alternatively, some data suggest adjuvants may enhance bowel cleansing quality and patient acceptance.
Aims & Methods: We performed a meta-analysis to determine the efficacy, willingness-to-repeat, and procedural outcomes of adding any type of adjuvant to a PEG bowel preparation, given as split-dose, in high (>3L) or low-volume (<2L) regimens.
We performed systematic searches of MEDLINE, EMBASE, Scopus, CENTRAL and ISI Web of knowledge from January 1980 to March 2015 for published results from randomized trials that assessed split-dose regimens of PEG with adjuvant vs split-dose PEG without adjuvant. We excluded studies that included pediatric, hospitalized, or inflammatory bowel disease patients, or trials in which the control group also received an adjuvant. Adjuvants were categorised as osmotic laxatives, irritant laxatives, antifoam products or other (prokinetics). The primary outcome was efficacy of bowel cleansing. Secondary outcomes included patients' willingness to repeat the procedure, polyp and adenoma detection rates.
Results: Of 2,813 citations, 11 trials (n = 2,252 intention to treat patients) fulfilled the overall inclusion criteria. Split PEG low-dose preparations complemented by an adjuvant were not inferior to split PEG high-dose (odds ratio (OR) = 0.82; 95% confidence interval (CI):0.62-1.08; 7 studies). Split PEG high-dose preparations plus an adjuvant resulted in a significantly greater proportion of patients with adequate preparations (OR = 2.98, 95%CI:2.00-4.42, 4 studies). To our knowledge, no study assessed split PEG low-dose versus split PEG low-dose with adjuvants. Willingness-to-repeat was significantly greater with the use of split PEG low-dose with adjuvants compared to split PEG high-dose preparations (OR = 7.46; 95%CI:3.07-18.14; 2 studies), but was lower for split PEG high-dose with adjuvants versus split PEG high-dose (OR = 0.33; CI95% 0.13-0.85). No differences were noted in polyp or adenoma detection rates.
Conclusion: Efficacy of bowel cleansing for split PEG low-dose with the addition of an adjuvant were not inferior to split PEG high-dose, and yielded a higher proportion of patient willingness to repeat the preparation. Split PEG high-dose was more efficient with an adjuvant compared to same dosage without adjuvant but was less tolerated. No differences were noted in polyp or adenoma detection rate. Additional research is required to further characterize adjuvants' impact in split-dose PEG low-volume.

Introduction: Constipation is one of the most encountered symptoms in Gastroenterology. It may result from several causes that can be diagnosed, for the most of them, with colonoscopy. The aim of our study is to determine the frequency of different colonoscopy findings related to constipation and to evaluate risk factors associated with a pathological colonoscopy.

Aims & Methods: 5222 colonoscopies were performed between January 2006 and March 2015, 511 patients (9.7%) underwent colonoscopy for constipation alone or associated with other symptoms. We excluded incomplete colonoscopies. Statistical analysis was performed using the Spss Software 10.0.

Results: 321 females (62.8%) and 190 males (37.1%) were included. The mean age was 51.21+/-15.47 years. All procedures were performed under sedation with propofol. The Boston score average was 5.21 +/- 1.5 points. Colonoscopy was performed in 108 cases with constipation as sole symptom. In the other cases, constipation was associated with: rectal bleeding in 173 cases (33.8%), abdominal pain in 172 cases (33.6%), alternating with diarrhea in 88 cases (17.2%), weight loss in 62 cases (12.1%), tenesmus in 12 cases (2.3%) and anemia in 7 cases (1.7%). Out of 511 colonoscopies performed we reported: polyps in 88 cases (17.2%), malignant tumors in 18 cases (3.5%), diverticula in 11 cases (2.1%), inflammatory bowel diseases in 11 cases (2.1%), lipomas in 6 cases (1.17%), angiodysplasias in 6 cases (1.17%), melanosis coli in 5 cases (0.9 %), solitary rectal ulcer in 2 cases (0.3%) and 1 case of extrinsic compression (0.1%) and 1 case of rectal varices (0.1%). Colonoscopy was normal in 335 / 511patients (65.5%) all symptoms combined, and in 100/108 patients who had constipation as the only symptom (92.5%). After univariate and multivariate analysis, only age (OR: 0.69, IC 95%: 0.30-0.92, p = 0.04) and rectal bleeding (OR: 0.31, IC 95%:0.15-0.70, p = 0.01) was significantly associated with a pathological colonoscopy (adjusted to gender and abdominal pain).

Conclusion: In our unit, 9.7% of colonoscopies were performed for constipation. Tumors were found in 20.7% cases of which 3.5% were malignant. The contribution of colonoscopy in isolated constipation is close to that of screening colonoscopy, but it keeps a major role when constipation is associated with other warning signs such as rectal bleeding, unintentional weight loss or anemia.

P1410 VALIDITY OF ENDOSCOPIC SUBMUCOSAL DISSECTION FOR COLORECTAL T1 (SUBMUCOSAL INVASION) CANCER

T. Maehata[1], T. Uraoka[1], O. Goto[1], T. Akimoto[1], S. Sagara[1], Y. Ochiai[1], A. Fujimoto[1], T. Nishizawa[1], N. Yahagi[1]
[1]*Division of Research and Development for Minimally Invasive Treatment, Cancer Center, Keio University, School of Medicine, Tokyo, Japan*

Contact E-mail Address: t2maehata@marianna-u.ac.jp

Introduction: Endoscopic submucosal dissection (ESD) has allowed the achievement of histologically curative en bloc resection of early colorectal cancer regardless of size, level of fibrosis, or location. Recently, ESD has been performed not only for therapeutic purposes, but also for diagnostic purposes to obtain total incisional biopsies in order to determine the necessity of additional therapy. However, owing to the presence of fibrosis from cancer submucosal (SM) invasion, ESD for patients with pSM is considered more difficult than ESD for patients with pM or adenoma. We investigated the safety and validity of ESD for patients with pT1 (SM) colorectal cancer at our institution.

Aims & Methods: The subjects were 403 patients who underwent ESD for colorectal cancer from January 2009 to August 2014. They were classified into an A group (adenoma/pM cancer) and B group (pSM cancer). Statistical analysis was performed to examine how pT1 (SM) was affected by different factors, including patient characteristics (age, sex), lesion characteristics (site, tumor diameter, macroscopic type), and outcome (en bloc resection rate, mean operation time, non-lifting signs [NLS], presence/absence of fibrosis, complications). Next, the outcomes for pT1 (SM) cases were compared between a vertical margin (VM)-positive group and VM-negative group.

Results: There were 348 lesions in the A group and 55 in the B group. In univariate analysis, the B group had significantly higher fibrosis (p = 0.0105) and NLS (p = 0.0236); in multivariate analysis, only fibrosis remained a significant factor in the B group. Outcomes for pT1 (SM) were 31/24 cases of SM1/SM2, respectively. Further, 83.6% of patients in group B underwent en bloc complete resection, and the complication was only postoperative hemorrhage. Seven cases of the patients in group B were VM-positive, and all were SM2 lesions. There were no significant differences in operation time, tumor diameter, presence/absence of fibrosis, or NLS between the VM-positive and VM-negative groups. The depth of SM invasion was significantly deeper in the VM-positive group than in the VM-negative group (P = 0.0346).

Conclusion: These results suggest that the ESD procedure might be safe and effective irrespective of the depth of invasion. However, this investigation examined cases where ESD was performed by skilled doctors, and there was significantly higher rates of fibrosis in pT1 (SM) colorectal cancer in this investigation, so the level of difficulty is anticipated to be higher. In case of deep SM invasion, there is the possibility of VM-positivity, and a preoperative diagnosis is important; we believe that when deep SM invasion is suspected, it is necessary to perform ESD after having affirmed additional therapy.

P1411 VALIDITY OF THE "RESECT-AND-DISCARD" STRATEGY FOR DIMINUTIVE COLORECTAL CARCINOMAS

T. Fujii[1], T. Fujimori[2]
[1]*Gastroenterology, TF CLINIC, Tokyo,* [2]*Shinko Hospital, Kobe, Japan*

Contact E-mail Address: tfclinic@khaki.plala.or.jp

Introduction: The "resect-and-discard" strategy has been drawing attention as allowing diminutive and small colorectal tumors, the majority of which tend to be benign, to be resected and discarded without pathologic assessment, as long as they can be endoscopically diagnosed as adenomas with confidence, thus saving the cost of such assessment. However, endoscopic evaluation of these lesions may be associated with the risk of submucosal invasive cancers of the colon being missed inadvertently.

Aims & Methods

Aims: To clarify the clinicopathological features of diminutive carcinomas of the colon measuring < 5 mm in size and to evaluate the validity of the "resect-and-discard" strategy for these lesions.

Methods: A total of 4.934 neoplastic lesions < 5 mm in size which were endoscopically resected between July 2003 and March 2015 and whose histological diagnoses became available were included for analysis. In this analysis, in addition to adenocarcinoma, high-grade dysplasia was handled as consistent with the definition of diminutive carcinoma.

Results: 1) Of all neoplastic lesions examined, malignant lesions accounted for 0.4% (22/4.934), with the histological diagnoses obtained being well differentiated adenocarcinoma (n = 2), one of which contained a depressed-type lesion measuring 1 mm, moderately differentiated adenocarcinoma (n = 1), high-grade dysplasia (n = 19), and low-grade dysplasia (n = 4.912); 2) a majority of the diminutive adenomas were found in the right colon, with 54.5% (12/22) of the diminutive carcinomas found in the transverse colon; 3) in terms of gross appearance, depressed-type lesions (IIa + IIc or IIc) were common and accounted for 45.5% (10/22) of the diminutive carcinomas, while depressed-type lesions accounted for 3.3% (162/4.912) of the low-grade dysplasia; 4) 68.5% (3.367/4.912) of the diminutive adenomas and 63.6% (14/22) of the diminutive carcinomas were subjected to magnifying observation; 5) the treatments implemented included endoscopic mucosal resection (EMR) in 50% (11/22) of the diminutive carcinomas and hot biopsy forceps polypectomy (HB) in 77.2% (3.791/4.922) of the diminutive adenomas.

Conclusion: Diminutive carcinomas were commonly found in the transverse colon as well as in depressed-type lesions, suggesting that diminutive lesions need to be examined for presence of depressed-type lesions using dye spraying and magnifying endoscopy, and all depressed-type lesions need to be completely resected, without resorting to the "resect-and-discard" strategy.

Contact E-mail Address: take8047@hotmail.com

Introduction: *Background and study aims:* Endoscopic submucosal dissection (ESD) is a promising treatment for large gastrointestinal superficial neoplasms, although the method is technically difficult, and perforation and delayed bleeding are well-known adverse events. However, there have been no large studies about electrocoagulation syndrome after colorectal ESD.

Aims & Methods: The aim of this study was to evaluate the incidence and clinical significant risk factors of post-ESD coagulation syndrome (PECS).

This was a retrospective cohort study conducted in a referral cancer center. A total of 336 patients with colorectal neoplasms (143 adenomas or serrated lesions, and 193 carcinomas) underwent ESD from January 2011 to June 2013. Incidence, outcome, and factors associated with occurrence of PECS were investigated. The study protocol was approved by the local ethics committee in our center as No. 1406025042.

Results: PECS occurred in 35 patients (9.5%). The median time until PECS was 15.5 h, and the median period of PECS was 32.5 h. Fever (≥37.6°C) after ESD was found in 41% of the PECS group and 9% of the non-PECS group ($P < 0.001$). All PECS cases were managed conservatively. On multivariate analysis, female patients [odds ratio (OR) = 3.2, $P = 0.002$], lesion location at ascending colon and cecum (OR = 3.5, $P = 0.001$), and resected specimen ≥40 mm (HR = 2.1, $P = 0.05$) were independent risk factors for PECS.

Conclusion: PECS occurred in 35 patients (9.5%) with colorectal ESD, however, all cases had a good outcome with conservative management. Female sex, tumor location at the ascending colon and cecum, and resected specimen ≥40 mm were independently significant risk factors for PECS.

Introduction: Endoscopic subumucosal dissection (ESD) for rectal neuroendocrine tumors (NETs) has been reported from referral institutions. However, little is known about the treatment outcome of ESD for rectal NETs in general hospitals.

Aims & Methods: The aim of the present study is to clarify the clinical short- and long-term outcomes in general hospitals and to raise issues concerning ESD for rectal NET. The present study is a retrospective cohort study conducted by Osaka Gut Forum. Patients undergoing endoscopic resection for rectal NETs from 2003 to 2012 were retrospectively investigated. Short-term outcomes (R0, R1 resection rate, and complications) were compared between the conventional EMR and the ESD group. Unclear resection margin was also analyzed as Rx resection. Follow-up survey was performed for patients followed more than 12 months, and long-term outcomes (local recurrence, distant metastasis rate, and survival) were investigated in these patients.

Results: Total 117 patients treated by endoscopic resection for rectal NETs were enrolled. Among these cases, 14 strip biopsy and 7 cap aspiration method were excluded. ESMR-L method was not performed in the present series. Patient age, gender, lesion site, and ulcerations were similar between groups. The lesion size was significantly larger in the ESD group than in the EMR group (6.6 ± 2.1 vs. 5.3 ± 1.7 mm, $p = 0.001$). ESD significantly decreased the R1 resection rate compared to EMR (5.9% vs. 23.3%, $p = 0.001$). The R0 resection rate, however, was similar between both groups because vertical Rx resection is more occurred in the ESD group than in the EMR group. The perforation and delayed bleeding rates were similar between groups. A multivariate analysis showed that ESD was an independent risk-reducing factor for R1 resection [OR = 0.183 (95%CI; 0.036-0.701), $p = 0.012$]. We performed follow-up in 79 patients, including 10 patients with Rx resection. There were no local recurrences or distant metastases [median follow-up period 42 months (19-115)].

Conclusion: In general hospitals, complete resection rate of rectal NET was similar between ESD and conventional EMR despite a decreased incidence of R1 resection in the ESD group. To improve the clinical outcomes of ESD for rectal NET, attention to the possible Rx resection should be paid.

P1414 ADVANTAGE OF THE ENDOSCOPIC SUBMUCOSAL DISSECTION (ESD) COMPARED TO THE CAP-ASSIST ENDOSCOPIC MUCOSAL RESECTION (EMR-C) IN RECTAL NEUROENDOCRINE TUMORS (R-NETS)

T. Kishihara[1], A. Chino[2], Y. Tamegai[2], M. Igarashi[1]
[1]*Gastroenterology & Endoscopy,* [2]*Cancer Institute Hospital, Tokyo, Japan*

Contact E-mail Address: teruhito.kishihara@jfcr.or.jp

Introduction: Conventional endoscopic mucosal resection (EMR) for Rectal neuroendocrine tumors (R-NETs) took the suggestions in vertical margin positives frequently. In the past we basically have resecting R-NETs by choosing the cap-assist and aspirational EMR method(EMR-C), and we thought the efficacy and conveniently it. However we experience lack of safety in some cases with EMR-C. Recently we treated R-NETs having the incident with endoscopic submucosal dissection (ESD).

Aims & Methods: The aim was to compare the clinical usefulness of ESD with EMR-C for the thorough resected R-NETs. In the period from January 2004 to October 2013, there were 110 cases of R-NETs that were estimated to be 10mm or less in diameter and without lymph node enlargement. The complete resection rate, incidence of complications, and procedure times associated with each two procedures (EMR-C, ESD) were analyzed.

Results: The 98 lesions were resected using EMR-C, and 12 lesions were resected by ESD. The complete resection rate was 93% (91/ 98) in the EMR-C group and 100% in the ESD group. All of them were pathologically negative findings of the involved lymphovascular or the muscle layer invasion. The average time of procedure was longer in ESD which was taken 32minutes than in EMR-C on 5minutes. One case has perforation in EMR-C for residual lesion after EMR at another hospital, the reason why that case had some fibrosis at submucosal layer. Such as the residual lesion with fibrosis should have taken ESD to avoid perforation and also thorough treatment. There was not any perforation case in ESD.

Conclusion: This comparison has some selection bias such as total cases and indication with two procedures. We recognize that EMR-C was not inferiority against ESD due to most R-NETs. However there are some cases lack of safety and also difficult of thorough resection with EMR-C. Such as the residual lesion with fibrosis and the unclear lesion of border should have taken ESD to avoid perforation and also thorough treatment.

P1415 AN INVESTIGATION OF DIAGNOSTIC ENDOSCOPY OF SESSILE SERRATED ADENOMA / POLYP (SSA/P): HOW TO SKILLFULLY PERFORM DIAGNOSTIC ENDOSCOPY

T. Nakaya[1], I. Koba[1]
[1]*Gastroenterology, Yamaga Central Hospital, Yamaga, Japan*

Contact E-mail Address: teruo28@hotmail.com

Introduction: Serrated lesions of the colorectum are classified as hyperplastic polyp (HP), traditional serrated adenoma (TSA), and sessile serrated adenoma/polyp (SSA/P). TSA and SSA/P are thought to undergo malignant transformation through the serrated pathway. The endoscopic and pathological characteristics of TSA have been elucidated, but the pathological diagnostic standards for SSA/P have only recently been established. Much is still unknown about its characteristics including those related to endoscopic findings.

Aims & Methods: 183 lesions identified via colonoscopy as possible serrated lesions and endoscopically resected prior to December 2014 were subjected to pathological diagnosis and classified as SSA/P (Yao et al. classification; 120 lesions), HP (46 lesions), and TSA (17 lesions). The 120 SSA/P lesions were compared to HP, from which they are difficult to differentiate, and the endoscopic characteristics of SSA/P were investigated.

Results: Our investigation of lesion location were as follows: 25 HP (54%) and 21 HP (46%) in the right-sided and left-sided colon respectively, 105 SSA/P (88%) and 15 SSA/P (12%) in the right-sided and left-sided colon respectively, indicating that SSA/P lesions in the right-sided colon were in the majority. Median values for the maximum diameter of the lesions were 7 mm (4-20) for HP and 10 mm (3-20) for SSA/P, indicating that SSA/P lesions were significantly larger. Gross examination of the morphology types of HP and SSA/P respectively indicated that there were 9 lesions (20%) and 13 lesions (11%) that were 0-I, and that there were 37 lesions (80%) and 107 lesions (89%) that were 0-II. In addition, of the SSA/P lesions that were 0-II, one lesion was IIb, 7 lesions were accompanied by small elevations (Is), all were 12 mm or larger, and in 6 cases the Is component was confirmed to be TSA. None of the HP lesions had co-existing lesions. It has been previously reported in Japan DDW that viscous yellowish mucus and a lobulated surface on the lesions were characteristic findings indicating SSA/P. In the present study these findings were observed in both HP and SSA/P in the following numbers: Viscous yellowish mucus was observed on 14 HP lesions (30%) and 107 SSA/P lesions (89%), lobulated surfaces were observed on 19 HP lesions (41%) and 108 SSA/P lesions (90%), indicating that SSA/P displayed these characteristics at a higher rate. Pit pattern diagnosis indicated that 31 HP lesions (67%) and 43 SSA/P lesions (36%) were type II, 15 HP lesions (33%) and 77 SSA/P lesions (64%) were either enlarged type II, type IIIH, or type IVH pit. SSA/P sensitivity was 88.4% and specificity was 71.1% for viscous yellowish mucus, and SSA/P sensitivity was 85.0% and specificity was 69.2% for lobulated surface. Sensitivity was 83.7% and specificity was 41.9% for enlarged type II-, type IIIH-, or type IVH-positive. In the present study, one case of SSA/P (0.8%) had comorbid intramucosal carcinoma.

Conclusion: SSA/P occurs more frequently in the right-sided colon. Conventional observation as type 0-II lesions with viscous yellowish mucus and lobulated surfaces and the additional use of magnifying endoscopy in pit pattern diagnosis for lesions can be expected to improve diagnostic accuracy.

P1416 ENDOSCOPIC MANAGEMENT FOR SIGMOID VOLVULUS: SHOULD WE PERFORM ENDOSCOPIC DETORSION IN ALL CASES?

T. Hirata[1], T. Uraoka[1], M. Kato[1], E. Sakaguchi[1], Y. Ishibashi[1], S. Banno[1], K. Abe[1], Y. Takada[1], Y. Takatori[1], M. Wada[1], S. Kinoshita[1], K. Takabayashi[1], M. Kikuchi[1], M. Kikuchi[1], Y. Fujiyama[1], M. Suzuki[1], T. Ohishi[2]
[1]*Department of Gastroenterology,* [2]*Department of Surgery, National Hospital Organization Tokyo Medical Centre, Tokyo, Japan*

Contact E-mail Address: t2ttesu@uranus.dti.ne.jp

Introduction: Sigmoid volvulus (SV) is a relatively common medical emergency. Endoscopic management is the first choice as an initial therapy for SV for the reasons of technical easiness and less invasiveness.

Endoscopic detorsion, untwist of sigmoid colon using colonoscope under radiographic guidance, is applied first, however, the successful rate of endoscopic detorsion is not actually high. Endoscopic exsufflation, just suction the gas into the lumen, is second choice after failure of endoscopic detorsion. However, it has not been clarified the outcomes of endoscopic management for SV, especially the difference between detorsion and exsufflation.

Aims & Methods: The aim of this study is to compare outcomes of these two different managements.

This was a retrospective cohort study from a tertiary hospital. SV was suspected in patients with intestinal obstruction symptoms, and was diagnosed with computed tomography finding of dilated sigmoid colon around its own mesentery. A total of 42 patients with SV hospitalized for the first time from April 2004 to December 2014 were enrolled. Recurrence cases were excluded in this study. Of these, 5 cases who underwent urgent surgery (3 due to colon gangrene, 2 due to repeated SV history), 4 cases who were not followed up after discharge and 1 case who refused surgery regardless of apparent colon gangrene sign were excluded, and a total of 32 patients were included into data analysis. It was

unknown whether detortion was superior as compared with exsufflation following unsuccessful detortion or not. Therefore we compared complication rate and hospitalization length as short-term outcomes and cumulative recurrence rate and mortality as a med- and long-term outcomes between detorsion and exsufflation group. Student's t analysis or Fischer's exact analysis was used for comparison of short-term outcomes and Kaplan-Meier method and log rank analyses were used to compare cumulative recurrence rate.
Results: Male-to-female ratio was 2.6: 1. Mean age was 80.5 ± 8.4 years old. Median observation period was 189 days [IQR 67-504]. Fifteen cases (47%) were initially managed by endoscopic detorsion and seventeen cases (53%) tried to untwist by endoscopy were managed by exsufflation alone. There were no adverse events associated with endoscopic management. Mean hospitalization length was significantly shorter in detorsion group than in exsufflation group (6.1 days vs 11.8 days, p = 0.0008). One-year cumulative recurrence rate of all included patients was 66%. There was no difference of cumulative recurrence rate between detorsion and exsufflation group (p = 0.45). Of 23 patients with recurrence, one (4%) died of colon gangrene at the time of first recurrence.
Conclusion: The outcomes of endoscopic detorsion and exsufflation were equivalent as management for SV except length of hospitalization. When considering the high recurrence rate of both treatments and the risk of death due to colon gangrene, elective surgery was recommended, if at all possible.

P1417 QUALITY IN ENDOSCOPY: A RETROSPECTIVE AUDIT OF RECTAL RETROFLEXION IN LOWER GI ENDOSCOPY

T. Mangala Murugesan[1], J. Aldridge[1], L. Burke[1], D. Vani[1], S. Shah[1]
[1]*Gastroenterology, Pinderfields General Hospital, Wakefield, United Kingdom*

Contact E-mail Address: mangala.murugesan@midyorks.nhs.uk
Introduction: Retroflexion in the rectum is recommended during lower GI endoscopy to avoid missing adenomatous polyps/cancer in the difficult to visualise anorectal region.[1] It is a recognised component of colonoscopy improvement bundles.[2] Retroflexion aids in detection of lesions missed by the straight viewing scope.[3] There is lack of data about quality standards of retroflexion in current clinical practice. The aim of this study was to audit practice of rectal retroflexion and image documentation at lower GI endoscopy in a non-tertiary endoscopy unit.
Aims & Methods: A retrospective analysis was performed of all flexible lower GI endoscopic examinations over a 2-month period between 1st January and 28th February 2015. Reports were accessed from the hospital endoscopy reporting system (HICSS) and corresponding images for each procedure performed were analysed for evidence of photodocumentation of rectal retroflexion and image quality. Image quality was recorded as either adequate or poor.
Results: A total of 1402 Lower GI endoscopies were performed between 1st Jan and 28th Feb 2015. Of the 1402 examinations 136 patients were excluded from the analysis. Overall there was evidence of retroflexion in only 31% of patients. There was variation of practice amongst different endoscopists with the highest percentage of photodocumentation of retroflexion being recorded by physician endoscopists (see table 1) Of the cases where there was evidence of retroflexion, image quality was of an acceptable standard in only 62%. Taking this into consideration, overall there was clear image documentation of retroflexion in only 19.1% of patients.
Table 1

Endoscopist	Adequate Reftroflexion	Poor retroflexion	No retroflexion
Physician(n = 509)	144(28.2%)	103(20.2%)	262(51.4%)
Surgeon(n = 607)	80(13.17%)	37(6.09%)	490(80.72%)
Nurse(n = 92)	11(11.9%)	7(7.6%)	74(80.4%)
GP(n = 58)	7(12.06%)	1(1.72%)	50(86.2%)

Conclusion: This study demonstrates the rectal retroflexion is poorly performed at flexible endoscopy. Photodocumentation was of an acceptable quality in the minority. Endoscopists should be educated about the importance of routine retroflexion and photodocumentation at flexible sigmoidoscopy and colonoscopy. Endoscopists should take time and care when examining the rectum in retroflexion to avoid missing low rectal lesions. There should be as great an importance given to photodocumentation of the rectum in retroflexion as a quality indicator of completion of colonoscopy /flexible sigmoidoscopy as is given to documentation of caecal intubation.

Introduction: Ultra-high magnifying endoscopy (Endocytoscopy: EC) enables us to observe *in vivo* cellular images at approximately 400x magnification. We have reported that EC images could distinguish between neoplastic and non-neoplastic lesions, and revealed that our EC classification had a good correlation with the degree of submucosal invasion. The aim of this study is to assess whether EC is capable of diagnosing the histological degree of differentiation that is recognized as one of the most important prognostic factors in colorectal cancers.
Aims & Methods: Between April 2001 and November 2014, a total of 23725 colorectal neoplasms excluding advanced carcinomas were resected endoscopically or surgically, and 678 lesions were examined by EC before resection at Showa University Northern Yokohama Hospital. Of these, a detailed verification between both EC images and histopathology of resected specimens were performed in 94 lesions. Histological differentiation was diagnosed according to the WHO classification. In addition, focusing on the size, shape and arrangement of carcinoma glands and nuclei, we divided the EC images into following types; Finding (A): enlarged nuclei and tubular gland lumen, finding (B): enlarged nuclei and unclear gland formation, finding (C): clumpy enlarged nuclei and fused gland formation, finding (D): fine granular structure. Finally, we compared these findings with their histological grade of differentiation in the superficial layer of the resected specimen.
Results: Histopathological examination of the 94 resected lesions revealed that 65 lesions were well differentiated adenocarcinoma (WELL) and 29 lesions were moderately differentiated adenocarcinoma (MODE). There was no poorly differentiated adenocarcinoma on the superficial layer. In 65 WELL lesions, finding (A) was observed in 65 lesions (100%), finding (B) in 20 lesions (30.8%), finding (C) in six lesions (9.2%) and finding (D) in 18 lesions (27.7%). On the other hand, in 29 MODE lesions, finding (A) was observed in 22 lesions (75.8%), finding (B) in 28 lesions (96.6%), finding (C) in 27 lesions (93.1%) and finding (D) in 15 lesions (51.7%). The sensitivity, specificity, accuracy and positive likelihood ratio that the presence of finding (C) predicted MODE were 93.1%, 90.7%, 91.5% and 10.1, respectively. Furthermore, they were 92.3%, 96.6%, 93.6% and 26.8, respectively for the presence of finding (A) and the absence of finding (C) predicting WELL.
Conclusion: The EC finding of clumpy enlarged nuclei and fused gland formation is possibly associated with the cribriform pattern that is peculiar to moderately differentiated adenocarcinoma. Endocytoscopy could have the promising ability of diagnosing the histological grade of differentiation in colorectal carcinomas.

Introduction: Endoscopic submucosal dissection (ESD) is one of the most useful methods for treating early colorectal neoplasms, and conventionally utilizes an IT knife, hook knife, or needle knife. However, because these devices are used without fixation to target, there is the potential risk for complications due to unexpected incision. To reduce risk of complications from ESD performed using a conventional knife, we utilized a scissors-type knife (SB knife: Akita Sumitomo Bakelite) that allows keeping an adequate dissection layer and preventing unexpected muscular layer injury. Nevertheless, a longer procedure time has been identified as a disadvantage of the SB knife. Recently, an advanced SB knife was developed to prevent scorching of the knife. In the study, we report the efficacy and safety of ESD using this advanced SB knife for early colorectal neoplasms.
Aims & Methods: The aims of our study were to evaluate the efficacy and safety of ESD performed with the advanced SB knife compared with the conventional SB knife in the treatment of early colorectal neoplasms. The procedure was performed in 160 lesions from 148 patients (M:F = 78:70; median age = 70), from October 2010 to February 2015. ESD was performed with the conventional SB knife in 115 lesions (Group A) and with the advanced SB knife in 45 lesions (Group B). We evaluated the en-bloc resection rate, complete resection rate, specimen size, tumor size, procedure time, and complications. Complete resection was defined as en-bloc resection, where both lateral and vertical margins were negative.
Results: The en-bloc resection rate was 96.5% (111/115) in Group A and 100% (45/45) in Group B (p = 0.58). The complete resection rate was 93.0% (107/115) in Group A and 95.6% (43/45) in Group B (p = 0.73). The mean diameter of the resected specimens was 34.0 mm (range, 12–112 mm) in Group A and 37.0 mm (range, 7–72 mm) in Group B (p = 0.19). The mean diameter of tumors was 26.6 mm (range, 4–99 mm) in Group A and 29.8 mm (range, 3–67 mm) in Group B (p = 0.23). The median procedure time was 80 min (range, 20–400 min) in Group A and 65 min (range, 15–420 min) in Group B (p = 0.49). The mean ratio of resected specimen area (diameter^2) to procedure time (min) was 15.2 mm^2/min in Group A and 18.9 mm^2/min in Group B, and therefore the resected specimen area per minute was significantly wider in Group B than in Group A ($p < 0.05$). In relation to complications from the procedure, there were no perforations in both groups. Only 5 cases of delayed hemorrhage occurred in Group A (4.3%), and all these cases were controlled with endoscopic hemostasis.
Conclusion: ESD performed using either the conventional or advanced SB knife can be adequately adopted as a technically efficient and safe method for resecting

early colorectal neoplasms. Moreover, the advanced SB knife offers the possibility of making the overall procedure time even shorter.

Introduction: Colonoscopy is the most popular examination in the diagnosis of colorectal diseases, but pain and discomfort generally require analgosedation performed with intravenous technique. Recently the use of conscious sedation with a mixture of 50% N_2O and O_2 (Livopan®) was introduced. A sufficient number of air exchanges through the use of scavenger systems should be provided because the exposure to N_2O is a risk factor for health personnel.
Aims & Methods: The aim of our study was to evaluate the efficacy and safety of N_2O/O_2 mixture vs. midazolam/meperidine (Mid/MEP), and the exposure to N_2O of health personnel both in presence or absence of a collecting system and active evacuation of N_2O.
The study was carried out in Endoscopy Suite of our University Hospital. The patients were divided into 3 groups: patients sedated with N_2O/O_2 mixture with the aid of a mobile system of evacuation with double mask (NIKI group); patients sedated with the same mixture without the aid of the system NIKI (NO NIKI group) and patients sedated with Midazolam 0.5-1.5mg and Meperidine 1-5mg (Mid/MEP group). To evaluate the clinical efficacy and safety were considered: vital signs (heart rate, blood pressure and SpO_2); Ramsay Agitation Sedation Scale (RASS); satisfaction of the operator; VAS; psycho-motor recovery time. The diffusion of environmental N_2O/O_2 was evaluated with infrared photoacoustic spectroscopy across five sampling points located within ambulatory endoscopy. Measured results were processed using descriptive statistical analysis using software "IC Stata 9.2 for Mac." The comparison analysis between groups were made using t-test and the "one way ANOVA", while for concentrations of N_2O between the two groups the Mann-Whitney U test was used, whereas, as statistically significant, a value of $p < 0.05$ was considered.
Results: We enrolled 86 patients of which 39 in NIKI group, 6 in NO NIKI group and 40 in Mid/MEP group. The three groups had similar demographic characteristics. The Mid/MEP group reported a mean VAS lower than NO NIKI group ($p < 0.05$). NIKI group reported a mean VAS lower than NO NIKI group but higher than Mid/MEP group. Mid/MEP group reported a mean RASS higher than NIKI and NO NIKI groups. Recovery time was higher in Mid/MEP group compared with both NIKI and NO NIKI group. Mean N_2O/O_2 concentrations in NO NIKI group was 450 ± 347 ppm, while in NIKI group was 28 ± 55 ppm ($p \leq 0.001$).
Conclusion: During colonoscopy the use of an anesthetic short-acting agent would be the best choice for providing adequate sedation and comfort and quick recovery of psycho-motor functions. Our study showed that the mixture of 50% nitrous oxide and oxygen offers these benefits and may represent an effective alternative to intravenous sedation. The environmental monitoring shows that the N_2O/O_2 concentrations varies considerably depending on the utilization, or not, of the scavenger system that is a valid tool to ensure the safety of the operators.

Contact E-mail Address: v.subramanian@leeds.ac.uk
Introduction: Patients with ulcerative colitis (UC) have an increased risk for colorectal cancer (CRC) compared to the general population. The yield of surveillance can be improved by addition of newer endoscopic methods that enhance the detection of subtle mucosal abnormalities like chromoendoscopy (CE)[1] and HDWLE[2] when compared to standard definition endoscopy. CE however is still not widely adopted and no studies have compared HDCE and HDWLE.
Aims & Methods
Aims: To compare the rate of detection of dysplasia in patients with long standing UC with HDWLE compared to high definition with CE (HDCE)
Methods: Parallel group randomized controlled trial (clinicaltrials.gov number NCT02138318) in which patients with long standing (>10 years) extensive UC requiring surveillance colonoscopy were randomized to either HDWLE or HDCE (with 0.2% indigo carmine spray). HD scopes (Olympus CF260L or 290L) and processors (Olympus Spectrum CV260 or Elite CV290) and HD monitors were used for all procedures. Time to reach caecum and withdrawal time was recorded. Presence of dysplasia was confirmed by two expert GI histopathologists. Data was analysed according to the number of patients who had dysplastic endoscopic lesions detected (per patient analysis) and also to the number of dysplastic lesions (per lesion analysis).
Results: In total 53 patients were randomized to HDWLE and 50 to the HDCE arm. Baseline characteristics including duration of disease, bowel preparation, endoscopists, concomitant PSC and previous dysplasia were similar in both arms. A total of 14 dysplastic lesions (1 with high-grade and 13 with low-grade dysplasia) were detected in 11 patients (22%) in the HDCE arm and 6 dysplastic lesions (all low grade dysplasia) in 5 patients (9.4%) in the HDWLE arm. HDCE was significantly better ($p = 0.04$) than HDWLE on a per patient basis for the detection of endoscopically visible dysplastic lesions. HDCE (0.26 ± 0.6) detected more dysplastic lesions per-patient than HDWLE (0.12 ± 0.4). Withdrawal time was significantly ($p < 0.001$) higher in HDCE (21.2 ± 5.8 min) compared to HDWLE (13.6 ± 3.3 min).
Conclusion: HDCE significantly improves the detection of dysplastic lesions in patients with long standing UC undergoing surveillance endoscopy and should be the procedure of choice in these patients. On average it increases procedure time by 8 minutes over HDWLE.

P1422 EFFECTS OF PLATELET-RICH PLASMA ON ENDOSCOPIC MUCOSAL RESECTION IN RAT AND PORCINE MODELS

V. Lorenzo-Zúñiga[1], J. Boix[1], V. Moreno de Vega[1], R. Bartoli[2]
[1]*Endoscopy Unit. Gastroenterology,* [2]*Gastroenterology, Hospital Universitari Germans Trias i Pujol/CIBERehd, Badalona, Spain*

Contact E-mail Address: vlorenzo.germanstrias@gencat.cat
Introduction: Platelet-rich plasma (PRP) is a concentrate from blood that contains 3 to 5 times more platelet than the normal concentration. PRP promotes several types of cell activity all of which are necessary in the process of wound and soft tissue healing. Endoscopic resection techniques produce mucosal lesions.
Aims & Methods: In this study we assess the efficacy of endoscope application of PRP to prevent complications and to induce mucosal healing after endoscopic resections. Colonic EMR-induced lesions were performed in rats ($n = 16$) and pigs ($n = 4$). Animals were randomized to receive one of the following sprayed treatments onto the lesions, as a shield (Endoscopic Shielding Technique or EST): saline (control; 8 rats and 2 pigs), and PRP (product; 8 rats and 2 pigs). Pigs underwent endoscopic follow-up at weeks 1 and 2. Rats were followed at 48 h and 7 days, being sacrificed at week 1 to perform histological evaluation of the lesions. Thermal injury was assessed with a 1-4 scale: (1) mucosal necrosis; (2) submucosal necrosis; (3) muscularis propria necrosis; and (4) serosal necrosis.
Results: All rats treated with PRP were alive after 7 days, whereas saline treatment showed 50% of mortality ($p = 0.02$). Mean ulcerated area after 48h and 7 days were significantly lower with PRP than saline (0.27 ± 0.02 cm^2 and 0.08 ± 0.01 cm^2 vs. 0.56 ± 0.1 cm^2 and 0.40 ± 0.06 cm^2; $p < 0.001$). Thermal injury was significantly lower with PRP (1.25 ± 0.46) than in controls (2.25 ± 0.50); $p = 0.006$. Descriptive analysis of porcine model showed a trend to higher mucosal restoration in animals treated with PRP than saline, at weeks 1 and 2 (Median area in cm^2: 0.55 and 0.40 vs 1.32 and 0.79).
Conclusion: The use of sprayed PRP onto EMR-colonic mucosal lesions showed strong healing properties in rat and porcine models.
Disclosure of Interest: None declared

P1423 ENDOSCOPIC SHIELDING TECHNIQUE WITH A NEWLY DEVELOPED HYDROGEL ON MUCOSAL THERMAL INJURY IN A PORCINE MODEL

V. Lorenzo-Zúñiga[1], R. Bartoli[2], V. Moreno de Vega[1], A. Hernández[3], J. Boix[1]
[1]. *Endoscopy Unit. Gastroenterology,* [2]*IGTP/CIBERehd,* [3]*Pathology, Hospital Universitari Germans Trias i Pujol/CIBERehd, Badalona, Spain*

Contact E-mail Address: vlorenzo.germanstrias@gencat.cat
Introduction: The incidence of deep thermal injury secondary to therapeutic endoscopy will increase in the future with the widespread use of advanced resection techniques. To prevent this coagulation syndrome we have developed a newly hydrogel (patent pending), that can be sprayed onto the lesions as a shield (Endoscopic Shielding Technique or EST), providing a direct administration through the endoscope channel.
Aims & Methods: The aims of this study were to evaluate the healing process of colonic EMR-induced ulcers in animals with the application of this hydrogel (product), and to verify experimentally the safety of this treatment procedure. Colonic EMR was performed in 8 pigs under general anesthesia. Three ulcers sites were prepared in each pig in left colon: one EMR-ulcer was performed with prior saline submucosal injection (A; EMR-saline), other EMR-saline ulcer was treated by applying a product shield (B; EMR-saline-P), while the other EMR-ulcer was performed with prior submucosal injection of the product and posterior EST with product (C; EMR-P-P). All animals underwent weekly endoscopic follow-up (weeks 1 and 2). At the end of the treatment period new lesions (EMR-saline; EMR-saline-P and EMR-P-P) were performed in healthy colonic mucosa to assess acute injury. All animals were

euthanized at week 2, and ulcers sites were macroscopically and histopathologically evaluated. Thermal injury was assessed with a 1-4 scale: (1) mucosal necrosis; (2) submucosal necrosis; (3) muscularis propria necrosis; and (4) serosal necrosis.
Results: Basal mean ulcerated area induced by EMR was comparable in the three groups (A = 2.12 ± 1.45 cm^2, B = 2.57 ± 1.53 cm^2, C = 2.66 ± 1.64 cm^2; p = n.s.). Submucosal injection of product induced a marked trend to less deep thermal injury (C = 2.25 ± 0.46 vs A and B = 2.75 ± 0.46; p = 0.127). Mucosal healing rate at week 2 (percentage of mucosal restoration) were significantly higher in animals treated with product (B = 90.2 ± 3.9%, C = 91.3 ± 5.5% vs A = 73.1 ± 12.6%; p = 0.002).
Conclusion: The application of this newly hydrogel in a porcine model with EMR-colonic ulcers has demonstrated strong healing properties. Otherwise, submucosal injection of this product is able to avoid high thermal load of the gastrointestinal wall. This technique is safe and easy to learn, and we can solve many drawbacks we have in the field.

P1424 PREDICTIVE ACCURACY OF HIGH-RISK SERRATED LESIONS AND THE IMPACT OF A BRIEF EDUCATIONAL INTERVENTION

V. Gupta[1], M. Pellise[1], M. J. Bourke[1]
[1]*Gastroenterology and Hepatology, Westmead Hospital, Sydney, Australia*

Contact E-mail Address: vikas.gupta@health.nsw.gov.au
Introduction: Real-time characterisation of advanced lesions during colonoscopy informs the therapeutic approach. Sessile serrated polyps (SSP) may be missed but even when detected are almost four times as likely as adenomas to be incompletely resected, especially if large. SSP with dysplastic foci (SSP-D) are considered high risk for malignant transformation. They may be mistaken for other lesions if only the dysplastic (adenoma-like) area of the lesion is appreciated, risking incomplete resection. However, dysplasia in serrated lesions may be detected endoscopically. The ability of expert and trainee endoscopists to do this is unknown.
Aims & Methods: To determine baseline accuracy for *in vivo* histology prediction of SSP-D and the impact of a brief educational intervention.
Seventy high-quality representative images were selected from a database of large sessile and flat polyps. Histopathology was used as the gold standard. The images were presented, in randomised order, to Australasian self-identified "expert" and "trainee" colonoscopists. Participants were asked to predict the underlying histology of each lesion from five options (SSP-D, SSP with no dysplasia (SSP-ND), tubulovillous adenoma, tubular adenoma, submucosal invasive cancer (SMIC)). Subsequently, a 60-minute educational session explaining the characteristic features of SSP-D was provided. Participants then repeated the test using the same polyp set with images in a different order.
Results: Responses were collected from 37 participants: 16 Trainees and 21 Experts. The groups were differentiated by years of colonoscopy (1.4 vs 12.8; $p < 0.001$) and average number of colonoscopies per week (8.5 vs 19.2; $p < 0.001$). Baseline accuracy (Table 1) was 66% for SSP-ND and 22% for SSP-D with experts demonstrating a significantly better predictive accuracy for SSP-D (p = 0.042).
Post training testing showed a threefold improvement in recognition of SSP-D for the whole cohort ($p < 0.001$). This effect was more pronounced for trainees (17.1% to 67.1%) than for experts (26.0% to 68.2%). Following training there was no significant difference in SSP-D recognition between trainees and experts (p = .837).

P1425 A SIGNIFICANT PROPORTION OF PATIENTS STILL REQUIRE COLONOSCOPY AFTER CT COLONOGRAPHY WITHIN THE NHS BOWEL CANCER SCREENING PROGRAMME

V. Sehgal[1], E. Harvey[1], J. Stein[1], S. Bloom[1], R. Vega[1], S. McCartney[1], A. Obichere[1], K. Besherdas[1]
[1]*Gastroenterology, University College Hospital London NHS Foundation Trust, London, United Kingdom*

Contact E-mail Address: v.sehgal@ucl.ac.uk
Introduction: Patients within the Bowel Cancer Screening Programme (BCSP) who are unsuitable for or decline colonoscopy are instead usually offered CT colonography (CTC). Whereas patients with a normal CTC are either discharged or returned back to biennial screening, colonoscopy is usually indicated if CTC demonstrates a suspected colorectal cancer (CRC) or large polyp/s (>10mm). Patients who have intermediate-sized polyps (6-9mm) or multiple diminutive polyps (<5mm) either proceed to colonoscopy (flexible sigmoidoscopy for left-sided polyps) or interval CTC. We investigated the number of patients who required colonoscopy after CTC within the BSCP. We hypothesised that a significant proportion of patients still require colonoscopy, thus questioning the utility of CTC in patients in the BCSP.
Aims & Methods: Patients who had a CTC within the BCSP at UCLH between September 2007-14 were identified retrospectively. All CTC examinations were performed using faecal tagging with laxatives wherever possible with or without intravenous contrast. Results of CTC were classified as normal, low-risk (1-2 polyps both <10mm), intermediate-risk (3-4 polyps <10mm or at least one ≥10mm), high-risk (≥5 small polyps or ≥3 intermediate-sized polyps with at least one ≥10mm) and suspected CRC.
Results: In total, 319 CTCs were performed in 292 patients. 39 patients (13%) had CTC after incomplete colonoscopy and were excluded. 253 patients (136 male, median age 70 years) underwent CTC as their primary investigation and their outcomes analysed.
98 patients (39%) proceeded to having a colonoscopy after their CTC. There was no significant difference in the reported study quality between those patients requiring a colonoscopy (good 44%, poor 10%) and not (good 52% poor 7%). 57 patients (92%) who had either intermediate/high-risk polyps or suspected CRC on CTC underwent colonoscopy. Of these 57 patients, 15 (26%) had either low-risk polyps (n = 9) or no abnormality at colonoscopy (n = 6). 37 patients (20%) whose CTC was either normal (n = 10) or revealed low-risk polyps (n = 27) were also referred for colonoscopy. No patient had their CTC diagnosis upstaged after colonoscopy.
The median time from CTC to colonoscopy was 35 days (5-1852 days). 72 patients (74%) had their colonoscopy within 3 months of their index CTC.
Conclusion: A significant proportion of patients who undergo CTC within the BCSP will still require a colonoscopy. Although the sensitivity of polyp detection between CTC and colonoscopy is comparable, CTC confers a not insignificant radiation burden. It is essential that all patients be counselled with this information upon entrance into the BCSP and in doing so, may reduce the number of CTCs as the primary investigation within the BCSP.

Introduction: Endoscopic balloon dilation (EBD) is the endoscopic treatment of choice for short stenosis in Crohn's diseases (CD). Several uncontrolled observational studies have shown that EBD in selected patients is a safe and an effective alternative to surgery. Previously published series have limitations due to heterogeneity of technique and different endpoints which makes comparisons difficult, and generally with small series of patients and performed at tertiary care centres.

Aims & Methods: To asses efficacy and safety of EBD in clinical practice setting in Spanish hospitals adhered to ENEIDA project. We identified all patients undergoing EBD from ENEIDA database. Additional information not included in the database was requested to the 16 participating centres: patient's clinical information; stenosis data;and information about effectiveness and complications of EBD. Technical success was defined when endoscope got pass through stricture after the procedure and therapeutic success when it was not necessary another endoscopic or surgical treatment after 1 year or until the end of the follow-up. A logistic regression analysis was performed to assess factors associated with therapeutic success. A survival analysis was done to evaluate predictive factors related to remain free of surgery.

Results: A total of 335 dilations were performed in 162 patients (147 CD, 13 UC and 2 IC) with a median of 2 dilation/patient. In 43.1% of cases strictures were in the anastomotic site. Technical and therapeutic success was achieved in 80.2% and 52.2% of EBD respectively with a median follow-up of 36 months (0-276). 72.4% of the patients were free of surgery or stent placement, 32% with one EBD. In the multivariate analysis, technical success with an OR of 2.62 ($p = 0.012$), the balloon diameter (>12 mm) with an OR of 2.5 ($p = 0.006$) and no need of anti-TNF therapy for the disease control with an OR of 1.71 ($p = 0.031$) were associated with therapeutic success. No related factors were found in the survival analysis. The rate of major complications was 2%.

Conclusion: In a clinical practice environment, EBD has a similar efficacy and safety than has been reported in tertiary care centres. Technical success, the balloon diameter (>12 mm) and not needing anti-TNF for disease control were the only factors associated with the therapeutic success. Randomized prospective studies are required to set what other factors are related to the response to EBD.

Contact E-mail Address: y2satou@marianna-u.ac.jp

Introduction: Endoscopic resection of colorectal adenomatous polyps effectively prevents colorectal cancer[1)]. But natural history of untreated colonic adenomatous polyps is uncertain. At our hospital, adenomatous polyps with a size of ≥6 mm or in which cancer is suspected on magnifying chromoendoscopy are subject to resection, and a follow up approach is adopted for adenomatous polyps with a size of ≤5 mm.

Aims & Methods: We retrospectively observed the natural history of adenomatous polyps and investigated the risk factors for polyp enlargement. We investigated 94 patients (362 adenomatous polyps) who underwent initial colonoscopy between 2007 and 2014 at our hospital and then continuously underwent at least four colonoscopies each year. For all polyps images taken by conventional white light endoscopy and magnified indigo carmine spraying, no polyps were biopsied. Endoscopic pit pattern diagnosis was performed using Kudo's classifications and, with III L pit patterns as subcategories, polyps were categorized into III L1 pit pattern composed of III L pit only, and III L2 pit pattern composed of both III L pit and I pit. Size was evaluated on comparison with the non-traumatic tube (outer diameter, 2.8 mm) in all polyps. Endoscopic reports and endoscopic images were reviewed and re-evaluated for the location, macroscopic type, size, and pit pattern of all polyps. We retrospectively investigated risk factors for polyp enlargement using univariate and multivariate analysis.

Results: A total of 284 polyps could have been followed up until the final endoscopy. The follow-up rate was 78.4%, the median follow-up period was 60 months (range, 46–84 months), and the median polyp size at initial colonoscopy was 3 mm (range, 2–13 mm). At the final endoscopy, 33 polyps (11.6%) had enlarged in size; the mean amount of enlargement was 1.78 ± 0.9 mm. When investigating the risk factors for polyp enlargement, univariate analysis indicated no significant differences in age, gender, initial size, or aspirin use; however, significant differences were noted for IV pit pattern ($P < 0.001$), III L1 pit pattern ($P = 0.009$), rectosigmoid colon ($P < 0.001$) and Is morphology ($P < 0.001$). Multivariate analysis results indicated that IV pit pattern ($P < 0.001$; OR 13.8, 95%CI: 3.5-55.3), III L1 pit pattern ($P = 0.004$; OR 4.3, 95%CI: 1.6-12.0) and rectosigmoid colon ($P = 0.01$; OR 3.0, 95%CI: 1.3-6.8) were independent risk factors for polyp enlargement.

Conclusion: Most polyps with III L2 pit pattern, size does not have a change even long-term follow-up. But resection should be considered for IV pit pattern polyps located in the rectosigmoid colon.

P1428 THERAPEUTIC STRATEGY OF ESD FOR COLORECTAL TUMORS ACCOMPANIED BY SEVERE DEGREE FIBROSIS IN THE SUBMUCOSAL LAYER

Y. Tamegai[1], T. Kishihara[1], A. Chino[1], H. Osumi[1], M. Igarashi[1]
[1]*Endoscopy Division, Cancer Institute Hospital, Tokyo, Japan*

Contact E-mail Address: yoshiro.tamegai@jfcr.or.jp

Introduction: The difficulty of one-piece resection of a colorectal tumor using ESD sometime due to the presence of fibrosis. We examined the causes and endoscopic findings of fibrosis in the submucosal layer (SM) in order to establish an appropriate therapeutic strategy for such lesions. From these observations, we developed a safe ESD technique we used.

Aims & Methods: We performed ESD on 981 colorectal tumors in 958 patients (male: female = 565:393; mean age, 65.8years). Among these 981 cases, 238 cases were accompanied by fibrosis in the SM. These cases were divided into three groups; absence of fibrosis (type A), fibrosis due to benign causes (due to biopsy, recurrence after EMR, etc. type B), and fibrosis due to cancer invasion in the SM layer (type C). The degree of fibrosis was classified into mild (grade 1), moderate (grade 2), and severe (grade 3) degree. In this study, we analyzed these lesions in order to establish a safe and curative ESD technique.

Results: These 238 cases accompanied by fibrosis were including 11 withdrawal cases, 84 cases were considered related to cancer invasion (type C), and 154 cases were related to benign cause (type B). The one-piece resection rates were as follows: Type A; 724/743(97.4%), type B-1; 73/76(96.1%), B-2:36/40(90.0%), B-3:22/38 (57.9%), type C-1:42/42(100%, average SM depth:713.8μm), C-2:15/16(93.8%, average SM depth:1.907.0μm), C-3:13/26(50%, average SM depth:2.800.0μm). We experienced three cases (0.3%) of perforation in type B. The tumors accompanied by mild to moderate fibrosis should be dissected carefully just above the muscle layer. In cases accompanied by severe degree fibrosis (type B-3), ESD becomes more difficult due to the risk of perforation. From the analysis of one-piece resection cases in type B-3, we developed the safe ESD technique to break these difficulties. The feasibilities to complete one-piece resection with type B-3 were as follows: 1) recognition of the narrow translucent area just above the muscle layer, 2) identification of the dissection line by linking with the normal SM layer of both ends of fibrosis, 3) using an endo-clip on the muscle layer to prevent perforation before dissection. Other cases of type B-3 were impossible to design the dissection line due to wide and firm fibrosis. The limitation of ESD is thought to be existed in these lesions from the viewpoint of safety and curability. From these reasons, we established the laparoscopy endoscopy cooperative surgery (LECS) procedure to complete a safe one-piece resection with adequate surgical margin. Otherwise, type C-3 was showing a deep cancer invasion about 3.000μm in the SM, and revealed very low one-piece resection rate. From these results, type C-3 endoscopic finding was thought to be an indication of laparoscopic surgery (LAC) due to the risk of lymph node metastasis.

Conclusion: The usefulness of ESD for lesions with fibrosis is limited from the viewpoint of safety and curability. We classified the endoscopic findings of fibrosis in order to establish a safe and curative ESD technique. The tumors accompanied by fibrosis of a mild to moderate degree become a standard indication for ESD. And the tumors accompanied by severe degree fibrosis without deep cancer invasion in the SM will become a relative indication of ESD and laparoscopy endoscopy cooperative surgery (LECS) procedure.

P1429 CLINICAL USEFULNESS OF DUAL RED IMAGING DURING COLORECTAL ENDOSCOPIC SUBMUCOSAL DISSECTION

Y. Ninomiya[1], S. Tanaka[1], S. Oka[1], D. Hirano[2], K. Sumimoto[2], Y. Tamaru[2], N. Asayama[2], K. Shigita[2], N. Hayashi[2], K. Chayama[1]
[1]*Endoscopy,* [2]*Gastroenterology and Metabolism, Hiroshima University Hospital, Hiroshima, Japan*

Contact E-mail Address: ikuyayimonin@hiroshima-u.ac.jp

Introduction: Dual red imaging (DRI), which is a new modality of image-enhanced endoscopy developed by Olympus, consists of 3 wavelengths different from narrow band images: the 540-nm wavelength can visualize small blood vessels in shallow tissue, and the 600-nm and 630-nm wavelengths can penetrate deep into the tissue. These wavelengths enable visualization of thick vessels, which is expected prompt identification of bleeding point in case of arterial hemorrhage. Because DRI results in a change in the color of the artery to orange, it is possible to discriminate between arteries and veins with clockwork

precision. However, there are no reports regarding the clinical usefulness of DRI during colorectal endoscopic submucosal dissection (ESD).
Aims & Methods: To assess the clinical usefulness of DRI during colorectal ESD, we evaluated the improved visibility of vessels, submucosal fibrosis, and the demarcation line of the muscle layer.
Seven physicians compared DRI to 17 corresponding white-light images during colorectal ESD. The physicians counted the number of vessels, and rated demarcation line between the submucosal and muscle layer after injection of hyaluronate sodium with minute indigo carmine, and the existence of fibrosis. The visibility from each image was rated as follows: +2 (improved), +1 (somewhat improved), 0 (equivalent to white light), -1 (somewhat decreased), and -2 (decreased). The 7 scores for each image were totalled and evaluated. If an image earned a total score of +8 or more, the image was considered improved, a score between +7 and –7 indicated no change, and a score of –8 or less indicated decreased visibility. Interobserver agreement was also examined using the kappa statistic. We also counted the number of arteries visible as orange vessels with DRI in comparison to the actual number of arteries identified by observing beating vessels or spurting bleeds on the video.
Results: The average number of vessels per picture was 5.1 ± 0.2 in white-light images and 4.1 ± 0.2 in DRI. The number of vessels visualized with DRI was significantly less than that seen with white-light images ($p < 0.01$). In regard to vessels, improved visibility was found in 59% (10/17) of images, equivalent visibility was found in 41% (7/17) of images, and there was no decreased visibility. In regard to the demarcation line of the muscle layer, improved visibility was found in 66% (11/17) of images, equivalent visibility was found in 35% (6/17) of images, and there was no decreased visibility. In regard to submucosal fibrosis, equivalent visibility was found in all images and there was no improved or decreased visibility. Interobserver agreement was 0.63 for vessels, 0.62 for the demarcation line of the muscle layer, and 0.47 for the existence of fibrosis. The average number of arteries per picture counted by using DRI (2.2 ± 1.4) was statistically equivalent to that counted by observing the video image (2.1 ± 1.5).
Conclusion: DRI improves the visibility of vessels, especially that of arteries, as they appear orange, and the demarcation line of the muscle layer. DRI may help to make colorectal ESD safer and faster.

P1430 A COHORT STUDY TO EVALUATE THE EFFECT OF ENDOSCOPIC SUBMUCOSAL DISSECTION FOR SUBMUCOSAL INVASIVE RECTAL CANCER

Y.-S. Zhong[1], S.-L. Cai[1], L.-Q. Yao[1]
[1]*Endoscopy Center, Zhongshan Hospital of Fudan University, Shang hai, China*

Contact E-mail Address: zhongyunshifd@126.com
Introduction: Endoscopic submucosal dissection (ESD) can be used to treat submucosal invasive rectal cancer (SM-RC). Patients who are at low risk for lymph node metastasis and local recurrence may simply undergo observational follow-up, while additional surgery is recommended for those with high-risk features. However, patients can suffer from persistent anorectal dysfunction after disfiguring rectal surgeries, such as the Dixon or Miles operations. Therefore, the objective of our study was to evaluate the outcomes of patients with SM-RC managed with either ESD or surgery to determine if ESD might be a suitable option with fewer negative side effects.
Aims & Methods: We retrospectively analyzed patients with SM-RC receiving treatment between 2009 March and 2013 September. SM-RCs with (1) a well or moderately differentiated adenocarcinoma, (2) negative vertical margins, (3) no sign of lymphovascular invasion, and (4) an invasion depth < 1000 μm were classified as low risk. Patients with SM-RCs without these characteristics were classified as high risk. Outcomes were assessed by complication rate, hospital stay length and cost, persistent anorectal dysfunction rate, recurrence rate, timeline for recurrence-free survival (RFS), and overall survival.
Results: During the study period, 76 patients with SM-RC who underwent ESD or surgery (32 ESD, 44 surgery) were enrolled (median follow-up ~35.0 months). There were 29 patients classified as low risk (16 ESD, 13 surgery) and 47 patients classified as high risk (16 ESD, 31 surgery). After we compared the complication rate, recurrence rate, recurrence-free survival, and overall survival, we found no obvious differences between ESD and surgery groups in both low-risk and high-risk patients. However, ESD had a lower occurrence of persistent anorectal dysfunction compared to surgery (low-risk: 6.3% vs. 61.5%, $p = 0.003$; high-risk: 0% vs. 41.9%, $p = 0.002$). At the same time, the average hospital stay length and cost of was lower with ESD for both high- and low-risk patients (low risk: 2.25 ± 1.39 days vs. 8.85 ± 3.31 day, $p = 0.000$; 10858.9 ± 1968.9 RMB vs. 26293.0 ± 6991.1 RMB, $P = 0.000$; high risk: 2.31 ± 0.95 day vs. 12.4 ± 15.8 day, $p = 0.015$; 11844.6 ± 2095.4 RMB vs. 32722.0 ± 5633.9 RMB, $P = 0.000$).
Conclusion: Long-term outcomes were favorable in patients with low-risk SM-RC treated with endoscopic resection alone. Endoscopic resection alone was considered an adequate treatment for this group, particularly with the interests of minimizing the occurrence of persistent anorectal dysfunction and reducing the length of hospital stay and in turn the cost. In patients with high-risk SM-RC and a clinicopathological examination showing deep invasion of the submucosa without venous or lymphatic invasion, ESD is often adequate, but follow-up is needed.

P1431 ENDOCUFF-VISION: IMPACT ON COLONOSCOPIST PERFORMANCE DURING SCREENING

Z. P. Tsiamoulos[1], R. Misra[1], P. Kinesh[1], A. Haycock[1], N. Suzuki[1], S. Thomas-Gibson[1], B. P. Saunders[1]
[1]*Wolfson Unit for Endoscopy, St Mark's Hospital/Academic Institute, London, United Kingdom*

Introduction: Although colonoscopy is considered the optimal procedure for bowel cancer screening, it remains an imperfect tool for cancer prevention, due to missed adenomas and early cancers. The Endocuff is a simple device attached at the end of the colonoscope that opens up the field of view by retracting folds during withdrawal. Little is known regarding the Endocuff's vision (new) impact on a colonoscopist's performance.
Aims & Methods: The aim of this study was to evaluate the impact of the Endocuff-vision (ARC Design Ltd, UK) on the quality indicators for each operator. A prospective observational evaluation study was performed from April 2013 to September 2014, divided in three consecutive periods: pre-cuff (no device used), during-cuff (device used) and post-cuff (no device used). Four screening endoscopists (BPS, STG, NS, AH) utilized the Endocuff-vision™ at their own discretion when device was available to them. Quality colonoscopy indicators (Adenoma Detection Rate (ADR), Mean number of adenomas per procedure (MAP), Caecal intubation time- CIT/Withdrawal time-WT/Total procedural time-TPT) were analyzed (t-test two sample assuming equal variances) in equivalent number of procedures. The total number of procedures performed was 399, 133 per period (BPS/26, STG/53, NS/31, AH/23).
Results: The mean ADR was 55.13% in the pre-cuff period, 68.98% in the during-cuff period and 61.74% in the post-cuff period. All four operators showed significant improvement in detection when using the device, which resulted in an overall increased ADR of **13.8%** ($p < 0.05$). During the post-cuff period, the detection performance of the three endoscopists declined to similar ADR pre-cuff level while one operator improved further the adenoma detection rate.
The mean MAP was 1.2 in the pre-cuff period, 2.2 in the during-cuff period and 1.55 in the post-cuff period. The mean MAP increased significantly in all four operators at the during-cuff period (**83%**, $p < 0.05$). During the post-cuff, three endoscopists returned almost to the baseline MAP pre-cuff level while one operator maintained the high MAP score.
The mean CIT was 9.66min in the pre-cuff period, 7.5min in the during-cuff period and 9.54min in the post-cuff period. A decrease in mean CIT was featured (**22.36%**, $p < 0.005$) to all operators when using the device, returning to about the pre-cuff levels afterwards.
No complications were reported from the use of the Endocuff-vision although it was electively removed in 4 cases with severe sigmoid colon diverticulosis and one case due to anal discomfort.
Conclusion: In this pilot evaluation study, the first use of the Endocuff-vision appears to improve overall performance of the operators by making colonoscopy a quicker (decrease CIT) and more efficient (increase MAP/ADR) procedure. Further randomized evaluation of this simple novel device combining the patient comfort score and sedation required is warranted.

P1432 PITFALLS IN PIECEMEAL RESECTION OF COMPLEX COLORECTAL POLYPS

Z. P. Tsiamoulos[1], T. Elliott[1], N. Suzuki[1], P. Bassett[2], B. P. Saunders[1]
[1]*Wolfson Unit for Endoscopy,* [2]*Statsconsultancy Ltd, St Mark's Hospital/Academic Institute, London, United Kingdom*

Contact E-mail Address: ztsiamoulos@nhs.net
Introduction: The role of piecemeal endoscopic mucosal resection (p-EMR) for sessile/flat colonic polyps previously destined for surgery is expanding. However, surgery remains appropriate in some cases. The objectives of this study were to determine the primary reasons in this decision-making, and factors associated with polyp non-excision, and the presence of submucosal invasive cancer (SMIC).
Aims & Methods: A prospective observational cohort study of all polyps referred for consideration of p-EMR to our tertiary centre between January 2010 and August 2012 was performed. For each case, a detailed endoscopic evaluation of the polyp was performed prior to the polyp being excised or not excised. The primary reason for polyp non-excision was documented. Univariable and multivariable analyses were performed to determine factors associated with (i) non-excision and (ii) submucosal invasive cancer (SMIC).
Results: Seventy-one of 419 (17%) polyps were not excised (p-EMR not attempted in 52/71 and abandoned in 19/71 cases). The primary reasons for non-excision were; suspected SMIC (36/71), polyp size +/- location, poor polyp access and patient comorbidities. On multivariate analysis, factors associated with polyp non-excision were increasing polyp size ($p < 0.001$), site (caecum and sigmoid colon, $p < 0.001$), surface features suggestive of SMIC (Paris IIc, Kudo V and NICE III, all $p < 0.001$) and female gender ($p = 0.04$). SMIC was present in 9% of polyps >2cm and was more prevalent in the rectum to the descending colon than in the transverse colon to caecum ($p = 0.04$). Although surface features were associated with SMIC on univariable analysis and the positive predictive values are relatively high (Paris IIc 80%, Kudo V 86% and NICE III 86%)., the sensitivity of these features for a diagnosis of SMIC were relatively low (Paris IIc 11%, Kudo V 49% and NICE III 51%).
Conclusion: A percentage of polyps referred to a tertiary institution were not suitable for p-EMR, most commonly because of suspicion of SMIC. Specific surface features of malignancy may be present but the physician's overall endoscopic evaluation was also useful in predicting suitability of polyps for p-EMR.
Disclosure of Interest: None declared

P1433 COMPLEX COLORECTAL POLYPS: A TERTIARY CENTRE EXPERIENCE; TAILORING THE EMR TECHNIQUE TO THE POLYP

Z. P. Tsiamoulos[1], T. Elliott[1], N. Suzuki[1], P. Bassett[2], B. P. Saunders[1]
[1]*Wolfson Unit for Endoscopy,* [2]*Statsconsultancy Ltd, St Mark's Hospital/ Academic Institute, London, United Kingdom*

Contact E-mail Address: ztsiamoulos@nhs.net

Introduction: The complexity of colorectal polyp referrals to tertiary centres is increasing. Features that characterise polyp complexity should be clearly defined and recognised to avert suboptimal piecemeal endoscopic mucosal resection (p-EMR) strategies and need for salvage surgery.

Aims & Methods: A prospective database of all colorectal polyps excised at our tertiary referral centre between Jan 2010 and August 2012 was collected. Standard p-EMR with a semi-stiiff snares (10mm/15mm) was performed but for polyps where this strategy was considered inadequate, p-EMR using a 20mm Spiral-snare (sp-EMR),(Olympus, KeyMed), or hybrid p-EMR (hp-EMR; p-EMR plus endoscopic-mucosal-ablation or endoscopic-submucosal-dissection) were performed. Multinomial logistic regression was performed including polyp characteristics and p-EMR techniques applied. The primary outcomes were to define characteristic features of complex polyps and factors associated with the chosen resection technique.

Results: Of 323 patients with 341 polyps (mean size 3.7cm), 81%(261/323) were tertiary and 19% were local referrals. 94/261(36%) tertiary referrals mentioned one or more previous endoscopic resection attempts. Endoscopic polyp access was described as difficult in 174/341(51%, p = .001), incomplete polyp lift in 179/341(52%, p = .002) cases and polyp size ≥4cm (median size 5cm) in 123/341(36%, p < .001) cases. Polyps ≥4cm were more frequently in a difficult position (≥4cm;63% vs <4cm;37%, p < .001). Polyps <4cm were more likely to be in the caecum or ascending colon (<4cm;35% vs ≥4cm;16%, p < .001).

Factors	Category	All polyps	≥2 - <4cm polyps	≥4cm polyps	P-value
Polyp lift	Full	162 (48%)	117 (54%)	45 (37%)	**0.002**
	Incomplete	179 (52%)	101 (46%)	78 (63%)	
Difficult polypposition	No	167 (49%)	121 (55%)	46 (37%)	**0.001**
Yes	174 (51%)	97 (45%)	77 (63%)		
Techniques used	pEMR	230 (67%)	173 (79%)	57 (46%)	**<0.001**
	Hybrid pEMR	63 (19%)	31 (14%)	24 (20%)	
	Spiral pEMR	48 (14%)	14 (6%)	34 (28%)	
Proceduralbleeding	No	306 (91%)	205 (95%)	101 (83%)	**<0.001**
Yes	32 (9%)	11 (5%)	21 (17%)		
Delayedbleeding	No	258 (78%)	181 (85%)	77 (66%)	**<0.001**
Yes	72 (22%)	32 (15%)	40 (34%)		

Endoscopically complete polypectomy was achieved in one session in 336/341(98%, p < .001) polyps. Procedural and delayed bleeding were significantly higher in the ≥4cm group where 2 of the 3 micro-perforations also occurred (3/341,0.9%) that were all treated successfully with endoscopic clipping. The overall long-term recurrence at 24 months was 17% (28% for ≥4cm/p = .02). Only eleven patients (4 benign-recurrence/7 cancer in histology,3%) in this cohort underwent surgery. Using multivariable analysis, factors associated with need for sp-EMR or hp-EMR were; **i) tertiary referrals** (sp-EMR, OR-3.41, p < .001**), ii) incomplete polyp lift** (hp-EMR, OR-8.3 > sp-EMR, OR-1.19, p < .001), **iii) previous polypectomy attempt** (hp-EMR, OR-2.77, p = .02), **iv) larger polyp size** (for an increase of 1cm - hp-EMR (OR-1.37)/sp-EMR (OR-1.66, p < .001), **v) polyps in the rectosigmoid location** (sp-EMR and hp-EMR, p < .001) and **vi) Paris IIa + IIb polyps** (sp-EMR, OR-5.01 and hp-EMR, OR-2.9, p-.007).

Conclusion: Complex colorectal polyps referred to this tertiary centre were characterised by polyp size ≥4cm, caecal location, previous unsuccessful polypectomy, difficult endoscopic access, or incomplete polyp lift. Advanced techniques such as hybrid-pEMR and spiral p-EMR were required in 33% of tertiary referrals.

P1434 DILATION-ASSISTED STONE EXTRACTION: AN ALTERNATIVE, EFFECTIVE AND SAFE METHOD FOR REMOVAL OF COMMON BILE DUCT LARGE STONES

R. Di Mitri[1], F. Mocciaro[1], G. M. Pecoraro[1]
[1]*Gastroenterology and Endoscopy Unit, ARNAS Civico-Di Cristina-Benfratelli Hospital, Palermo, Italy*

Contact E-mail Address: fmocciaro@gmail.com

Introduction: Large stones of common bile duct (CBD) are a hard challenge after endoscopic sphincterotomy (EST) especially in those that are unable to be managed with standard techniques including mechanical lithotripsy. Dilation-assisted stone extraction (DASE) after EST can be more efficient than EST alone for removal of large CBD stones.

Aims & Methods: The aim of this study is to report the experience of a referral centre on the efficacy and complications of DASE for CBD large stones treatment. From January 2013 to March 2015 data of all consecutive patients who underwent DASE due to large stones, evidenced by CT-scan or MRI, were collected and recorded in an electronic database for the final analysis. After selective cannulation of the CBD, an initial cholangiogram was taken before balloon placement. The size of the balloon was matched to the diameters of the bile duct and stones. The balloon was gradually filled with diluted contrast medium under endoscopic and fluoroscopic guidance to observe the gradual disappearance of the waist in the balloon, which was taken to indicate progressive dilation of the orifice. Once the waist disappeared, the balloon remained inflated for 60 s.

Results: A total of 27 patients with CBD large stones were evaluated: 10 male (37%)/ 17 female (63%) with a mean age of 71.1 ± 14.2. Technical success (complete dilation) was reached in all patients (100%) with a median final dilation of 15 mm in diameter: 10 mm in 4 patients (15%), 15 mm in 11 patients (41%), 18 mm in 10 patients (37%), 20 mm in 2 patients (7%). In 6 patients (22%) EST was done before the current procedure and DASE was performed due to stones recurrence. In all patients but two (93%) large stones were successful removed from the CBD (17 with retrieval balloon and 8 with aid of mechanical lithotripsy). In those with DASE failure: 1 was treated with intracoledocical laser lithotripsy and 1 with surgical approach. Only 2 early complications were recorded (7%): both mild bleeding resolved after endoclips placement. In one patient CBD stones recurred after 2 months.

Conclusion: DASE after EST is an alternative, effective and safe method for removal of CBD large stones.

P1435 ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY FOR PRIMARY AND SECONDARY ("RESCUE") MANAGEMENT OF PERIHILAR MALIGNANT BILIARY STRICTURES: A TERTIARY CENTRE EXPERIENCE

S. Mahmood[1], L. Hodges[1], J. Iqbal[1], H. Kaltsidis[1]
[1]*Gastroenterology, University Hospital South Manchester, Manchester, United Kingdom*

Contact E-mail Address: smkahlon@hotmail.com

Introduction: Biliary decompression and palliation of patients with perihilar malignant strictures due to cholangiocarcinoma is historically achieved via percutaneous trashepatic drainage (PTD) and placement of uncovered self expandable metallic stents (UC-SEMS). PTD in this setting carries significant morbidity (bleeding, bile leaks, biloma formation) and mortality up to 20% in retrospective audit conducted by the British society of Radiology.

Endoscopic management of perihilar malignant biliary strictures is an alternative approach adopted by very few high-volume tertiary Centres in the UK. Here we describe our experience in a total of 15 patients who were successfully managed with the placement of UC-SEMS.

Aims & Methods: To review the safety, feasibility and outcomes of the endoscopic retrograde approach as primary method of achieving biliary decompression in malignant perihilar strictures.

Retrospective case series between March 2013 to Feb 2015, 15 patients with malignant perihilar strictures were identified during the period and data collected reviewing medical notes and electronic patient records.

End-points were technical success(correct unilateral or bilateral UC-SEMS placement confirmed radiologically at the time of procedure), and clinical success (>50% fall in bilirubin 2 weeks post procedure or patient eligibility for palliative chemotherapy post intervention, or provision of initial definitive treatment in patient for best supportive care). UC-SEMS with a length of 80-100mm and diameter of 10mm were used. Depending on the type of the stricture, either a unilateral (6 patients) or bilateral (8 patients) SEMS were used.

Results: 15 patients in total (5M,10F, median age 69 years, age range -89). Table shows the primary site of malignancy.

Cholangiocarcinoma	8
Colorectal cancer with metastases	3
Pancreatic cancer with Liver metastases	2
Hepatocellular cancer	1
Metatstatic Breast cancer with liver hilar stricture	1

All patients were successfully managed with UC-SEMS at first ERCP with a procedural success rate of 100%. Clinical success was 93% (1 patient needed PTD after 12 days due to incomplete resolution of jaundice). One patient needed further ERCP 50 days after the index ERCP because of proximal extension of the stricture (type IIIa), a single UC-SEMS was successfully placed.

3 patients had previous PTD with single metal stent in situ and presented with persistent or recurrent jaundice for secondary "rescue" ERCP; 2 patients had percutaneous external biliary drain only in situ prior to the index ERCP; the remaining 10 patients had ERCP as primary biliary intervention. 5 patients received palliative chemotherapy and one patient was offered chemotherapy but subsequently declined.

No significant peri-procedural complications were recorded in our group of patients and the 30-day mortality was 0%. 5 patients reported some discomfort 24-48h post procedure attributed to stent expansion. One patient had mild pancreatitis, symptoms resolved on day 3.

Conclusion: In a high-volume Centre with expertise in the technical aspects of management of hilar lesions ERCP is highly effective and safer alternative to PTD as evident in this small retrospective study. A large prospective randomised trial is needed in order to compare PTD vs ERCP as a primary approach for biliary decompression in this group of patients.

P1436 RETROSPECTIVE COMPARATIVE STUDY FOR THE EFFECTIVENESS AND SAFETY OF EXTRACTING BILE DUCT STONES LESS THAN 10MM; ENDOSCOPIC PAPILLARY BALLOON DILATION BY 5-MINUTE DILATION WITH 10MM DIAMETER BALLOON VS. ENDOSCOPIC SPHINCTEROTOMY

S. Asai[1], N. Fujimoto[1], K. Takeshita[1], Y. Kanou[1], E. Nakao[1], K. Hashimoto[1], T. Ichinona[1], E. Akamine[1], A. Ogawa[1]

Introduction: Endoscopic Papillary Balloon Dilation (EPBD) has a lower risk of hemorrhage and is easier to perform but has higher incidence of pancreatitis than Endoscopic Sphincterotomy (EST). It is reported that 5-minute EPBD improves efficacy of stone extraction and reduces the risk of pancreatitis compared with conventional 1-minute EPBD. Therefore we conducted retrospective comparative study of 5-minute EPBD vs. EST with respect to stone extraction and pancreatitis.
Aims & Methods: All enrolled cases had bile duct stones less than 10mm. Consecutive 79 cases treated by 5-minute EPBD from Oct. 2013 to Apr. 2015 were compared to consecutive 82 cases treated by EST from May 2010 to Oct. 2013. EPBD balloon diameter used in this trial was all 10mm.
Results: Mean age was 74 in EPBD group and 70 in EST group ($p < 0.05$). Sex, stone diameter and number of stones did not statistically differ between two groups. The rate of complete extraction of bile duct stones in first session was 100% in both groups. Procedure time was approximately 30 minutes in both group and did not show statistical difference. Cannulation time of EPBD group and EST group was 14 minutes and 9 minutes ($p = 0.05$), respectively. The rate of novices and intermediates as 1st endoscopist was significantly higher in EPBD group (EPBD: 89% vs. EST: 71%, $p < 0.05$). Pancreatitis was seen 3.8% of EPBD group and 6.1% of EST group and bleeding occurred only in EST group (2.4%) but neither pancreatitis nor bleeding showed statistical differences.
Conclusion: 5-minute EPBD had high performance of stone extraction and low incidence of pancreatitis. It may be first choice as a method for extracting bile duct stones less than 10 mm because we can expect better long-term outcomes to EPBD than EST. However we need to conduct randomized trial and reveal long-term outcomes.

Introduction: Periampullary tumors represent a group of rare gastrointestinal tumors. Almost 95% of lesions of the ampulla of Vater correspond to adenomas or adenocarcinomas. These tumors can occur sporadically or in association with hereditary polyposis syndromes such as familial adenomatous polyposis (FAP). Endoscopic advances in ERCP and Endoscopic Ultrasound have changed the management of these tumors in recent years.
Aims & Methods
Aim: To present results of endoscopic papillectomy.
Patients: The database was reviewed to obtain 15 patients (8 men) with a mean age of 51.2 years (range 25-74) with papillary tumors, in whom endoscopic papillectomy was performed, between December 2006 and November 2013. The most common form of presentation was asymptomatic (53.3%), pain (40%), choledochal syndrome (13.3%) and weight loss (13.3%). Forty percent was related to FAP.
Methods: All patients had previous Endoscopic Ultrasound, biopsy with forceps, and met criteria for endoscopic resection. The procedure was performed with a duodenoscope, using the "en block" resection with snare technique, without previous injection. In all patients a 5 Fr / 3 cm length pancreatic stent was placed, after resection, as well as biliary sphincterotomy.
Results

Procedure characteristics n (%)	
Number of procedures	Total 1 61= 14 patients (93.3) 2= 1 patients (6.7)
Complications	Bleeding 3/15 (2%)
Surgery	0
Clinical success (30 days)	15 patients 13/15 (86)=2 patients with adjuvant therapy (EMR 1, APC 1)
Long-term success (>6 months)	11 patients (73) Of the 11 patients followed long-term success was achieved in 81.8% (9/11)
Follow-up mean (range)	26.4 months (6-61)
Relapses	3/11 (27)-1/11 responded to EMR + APC
RF for relapse	2/3: FAP3/3: LGDMean size: 18 mm

16 procedures were performed in 15 patients. The histological analysis of the lesions showed 11 (73.3%) had low-grade dysplasia, 2 (13.3%) had high-grade dysplasia, 1 was an intramucosal adenocarcinoma and 1 was invasive adenocarcinoma. The frequency of false negatives for cancer obtained with biopsy-forceps was 13%. The short-term treatment success, defined as absence of disease in control duodenoscopy at 30 days, was 86%.
Eleven patients were followed for 6 months or more (mean 26.45). Of these, 3 had relapses (27%), 1 was treated with ablative therapy (argon plasma coagulation). Success in monitoring for more than 6 months was 81.8% (9/11).
Immediate bleeding was the most common major complication (2%), being controlled with injection of adrenaline. No cases of acute pancreatitis (AP) were recorded. At follow-up one patient had invasive adenocarcinoma and received chemotherapy because of inoperability criteria.
Conclusion: papillectomy is a safe and proven choice, with good results in the short and long term. Forceps biopsies present a considerable false negative rate. Pancreatic plastic stent placement prophylaxis of AP is mandatory to avoid this complication. Relapse may relate, among other factors, with the association with FAP.

P1438 FEASIBILITY OF DIRECT PERORAL CHOLANGIOSCOPY USING AN ULTRASLIM UPPER ENDOSCOPE FOR EVALUATING RESIDUAL STONES OF COMMON BILE DUCT STONE

S. Omuta[1], I. Maetani[1], K. Gon[1], M. Saito[1], M. Naruki[1]
[1]*Div. of Gastroenterology and Hepatology Dept. of Internal Medicine, Toho University Ohashi Medical Center, Tokyo, Japan*

Contact E-mail Address: muta@oha.toho-u.ac.jp
Introduction: In endoscopic lithotomy for common bile duct (CBD) stone, with small residual stone in enlarged bile duct and/or maked pneumobilia, confirmation of complete removal stone is rather difficult even with balloon-occlusion cholangiography. And the frequency of residual CBD stones after stone removal was investigated that 40% had small residual stones not seen on cholangiography [1)]. Recently, direct peroral cholangioscopy (DPOCS) using an ultraslim upper endoscope has been reported to be useful for confirmation of residual CBD stone [2)]. However, accessing to biliary system and performing lithotomy is still more challenging. We performed DPOCS using an ultraslim upper endoscope, for evaluating of residual stones after endoscopic lithotomy with ERCP and technical feasibility.
Aims & Methods: From November 2009 to December 2014, thirty-seven patients (men 11) who had undergone endoscopic lithotomy for retained stone with no evidence of filling defects in balloon cholangiography were identified. The ultraslim endoscopes were used GIF-XP260N (Olympus, Tokyo, Japan) and EG-580NW2 (Fujinon, Tokyo, Japan) in this study. Endoscopic procedure for accessing biliary system followed our previous report [3)]. If any residual stone was found, it was removed directly under DPOCS with a slim basket catheter and/or suction. The rate of accessing to biliary system, present residual stone, successful residual stone removal, adverse events were analyzed.
Results: The mean age of patients was 81.4 years , the mean CBD diameter and the number of residual stones were 14.0mm, 1.6, respectively. DPOCS was successfully performed in 35 of the 37 patients (94.6%). The mean time for accessing to biliary system was 12.3 minutes in the 35 patients. The rate of application of ML was 24.3% (9/35), residual stone was identified in 7 of the patients with successful DPOCS (7/35, 20%). For all seven patients underwent endoscopic lithotomy under DPOCS, complete stone removal was accomplished (7/7, 100%). Adverse events were 16.2% (6/37), mild pancreatitis (1), mild cholangitis (5). All patients were successfully managed with conservative treatment.
Conclusion: DPOCS using an ultraslim upper endoscope is a useful and feasible endoscopic procedure for evaluation of residual CBD stones.

P1439 HEMOCLIP APPLICATION USING CAP-FITTED FORWARD ENDOSCOPY TO TREAT POST-SPHINCTEROTOMY BLEEDING IN PATIENTS UNDERGOING ERCP

T. H. Kim[1], Y. W. Sohn[2]
[1]*Internal Medicine, Wonkwang university Hospital, iksan,* [2]*Internal Medicine, Wonkwang university Hospital, Sanbon, Korea, Republic Of*

Introduction: The risk of immediate or delayed bleeding following endoscopic biliary sphincterotomy (ES) during endoscopic retrograde cholangiopancreatography (ERCP) is reported from 2.0-5.3%. Clinically, bleeding can range from insignificant to life threatening. Although endoscopic clipping may effective method treatment of a wide variety of bleeding lesions of GI tract, mechanical clipping of post-ES bleeding has not been widely studied, in part due to the difficulty in placing the current generation of clips using ERCP endoscopes. A cap-fitted forward viewing endoscope can easily visualize the ampulla of Vater.
Aims & Methods: To determine the efficacy of a cap-fitted endoscopy to treat bleeding on the bleeding on the ES site in patients who undertook ERCP with ES.

Patients and methods: The study included 1.248 consecutive patients who underwent 1.248 ERCP with ES procedures between January 2011 and August 2014. ES-induced hemorrhage occurred in 45 patients (3.6%). Bleeding patterns (trickle, oozing, pulsatile, and exposed vessel) were recorded. Patients with oozing or trickle bleeding who did not respond to balloon compression or epinephrine solution injection and all the patients with pulsatile bleeding and/or exposed vessel on the ES site, received clipping.
Results: The mean age was 69.1 ± 14.3 and sex ratio (M/F) was 32 (71.1%): 13 (28.9%) in 45 patients. Thirty nine patients had immediate endoscopic visible bleeding signs during ES, and 6 patients without endoscopic visible bleeding signs during ES who did not undergo clipping (0.48%) presented with delayed hemorrhage. Visible bleeding pattern following ES were: 19 trickle (42.2 %), 22 oozing (48.9 %), 3 pulsatile (6.7 %), and 1 exposed vessel (2.2%). Hemostasis was achieved by clipping in 45 of 45 patients (100%) who included patients with antiplatelet drug (n = 9) and warfarin (n = 2). The median number of clips used in all patients was 2.0 (range: 1-3). No patients had evidence of delayed bleeding after clipping on all visible bleeding signs. No patients had evidence of complication related to this procedure after clipping.
Conclusion: Hemoclip application using cap-fitted forward viewing endoscopy is feasible, safe and may be an effective technique for the treatment and/or prevention of post-ES bleeding.

Contact E-mail Address: ptymd@hotmail.com
Introduction: Liver transplantation (LT) has been applied for treatment of liver cirrhosis (LC), hepatocellular carcinoma, primary biliary cirrhosis, and fulminant hepatic failure. Spontaneous hemobilia is an uncommon LT-related biliary complication. The frequency, etiology and mechanism of spontaneous hemobilia after LT have not been known. Spontaneous hemobilia has clinical implication that blood clots in bile duct can cause biliary obstruction and cholangitis, and result in graft dysfunction. This condition may require removal of dysfunctional graft and transplantation of new graft.
Aims & Methods: This study aimed to assess outcome of endoscopic management for spontaneous hemobilia after LT, and to investigate its frequency and risk factors. The records of 53 patients who underwent ERCP to diagnose and manage hemobilia after LT at Asan Medical Center in Korea between January 2006 to April 2014 were retrospectively reviewed. To investigate the risk factors for spontaneous hemobilia after LT, control group matched according to age (± 2 years) and sex with fourfold number of study group was randomly selected from LT patients without spontaneous hemobilia during the same period.
Results: Of the 53 patients, 33 patients were included to study group. The mean age of study patients was 52.4 ± 8.7 years and 24 (72.7%) patients were male. The indications for LT were hepatitis B virus-associated LC in 19 cases (57.6%), alcoholic LC in 7 cases (21.2%), fulminant hepatic failure in 5 cases (15.2%), and cryptogenic LC in 2 patients (6.0%). Endoscopic nasobiliary drainage (ENBD) was achieved in 33 cases (100%). Hemobilia was stopped in 29 of 33 patients (87.9%). The frequency of spontaneous hemobilia was 1.22% (33/2701). On multivariate analysis, United Network for Organ Sharing (UNOS) status I or IIa (OR 3.095, 95% CI 1.097–8.732, $P = 0.033$), alcoholic LC (OR 3.942, 95% CI 1.261–12.324, $P = 0.018$), and body mass index (BMI) < 24.5 kg/m^2 (OR 2.329, 95% CI 1.005–5.397, $P = 0.049$) were significant risk factors for spontaneous hemobilia after LT.
Conclusion: ENBD was feasible method for management of spontaneous hemobilia after LT. In patients with UNOS status I and IIa, alcoholic LC, or BMI < 24.5 kg/m^2, special attention should be paid to occurrence of spontaneous hemobilia after LT.

P1441 DIRECT VISUALIZATION FOR THE ACCESSMENT OF PANCREATIC NEOPLASM WITH SPYGLASS DIRECT VISUALIZATION PROBE (SDVP) THROUGH UNEVEN DOUBLE LUMEN CANNULA IN ENDOSCOPIC RETROGRADE PANCREATOGRAPHY (ERCP)

T. Hisano[1], Y. Nagashio[1], R. Hashimoto[1], R. Sugimoto[1], Y. Aratake[1], H. Tajiri[1], M. Furukawa[1]
[1]*Department of Hepato-Biliary-Pancreatology, National Kyushu Cancer Center, Fukuoka, Japan*

Contact E-mail Address: idling3000@yahoo.co.jp
Introduction: Direct visualization of pancreatic ductal epithelium with peroral pancreatoscopy (POPS) could be useful for the diagnosis because most pancreatic neoplasms are derived from the epithelium. Insertion of POPS into the duct, however might be impossible in the cases with no ductal dilatation or existence of strong flexure part in it. If the insertion would be succeeded viscous liquid could disturb visualization of epithelium. Furthermore the POPS is not widely accepted for routine use for the diagnosis of pancreatic neoplasm in ERCP because of the fragility of the scope. Spyglass Direct Visualization Probe (Boston Scientific, MA, USA)(SDVP) is a very thin probe to visualize directly pancreatic ductal epithelium which is 1mm in diameter and go through one lumen in double lumen cannula in ERCP. Direct visualization of the epithelium with SDVP could be done while using the other lumen, inserting gidewire into it or washing it with saline, etc. That is why SDVP could have several advantages when it comes to user-friendness for routine use in ERCP compared to conventional POPS.
Aims & Methods: To evaluate the efficacy and the safety with SDVP in conjunction with an uneven double lumen ERCP cannula (Piolax, Yokohama, Japan) for direct visualization for the assessment of various pancreatic neoplasms. We reviewed our experience with 16 patients underwent this novel visualization, EUS, and/or intraductal ultrasonography (IDUS) for the assessment of pancreatic neoplasms at our institution from 2012 to 2014. The rate of the probe to reach the lesion, the mean time required for the examination, the breakage rate of the probe, and the complication were retrospectively evaluated.
Results: Among 16 patients, there were 10 patients with intraductal papillary neoplasm (IPMN). 2 patients had unexplained main pancreatic duct dilatation. Besides, pancreatic adenocarcinoma (PDAC), pancreatic neuroendocrine tumor (PNET), carcinoma of papilla Vater, and pancreatic cyst was one, respectively. The rate of the probe to reach the lesion was no less than 100% without need for papillotomy. Each of the main pancreatic duct diameter in 6 patients was within normal range. The orifices of papilla Vater in 7 patients were wide open but those in 9 patients showed normal orifices. In 14 patients a drainage tube was placed in MPD just before completion of the examination. Mild pancreatitis occurred in 2 patients (16%) in 16 patients after the examination. Both recovered with conservative treatment of fasting and infusion within 2 days. Any probe did not break during the examination. Stenosis and obstruction of the lumen in MPD was observed in PDAC. Invasion of the tumor into the MPD epithelium was recognized in PNET. Protruding lesion like granular type or fish-egg–like type was visualized by the SDVP in 5 patients, but it was not detected by other examinations in 3 patients of them. Double lumen cannula made washing viscous liquid, linearizing flexure in MPD by guide-wire and inserting the probe possible.
Conclusion: This novel method could be considered useful for the assessment of pancreatic neoplasm by routine use following ERCP.

P1442 TECHNICAL SUCCESS AND PATIENT-RELATED OUTCOMES IN AN ERCP TRAINING PROGRAM: RESULTS FROM A PROSPECTIVE SINGLE-CENTER STUDY

T. A. Voiosu[1], A. Bengus[1], A. Voiosu[1], A. Haidar[1], M. Rimbas[1], A. Zlate[1], B. Mateescu[1]
[1]*Gastroenterology, Colentina Clinical Hospital, Bucharest, Romania*

Contact E-mail Address: theodor.voiosu@gmail.com
Introduction: Endoscopic retrograde cholangiography (ERCP) has evolved from a diagnostic to a mainly therapeutic procedure, with a complication rate of about 10% and associated mortality below 1%. Current quality standards recommend a selective cannulation rate of above 85% and a technical success rate of 80-90% for biliary procedures.
The case-volume and experience of the endoscopist are key factors influencing technical success and complication at ERCP. An estimated 200 procedures are required before attaining competency in ERCP, but training programs vary widely across institutions. Furthermore, there is little data available concerning the impact of training programs on patient-related outcomes.
Aims & Methods: We evaluated the factors affecting technical success rate and procedure-related complications in an ERCP training program. We conducted a prospective observational study of all ERCPs performed in our unit over a 12 month period and analyzed single operator biliary procedures in native papilla cases.
Procedures were conducted under deep sedation; initial cannulation was attempted using the guidewire technique with subsequent alternative techniques at the operator's discretion. Trainees were supervised by an expert endoscopist. Patients received 100mg Diclofenac intrarectally after the procedure to prevent postERCP pancreatitis (PEP).
Relevant clinical and laboratory data, the indication of the procedure, cannulation method, technical success of planned intervention and complications up to 30 days were recorded using standard forms. The experience of the operator (trainee or expert) and the complexity of the procedure according to the ASGE difficulty scale were also noted.

We compared cannulation rate, technical success and complication rates between trainee and expert endoscopists and analyzed risk factors for postERCP complications.
Results: 581 ERCPs were performed in our service during 2014 by one expert endoscopist (>1000 ERCPs) and 4 trainees (<200 ERCPs). 411 cases (70.7%) fulfilled inclusion criteria; 218 (53%) patients were female and mean age was 64 (±14) years. 209 procedures were performed by trainees (50.5%) and 202 procedures by the expert endoscopist (49.5%).
Overall successful cannulation rate was 85.6%, with no statistically significant difference between the two groups (p = 0.57). Adjusting for reinterventions, the successful cannulation rate per patient was 92%, with a technical success rate of 87% in the trainee group versus 89% in the expert group (p = 0.86). Procedure-related complications occurred in 33 patients (8%); there were 27 cases of PEP (6.5%) and 4 cases of acute cholangitis (0.9%), with a 30-day mortality rate of 0.7% (3 cases).
On logistic regression only female gender and higher bilirubin levels were associated with an increased risk of developing procedure-related complications. There was no statistically significant difference between expert and trainees regarding complication rate and 30-day mortality on either univariate or multivariate analysis.
Conclusion: ERCP procedures carried out by supervised trainees have a high success rate and carry no additional risk of procedure-related complications, complying with current quality indicators.

Contact E-mail Address: thibault.degand@gmail.com
Introduction: Besides European guidelines(1) recommending endoscopic treatment for benign stricture calibration with multiple plastic stents, fully covered self expanding metal stent (FCSEMS) arise in this indication with equivalent success rates, lower rates of obstruction and less procedures. However, high rates of stent migration, leading to treatment failure, have been reported with FCSEMS(2.3). We aimed to report our experience of endoscopic management of BBS using Kaffes™(Taewoong©) FCSEMS(4) in two French university hospitals.
Aims & Methods: We analyzed retrospectively all patients who underwent a placement of Kaffes™ FCSEMS for the treatment of BBS from 2006 to 2014 in two French university hospitals. Kaffes™ stent have an antimigration system with a 2mm narrowered waist at mid portion of the stent, which allows the radial force of the metallic stent to be directed maximally to the center hence inhibiting stent migration. A retrieval string permits removal of the stent that may thus be placed in the upper common bile duct. The main evaluation criterion was stricture resolution and secondary were stent migration, adverse events and removal success.
Results: Eighteen patients had a placement of Kaffes™ stent for BBS, five post cholecystectomy, 12 after orthotopic liver transplantation and one after hepatectomy. Median stenting time was 161 days [IQR,105-193 days] for the first procedure. The median time of follow up was 9.5 months [IQR,3-12.2 Mo]. Stricture resolution was observed in 12/18(62%) patients after the first ERCP and in 15/18(83%) after the second ERCP procedure using Kaffes™, stent. Stent migration was observed in 3 patients (17%). Stent removal was always possible, 8(62%) without any complication. There were one impaction, requiring removal by stent-in-stent procedure (366 days after stenting), two obstructions (193 and 366 days), and two breaks of the removal string (259 and 366 days).Three(17%) post ERCP moderate acute pancreatitis were observed.
Conclusion: In the largest retrospective cohort, Kaffes™, stent is an effective and safe technique to treat BBS. The design of this stent is interesting for treatment of stricture located next to the biliary convergence and allows longstanding stenting and fewer procedures where only plastic stents were relevant before.

Introduction: Several endoscopic retrograde cholangiopancreatography (ERCP)-related procedures have been performed for biliary tract diseases in patients with surgically reconstructed intestinal tracts using double- and single-balloon enteroscope (BE). Short-type BE with an effective length of 1520 mm has been useful for ERCP because most of ERCP-related devices are applicable for short-type BE. With recent advance in ERCP-related devices, ERCP with a long-type BE with an effective length of 2000 mm can be applicable for ERCP. The present pilot trial in Ureshino Medical Center aimed to demonstrate whether long-type BE was useful for ERCP for the patient with altered gastrointestinal anatomy by the surgical procedure.
Aims & Methods: Totally 10 patients (15 cases) who underwent ERCP with long-type single BE in Ureshino Medical Center were enrolled in the pilot study during the period from October 2013 to March 2015. The mean patient age was 71.4 years, and the male:female ratio was 8:2. The types of intestinal tract reconstruction were as follows: Roux-en-Y hepaticojejunostomy in 3 patients, Billroth II with Braun anastomosis in 2 patients, Roux-en-Y gastrectomy in 4 patients, and pancreaticoduodenectomy and modified Child method in 1 patient. The goals of treatment in a total of 15 cases were as follows: biliary stone removal in 6 cases, biliary drainage in 5 cases, collection of foreign bodies (pancreatic stents) in the bile tract in 3 cases, and dilatation of choledochojejunostomy site in 1 case. The usefulness of long-type BE was evaluated based on following criteria: the arrival rate at the blind end, time required for arrival, total time required for procedures, treatment completion rate, safety based on the incidence of adverse events.
Results: The arrival rate at the blind end in long-type BE was 15/15 (100%), the median time required for arrival was 28 min (range, 7-59 min), the median total time required for the procedures was 118 min (range, 43-173 min), and the treatment completion rate was 12/15 (80.0%). Regarding adverse events, acute cholangitis, which rapidly resolved with conservative therapy, occurred after treatment in 1 patient (6.7%). In patients with uncompleted treatment, percutaneous transhepatic treatment and surgery were subsequently performed.
Conclusion: Although many limitations with a scope length of 200 cm and a forceps diameter of 2.8 mm, the present pilot study, with high achieved rate and minimum adverse events, clearly suggested that ERCP with long-type BE might be a first line treatment in the patient with the surgically reconstructed intestinal tracts. This pilot trial warrant further examination to compare the availability for ERCP between the short- and long-type BEs.

Introduction: Single-operator cholangioscopy (SOC) with the SpyGlass™ Direct Visualization System was introduced into clinical practice in 2007 by Boston Scientific (Natick, MA, USA). Since then its clinical application and benefits in different indications e.g. evaluation of indeterminate biliary strictures or cholangioscopic-guided removal of refractory bile duct stones were reported in several publications. Image-quality of the precursor generation was substantially limited by the number of optical fibres. The new fully integrated SpyGlass™DS System enables videoendoscopic image quality and an improved four way deflection of the scope, which is introduced over a standard duodenoscope.
Aims & Methods: Objective of the current registry of the first 21 consecutive clinical applications in Europe was to assess procedural and technical aspects of SOC with the new SpyGlass™DS-System. Data was collected prospectively, descriptive statistics were used for analysis. All procedures were conducted by experienced endoscopists (H.N., T.B., A.D., A.H., R.K.) at three tertiary referral centers with great experience in hepatobiliary interventions and cholangioscopy. SOC was conducted in n = 21 patients (male 15, female 6, age 18-94 years). Indications for cholangioscopy were indeterminate biliary strictures or irregularities (n = 16, 76%) and/or complex biliary stones or filling defects (n = 6, 29%) in fluoroscopy.
Results: Technical success (target site of the bile duct system reached) was achieved in 100% of the cases. In all patients biliary sphincterotomy was conducted before cholangioscopy for papillary access, in 3 cases (14%) with an additional balloon dilation. Direct introduction of the SpyScope was possible in 43% of the cases (9/21), in 57% (12/21) a wire-guided access was achieved. In 91% (19/21) of all cases the scope was advanced into intrahepatic bile ducts, in 2 cases (9%) to the upper CBD. Neoplasms were diagnosed in 8 cases (38%, cholangiocarcinoma 7, biliary IPMN 1), 6 strictures were found to be

inflammatory and/or benign (29%, PSC 3, scarring 3). Biliary stones were identified cholangioscopically in 6 patients and successfully fragmented by laserlithotripsy (n = 5, 24%) and removed completely in all cases (6/6). Cholangioscopic intervention was undertaken in 14/21 patients (biopsy 9, laser lithotripsy 4, both 1) and was successful in 100%. Cholangioscopic findings led to changes in overall treatment in 13 of 21 patients (62%). Mean duration of the procedure was 25.6 minutes (11-58). Image quality of the new system was rated excellent by all investigators in 100% of the cases. No complications related to the intervention occured.

Conclusion: Our first data of the new generation of the SpyGlass™-System suggest that it can further simplify and shorten the procedure of cholangioscopy. Simultanously, the high image quality and maneuverability of the scope improve the ability to evaluate biliary lesions and conduct intraluminal therapy even in intrahepatic bile ducts. It now combines the advantages of a catheter-based single-operator system with the superior image quality of a videoendoscopic system.

Introduction: Duodenal perforation is a rare, but serious adverse event of ERCP. There is no consensus to guide the clinician on the management of ERCP-related perforations, with considerable controversy surrounding the immediate surgical management of duodenal perforation due to overextension of the sphincterotomy.

Aims & Methods

Aims: To assess patient outcomes using a predetermined algorithm based on managing ERCP-related duodenal perforations according to the mechanism of injury.

Methods: A retrospective single-center study of all consecutive patients with Stapfer type I and II perforations between 2000 and 2014 were included. Stapfer type I perforations were defined as luminal perforation by the endoscope (1). Stapfer type II perforations were defined as extension of a sphincterotomy incision beyond the intramural portion of the bile or pancreatic duct (1). Our institutional algorithm since 2000 mandated that Stapfer type I perforations were managed surgically unless prohibited by underlying comorbidities and Stapfer type II perforations were managed non-surgically and only preceded to surgery if their clinical status deteriorated.

Results: A total of 61 (mean age 51 years, female 80%) patients were analyzed with Stapfer type I perforations diagnosed in 7 (11.5%) and type II in 54 (88.5%) patients. Table 1 shows the characterisics of these perforations. There were only 4 (7.4%) patients with Stapfer type II perforations that failed medical management and underwent surgery. The mean length of stay in the entire cohort was 9.6 days with a low mortality rate of 3.3%. Systemic inflammatory response syndrome (SIRS) was observed in only 18 (33.3%) patients with Stapfer type II perforations and was not associated with the need for surgery. Concurrent post-ERCP pancreatitis was diagnosed in 26 (42.6%) patients and was associated with an increased length of stay. There were 17 (27.9%) patients that had a Stapfer type II perforation due to extentsion of a pre-existing sphincterotomy using electrocautery. [Table 1 N ± 61, *N ± 55]

Time point of diagnosis	
Intra-procedural	6 (9.8)
Post-procedural	55 (90.2)
Post-procedural modality of diagnosis	
CT	45 (81.8)*
X-ray	10 (18.2)*
Imaging characteristics	
Retroperitoneal collection	17 (31.5)*
Retroperitoneal gas only	20 (37.0)*
Retroperitoneal gas + pneumoperitoneum/ pneumomediastinum	12 (22.2)*
Oral contrast extravasation on imaging	6 (11.1)*
Additional adverse events	
Post ERCP pancreatitis	26 (42.6)
Mortality	2 (3.3)

Conclusion: This study validates a predefined treatment algorithm for the management of ERCP-related duodenal perforations. Our results suggest that Stapfer type II perforations have excellent outcomes when treated non-surgically, challenging the belief that these patients are best managed operatively.

Introduction: Iatrogenic perforations in endoscopic retrograde cholangiopancreatography (ERCP)-related interventions are rare. Diagnosis and treatment of such perforations are difficult.

Aims & Methods: Aims of this retrospective study were to identify risk factors, to assess morbidity and mortality associated with perforation and to review management of these patients. Patients were retrospectively identified by a full-text search within the endocospic database (Endobase, Olympus) and by radiological reports of CT scans (Centricity PACS, GE Healthcare) demonstrating the perforation. All cases (2007-2015) were reviewed for clinical plausibility, all ERCP procedures were performed as therapeutic intervention.

Results: 44 perforations occurred (19 in women, 25 in men) during 5845 ERCPs (0.75%) with 23 symptomatic and 21 asymptomatic patients. The mean age of patients with perforation was 57.5 ± 15.2y and the mean hospitalisation was 16 days. Causes of perforation were guidewire associated (18), needle knife sphincterotomy (8), standard sphincterotomy (4), endoscope-related (3), and other mechanisms (6). In 5 cases the cause for perforation remained unclear. Only four patients had a perivaterian diverticulum. Following the classification of Stapfer et al. [1] there were 3 type 1, 15 type 2, 18 type 3 and 8 type 4 perforations. Eight patients underwent surgery, though a leakage could be identified only in patients with type 1 perforation (2). Patients receiving a stent during ERCP less often underwent surgery than patients who did not receive one (3 of 27 vs. 5 of 17). Most of the perforations were guidewire-related and were rarely associated with significant complications (1/18). In contrast, sphincterotomy-related perforations relevant complications occurred significantly more often (7/12; Fisher's exact test: $p < 0.003$). 14 patients suffered from post-procedural pancreatitis (32%). Nine patients died during their stay in hospital (two in the operative group, 7 under conservative treatment). Only one death seemed to be associated with the ERCP procedure. Interestingly, no correlation was found between endoscopists' experience and the likelihood of a perforation. Most perforations occurred between 350 and 700 performed ERCPs.

Conclusion: ERCP associated perforations remain a rare but severe complication. Experience of the endoscopist and the likelihood of a perforation were not correlated. Conservative treatment of perforations except for type 1 seems safe, as surgical intervention can rarely identify the perforation site. The placement of a biliary stent may have a protective effect in case of perforations.

P1448 BIPOLAR RADIOFREQUENCY ABLATION OF TISSUE INGROWTH IN SELF-EXPANDABLE METAL STENT INSERTED TO THE BILE DUCT: IN VITRO STUDY

W. J. Yoon[1], Y.-T. Kim[2]

Introduction: Bipolar RFA catheters for endobiliary RFA of biliary malignancy have been introduced. Animal study using porcine model showed that there is a linear relationship between the power of bipolar RFA and the depth bile duct ablation. Bipolar RFA of the tissue ingrowth in self-expandable metal stents (SEMSs) might restore the stent patency. However, there is no in vivo model to simulate tissue ingrowth in SEMS.

Aims & Methods: The aim of this study was to simulate the bipolar RFA effect on tissue ingrowth that causes SEMS occlusion using polyacrylamide gel phantom model. In vitro simulation of RFA of tissue ingrowth in SEMS was done using polyacrylamide gel phantom model. In brief, the gel fluid was poured into 4-mL, cuboidal cuvettes (Ratiolab, Dreieich, Germany). For bipolar RFA, we used ELRA RFA catheter and VIVA RF generator (STARmed, Gyeonggi-do, Korea). The power was set at 10 W. The RFA setting that resulted in the optimal RFA depth of the model was determined in the plain gel phantoms (i.e., gel phantoms without SEMS embedded). Bipolar RFA was done to uncovered SEMS-embedded (n = 10) and damaged covered SEMS-embedded (n = 10) gel phantoms. The RFA effects were compared.

Results: The optimal RF setting for *in vitro* evaluation of bipolar RFA using the plain gel phantom was 10 W, temperature range of 65-75°C, with a duration of 30 seconds. This setting resulted in an ellipsoid coagulated area with mean short

axis of 9.1 ± 0.21 mm and long axis of 11.8 ± 1.1 mm (n = 10). The short axis of the coagulated area just reached the wall of the cuvette at this setting. The mean cross-sectional area of coagulation was 84.3 ± 7.4 mm^2. Bipolar RFA of the uncovered SEMS-embedded gel phantom model resulted in early termination of RF generation. In detail, during the early course of RFA, a rapid drop in the impedance of the circuit was observed when the coagulated area came into contact with the wire of the uncovered SEMS. Subsequently the generation of RF was terminated, and re-initiation of RF generation was not possible. This phenomenon was observed in all 10 uncovered SEMS-embedded gel phantoms. Only small areas of coagulation confined near to individual electrodes were observed. The mean cross-sectional area of coagulation was 16.2 ± 11.0 mm^2, which was significantly different when compared to that of the plain gel phantoms ($P < 0.001$). No damage to the SEMSs was noted in the gel phantom model. Bipolar RFA of the damaged covered SEMS-embedded gel phantom model resulted in an ellipsoid area of coagulation. No early termination of RF generation was observed. In 5 models, the coagulated area was confined within the SEMS lumen. In the other 5 models, the coagulated area expanded beyond the wall of SEMS. The mean cross-sectional area of coagulation of 10 gel phantoms was 73.0 ± 14.9 mm^2. There was statistically significant difference between the mean areas of coagulation of plain gel phantoms and damaged covered SEMS-embedded gel phantoms ($P = 0.047$).
Conclusion: Power shut-off of the generator resulted when the coagulated area became in contact with the metal wire. Bipolar RFA of tissue ingrowth in uncovered SEMS might be of limited efficacy, as the RFA effect is limited around the individual electrodes and cannot reach beyond the SEMS wall. Ablation of the tissue outside the SEMS is likely to be limited.

P1449 A NEW TECHNIQUE OF THE WIRE-GRASPING METHOD IN FORCEPS BIOPSY FOR BILIARY STRICTURES; A PROSPECTIVE RANDOMIZED CONTROLLED STUDY OF EFFECTIVENESS

Y. Yamashita[1], K. Ueda[1], Y. Kawaji[1], T. Tamura[1], M. Itonaga[1], H. Maeda[1], H. Magari[1], J. Kato[1], M. Ichinose[1]
[1]*Second Department of Internal Medicine, Wakayama Medical University, Wakayama, Japan*

Contact E-mail Address: yasunobu@wakayama-med.ac.jp
Introduction: Although transpapillary forceps biopsy is an effective diagnostic technique in patients with biliary stricture, forceps insertion into the bile duct without endoscopic sphincterotomy (EST) is difficult. The aim of this prospective randomized controlled study was to determine the usefulness of the wire-grasping method, a novel technique for performing forceps biopsy.
Aims & Methods: Consecutive patients with biliary stricture or irregularities of the bile duct wall were randomly allocated to either the direct or the wire-grasping method group. In the wire-grasping method, a guide-wire placed into the bile duct beforehand is grasped by forceps in the duodenum, and then the forceps are pushed through the papilla without EST. In the direct method, forceps are directly pushed into the bile duct alongside a guide-wire. The primary endpoint was the success rate of obtaining specimens suitable for adequate pathological examination.
Results: In total, 32 patients were enrolled, and 28 (14 in each group) were eligible for analysis. The success rate of obtaining adequate specimens for pathological examination was significantly higher using the wire-grasping method than the direct method (100% vs. 50%, $P = 0.016$). Sensitivity and accuracy for diagnosis of cancer were also higher in the wire-grasping method group (91% vs. 42%; $P = 0.019$, and 93% vs. 46%; $P = 0.011$, respectively). No procedure-specific complications were observed in the wire-grasping method group.
Conclusion: The wire-grasping method is useful for diagnosing patients with biliary stricture or irregularities of the bile duct wall.

Contact E-mail Address: paleblue0314@hanmail.net
Introduction: Covered self-expandable metal stents (CSEMS) has the risk of obstruction of the cystic duct, and the main and branch pancreatic ducts due to strong radial force and covering material, which results in cholecystitis and pancreatitis. A flower-type covered self-expandable metal stents (F-CSEMS) having a five-petal shaped design with side grooves was constructed to prevent the obstruction of the cystic duct orifice.
Aims & Methods: This study investigated the value of the F-CSEMS in protection for cholecystitis in a pig model. Fourteen pigs randomly underwent endoscopic placement of either F-CSEMS or conventional CSEMS (C-CSEMS). The stent was placed across the cystic duct orifice to impede bile drainage from the gallbladder. Drainage was checked at 24, 48, 120 and 168 hours after implantation. Blood was collected at baseline, on days 2 and 7 following implantation. The animals were sacrificed for histologic evaluation on day 7.
Results: All stents were successfully inserted into bile duct without any procedure-related complications. At 48 hours, the rate of contrast drainage from the gallbladder was higher in the F-CSEMS group than the C-CSEMS group without significant difference (71.4% vs. 28.6% p = 0.28). C-CSEMS was associated with higher levels of C-reactive protein (35.2 μg/dl vs. 20.5 μg/dl, p = 0.03) and histologic inflammatory scores of gallbladder (score 4 vs. 2; p = 0.03).
Conclusion: The F-CSEMS appears safe and helpful to prevent cholecystitis without disturbance of bile flow in a pig model.

Introduction: Although tissue sampling on ERCP is an initial procedure for histologic diagnosis of malignant biliary obstruction (MBO), EUS-guided sampling is emerging as an accurate diagnostic procedure. However, the diagnostic yields of EUS and ERCP-guided sampling on MBO were reported variously.
Aims & Methods: The aim of this study was to evaluate the usefulness of the diagnostic approach using EUS-guided fine needle biopsy (EUS-FNB) and ERCP-guided transpapillary forceps biopsy (TPB) combined according to an origin of stricture in patients with suspected MBO. A total of 151 patients with suspected MBO underwent intraductal ultrasonography (IDUS) and TPB during ERCP at first. Based on the results of cross sectional imaging study and IDUS, all patients were classified as 72 patients (47.7%) with intrinsic type and 79 patients (52.3%) with extrinsic type of MBO. If the malignancy was not confirmed by initial TPB, 2nd endoscopic TPB for intrinsic type of MBO and EUS-FNB using a core biopsy needle for extrinsic type of MBO was performed, respectively.
Results: The overall diagnostic accuracy of 1st endoscopic TPB was 76.2%. The diagnostic accuracy of 1st endoscopic TPB in intrinsic type was significantly higher than in extrinsic type (84.7% vs 68.4%; $p = 0.022$). In 11 patients of intrinsic type with negative for malignancy by 1st TPB, 2nd endoscopic TPB was achieved a diagnostic accuracy with 72.7%. In 25 patients of extrinsic type with negative for malignancy by 1st TPB, the diagnostic accuracy of EUS-FNB was 88.0%. The overall diagnostic accuracy of 1st TPB combined with 2nd TPB in intrinsic type and EUS-FNB in extrinsic type was 96.0%.
Conclusion: The TPB appears still a useful initial tool to be able to diagnosis and treatment of patients with MBO at the same time on ERCP. In addition, the diagnostic approach using 2nd endoscopic TPB or EUS-FNB according to the origin of MBO is considered highly effective to improve a histologic diagnostic accuracy of MBO in patients with negative for malignancy by 1st trial of endoscopic TPB.

Contact E-mail Address: ishida_yuusuke@kurume-u.ac.jp
Introduction: The utility of peroral cholangioscopy (POCS) has been reported since a new video POCS was developed. However, endoscopic diagnosis of bile duct mucosa using POCS with narrow band imaging (NBI) has not yet been fully established. We investigated to assess the association between magnifying endoscopic findings and histopathological findings of the bile duct ex vivo.
Aims & Methods: 41 common bile ducts which were surgically resected were enrolled in this study. These specimens included non-neoplastic and neoplastic mucosa obtained from the patients who underwent pancreatoduodenectomy, bile duct resection, or hepatectomy. We cut each common bile duct open for ex vivo endoscopic observation of its mucosa. We used a magnifying endoscope (FH-260AZI or H-260Z; Olympus Medical Systems, Tokyo, Japan) commonly used for the gastrointestinal tract, and we utilized both conventional white light imaging (WLI) and NBI (CV-260SL processor, CVL-260SL light source; Olympus). After histological diagnosis, we assessed the association between the magnifying endoscopic findings (using WLI and NBI) and histopathology.
Results: 41 specimens consisted of 28 non-neoplastic mucosa and 13 neoplastic mucosa. In nine regions of 28 non-neoplastic mucosa, many oval-shaped, depressed areas and a fine, regular network were observed using magnifying endoscopy. These regions were histologically confirmed of non-inflammatory mucosa. In the 11 regions of 28 non-neoplastic mucosa, these oval-shaped, depressed areas and the network could not be clearly seen. These regions were confirmed by histology of inflamed mucosa. In eight regions of 28 non-neoplastic mucosa, the depressed areas and network could not be found, and just irregular mucosa and microvessels were observed. Additionally, in four of the eight regions, the endoscopic image of these mucosa mimicked neoplastic mucosa. These regions were histologically identified as severe inflammatory or regenerative mucosa. Dilated and tortuous microvessels could be detected in 10 regions of 28 non-neoplastic mucosa, which were histologically confirmed of inflamed mucosa. In eight regions of 13 neoplastic mucosa, tumor margin could be recognized. Tumor margin was obscured in five regions of 13 neoplastic mucosa. Especially in the case of tumor with severe inflammation, it was difficult to

distinguish the tumor margin. Dilated and tortuous microvessels could be observed on the tumor surface in 12 regions of 13 neoplastic mucosa. In all cases, these findings could be more clearly seen by magnifying endoscopy with NBI.
Conclusion: Oval-shaped, depressed areas and a fine, regular network of microvessels are the characteristic features of normal bile duct mucosa. Inflammation obscures these features. Especially in case with severe inflammation, distinguishing neoplasm from non-neoplasm may be difficult. Dilated and tortuous microvessels can be detected on both non-neoplastic and neoplastic mucosa, therefore it may be risky to distinguish neoplasm from non-neoplasm only by detecting these vessels. NBI can depict mucosal architecture and microvessels of the bile duct in minute detail.

P1453 AN INTERNATIONAL SURVEY ON EUS-GUIDED TISSUE SAMPLING; PREFERENCES FOR TISSUE ACQUISITION AND PROCESSING

P. Van Riet[1], M. J. Bruno[1], J. W. Poley[1], D. L. Cahen[1]
[1]*Gastroenterology and Hepatology, Erasmus MC University Medical Center Rotterdam, The Netherlands, Rotterdam, Netherlands*

Contact E-mail Address: p.vanriet@erasmusmc.nl
Introduction: Endoscopic ultrasound (EUS)-guided tissue sampling has become invaluable in the diagnostic work-up of lesions in and around the gastrointestinal tract. As a result, EUS is used all over the world. Unfortunately, practice guidelines are lacking and execution is based on local expertise and consensus.
Aims & Methods: This survey was performed to gain insight in current tissue sampling routines and to assess intercontinental differences. An online survey was conducted among 400 endosonographists from Europe, the United States (US), and Asia. It contained 60 multiple-choice questions regarding specifics on tissue acquisition and specimen processing. Questions concerned both fine needle aspiration (FNA) and fine needle biopsy (FNB) procedures.
Results: Hundred eighty-six surveys were returned (47%); 85 (46%) from Europe, 54 (29%) from the US, and 47 (25%) from Asia. The median age of the respondents was 46 (IQR 41-52) years. Most were male (90%), gastroenterologists (96%), working in an academic setting (79%), and performing >100 EUS-FNA procedures per year (68%). Overall, the 22G needle was most preferred (55%). For FNB of submucosal masses, a 19G needle was preferred (63%). The reported number of needle passes varied according to target lesion; single for cystic lesions (80%) and two to three for solid lesions (53%). Most respondents preferred fanning as a needle motion technique for FNA (64%), while for FNB, fanning and "to and fro" were equally favored (44% and 46%, respectively). To increase the yield, 134 respondents (73%) routinely looked for tissue cores after FNA, and 136 (73%) prepared a cytological sample after FNB. FNA specimens were preserved in Cytolit by 72 (52%) of the European and US respondents, whereas in Asia, a tied standing was reported for the use of saline (27%) and alcohol (38%, $p < 0.001$). Rapid on-site pathological evaluation (ROSE) was used by half (51%) of the respondents from Europe and Asia, while almost all American participants (98%) had ROSE at their disposal ($p < 0.001$). Limited pathology staffing was given as the primary reason to omit ROSE (n = 49, 74%).
Conclusion: For EUS-guided tissue sampling, the majority of respondents prefer a 22G needle, for all but submucosal lesions. Most endosonographers carry out 2-3 needle passes, except for cystic lesions, where a single pass is generally performed. Specimens are mostly preserved in Cytolit in Europe and the US, while alcohol and saline are preferred in Asia. On-site tissue evaluation is standard practice in the US, but not in Europe and Asia, because of shortage in manpower. The consequences of these differences on diagnostic accuracy have yet to be evaluated in prospective studies.

P1454 A GLOBAL SURVEY ON THE PERI-PROCEDURAL PRACTICE OF EUS-GUIDED TISSUE SAMPLING; USE OF ANTICOAGULANTS, ANTIBIOTICS, AND SEDATION

P. Van Riet[1], D. L. Cahen[1], J. W. Poley[1], M. J. Bruno[1]
[1]*Gastroenterology and Hepatology, Erasmus MC University Medical Center Rotterdam, The Netherlands, Rotterdam, Netherlands*

Contact E-mail Address: p.vanriet@erasmusmc.nl
Introduction: Although endoscopic ultrasound (EUS) guided tissue sampling is widely executed, guidelines are lacking and practice differs according to local expertise and consensus.
Aims & Methods: This survey was performed to gain insight in current routines regarding peri-procedural measures, and to evaluate intercontinental differences. Four hundred endosonographers from the United States (US), Europe, and Asia were approached to complete an online survey, consisting of 18 multiple-choice questions regarding the peri-procedural management of anticoagulants, antibiotics, and sedation.
Results: Hundred eighty-six surveys were returned (47%); 85 (46%) from Europe, 54 (29%) from the US, and 47 (25%) from Asia. The median age of the respondents was 46 (IQR 41-52) years. Most were male (90%), gastroenterologists (96%), working in an academic setting (79%), and performing >100 EUS-FNA procedures per year (68%). Acetylsalicylic acid was continued by 87% of European and 50% of Asian respondents, whereas in the US, all respondents continued it ($p < 0.001$, Table 1). Thienopyridines, heparin, coumarins, and new oral anticoagulants (NOACs) were discontinued by most respondents (>73%). In Europe, heparin was stopped by 75% of the respondents, compared to 94% and 100% in Asia and the US ($p = 0.022$). The coagulation status was routinely checked by 66% of European and 68% of Asian respondents, but only by 20% of the US respondents ($p < 0.001$). Although most (80%) respondents considered an INR <1.5 to be safe, discontinuation of coumarins differed between the three continents. Most (86%) European respondents reported temporary discontinuation, while only 59% and 46% of their Asian and US colleagues did ($p = 0.003$). Virtually all respondents prescribed antibiotic prophylaxis when sampling a cystic lesion (95%). A minority (<39%) used antibiotic prophylaxes for other indications, such as a prosthetic cardiac valve, vascular graft, previous infective endocarditis, or congenital heart disease. For these conditions, European and Asian physicians prescribed antibiotic prophylaxes significantly more often ($p < 0.045$). Conscious sedation was favored by 52% of European and 84% of Asian respondents, while Propofol was preferred by US respondents (83%, $p < 0.001$). On-site anesthesiological assistance was routinely available for all US respondents (100%), as compared to 66% of European and 50% of Asian respondents ($p < 0.001$).
Table 1: Discontinuation of anticoagulants according to continent

Anticoagulant -no.stopped (%)	Europen = 56	Asian = 32	USn = 11	Alln = 99	p-value*
Acetylsalicylic acid	7 (13)	16 (50)	0 (0)	23 (23)	<0.001
Thienopyridines	47 (84)	25 (78)	8 (73)	80 (81)	0.618
Heparin	42 (75)	30 (94)	11 (100)	83 (84)	0.022
Coumarins	48 (86)	19 (59)	5 (46)	72 (73)	0.003
NOAC's	49 (88)	21 (66)	10 (91)	80 (81)	0.029

NOAC, new oral anticoagulants. *A chi square test was used to compare the three continents.

Conclusion: Overall, peri-procedural management for EUS-guided tissue sampling in Europe and Asia differs notably from the US. First, the majority of European and Asian respondents routinely check the coagulation status and more often decide to discontinue acetylsalicylic acid. In addition, Europeans reported to use antibiotic prophylaxis more often. Finally, conscious sedation is preferred in Europe and Asia, while the use of Propofol and the presence of anesthesiological assistance is more common in the US.

P1455 EUS-GUIDED FNA FOR SUSPECTED TUBERCULOUS LYMPHADENITIS- YIELD OF FNA AND CULTURE- SCOPE FOR IMPROVEMENT?

R. Shah[1], J. K. Jena[1], C. Patel[1], V. Rathod[1]
[1]*Gastroenterology, Hepatology, Endoscopy, Endoscopy Asia, Mumbai, India*

Contact E-mail Address: rahulhshah@hotmail.com
Introduction: The most common form of extrapulmonary tuberculosis is tuberculous lymphadenopathy and its diagnosis remains a challenge since granulomatous lymphadenopathy has an extensive differential diagnosis. Several conditions, including sarcoidosis, fungal infections, and other inflammatory conditions, can present the same cytology and histopathology as tuberculous lymphadenopathy.
Definitive and rapid diagnosis of extrapulmonary tuberculosis is challenging since conventional techniques have considerable limitations.
The main difficulty with extrapulmonary specimens is that they yield very few bacilli and consequently are associated with low sensitivity of acid-fast bacillus (AFB) smear and culture. Acid-fast staining was positive in fewer than 10% of patients in most reports.
In view of the prevalence of multi drug resistant tuberculosis (MDR TB) culture and sensitivity forms the cornerstone of current anti tuberculous therapy.
Aims & Methods: Our aim was to evaluate the EUS guided FNA cytology of patients with suspected TB lymphadenopathy and in particular yield of the culture.
We collected data of all patients from January 2013 to January 2014 who had EUS guided FNA for suspected TB lymphadenopathy.
We had a total of 64 patients with suspected peri luminal lymphadenopathy.
Results: 4 patients had reactive nodes, 2 were non diagnostic, and 4 had granulomatous inflammation which was not diagnostic of TB. 1 patient had subsequent tests confirming sarcoidosis whilst the other had fungal infection.
52 patients had FNA cytology suggestive of TB of which only 1 patient had positive Ziehl Neelsen staining and subsequent positive culture at 6 weeks. 2 other patients had positive culture at 6 weeks. The remaining patients were treated on the basis of history, cytology and clinical evaluation.
15 out of 52 patients were lost to long term follow up as they were only tertiary referrals for EUS FNA, 33(63%) have had good response to treatment so far whereas 4(10.81%) patients have had further progression and eventually been diagnosed with MDR TB.
Of the 64 patient's 3 had repeat EUS FNA due to inadequate sampling or non diagnostic cytology.
Conclusion: The diagnosis of extrapulmonary tuberculosis is challenging for a number of reasons: the lack of adequate sample amounts or volumes; the apportioning of the sample for various diagnostic tests (histology/cytology, biochemical analysis, microbiology, and PCR), resulting in non uniform distribution of microorganisms; the paucibacillary nature of the specimens; the presence of inhibitors that undermine the performance of nucleic acid amplification-based techniques(NAAT); and the lack of an efficient sample processing technique.
As in our case 10.81% patient's had a delayed diagnosis of MDR TB.

PCR based tests i.e. NAAT may be especially useful in certain patient groups such as persons infected with human immunodeficiency virus (HIV) and children, who are disproportionably affected by smear-negative and extrapulmonary disease and who are also most adversely affected by delays in TB diagnosis and treatment but the cost and availability is an issue.
With the increased incidence and prevalence of multi drug resistant TB in the Indian sub continent alternative means must be sought, not only to obtain definite diagnosis but also to attain positive mycobacterial culture results which can identify MDR TB patients early on.

P1456 ENDOSCOPIC ULTRASOUND (EUS) - A MUST FOR SUSPECTED CHOLEDOCHOLITHIASIS PRIOR TO ERCP?

R. Shah[1], C. Patel[1], J. K. Jena[1], V. Rathod[1]
[1]*Gastroenterology Endoscopy and Hepatology, Endoscopy Asia, Mumbai, India*

Contact E-mail Address: rahulhshah@hotmail.com
Introduction: Endoscopic retrograde cholangiography (ERCP) has long been considered the most accurate method to detect CBD calculi but several studies confirm a similar accuracy rate (> 90%) for EUS. Direct comparison between EUS and MR cholangiography shows EUS to be the more accurate test. The sensitivity of both modalities is equally impressive at 100% but EUS had a specificity of 95% as opposed to a figure of 73% reported for MRI.
Aims & Methods: In the clinical setting, however, to determine the presence of ductal calculi remains a significant dilemma; a balance must be struck between invasive ERCP, associated complications and potential inaccurate diagnosis. Hence we prefer EUS as the preferred investigation prior to ERCP during the same sedation regardless of the results of previous imaging studies.
Hence we evaluated all patients with EUS who were referred to our center for ERCP for suspected choledocholithiasis. Each patient had at least 1 additional modality of imaging other than US Abdomen with cholestatic liver function test.
Results: A total of 179 patients were referred for ERCP in the year 2014. Each patient had an Ultrasound with either CT scan or MRCP indicative of choledocholithiasis.
Of these 37 (20.67%) patients avoided unnecessary ERCP's of which 23 had presumed spontaneous passage of stones, 5 had type 1 Choledochal cyst wherein the treatment is surgical excision, 3 had perivaterian diverticulum with dilated CBD and no stones and 6 had stones stuck in the Hartman's pouch.
Of the 37 patients 31 had gall stones, 4 had imaging microliths and 2 had a normal gall bladder.
In the latter 2 patient's it was presumed spontaneous passage of stones as previous imaging had suggested CBD stones.
Conclusion: EUS has remarkable accuracy in detecting choledocholithiasis and avoids unnecessary ERCP's even in patients who have had US, CT scan or MRCP.
A total of 20.67% patients avoided unnecessary ERCP's at our institution and only needed definitive cholecystectomy except the 2 patients who had normal gall bladder.
A small caveat being that the imaging quality and reporting can vary vastly in the Indian sub continent hence perhaps a good quality EUS with an experienced operator is a must prior to ERCP.
In particular, EUS is more accurate when choledocholithiasis occurs in the presence of an undilated bile duct.
EUS is useful in picking up stones in the Hartman's pouch and for detection of small stones 2-3 mm which can be best seen on higher frequency scanning. These are often termed as imaging microliths (starry night gall bladder) and missed in patients with biliary colic and recurrent acute pancreatitis.
EUS-ERCP interface is more cost effective than performing CT, MRCPs in these patients.

P1457 DIAGNOSTIC EFFICACY OF LIQUID-BASED VERSUS SMEAR CYTOLOGY FOR PANCREATIC SOLID LESIONS OBTAINED BY ENDOSCOPIC ULTRASOUND-GUIDED FINE-NEEDLE ASPIRATION

S. Hashimoto[1], H. Taguchi[1], M. Higashi[2], T. Fujita[1], S. Arima[1], J. Nakazawa[1], H. Iwaya[1], Y. Iwashita[1], F. Sasaki[1], Y. Nasu[1], S. Kanmura[1], M. Numata[1], A. Ido[1]

Contact E-mail Address: kumdsh@m.kufm.kagoshima-u.ac.jp
Introduction: Traditionally, conventional Papanicolaou smear (CPS) analysis was performed after endoscopic ultrasound-guided fine needle aspiration (EUS-FNA), but cytohistological diagnostic methods such as rapid on-site cytological evaluation (ROSE) and the cell-block method have been developed recently. Compared to CPS, liquid-based cytology (LBC) has diagnostic utility in cervical cancer. However, there is a paucity of data on the diagnostic efficacy of LBC for pancreatic tumor samples obtained by EUS-FNA. We retrospectively analyzed the additional diagnostic efficacy of LBC using the SurePath™ method compared with CPS for samples of solid pancreatic lesions obtained via EUS-FNA without ROSE.
Aims & Methods: There were 283 consecutive patients who underwent initial EUS-FNA for solid pancreatic lesions between January 2007 and August 2014 included in this study. CPS was used for cytology of EUS-FNA samples obtained by May 17, 2012 (130 patients). Subsequently, LBC was used for cytological analysis (153 patients). The cell-block method was used for histological analysis. Cytohistological results were based on the combination of cytological and histological results. The cytological and cytohistological diagnostic yields for malignancy of CPS and LBC were compared.
Results: Overall, the proportion of total malignancy diagnosed was 85% (CPS 82%, LBC 89%). The diagnostic sensitivity and accuracy of LBC were significantly higher than those of CPS (89.0% vs. 59.4%, $P < 0.01$ and 90.2% vs. 66.9%, $P < 0.01$) and cytohistological analysis (94.9% vs. 82.1%, $P < 0.01$ and 95.4% vs. 85.4%, $P < 0.01$). LBC had also higher sensitivity and accuracy for pancreatic head lesions than CPS (85.7% vs. 53.8%, $P < 0.01$ and 86.8% vs. 61.0%, $P < 0.01$) and cytohistological analysis (92.9% vs. 75.4%, $P < 0.01$ and 93.4% vs. 79.2%, $P = 0.01$). LBC had higher cytological sensitivity and accuracy for pancreatic body or tail lesions than CPS (92.4% vs. 68.3%, $P < 0.01$ and 93.5% vs. 75.4%, $P < 0.01$) whereas the cytohistological correlation was similar in both groups (97.0% vs. 92.7%, $P = 0.37$ and 97.4% vs. 94.3%, $P = 0.40$).
Conclusion: Compared to CPS, LBC of EUS-FNA samples contributes to the diagnosis of malignancy in solid pancreatic lesions, and was especially useful for confirming malignancy in lesions of the pancreatic head.

P1458 DOES NEEDLE-BASED CONFOCAL LASER ENDOMICROSCOPY IN PANCREATIC CYST EVALUATION AFFECT MANAGEMENT?

S. Gupta[1], L. G. Khanna[2], A. R. Shah[2], J. P. Poneros[2], T. A. Gonda[2], F. G. Gress[2], A. Sethi[2]
[1]*Internal Medicine,* [2]*Med Div Digestive & Liver Diseases, Columbia University Medical Center, New York, United States*

Contact E-mail Address: sg3121@cumc.columbia.edu
Introduction: Incidental detection of pancreatic cysts is increasing due to increased radiologic imaging, which poses a source of uncertainty among clinicians who must distinguish benign from pre-malignant/malignant lesions. Needle-based confocal laser endomicroscopy (nCLE) may aid in determining type of pancreatic cyst.
Aims & Methods: The aim of this study is to determine if use of nCLE during EUS-guided evaluation of pancreatic cysts impacted clinical management, particularly decision to proceed to surgery. This observational retrospective chart review included all patients undergoing EUS with nCLE for pancreatic cysts with pathologic specimen confirmation performed at Columbia University Medical Center (CUMC) from 3/2014-4/2015. Data regarding patient demographics, radiologic studies, EUS appearance of pancreatic lesion, nCLE appearance and diagnosis, fluid CEA/amylase levels, FNA cytology, and surgical pathology, if available, were extracted. Based upon this information, the clinician who performed the EUS with nCLE rendered a final clinical impression, defining the pancreatic lesion as serous cystadenoma (SCA), intraductal papillary mucinous neoplasm (IPMN), neuroendocrine tumor, or other.
Results: Fourteen patients were identified. 57% were female. Mean age was 69 years. The majority of pancreatic cysts were located in the body/tail region of the pancreas (57%). Mean size was 29 x 27 mm with range of 10 x 9 mm to 60 x 40 mm. Based upon all available clinical data, 8 pancreatic lesions were classified as SCA, 3 IPMN, 1 gastrointestinal stromal tumor (GIST), and two neuroendocrine tumor, which were consistent with the gold standard of cytology in 10/14 cases and further corroborated by surgical pathology in 1 of these 10 cases. In the remaining 4 instances, cytology was nondiagnostic. In the majority of cases, nCLE appearance correlated with cytology (7/10) and the final diagnosis (11/14) but failed to do so when image quality was poor or had characteristics of multiple types of cysts. In all 4 cases lacking cytologic confirmation, nCLE imaging features confirmed the overall clinical impression. With the exception of one of these subjects who was referred for other indication, these individuals did not undergo surgical resection due to low malignant potential.
Table 1: nCLE Diagnosis of Pancreatic Cysts

Number of Patients	nCLE Diagnosis	nCLE Features	Overall Clinical Impression
6	SCA	Superficial vascular network	SCA
3	IPMN	Band-like projections	Side branch IPMN
2	Neuroendocrine	Dark clumps with bands	Neuroendocrine
1	Neuroendocrine > IPMN	Few areas of dark clumps	SCA
1	Nondiagnostic	Debris, poor imaging	SCA
1	Indeterminate	Rings, thick white bands with flow, papillary projections	GIST

Conclusion: nCLE findings correlated with both the gold standard of cytology and the overall clinical impression of the pancreatic lesion in the majority of cases. In cases in which cytology was nondiagnostic, nCLE proved particularly useful in providing further clinical confidence to support the diagnosis that did not warrant surgery. nCLE appears to have an emerging role in distinguishing

different types of pancreatic lesions and provides useful and clinically relevant information that impacts further patient management.

Contact E-mail Address: takuji@w7.dion.ne.jp
Introduction: Endoscopic ultrasound-guided fine needle aspiration (EUS-FNA) is a safe, reliable, and widely used method for obtaining pathological specimens from lesions around the upper intestine. Evaluation of tissue architecture or immunostaining by using histological samples is essential for diagnosing certain diseases, such as lymphoma, gastrointestinal stromal tumor, and autoimmune pancreatitis; furthermore, it is important in deciding optimal chemotherapy regimens. A 19-gauge histology needle (PC19; EchoTip®ProCore™, Cook Medical) has recently been developed and showed a high single-pass core tissue acquisition rate and histological diagnostic yield in the initial pilot study.
Aims & Methods: The aim of this study was to compare the histological diagnostic yield in single-pass EUS-FNA for solid lesions by using PC19 and a standard 19-gauge needle (EC19, EchoTip®Ultra, Cook Medical).
Consecutive patients (n = 115) with solid lesions, measuring ≥ 20 mm and located around the upper intestine, were enrolled in the study from five tertiary hospitals between 11/2013 and 8/2014. The patients underwent one pass each of EUS-FNA using PC19 and EC19 with randomization in order of using FNA needles. The presences of histologic core as well as histologic and cytologic findings were evaluated by pathological analysis. The primary endpoint was the histologic diagnostic accuracy. The secondary endpoints were the feasibility of FNA, the rates of presence of histological core, the cytological and overall diagnostic accuracy, and adverse events.
Results: Of the 115 patients, 110 (median age = 69; interquartile range 61-77; 49 women) underwent EUS-FNA, and 5 were excluded from the study because of lesion size < 20 mm on EUS. Lesions were located in the pancreas (70), lymph nodes (30), liver (5), gastric subepithelial tumor (4) or retroperitoneal mass (1), and were of a median size of 35.5 mm. EUS-FNA was performed from the esophagus (4), stomach (80), or duodenum (26). The final diagnosis was 100 malignant cases and 10 benign cases. The feasibility of EUS-FNA was 98.2% and 97.3% with PC19 and EC19, respectively (p = 1.0). The rate of presence of histological core, and histological, cytological, and overall diagnostic accuracy for PC19 and EC19 were 84.6% and 80.9% (p = 0.59), 83.6% and 73.6% (p = 0.10), 63.6% and 56.4% (p = 0.34), and 90.0% and 79.1% (p = 0.04), respectively. Adverse events were observed in four patients; these were mild abdominal pain (1), intramural hematoma (1), self-limited bleeding (1), and mild bleeding (1).
Conclusion: Single-pass EUS-FNA with PC19 was feasible and showed significantly higher overall diagnostic accuracy, and higher tendency for the rate of histological core acquisition, histological, and cytological diagnostic accuracy, compared with EC19.

P1460 COMPRESSION ELASTOGRAPHY AT ENDOSONOGRAPHY: CLINICAL AND DIAGNOSTICAL VALUE IN COMPLEX ALGORITHM OF PATIENTS WITH PANCREAS DISEASES EXAMINATION

T. Morozova[1], A. Borsukov[1]
[1]*the Problem Scientific-Research Laboratory "Diagnostic researches and mini-invasive technologies", Smolensk State Medical University of the Ministry of Health, Smolensk, Russian Federation*

Contact E-mail Address: t.g.morozova@yandex.ru
Introduction: Nowadays there are too many patients, suffering from pancreas diseases. Compression elastography in combination with endosonography becomes widespread technique in diagnostic of acute pancreas inflammation, pseudotumor and tumor foci.
Aims & Methods: To determine clinical and diagnostical value of compression elastography at endosonography incomplex algorithm of patients with pancreas diseases examination 119 patients at the base of Smolensk City Clinical Hospital from December 2012 till April 2015 were examined. There were (67 (56.3%) - men and 52 (43.7%) - women in the age from 31 till 67 (p > 0.05)), diagnosis: acute pancreatitis–in 45 (37.8%) patients, pseudotumor pancreatitis - 51 (42.9%), malignant pancreas foci in 23 (19.3%) patients (p ≥ 0.05). Compression elastography at endosonography was made at scan «HITACHI PREIRUS» with compression elastography regime «PENTAX EG 387OUTK». Convex sensor at endoscope with frequency 7,5 MHz– 15,0 MHz was used; water nozzle for ultrasound sensor was not used while the research. Parenchymal lay of right and left kidney was a control zone at semi-quantitative evaluation, if there were no opportunity to kidneys measurement, the retroperitoneal tissue or the parenchyma of spleen were used as the control zone. The pancreas biopsy (per cutaneous) under ultrasound control was the referent method at 92 (77,3%) patients, and spiral computer tomography of pancreas - at 54 (45,4%) patients
Results: Emiquantitative and qualitative evaluation of elastographic images results was hold. At qualitative evaluation of elastographic image of pancreas and foci: chronic pancreatitis - predominance of green color; pseudotumor pancreatitis -mix type of color; malignant changes - hard type of staining (blue hue); At semiquantitative evaluation there was a calculation of comparative SR-coefficient. Coefficient of SR difference at acute pancreatitis - till 2 conventional units (c.u.), at pseudotumor pancreatitis - from 3 till 5 c.u., at malignant lesion - more than 5 c.u. SR data coincidence at pseudotumor pancreatitis and malignant changes of pancreas indicates the neccessarity of additional qualitative evaluation, which is useful for the diagnosis elaboration. The coincidence of biopsy results and compression elastography at endosonography results were in 87 (94.7) patients (p ≤ 0.05). The sensitivity of compression elastography at endosonography was 97.7%, specificity – 91.3%, accuracy - 94.8%
Conclusion: Compression elastography of pancreas at endosonography has clinical value for the correct diagnosis and important diagnostic value in complex algorithm of patients examination. Qualitative and quantitative evaluation are important additions for the diagnosis elaboration.

Introduction: In patients with suspected choledocholithiasis, the American Society of Gastrointestinal Endoscopy (ASGE) guidelines recommend different approaches depending on the probability of common bile duct (CBD) stones, based on clinical predictors. Endoscopic retrograde cholangiopancreatography (ERCP) is suggested in patients with high probability.
Aims & Methods: We aimed to assess the benefit of endoscopic ultrasound (EUS) in suspected choledocholithiasis and the impact on ERCP burden, not only in patients with intermediate probability, but also in those with high probability. Patients undergoing EUS for suspected choledocholithiasis between June 2011 and June 2014 were retrospectively evaluated. According to clinical data, patients had been classified as high or intermediate probability of choledocholithiasis. ERCP was performed whenever EUS revealed CBD stones. The remaining patients were followed for at least six months.
Results: We included 42 patients (59.5% female, mean age 55.1 ± 21,3 years), 22 with high probability of choledocholithiasis and 20 with intermediate probability. In 22 (high probability = 14, intermediate = 8) EUS showed choledocholithiasis (21 truly positives) and ERCP was performed, mostly in the same session (66.7%). "High probability" had a specificity of 57.1% (42.9% false positives) for diagnosis of choledocholithiasis. Sensitivity, specificity, positive predictive value and negative predictive value of EUS were 100%, 95.2%, 95.5% and 100%, respectively. It was found that the diameter of CBD was higher in patients with choledocholithiasis (9.3 ± 6.9 vs 4.3mm ± 3.0mm, p < 0.05). There were no differences in the level of total bilirubin, alkaline phosphatase, gamma-glutamiltranspeptidade or transaminases.
Conclusion: This study demonstrates that the use of clinical criteria alone might not adequately predict the presence of choledocholithiasis. EUS had a high diagnostic accuracy in the detection of CBD stones, preventing ERCP in 36.4% of high probability patients. EUS should be considered prior to ERCP, regardless of the probability of choledocholithiasis.

P1462 ROLE OF EUS-GUIDED NEEDLE BASED CONFOCAL LASER ENDOMICROSCOPY IN ASSESSMENT OF PANCREATIC CYSTIC NEOPLASMS

V. Kim[1], E. Bystrovskaya[2], E. Kostyreva[2], Y. Orlova[2], K. Noskova[2]
[1]*Moscow Clinical Scientific Center,* [2]*Moscow Clinical Scientific Center, Moscow, Russian Federation*

Contact E-mail Address: v.kim@mknc.ru
Introduction: The differential diagnosis of pancreatic cystic neoplasms (PCN) is still a challenge. Clinical tools used for this purpose are cross sectional imaging, endoscopic ultrasound (EUS), cytology and cyst fluid analysis. EUS-guided needle based confocal laser endomicroscopy (nCLE) enhances the diagnostic arsenal in the evaluation of PCN and seems to be promissing technique.
Aims & Methods: Aim: to improve diagnosis performing EUS –guided nCLE in patients with pancreatic cystic neoplasms.
Material and methods: 69 patients with pancreatic cystic neoplasms(M-15, F-54, mean age – 59,4 ± 19,7 yrs) underwent complete investigation including transabdominal ultrasound, CT, EUS. In 11 (16%) cases imaging characteristics were uncertain that required EUS-guided nCLE, FNA with cytology and cyst fluid analysis (CEA).
Results: Cross-sectional imaging, EUS of 69 patients established IPMN in 45 (65%) cases: MD –IPMN in 5, BD-IPMN- 36, IPMN invasive carcinoma – 4 cases, SCN in 10 (14.5%) patients, MCN in 2(3%) patients, SPN in 2(3%) case, pseudocyst (14.5%) in 10 patients. The size of cyst ranged from 5 to 110 mm. EUS-guided nCLE was performed in 11(16%) patients with cyst size above 2 cm and revealed IPMN in 3 cases, SCN - in 7, SPN in 1 case. Cyst fluid CEA

level in IPMN patients reached 83 ± 53.6, ng\ml, in SCN patients - 7.3 ± 3.2 ng\ml. In 3 cases the results of nCLE influenced on the diagnosis and management of cystic lesions. In 2 cases suspected to MCN and neuroendocrine tumor nCLE revealed superficial vascular network pattern typical to SCN, which is considered to be benign and requires follow-up. In 1 case of BD-IPMN with cyst size < 3cm nCLE revealed typical fingerlike papillary projections and focus of high-grade dysplasia that was confirmed by cytology and refer the patient to resection.
Conclusion: EUS-guided nCLE in combination with EUS FNA may improve diagnosis and management of pancreatic cystic neoplasms. In experienced hands it allows to avoid unnecessary intervention or observation and establish indications to well-timed surgery.

P1463 EFFICACY OF EUS-GUIDED ANTEGRADE TRANSPAPILLARY STENTING IN CASE OF FAILED ERCP: RETROSPECTIVE ANALYSIS IN TWO LARGE-VOLUME CENTRES

V. Dhir[1], T. Itoi[2], S. Bhandari[1], A. Maydeo[1]
[1]*Baldota Institute of Digestive Sciences, Mumbai, India,* [2]*Tokyo Medical University, Tokyo, Japan*

Contact E-mail Address: vinaydhir@gmail.com
Introduction: EUS-guided biliary drainage (EUS-BD) has evolved as a viable alternative for biliary drainage. Published studies about EUS-BD have shown a lower rate of post-procedure pancreatitis, presumably due to bile duct access being away from papilla. EUS-guided antegrade transpapillary stenting resembles ERCP or PTBD as the stent exits through papilla, and not trans-luminally. There are no major published studies of EUS-AG
Aims & Methods: Aims: To assess safety and efficacy of EUS-AG for biliary drainage.
Setting: Two tertiary care centres.
Patients: Patients with obstructive jaundice and failed ERCP or ERCP is not possible.
Study design: Retrospective analysis.
Methods: Left hepatic duct puncture was done from proximal stomach using a 19 gauge needle. Guidewire was manipulated across the hilum, and papilla in to duodenum. After track dilation with a biliary balloon or a cystotome, a stent was inserted and positioned across the papilla.
Results: There were 56 patients (median age 65 years, 24 females). Fifty four patients had a malignant distal obstruction (pancreatic 50, ampullary 3, bile duct 1), and two had a proximal obstruction (bile duct 1, nodal 1). Twenty one patients (37.5%) had normal duodenum, 26(41%), had duodenal stenosis, while 9(16%) had post operative anatomy (Whipples 6, Billroth II 2, total gastrectomy 1). The mean pre-procedure bilirubin was 14.6 mg%. Technical success was achieved in 53 patients (94.64%). Expandable metal stents were placed in 49 patients while 4 patients had plastic stents. Six patients (10.71%) developed 8 adverse events (14.28%). Adverse events were highest in the prior surgery group (2/9, 22.2%, followed by those with duodenal stenosis (3/26, 11.53%, and normal duodenum (1/21, 4.3%). The difference however was not statistically significant ($p = 0.6$). Adverse events included pancreatitis in 2 (3.57%), bleeding in 2 (3.57%) and cholangitis, perforation, and stent migration in one patient each(1.78%). There was no mortality. Both the patients with pancreatitis had not undergone a prior ERCP. One patient developed mild, and another moderate pancreatitis. Over a median follow up of 280 days, 3 patients (5.6%) had partial stent migrations, while stent block developed in 14 patients (26.41%). Sixteen patients(30.1%) died with stent in situ. Kaplan-Meier curves for stent patency show that median stent patency was > 210 days.
Conclusion: EUS-AG procedure has safety and efficacy profile similar to other EUS-BD procedures. However the post-procedure pancreatitis rates appear higher, and are equivalent to those reported for ERCP. This could be due to papillary manipulation during antegrade stent placement. Prospective study compared with conventional ERCP is warranted.

P1464 VISUALIZATION AND NEUROLYSIS OF CELIAC GANGLIA WITH ENDOSCOPIC ULTRASOUND: RESULTS OF A CLINICAL CROSS-SECTIONAL AND HUMAN CADAVER STUDY

W. Kappelle[1], R. Bleys[2], A. Van Wijck[3], P. Siersema[1], F. Vleggaar[1]
[1]*Gastroenterology and Hepatology,* [2]*Anatomy,* [3]*Anesthesiology, UMC Utrecht, Utrecht, Netherlands*

Contact E-mail Address: w.f.w.kappelle@umcutrecht.nl
Introduction: Endoscopic ultrasound-guided celiac ganglia neurolysis (EUS-CGN) by injecting ethanol in individual celiac ganglia has recently been introduced as an alternative to celiac plexus neurolysis. However, there is little evidence that the structures targeted during EUS-CGN are indeed celiac ganglia and that selective ethanol injection into ganglia is feasible.
Aims & Methods: The aim of this study was to assess the proportion of patients in which ganglia can be visualized with EUS, to evaluate whether these structures are indeed celiac ganglia and to visualize the local spread of ethanol after EUS-CGN. In 100 consecutive patients (44 male [44%], median age 60, IQR 45-68) undergoing linear EUS, ganglia were identified and their characteristics recorded. Furthermore, a linear echo-endoscope was placed in the region next to the celiac trunk in a prosected human cadaver. A hypodermic needle was inserted into a ganglion after identification and the tissue surrounding the needle was removed, dissected to visualize the ganglion and subsequently sectioned and stained. Finally, EUS-CGN was performed with ethanol 96%, mixed with orange dye, in a nonembalmed human cadaver. Thereafter, the entire region around the celiac plexus was removed and consecutive transverse sections were obtained with a heavy duty cryomacrotome, whilst taking high-quality pictures every 75μm. Afterwards, a 3D-reconstruction was used to obtain sagittal and coronal images.
Results: In total, 211 ganglia were detected in 86/100 patients. Median number of ganglia was 2 (range 1-9), median sizes of the long and short axis were 6.2 mm (IQR 4.5-8.6 mm) and 2.8 mm (IQR 2.2-4.0 mm), respectively. The ganglia were most commonly located anteriorly (n = 65, 31%), left (n = 64, 30%) or anteriorly and left (n = 75, 36%) of the celiac trunk. Histology of the dissected region in the cadaver showed numerous nerve cell bodies around the needle and no other structures with comparable echogenic characteristics, such as lymph nodes. In total, two ganglia were visualized with EUS in the nonembalmed cadaver and both were injected with 1mL of ethanol under EUS-guidance using a 25G FNA-needle. More than 2,200 images were taken during transverse sectioning with the cryomacrotome. 3D-reconstruction showed spreading of the dye in the celiac region, well beyond the ganglia, with a total spread of 80 x 70 x 53 mm.
Conclusion: Using EUS, it is possible to visualize celiac ganglia in the majority of patients, most commonly anteriorly and to the left of the celiac trunk. Histology from a cadaver confirmed that the visualized structures are indeed celiac ganglia. As a low dose (1 ml) of ethanol already spreads well beyond the injected celiac ganglion after EUS-CGN, it is doubtful whether selective celiac ganglia neurolysis is feasible.

P1466 SUPERIORITY OF THE SPLIT-DOSE PEG REGIMEN FOR SMALL-BOWEL CAPSULE ENDOSCOPY. A SINGLE-CENTER PROSPECTIVE RANDOMIZED CONTROLLED TRIAL

P. Magalhães-Costa[1], J. Carmo[1], M. Bispo[1], S. Santos[1], C. Chagas[1]
[1]*Gastrenterology, Hospital Egas Moniz - Centro Hospitalar Lisboa Ocidental, Lisboa, Portugal*

Contact E-mail Address: pmagalhaescosta@gmail.com
Introduction: Over the last years, it has become apparent that fasting and clear fluids alone obtain inferior small-bowel visualization when compared to what it is achieved with purgatives use. PEG (polyethylene glycol) lavage solutions has accumulated evidence and is, therefore, recommended by the last ESGE guideline. Whether this regimen can be further improved by changing the timing of administration is unknown.
Aims & Methods: To evaluate small-bowel cleansing quality, diagnostic yield, transit time and patients' tolerability, comparing two different PEG administration schedules (single-dose vs split-dose). Fifty-seven patients were prospectively enrolled and randomized in two groups: Group 1 (n = 29) were administrated 2L of PEG in the day before SBCE, time between PEG administration and SBCE = 10 hours; and Group 2 (n = 28) were administrated 1L of PEG in the day before SBCE and 1L of PEG in the morning before SBCE, time between PEG administration and SBCE = 4 hours. Small-bowel cleansing was independently assessed by four experienced gastroenterologists and the cleansing quality of the small-bowel was evaluated according to the system described and validated by Brotz *et al*[1] using the quantitative index (QI). SBCE image quality, detection of any mucosal abnormality, clinically relevant lesion (according to Saurin classification), transit times and patients' tolerability during preparation and after SBCE ingestion were compared.
Results: Groups were age and sex-matched. The entire and distal half small-bowel cleansing scores were significantly higher among G2 (median score 8 points vs 10 points, $p = 0.012$; median score 6 points vs 8 points, $p = 0.05$, respectively). Despite an higher proportion of patients in G2 with an adequate preparation (≥ 8 points), there was no statistical difference regarding the entire and distal half of the small-bowel cleansing (66% vs 82%, $p = 0.230$; 41% vs 54%, $p = 0.431$, respectively). Regarding the elementary assessment of the entire small-bowel cleansing, G2 had a significantly higher proportion of patients with a maximum elementary score (2 points) in the percentage of mucosa visualized ($p = 0.045$) and fluid/debris ($p = 0.016$). Although not reaching statistical significance, a trend was noted regarding better scores in the bile/chyme staining ($p = 0.141$) and brightness ($p = 0.070$) scores among G2 in the entire small-bowel assessment. A clinically relevant lesion was observed in 58% of the examinations, without statistical difference between the two preparations (52% vs 64%, G1 and G2, respectively, $p = 0.424$). There were no significant differences in transit times among the two PEG regimens. Both schedules were fairly well tolerated, showing no differences regarding symptoms while ingesting the preparation or after SBCE ingestion.
Conclusion: Split-dose PEG regimen for SBCE preparation improved the small-bowel cleanliness, didn't interfere with transit times and was equally well tolerated by patients. No differences were observed regarding diagnostic yield.

Introduction: Vascular lesions such as angioectasia and erosions are the main causes of unidentified hemorrhages in the digestive tract. However, the frequency of the primary disease varies according to patient age. Especially among people ≥65-years-old (elderly, according to the World Health Organization definition), multiple comorbidities are often present in those taking antithrombotic drugs, and the incidence of the small intestine lesions increases with the use of these drugs. We compared groups of people <65-years-old and ≥65-years-old relative to obscure gastrointestinal bleeding (OGIB) in our hospital.

Aims & Methods: We examined 446 patients using small intestine capsule endoscopy (CE) and balloon endoscopy (BAE) between December 2014 and April 2004. Their small intestinal lesions were examined to determine the underlying disease, and their oral medications and small intestine transit times were compared.

Results: Among the 239 individuals in the <65-years-old group, we found cases of occult OGIB (n = 25), overt OGIB (n = 87), disease of the small bowel (n = 78), and others (n = 49). Among the 207 patients in the ≥65-year-old group, we found occult OGIB (n = 31), overt OGIB (n = 104), disease of small bowel (n = 51), and others (n = 21). In the <65-years-old group, 9% (20/239 patients) were taking antithrombotic drug and/or anticoagulant drug, and 30% (6/20 patients) were associated with angioectasia and/or erosions. In the ≥65-years-old group, 22% (43/207 patients) were taking antithromobotic drug an/or anticoagulant drug internal use, and 49% (21/43 patients) were associated with antioectasia and/or erosions. The intestinal transit time was significantly longer in the ≥65-years-old group (313 min) than in the <65-years-old group (265 min).

Conclusion: In individuals ≥65-years-old, there were many individuals using antithrombotic and/or anticoagulant drugs, and many cases with angioectasia and/or erosions were observed using CE. The small intestine transit time was also longer in the ≥65-years-old group, suggesting that an increased risk of mucous membrane disorders with the use of drugs. CE searches in elderly people with suspected OGIB are thought to be necessary to confirm the diagnosis.

Contact E-mail Address: ryoswd923@gmail.com

Introduction: Although overt obscure gastrointestinal bleeding (OGIB) is difficult to diagnose, capsule endoscopy (CE) and balloon-assisted enteroscopy (BAE) are effective and essential devices for diagnosing small intestinal bleeding. Despite great progress, some OGIB cases cannot be detected using CE and BAE. Based on our data, we compared the detection rates for both methods, and checked undetected cases with CE and BAE.

Aims & Methods: CE and BAE were performed on 433 patients (285 male, 148 female), between April 2005 and September 2014, at our institute. A total of 167 patients were diagnosed with OGIB. For diagnosing overt OGIB, CE (Pillcam SB2; Covidien, Mansfield, USA) was employed first; BAE (single balloon enteroscopy; Olympus Medical Systems, Tokyo, Japan) was also used for both diagnosis and treatment. If small intestine lesions were suspected, based on another modality, BAE was used, despite negative CE findings. CE results were independently checked by at least two doctors. BAE was performed using either an oral and/or anal approach, depending on the CE results. Prior to checking for small intestinal lesions, esophagogastroduodenoscopy and total colonoscopy were both performed to ensure the absence of gastrointestinal bleeding from areas other than the small intestine.

Results: The CE diagnoses of the 167 cases of overt OGIB cases included angiectasia (29%), erosion/ulcer (29%), carcinoma (6%), and Crohn's disease (1%). Active bleeding was observed in 47 (28%) patients using CE, and all cases were rechecked using BAE. BAE diagnosed 39 (83%) of the 47 cases of active bleeding, and some cases (such as those with angiectasia) were simultaneously treated with BAE; 17 (36%) of the 47 cases were not diagnosed using BAE. In the 167 cases of overt OGIB, the sites of active bleeding could not be determined using CE in 108 (65%) cases; 5 (3.0%) cases were diagnosed using other modalities, such as scintigraphy or BAE. These 5 cases included 3 cases of Meckel's diverticulum, 1 jejunal sarcoma, and 1 ileal angiectasia; CE images were not taken, precluding diagnosis using CE only.

Conclusion: Both CE and BAE are very useful for the detection and diagnosis of OGIB. However, there are some cases that cannot be detected using either methodology. Therefore, if bleeding points are not detected using CE, but bleeding recurs, other modalities, including BAE, should be used.

Contact E-mail Address: sara.s.o.monteiro@gmail.com

Introduction: Unclassified colitis is defined as an inflammatory bowel disease limited to the colon, whose combination of clinical, imaging, endoscopic and histological elements does not allow a differential diagnosis between Crohn's disease (CD) and Ulcerative Colitis (UC).

Aims & Methods: The aim of this study was to evaluate the role of small bowel capsule endoscopy (SBCE) on the reclassification of unclassified colitis.

We performed a multicenter, retrospective study including patients with unclassified colitis undergoing SBCE, between 2002 and 2014. SBCE studies were reviewed and the inflammatory activity was evaluated by determining the Lewis Score (LS). Inflammatory activity was considered significant and consistent with CD when the LS ≥ 135. The definitive diagnosis during follow-up was based on the combination of clinical, imaging, endoscopic and histological elements.

Results: Thirty-six patients were included, 21 females (58%) with mean age at diagnosis of 34 ± 13 (15-64) years. The mean follow-up time after the SBCE was 52 ± 41 (12-156) months.

The SBCE revealed findings consistent with significant inflammatory activity (LS ≥ 135) in 9 patients (25%); in all of them the diagnosis of CD was confirmed during follow-up. In 27 patients (75%), the SBCE revealed no significant inflammatory activity (LS < 135); in these patients, the diagnosis of UC was established in 16 cases (59.3%), CD in 1 case (3.7%) and 10 patients (37%) maintained a diagnosis of unclassified colitis during follow-up. A LS ≥ 135 at SBCE had a sensitivity = 90%, specificity = 100%, Positive Predictive Value = 100% and Negative Predictive Value = 94% for the diagnosis of CD.

Conclusion: SBCE proved to be very important in the reclassification of patients with unclassified colitis. In this study, absence of significant inflammatory activity in the small intestine allowed exclusion of CD in 94% of cases.

P1471 PILLCAM SB2 AND SB3 SMALL BOWEL CAPSULE ENDOSCOPY –COMPARISONS AND IMPLICATIONS FOR PRACTICE

S. Dunn[1], L. Neilson[1], C. Davison[1], F. Butt[1], S. Panter[1]
[1]*South Tyneside NHS Foundation Trust, South Shields, United Kingdom*

Contact E-mail Address: simon.dunn@doctors.org.uk

Introduction: South Tyneside Hospital has been a referral centre for capsule endoscopy since 2005, performing over 1000 studies. We have previously shown that the diagnostic yield (DY) of the PillCam SB3 capsule (Given Imaging, Israel) is significantly higher than that of the PillCam SB2[1]. Here we present additional data on ''learning curve'' and offer suggestions for practice.

Aims & Methods: Previous work compared the DY of the last 100 SB2 capsules with the first 100 SB3s. To assess for a ''learning curve'' effect we reviewed our first 100 SB2 capsules (Oct 2007–Aug 2008). Indications, completion rates, small bowel recording times and pathology were recorded. Pathology was classed as significant if it related directly to indication.

Results: 46 of the first 100 SB2 capsules were abnormal, of which 31 had significant pathology; almost identical to the last 100 SB2s (45 abnormal, 30 significant). Most tests (255/300, 85%) were for unexplained anaemia or Crohn's disease assessment. More capsules are now done for acute GI bleeding; 4 of the first 100 SB2 capsules, 12 of the last 100 SB2s and 15 of the first 100 SB3s. There were 23 incomplete SB2 capsules (11.5%) of which 18 (9%) were in small bowel at the end of recording and 5 were held up by pathology (2.5%). Only 5 SB3 studies (5%) were incomplete, with 4 (4%) not entering the colon and 1 (1%) held up by pathology. On average SB3 capsules had a longer recording time of 9 hours and 24 minutes compared to 8 hours and 2 minutes for the SB2s.

Table 1: Pathology by capsule group

	Capsule Type		
First 100 SB2	**Last 100 SB2**	**First 100 SB3**	
Angioectasia	7	6	18
Blood	4	3	4
Coeliac changes	2	3	1
Polyp/Mass	1	1	4
Stricture	1	3	1
Ulcers/erosions	16	14	20
Other	0	0	1
Total	31	30	49

Conclusion: 219 capsules were reported before the SB2 was introduced. Between the first hundred and last hundred SB2 capsules there were 1003 SB2 studies. This suggests that the increased DY is not due to a ''learning curve'', supporting our finding of increased DY with the SB3. Any ''learning curve'' is likely to be from the first 200 studies. Most studies are for iron deficiency anaemia and Crohn's disease assessment but there is a trend towards using capsules as a diagnostic tool in overt GI bleeds. Fewer SB3 studies were incomplete compared to SB2s. Our unit is now more proactive in monitoring gastric transit and colonic entry using the real time viewer and this change in practice may have helped with this. Longer recording times due to increased battery life may also play a part. We recommend monitoring capsules in real time and leaving the recorder on for longer if gastric transit is delayed or colonic entry is not clear.

P1472 DIAGNOSIS OF SMALL INTESTINAL LESIONS BY THE PILLCAM SB3-IS THE EFFICIENCY OF IMAGE READING IMPROVED IRRESPECTIVE OF EXPERIENCE?

T. Omori[1], T. Hara[1], T. Kuriyama[1], A. Ito[1], M. Yonezawa[1], B. Iizuka[2], S. Nakamura[1], K. Tokushige[3]

Contact E-mail Address: tohmori@ige.twmu.ac.jp

Introduction: The PillCam SB3 is a third-generation small intestinal capsule endoscope that features automatic conversion of the imaging frame rate and improvement of image resolution when used in combination with the DR3 recorder. In addition, the efficiency of lesion detection has been improved by advances in video processing when the PillCam SB3 is used in combination with RAPID Reader8 interpretation software. In the present study, we investigated whether the efficiency of image reading could be improved by using the PillCam SB3 irrespective of the experience of the reader.

Aims & Methods: Sixty-four patients underwent small intestinal capsule endoscopy around May 2014 when the PillCam SB3 was introduced to our hospital. Among them, 30 and 34 patients were assigned to the SB2 plus and SB3 groups, respectively, and 10 patients with an average small intestinal transit time were extracted from each group. Data obtained from these 20 patients were randomized and were assessed by 3 readers with different levels of experience (beginner: <20 images, intermediate: ≥ 50 images, expert: ≥ 600 images). Then the reading time and the findings were compared among these readers. RAPID Reader8 was used as the interpretation software. After preparation of a start-point thumbnail for each gastrointestinal tract, image reading was performed under the conditions of manual mode, 4 images, and 28× speed in the SB2 plus group, while the conditions were review mode, 4 images, and 28× speed in the SB3 group. The reading time was defined as the period required for image reading and preparation of the thumbnail comment.

Results: There were no significant differences of patient background factors between the two groups. The gastrointestinal transit times of the SB2 plus group and the SB3 group were as follows: the esophageal transit time was 3.7 ± 2.4 vs. 2.9 ± 1.8 seconds, the gastric transit time was 16 ± 17.9 vs. 16 ± 13.3 minutes, the small intestinal transit time was 244.5 ± 47.3 vs. 232.7 ± 30.7 minutes, the large intestinal transit time was 121.1 ± 52.4 vs. 135.4 ± 52.5 minutes, and the tota test time was 381.6 ± 46.3 vs. 384.1 ± 43.2 minutes. There were no significant differences between the two groups. The reading time up to the small intestine was shorter in the SB3 group for each reader (SB2 plus group vs. SB3 group: beginner, 40.2 ± 10.1 vs. 23.7 ± 6.7 ($p = 0.0009$); intermediate, 21.4 ± 4.9 vs. 10.3 ± 2.9 ($p = 0.0003$); expert, 23.2 ± 5.6 vs. 11.1 ± 2.9 ($p = 0.0002$)). The total reading time up to the large intestine was also shorter for each reader in the SB3 group (beginner: 49.9 ± 10.4 vs. 24.9 ± 6.7 ($p = 0.0002$), intermediate: 30.4 ± 6.4 vs. 11.4 ± 3.7 ($p = 0.0002$), expert: 31.7 ± 4.1 vs. 12.1 ± 3.4 ($p = 0.0002$)). The correspondence of findings with those obtained by the expert reader was 84.6% for the beginner and intermediate readers.

Conclusion: When the RAPID Reader8 and SB3/DR3 recorder were used in the SB3 group, the reading time was much shorter than in the SB2 plus group irrespective of the experience of the reader. It is concluded that examination using the PillCam SB3 can reduce the burden placed on readers.

P1473 COMPARISON BETWEEN SIDE VIEW (CAPSOCAM) AND FRONT VIEW (PILLCAM SB, MIROCAM) CAPSULE ENDOSCOPES IN CROHŃS DISEASE AND IRON-DEFICIENCY ANEMIA. A SINGLE-CENTER EXPERIENCE

T. Pachofszky[1], L. Wagner[1], C. Madl[1]
[1]*IV. Department of Internal Medicin, KA Rudolfstiftung, Vienna, Austria*

Contact E-mail Address: thomas.pachofszky@wienkav.at

Introduction: Capsule endoscopy is an established method for the exploration of the small bowel with a high diagnostic yield.

Since 2012 we are using a new developed capsule system with 4 cameras (Capsocam; SV1, SV2, Capsovision, Saratoga, CA) for a 360° panorama lateral viewing and on board storage.

Aims & Methods: The aim of our clinical observation was to evaluate if there is a difference between relevant findings of front view systems and the new side view capsules. Relevant findings are defined as lesions that changed the patient's therapy (endoscopic treatment or medication).

We used Capsocam for 200 patients (102 female, 98 male, mean age 52.6), 812 for front view capsules (related distribution for gender and age).

Included are patients with suspected Crohn's disease or known crohńs disease with unknown lesions in the small bowel (57 Capsocam, 116 front view capsules) and patients with iron-deficiency anemia with negative upper and lower gastrointestinal endoscopy (61 Capsocam, 213 front view capsules).

Results: For the indication Crohn's disease or iron-deficiency anemia we have done 118 examinations.

In the Crohn's group with side view capsules we included 57 examinations, 28 with relevant pathological findings (49.1%); with front view capsules 116 examinations, 26 with relevant pathological findings (22.4%).

In the iron-deficiency anemia group with side view capsules we included 61 examinations, 36 with relevant pathological findings (59.0%); with front view capsules 213 examinations, 67 with relevant pathological findings (31.5%).

DIAGNOSTIC YIELD	side view	front view	Chi square	Chi square equal
Crohn's disease	49,1%	22,4%	$p < 0,001$	12,974
Iron-deficiency anemia	59%	31,5%	$p < 0,001$	15,354

In 200 examinations we found a complete small bowel passage in 96.8%, with a mean examination time of 974 min (374 - 1376 min). 7 patients lost the capsule (3.5%). No capsule retention occurred. In 3 capsules there was one of the four cameras defect. The duodenal papilla was detected in 78.9%.

Conclusion: In our series for Crohn's disease and iron-deficiency anemia the new side view capsule endoscope (Capsocam) shows significant better results in comparison to the established front view systems (PillCam SB, Mirocam).

Introduction: Sodium phosphate (NaP) is a key component of the standard bowel preparation regimen for colon capsule endoscopy (CCE), particularly to cause excretion of the capsule endoscope while the battery is still functioning. However,

the use of NaP is limited due to the possibility of causing severe adverse events, e.g. acute phosphate nephropathy, acute renal failure, hypertension, or mineral imbalance. According to the latest report investigating the performance of CCE compared with CT colonography, Gastrografin (the water-soluble iodinated radiopaque oral contrast medium) was first used for the CCE regimen, because Gastrografin is generally used as part of the CT colonography regimen for "fecal tagging". In our experience, a CCE regimen using Gastrografin without NaP, achieved a very high capsule excretion rate.
Aims & Methods: The aim of this study is evaluate the use of Gastrografin in the bowel preparation regimen for CCE.
From June 2014 to March 2015, 37 patients (median age 65.2 years; 11 males, 26 females) underwent CCE. All had a history of laparotomy and/or previously incomplete colonoscopy. Bowel preparation started from breakfast the day before examination. Patients had low-residue meals at breakfast and lunch, and drank 1L of polyethylene glycol (PEG) plus ascorbic acid with 0.5L of water in the evening, and 10mL of sodium picosulfate hydrate at bedtime. On the morning of the examination, patients again drank 1L of PEG plus ascorbic acid with 0.5L of water. After capsule ingestion, 50mL of Gastrografin diluted with 0.9L of magnesium citrate was administered to facilitate capsule excretion. Gastrografin with magnesium citrate was given again after one hour. If the capsule was not expelled within four hours of ingestion, 50mL of Gastrografin with water and/or a bisacodyl suppository were added.
Results: The capsule excretion rate was 97% (36/37). The one patient who did not expel the capsule within the duration of battery life was a 51-year-old man with severe diverticular disease of the sigmoid colon. The median GI transit time was 4h 26 min (range 1h 9 min to 10h 11 min). The median colon transit time was 2h 43 min (range 16 min to 8h 34 min). GI transit time as well as colon transit time was lower than previously reported. Bowel cleansing was adequate (excellent/good) in 90% of patients. The polyp (≥6 mm) detection rate was 64.9% (24/37). Diluted Gastrografin was well tolerated by all patients. No adverse events occurred in this pilot study.
Conclusion: The use of Gastrografin in CCE bowel preparation regimen is promising. However, other modifications might influence the high excretion rate and short transit time. A clinical trial to compare regimens with and without Gastrografin is warranted.

P1475 UTILITY OF THE CAPSULE ENDOSCOPY IN THE DIAGNOSIS AND MONITORING OF CELIAC DISEASE

V. A. Jimenez-Garcia[1], F. Argüelles-Arias[1], M. Rodriguez-Tellez[1], F. Pellicer-Bautista[1], A. Caunedo-Alvarez[1], J. M. Herrerias-Gutierrez[1]

Contact E-mail Address: drajimenezg@hotmail.com
Introduction: For its minimal invasiveness, capsule endoscopy is a useful tool in the exploration of the small intestine. It has been proposed to be useful in the diagnosis and management of patients with celiac disease, however, evidence that supports and enables a broad recommendation to use the capsule in this entity is still controversial and limited.
Aims & Methods: Aim. To determine the utility of capsule endoscopy (CE) in the diagnosis and monitoring of celiac disease (CD).
Methods. Single-center, retrospective and comparative study of patients with indication for CE study by suspected CD or disease monitoring. Were distributed according to the indications in two groups: patients previously diagnosed of CD with persistent symptoms despite gluten free diet (GFD) (Group A) and patients with clinical suspicion of CD (Group B). The parameters examined were: clinical findings, capsule-endoscopic findings (CEF), duodenal biopsy by Marsh scale and serology by anti-tissue transglutaminase antibodies (anti-tTG).
Results: 60 patients were included in this research (31F/29M; 48.95 ± 17.13 years). We included in Group A 8 patients previously diagnosed of CD with persistent symptoms and GFD, observed in all CEF with celiac pattern (villi-denuded, atrophy and/or intestinal scalloped) and one of them was observed ileal neoformation not stenosing that was resected 3 weeks after (T-cell lymphoma). In group B included 52 patients with clinical suspicion of CD [iron deficiency anemia (IDA) 17/52, chronic diarrhea (CrD) 16/52, CrD + IDA 12/52, vitamin B12 deficiency 3/52, chronic abdominal pain 2/52, IDA + osteopenia 1/52 and herpetiform dermatitis 1/52]. Of these 52 patients, 33 had positive anti-tTG and 19 anti-tTG negative. Of the 33 patients with positive serology, 22 had CEF positives and all biopsies were positives according to the Marsh scale (6/22 M1, 8/22 M2 y 8/22 M3). Eleven patients had CEF negatives and in 8 of them the biopses were negative too. On the other hand, of the 19 patients with negative serology, 10 had CEF positives and in 2 cases of them the biopsies were positives, as long as the other 9 patients had CEF negatives and in 8 of them the biopsies were negatives too. So, finally in 24 of the 32 patients with CEF positives was confirmed CD. The extraintestinal findings most frequently observed were: colonic diverticulum, polyps > 4mm and hemorrhoids.
Conclusion: CE in our experience is a useful tool in the diagnosis and monitoring of CD. In all patients with positive serology and CEF positives the diagnosis of CD was confirmed by biopsy, so it could arise in certain cases establish the diagnosis without performing gastroscopy and biopsy, however more studies are needed to confirm this.
Also, in accordance with the literature, it is useful to rule out complications in patients with persistent symptoms despite GFD. Finally, in our experience in cases of negative serology and CEF negatives yield gastroscopy and biopsy is low.

Contact E-mail Address: yakakuga@ncc.go.jp
Introduction: We previously reported that the sensitivity of colon capsule endoscopy (CCE) for clinically significant polyps in a Japanese multicenter trial was 94% when results of the first colonoscopy (CS) was set as the gold standard. The aim of this additional study is to clarify the per-polyp sensitivity according to the pathological diagnosis.
Aims & Methods: This multicenter trial was conducted from December 2011 to May 2012. Written informed consent was obtained from all patients prior to enrollment. Eligible patients with significant polyps detected by the first CS received CCE (PillCam® COLON 2) procedures in tertiary-care centers. Then, a second CS was conducted to remove the significant polyps. We retrospectively reviewed the endoscopic reports from the second CSs and the pathological diagnoses, and calculated the per-polyp sensitivity of CCE according to the diagnosis.
Results: After CCE, a second CS was performed in 66 subjects to remove lesions. In total, 268 lesions were confirmed by CCE and/or second CS in the 66 subjects. Among the 268 lesions, 111 lesions were detected only by CCE, 136 lesions were detected by both CCE and the second CS, and 21 lesions were detected only by the second CS. The 157 lesions that were detected by the second CS were resected endoscopically during the second CS, and the pathological diagnosis was confirmed. The per-polyp sensitivity was estimated as 87% (136/157). Regarding the pathological findings, the per-polyp sensitivities were 100% (7/7) in cancer, 86% (18/21) in high grade dysplasia, 85% (94/110) in low grade dysplasia, 86% (6/7) in hyperplastic polyp, and 92% (11/12) in sessile serrated adenoma/polyp (ns), respectively.
Conclusion: The per-polyp sensitivity was estimated as 87% in our analysis. There was no statistical significance in the per-polyp sensitivity of different pathological lesion types.

Introduction: Benign esophageal strictures (BES) need repeated dilations to relieve dysphagia. Literature is scarce on risk factors for refractoriness of BES.
Aims & Methods: Assess risk factors for refractoriness of BES to esophageal dilatation (ED). Cross-sectional study of patients with BES referred to ED during a period of three years.
Results: Three hundred and twenty seven ED were performed in 103 patients. Thirty-seven percent of the patients reported dysphagia for solids. Forty-four percent of the patients had anastomotic strictures, 17% were peptic, 6% were caustic. Strictures were complex in 13% of the patients. After dilation, stenosis was transposed in 95% of patients. There was need for further dilations in 54% of patients, being more frequent in patients with dysphagia for solids (81% *vs* 66%, p = 0.003, OR 2.160), with caustic strictures (89% *vs* 70%, p = 0.007, OR 3.487) and with complex strictures (83% *vs* 70%, p = 0.047, OR 2.132). Dysphagia for solids and caustic strictures kept statistical significance in the multivariate analysis (respectively, p = 0.01 and 0.021). Time until subsequent dilations was lower in patients with dysphagia for solids (42 days *vs* 135 days, p < 0.001), in peptic strictures (49 days *vs* 98 days, p = 0.004), in caustic strictures (49 days *vs* 78 days, p = 0.005) and in complex strictures (47 days *vs* 80 days, p = 0.009). In multivariate analysis, further dilations occurred earlier when dysphagia for solids (HR 1.673, p < 0.001), in peptic strictures (HR 1.608, p = 0.003) and in caustic strictures (HR 1.685, p = 0.005). The median time between dilations was 42 days (IQR: 15 – 87).
Conclusion: Dysphagia for solids and caustic strictures are associated with a greater need for subsequent dilations; the time until subsequent dilatations is lower in patients with dysphagia for solids, caustic strictures and peptic strictures.

Introduction: Self-expanding metal stents (SEMS) are the treatment of choice for advanced esophageal cancers. Literature is scarce on risk factors predictors for the occurrence of complications after SEMS placement.
Aims & Methods: Assess risk factors predictors for the occurrence of complications after SEMS placement for advanced esophageal cancer. Cross-sectional study of patients with advanced esophageal cancer referred for SEMS placement, during a period of 3 years.
Results: Ninety-seven patients with advanced esophageal cancer placed SEMS. The tumor was located in the proximal/mid esophagus in 59% of the patients and in the distal esophagus/cardia in 41%. Dilation previous to SEMS placement was performed in 14% of the patients. Fluoroscopy was used in 36% of the patients. SEMS had < = 11cm of extension in 40% of the cases. Stent migration occurred in 21% of patients, obstruction in 7%, fistula in 3% and hemorrhage in 2%. Complications were more common in the tumors located at the level of the distal esophagus/cardia (47.5% *vs* 22.8%, p = 0.011), with statistical significance being kept in the multivariate analysis (OR 3.1, p = 0.018, $CI_{95\%}$ 1.2 – 7.8). Time until development of complications was lower in the tumors located at the level of the distal esophagus/cardia (p = 0.036). Fluoroscopy did not influence the occurrence of migration (22.9% *vs*19.4%, p = 0.682), fistula (2.9% *vs* 3.2%, p = 0.919), obstruction (2.9% *vs* 9.7%, p = 0.182) or bleeding (0% *vs* 3.2%, p = 0.178). The occurrence of complications was not influenced by dilation previous to SEMS placement (p = 0.404), kind of stent used (p = 0.644) nor stent extension (p = 0.611).
Conclusion: The occurrence of complications after SEMS placement for advanced esophageal cancer is not influenced by the use of fluoroscopy nor by the stent used. Tumors located at the level of the distal esophagus/cardia are associated with a greater number of complications, which also occur earlier.

Introduction: Esophageal fistulas (EF) secondary to surgery have a high morbidity and mortality. Self-expanding metal stents (SEMS) have been used as an alternative to re-operation, however, there are no comparative studies of efficacy.
Aims & Methods: Assess clinical efficacy of SEMS in post-surgical EF. Cross-sectional study of patients with post-surgical EF referred for SEMS placement in a reference center during a period of 3 years. Clinical success was defined as closure of the EF in barium swallow at 15 days.
Results: Thirteen patients (11 male) with a mean age of 63 years (20 – 83) placed SEMS. EF had in median 20mm of size (8 – 40). The EF was secondary to Ivor-Lewis esophagectomy in 6 patients, total gastrectomy in 2, thoracic surgery in 2, Nissen fundoplication in 1, after cervical esophagostomy reconstruction in 1 and excision of esophageal diverticulum in 1. The median time between surgery and SEMS placement was 20 days (8 – 178). SEMS had < = 11cm of extension in 5 patients. One patient died 2 days after SEMS placement and one had worsening of the fistula after SEMS expansion. Four patients had migration of the SEMS, with placement of a second stent in 3 of them and repositioning of the first stent in the other one. Time till stent migration was 9 days (2 – 23). Clinical success was achieved in 8 of 11 patients, with removal of the stent without recurrence of EF in 4 patients (median: 46 days after placement). All fistulas with less than 20mm were solved endoscopically. In the 10 patients who died during follow-up, median survival was 59 days ($CI_{95\%}$: 45 – 73).
Conclusion: Clinical success of SEMS in EF is higher than 70%, however, due to high morbidity and mortality, only 36% of the patients have their stent removed, being removal more common when fistulas have less than 20mm.

P1480 CLINICAL OUTCOMES OF SELF-EXPANDABLE METAL STENTS FOR MALIGNANT RECTAL OBSTRUCTION, COMPARED WITH LEFT COLONIC OBSTRUCTION

H. J. Lee[1], S. P. Hong[1], J. H. Cheon[1], T. I. Kim[1], W. H. Kim[1], S. J. Park[1]
[1]*Internal Medicine, Gastroenterology, Seoul, Korea, Republic Of*

Contact E-mail Address: guswjd@yuhs.ac
Introduction: The placement of self-expandable metal stents (SEMS) is widely used for treatment of malignant colorectal obstruction. However, SEMS placement is still considered unsuitable or contraindicated for patients with malignant rectal obstruction within 5cm of the anal verge because of anal pain and foreign body sensation.
Aims & Methods: The aim of this study was to investigate clinical outcomes and complications of SEMS in patients with malignant rectal obstruction including lower rectal obstruction. From January 2005 to December 2014, medical records of patients with malignant rectal or left colonic obstruction who were treated with SEMS were reviewed retrospectively. Technical and clinical success rates and complication rates including pain were evaluated.
Results: SEMS insertion was attempted in a total of 573 patients; 419 for left colon obstruction and 154 for rectal obstruction. Rates of extrinsic colonic malignancy and palliative intention was higher in patients with rectal obstruction than those with left colon obstruction. Technical success rates were similar between two groups (93.2% vs 93.1%, $p = 0.857$), however, clinical success rates were lower and complication rates were higher in patients with rectal obstruction (92.1% vs 85.4%, $p = 0.022$; 25.1% vs 36.6%, $p = 0.014$, respectively). Multivate analysis revealed that extrinsic colonic malignancy and covered stents were significant risk factors for clinical failure, and complete obstruction and palliative intention were associated with complications. Although overall complications were not different in patients with lower rectal obstruction (33.3% vs 27.7%, $p = 0.526$), patients with lower rectal obstruction complained pain due to SEMS placement (11.1% vs 1.5%, $p = 0.014$), two of whom required stent removal and surgical intervention.
Conclusion: SEMS placement in patients with rectal obstrcution including lower rectal obstruction is acceptable for decompression of obstructive symptoms. However, patients with rectal obstruction tended to have extrinsic colonic malignancy and place SEMS as a palliative intention which could influence clinical outcomes.

Introduction: The efficacy and safety of self-expandable metallic stent (SEMS) for patients with acute malignant colorectal obstruction (AMCO) are still controversial.
Aims & Methods: We conducted this study to evaluate the safety and efficacy of SEMS for AMCOs. From January 2010 to July 2014, a total of 171 patients with AMCOs were retrospectively enrolled in this study: 120 patients received emergency stent placement followed by selective operation as stent group, and 51 patients received emergency operation as emergency-surgery group.
Results: The operation time and hospital stay were significantly shorter in stent group (114.51 ± 28.65 min vs 160.39 ± 58.94 min, $P < 0.001$; 8.00 ± 3.97 d vs 12.59 ± 9.07 d, $P < 0.001$). Stent placement also significantly reduce the intraoperative blood loss (61.00 ± 43.70 ml vs 121.18 ± 85.90 ml, $P < 0.001$). The incidence of postoperative complications in stent group was lower than emergency-surgery group (16.7% vs 37.3%, $P < 0.05$). In subgroup analyses, patients received laparoscopic surgery after stent placement had significantly shorter days to first flatus (3.37 ± 1.04d vs 4.47 ± 1.95d, P = 0.041) and postoperative hospital stay (7.10 ± 1.43d vs 8.47± 1.43d, P = 0.001) than open surgery. In stent group, 5-year overall survival (OS) values were significantly better than those in emergency group (47% vs 37%, P = 0.02).
Conclusion: Stent placement as a bridge followed by selective operation is a safe and feasible procedure, providing significant advantages of short-term outcomes and a favorable prognosis for patients with AMCOs. Laparoscopic surgery could be considered as an optimal treatment after stent placement.

Contact E-mail Address: lamine015@yahoo.fr
Introduction: Endoscopic balloon dilatation (EBD) is one of the methods among patients with benign gastric outlet obstruction (GOO). The prevalence and underlying etiologies of GOO in various populations are different.
Aims & Methods: This retrospective study evaluates the effectiveness, safety, long term outcomes of EBD and factors that would affect its success rate in patients with GOO related to peptic ulcer disease (PUD).
We reviewed the charts of 104 patients with GOO related to PUD. Only 62 patients required EBD after failure of medical treatment. The dilatation was performed using a hydrostatic balloon (through the scope) with a mean diameter of 15.9 mm (range 12-20 mm). Eradication of *Helicobacter pylori* (H. pylori) was associated to the endoscopy treatment. Endoscopic check-up examinations were carried out 4 to 6 weeks later, and in case of relapse. The mean follow-up period was 25.7 months (range 1-126).
Results: Eighty seven dilatations were performed in the 62 enrolled patients (51 men and 11 women). The mean age was 49.5 years (20-85 years). A reliable post-eradication *H. pylori* status was available in 40 and was negative in 29. Non steroidal anti-inflammatory drugs were stopped in all patients. Patients on aspirin for the prevention of atherosclerosis received concomitant antisecretory therapy (AST). Symptomatic relief was obtained immediately in 96%, at 6 weeks in 83.8%, at 12 months in 69%, at 24 months in 60% and at 30 months in 55%. The average number of dilatations was 1.4 per patient (1-4). Twenty patients had recurrent stenosis (22.9%) between 2 and 116 months after the first dilatation. Complications occurred in 3 cases (3.4%): perforation in 2 patients and bleeding in one case. Surgery was indicated in 16 patients. Factors predicting referral for surgery included smoking, need for multiple procedures, and dilatation of the stomach. Eradication of *H. pylori* was associated with successful relief of obstruction without surgery.
Conclusion: Balloon dilatation is an effective and safe treatment for GOO related to PUD, avoiding surgery in up to 70% of patients.

Contact E-mail Address: luisclourenco@gmail.com

Introduction: The short-term results of colonic stenting followed by elective surgery (bridge to surgery, BTS) for malignant large-bowel obstruction (MLBO) have been well described. However long-term oncological outcomes are still debated and international endoscopy societies have recently not recomended it as a first-line approach.

Aims & Methods: A comparative observational cohort study was performed based on clinical data review from patients treated in our center between 2006 and 2012 (6 years). We analysed overall survival (OS), disease-free survival (DFS) and recurrence as primary end-points. We also reviewed demographic data, disease staging and peri-operatory morbility and mortality (Clavien-Dindo Classification).

Results: A total of 126 patients were included: 79 (62.7%) were treated with a BTS strategy (group 1) and 47 (37.3%) underwent an emergent surgery (group 2). The distribution by sex, age (70.9 ± 11.4 years) and TNM stage was similiar. The median follow-up was 43.2 ± 3.6 months. There was no significant difference in peri-operatory complications ($p = 0.23$) and adjuvant chemotherapy ($p = 0.53$). The need for a definite stoma was higher in group 2 ($p < 0.001$). The recurrence did not differ significantly between the two groups, although it was superior in group 2 (34.5% vs. 42.5%, $p = 0.492$). DFS (22.2 vs 19.7 months; $p = 0.652$) and OS (43.2 vs. 31.9 months, $p = 0.096$) also did not differ signficantly between the two groups, being slightly longer in group 1.

Conclusion: Results of our study on oncological outcomes, as stated in most recent meta-analysis, as well as well-described short-term outcomes, suggest that BTS could be a promising alternative strategy for MLBO. Larger prospective studies and randomized clinical trials are definetely needed.

Introduction: Colonic self-expandable metal stent (SEMS) placement is recommended and widely used for palliation of obstructive colorectal cancer (CRC). However, the role of SEMS in CRC as a bridge to elective surgery remains unclear.

Aims & Methods: The aim of this study is to evaluate the efficacy and safety of SEMS placement in obstructive CRC and discuss current recommendations in this procedure. Patients with CRC who underwent endoscopic stent placement between January 2012 and January 2015 were retrospectively analysed. Statistical analysis was performed with SPSSv22.

Results: We included 28 patients, 17 (61%) women, mean age 71 ± 11.9 years. Obstructive CRC demanding urgent stent placement occurred in 96% ($n = 27$) of patients. Stent placement as a bridge to elective surgery was performed in 82% ($n = 23$) and as a palliation treatment in 18% ($n = 5$). In 96% ($n = 27$) of procedures, technical and clinical success was achieved. No procedure-related death was recorded. Three (11%) complications were observed: 2 migrations and 1 perforation. When SEMS were placed as a bridge to surgery, average time between endoscopic procedure and surgery was 3 ± 9.7 days (excluding patients who underwent neoadjuvant chemotherapy). Five perforations were registered: 3 during surgery and 2 only after histological review. All patients underwent adjuvant chemotherapy. During the follow-up period (15.6 ± 9.3 months) no recurrence was recorded.

Conclusion: In this study, SEMS placement was an effective procedure in obstructive CRC. It was mainly used as a bridge to elective surgery. However, a significant (20%) rate of macro and microscopic perforation was observed, which might increase recurrence rate and decrease overall survival in potentially curable patients. In this study, stent placement followed current recommendations in 64% of patients.

Contact E-mail Address: m-yoshioka@saiseidr.jp

Introduction: Although self-expandable metal stents (SEMS) is useful to palliation of inoperable malignant colorectal obstructions[1)], long time prognosis is unclear. The present study examined the long time benefits of SEMS for palliation of inoperable malignant colorectal obstructions.

Aims & Methods: Between 2008 and 2013, a total of 57 patients underwent colorectal CEMS placement in Okayama Saiseikai General Hospital. We reviewed 20 patients who were treated in order to palliation of inoperable malignant colorectal obstructions. We examined prognosis of the 20 patients. The mean age of the patients (12 males, 8 females) was 69 (range 37 to 94). Their primary disease were gastric cancer ($n = 6$), pancreas cancer ($n = 2$), and colorectal cancer ($n = 12$). We used WallFlex stent or Niti-S stent.

Results: We experienced no severe complication by stenting. Three gastric cancer patients (15%) needed another stenting in stomach or jejunum. Two patients (10%) needed second colorectal CEMS placement, and two patients needed ileostomy due to stent obstruction. After first placement, they survived a median of 210 days (range 5 to 728 days). Sixteen patients (80%) could stay at home. They were able to stay at home for a median of 54 days (range 1 to 572 days). One patient (5%) could receive end-of life care at home. Others died in hospital. We treated 13 patients (65%) with chemotherapy. One gastric cancer patient treated with S-1-CDDP-PTX-DTX and CPT-11 could stay at home for over 500 days. The patients with chemotherapy stayed at home for a median of 33 days (range 0 to 572 days), without chemotherapy stayed at home for a median of 25 days (range 0 to 372 days) ($p = 0.38$).

Conclusion: Palliation of inoperable malignant colorectal obstructions by stenting is effective for home care. Some patients can stay long time at home with additional chemotherapy.

Introduction: Complete obliteration in the proximal oesophagus is a rare scenario, for instance after radiotherapy in patients with head and neck cancers. Antegrade dilatation is often unsuccessful but retrograde endoscopic rendez-vous dilatation can be a treatment option to restore oesophageal patency and to to resolve patients from PEG tubes.

Aims & Methods: We aimed to describe the technical feasibility and long-term clinical outcome of this technique, as the data in theliteratue is scarce.
This single-centre case series included all patients in a tertiary referral centre 7/2005 -2/2015 with complete obliteration in the proximal oesophagus, who were unable to swallow and were treated by retrograde endoscopic rendez-vous dilatation by endoscopists and ENT surgeons in general anaesthesia. Technical success was defined as achievement of a retrograde puncture and passage with the endoscope to apply a nasogastric tube. The long-term clinical success was defined as either independency from PEG-tube and/or ability of oral food intake. Follow-up was assessed by the validated Functional Oral Intake Scale (FIOS).

Results: Between 7/2005 and 2/2015 six patients (5 males; mean age 71 years [range 54-74]) underwent retrograde endoscopic rendez-vous dilatation(all nasal endoscopes). Apart from one patient with complete occlusion of sinus piriformis after Lyell syndrome, the remaining had undergone radiotherapy due to head &neck cancer (median interval fromradiotherapy to dilatation: 16 months, [range 14-90]). Technical success was achieved in 5 out of 6 patients (Table 1). During follow-up (mean 27 months, range 2-115) half of the patients stayed dependent on the PEG-tube, the other half achieved freedom from PEG-tube and were able to eat oral food. No major complications happened.

Table 1: Technical details and long-term clinical success of endoscopic rendez-vous dilatation in patients with complete obliteration of the proximal oesophagus or hypopharynx

Number and sex of patients (m:f)	6 (5:1)
Antegrade endoscopy, rigid, flexible	4, 2
Puncture with VisiGlide guidewire, Argon beamer	4, 1
Size of first dilatation (balloon and bougie)	median 10 mm (range 6 - 10 mm)
Success Technical success Need for recurrent dilatations or stent after discharge Long-term clinical success (f/u): median (range), months Need for long-term PEG tube Oral food intake without PEG	5/6 (83%)5/6 (83%) 27 months (2-115)3/63/6
Subsequent dilatations before dischargewith balloon, with bougie (range, in mm)	3, 2 patients (15-16.5 mm, 12-15 mm)
Complications: Death, Mediastinal emphysema	01/6

Conclusion: Endoscopic retrograde rendez-vous dilatation offers a safe and viable alternative to high-risk blind dilatation of the proximal oesophagus

and hypopharynx or surgical approaches in patients with complete proximal oesophageal obliteration. We found that technical success was fairly high. However in long-term follow-up only half of the patients remained independent from PEG-tube.

Introduction: Symptomatic stenosis of colorectal anastomosis after low anterior resection of rectum (LAR) is observed in 4–10% of patients. Purpose of our study was to evaluate endoscopic dilation treatment of anastomotic stenosis with through the scope (TTS) endoscopic balloons.
Aims & Methods: Retrospective analysis of all patients with symptomatic anastomotic stenosis after LAR from 2011 to 2014 was performed. We analyzed time interval from LAR to symptomatic stenosis development, number of dilations, size of balloons and X-ray control during dilation. Dilations were performed in 4 week intervals. Successful treatment was defined as ability to pass standard colonoscope through the anastomosis 3 months after dilation and resolution of patients symptoms. All patients were evaluated for anastomotic recurrence of primary tumor with endoscopic biopsies and CT scan.
Results: Our group consists of 5 patients (4 males, 1 female). Mean age was 71 (range 64-80) years. In three patients LAR was performed for colorectal cancer, in one for GIST and in one for benign condition. Mean interval from operation to development of symptomatic stenosis was 10 (range 2-20) months. In one male patient colostomy had to be performed for ileus before dilation. We have performed 31 balloon dilations (2-18 in one patient) in total. For initial dilation 15mm balloons and combined endoscopic and X-ray control were used. Subsequent treatment was performed with 20mm ballon and endoscopic control only. We have achieved successful treatment in all of our patients. There was no recurrence of primary tumor in anastomosis. Complications: There were no perforation or bleeding complication in our group of patient. One patient had symptomatic hypotension after dilation that was treated with i.v. fluids. In one patient with stenosis resistant to treatment series of 10 dilations in one week interval was performed with good endoscopic and clinical effect.
Conclusion: Endoscopic dilation treatment of colorectal anastomotic stenosis after low anterior resection with TTS balloons is safe and effective. We have achieved treatment goals in all patients. Multiple dilations with increasing baloon diameter are often neccessary. We recommend X-ray control for initial dilation of tight stenosis.

Introduction: Dual endoscopic stenting (DES) for palliation of concurrent biliary and gastric outlet obstruction (BGOO) caused by unresectable malignancy is not always possible. Endoscopic ultrasound (EUS) may help overcome limitations of ERCP in this difficult setting by allowing transmural biliary drainage where cannulation is hampered by duodenal strictures.
Aims & Methods: To define the need for EUS-guided biliary drainage (EUSBD) in the setting of BGOO and to assess long-term clinical outcomes of endoscopic palliation of BGOO. Consecutive patients with BGOO in whom DES was attempted at a tertiary Unit between 2010 and 2014 were prospectively identified. Baseline patient and stricture features, chronology of BGOO, endoscopic method of stent insertion, postprocedure adverse events and stent dysfunction rates were retrospectively assessed. Adverse events were defined and graded according to consensus. Follow-up data were obtained from clinical records and/or telephone contact. Length of follow-up was determined from DES until death or last recorded clinical evaluation. Chi-squared test was used for comparisons.
Results: DES was attempted in 61 patients (42 male, mean [range] age = 77 [30-92] years). Background malignancies were pancreas (55.7%), gastric (13.1%) and other (31.1%). Time sequence of BGOO was synchronous in 44.3%, first biliary then GOO in 41%, and first GOO in 14.1%. Location of strictures was duodenal bulb in 26 patients, second duodenum in 34, and third duodenum in 1. Biliary stents were successfully placed in 100% and duodenal stents in 98%. Method of biliary stent placement was ERCP in 60.7% and EUSBD in 39.3%. There were 4 immediate post-procedure adverse events, 2 mild (pancreatitis, bile leakage) and 2 severe (perforations resulting in death). Long-term follow-up data were available for 50 patients. Symptom recurrence leading to repeat hospital admission developed in 68.9% (cholangitis in 15, jaundice without cholangitis in 8, GOO in 9). Overall, 39 patientes experienced any stent dysfunction. Biliary stent dysfunction developed in 48.7%, duodenal in 41%, and combined in 10.3%. 67.4% were single-episode stent dysfunction and 32.6% relapsing episodes. All single-episode dysfunctions were managed endoscopically. 46/50 patients were dead at the end of follow-up, with a mean (SD) survival after DES of 21.5 (9.2) weeks. There were no significant differences in survival or stent dysfunction rate according to clinical presentation or transmural vs transpapillary biliary stent placement.
Conclusion: EUS-guided biliary drainage is required in 40% of patients undergoing endoscopic palliation of BGOO. Even if virtually all patients with BGOO can be palliated endoscopically avoiding percutaneous access by the combined use of ERCP and EUS, stent dysfunction leading to symptom recurrence is an issue in two thirds of patients, even if it can be solved by repeat endoscopy.

Introduction: Fully covered self-expandable metal stents (FCSEMSs) have increasingly been used in benign conditions. Stent migration is the major limitation and occurs in 50% of cases. Endoscopic suture fixation (ES) of FCSEMS can potentially decrease migration risk and improve outcomes. The efficacy of this practice is currently unknown.
Aims & Methods: The aims of this study were to 1) evaluate the effect of ES on FCSEMS migration rate and clinical successand 2) compare outcomes of patients who received ES to those who did not receive stent fixation (NS group). This was a retrospective review of consecutive patients who underwent FCSEMS placement for benign UGI diseases (strictures, leaks, perforations or fistulae) at seven tertiary care centers. Patients were divided into either the NS group or the ES group. Outcome variables, including stent migration, clinical success (resolution of underlying pathology), and adverse events, were compared.
Results: A total of 125 (ES 44, NS 81) patients (males 53%, mean age 53 yr) underwent 224 stenting procedures. Stent placement was performed for benign strictures in 56 (45%) cases and leaks/fistulae/perforations in 69 (55%) cases. Stent migration was significantly more common in the NS group as compared with the ES group (33% vs. 16%, $p = 0.03$). In addition, time to stent migration was significantly longer in the ES group ($p = 0.02$). ES was significantly associated with a higher rate of clinical success (60% vs. 38%, $p = 0.03$). Rate of adverse events was similar between the two groups (19% vs 20%, $p = 0.84$). There were no adverse events directly related to the suturing procedure.
Conclusion: ES for stent fixation is safe and associated with decreased migration rate. It may also improve clinical response, likely due to reduction of stent migration.

P1490 THE EFFICACY OF AN ENDOSCOPIC SELF-EXPANDABLE METAL STENT FOR GASTRIC OUTLET OBSTRUCTION BY MALIGNANCIES

T. Ito[1], Y. Taniguchi[1], M. Wada[1], T. Inokuma[1]
[1]*Gastroenterology, Kobe City Medical Center General Hospital, Kobe-City, Japan*

Contact E-mail Address: jagapokkuruum@gmail.com
Introduction: Gastric Outlet Obstruction (GOO) may be caused by malignant diseases of the stomach, pancreas and duodenum or by lymphonodal metastasis. GOO causes intractable nausea and vomiting, abdominal distention and deficient oral intake, resulting in progressive deterioration of the patient's quality of life (QOL). Advances in chemotherapeutic treatment have improved the prognoses of these types of cancer and the incidence of malignant GOO has increased both at the time of diagnosis and during the course of anticancer treatment.
The main goal of treatment in these patients is palliation of obstructive symptoms, thereby improving the QOL. Most patients at such a highly advanced stage of malignancy cannot tolerate surgical procedures. In Japan, the use of a self-expandable metal stent (SEMS) was approved for clinical application in April 2010, and before this, esophageal stent was used. Endoscopic placement of a SEMS into the narrowed portion of the duodenum has emerged as an alternative, minimally invasive procedure in cases of GOO and also has a high clinical success

rate. The purpose of this study was to review the clinical efficacy, safety and patency rate of placement of a SEMS and its overall clinical prognosis.
Aims & Methods: A total of 33 patients were retrospectively enrolled from April 2005 to March 2015. All patients had malignant GOO and also symptoms such as nausea, vomiting or reduced oral intake. Main outcome measurements were the type of stent, technical success, clinical response, early complications, patency and clinical course. We evaluated clinical response by using the four-point Gastric Outlet Obstruction Scoring System (GOOSS).
Results: The mean age of the patients was 66.8 years old. Of the 33 patients, 18 were male and 15 were female. The most frequent cause of GOO was pancreatic cancer, followed by gastric cancer. A SEMS was placed between the pylorus and the horizontal portion of the duodenum in most cases, and multiple SEMSs were used in 7 cases for initial therapy. 7 covered stents and 26 uncovered stents were used. There were no complications during procedures and the technical and clinical success rates were 100% and 94.0% respectively. The GOOSS was significantly improved from 0.48 to 2.55 by duodenal stenting. The major complication was stent occlusion which occurred in 5 cases (15.2%); stent dislocation which occurred in 4 cases (12.1%); and perforation which occurred in 2 cases (6.1%). Eight patients reached initiation of chemotherapy after stenting, and the mean period from stenting to chemotherapy was 13.4 days.
Conclusion: Stent dislocation occurred most commonly as a complication of covered SEMS, whereas tumor ingrowth became a problem in uncovered SEMS. However, duodenal stent placement contributed in a significant way to the management of malignant GOO. Not only did it result in improvement of quality of life in patients with limited life expectancy, but also lead to prolongation of overall survival by early resumption of chemotherapy, as evidenced in some cases.

P1491 ENDOSCOPIC GASTROINTESTINAL BYPASS PERFORMED UNDER X-RAY CONTROL USING AIR AS A CONTRAST

U. C. Cotta[1], K. Hashiba[1], P. R. Siqueira[1], H. A. Brasil[1], J. M. Drigo[1], F. P. Marson[1], M. Yoza[1]
[1]*Endoscopy, Hospital Sirio Libanes, Sao Paulo, Brazil*

Contact E-mail Address: ulisses_cotta@hotmail.com
Introduction: Surgical complications like high-grade stenosis, fistulas and obstructions in the digestive tract often required open or laparoscopic surgical repair. Novel less invasive endoscopic techniques that allow the creation of fistulas in the gastrointestinal tract used to avoid surgery and were described as an alternative treatment for selected patients.
Aims & Methods: All endoscopic procedures were based in the same endoscopic technique: the use of air to distend an enteric segment followed by a fluoroscopy guided puncture using a FNA needle and wire advancement. Over the wire a balloon with 8 to 10 mm in diameter was inserted for dilation followed by stent placement. A gastrointestinal lumen-to-lumen communication was then created. Four patients with post surgical complications were treated with the same technique.
The first case is a high-grade ischemic stenosis of the colon after a partial colectomy for colon cancer treatment. A fully covered self expandable metal stent was deployed. A fistula of the distal colon to the ileum was created allowing the surgical closure of a protective ileostomy.
In second case, a patient with biliary-enteric anastomosis and Roux en Y anatomy performed for treatment of a cross-section of the common bile duct during an open cholecystectomy. She presented one year after the surgery with repeated acute cholangitis due to stenosis of the biliary-enteric anastomosis. Prior attempts to access the afferent limb with double ballon enteroscopy were unssuccessful. A fistula was created from the stomach to the jejunal loop, to access the biliary-enteric anastomosis at the afferent limb with a duodenoscope to treat the stenosis with the placement of plastic stents.
The third case is a stenosis in the esophagojejunal anastomosis after multiple procedures to treat dehiscences of a total gastrectomy procedure for treatment of a gastric adenocarcinoma. A fistula was created from the esophagus to jejunal loop to allow oral feeding.
The last case had a wide gastrocutaneous fistula in the gastric stump after gastric bypass for obesity treatment, that failed prior endoscopic treatment attempts. A neofistula was created from gastric stump to the jejunal loop to decrease the pressure in the gastric stump. After that, the gastrocutaneous fistula closed.
Results: All the procedures were successful. Follow-up of at least 3 years demonstrated a successfully bypass in all patients.
Conclusion: Creation of a lumen-to-lumen bypass by endoscopic means is feasible and safe in selected patients for treatment of post surgical complications.

P1492 EFFICACY AND SAFETY OF NON-EXPOSED ENDOSCOPIC WALL-INVERSION SURGERY (NEWS) AS AN ADVANCED METHOD OF FULL-THICKNESS RESECTION TECHNIQUE FOR GASTRIC TUMOR

K. Niimi[1], S. Aikou[1], D. Yamaguchi[1], Y. Sakaguchi[1], S. Kodashima[1], N. Yamamichi[1], H. Yamashita[1], M. Fujishiro[1], Y. Seto[1], K. Koike[1]
[1]*The University of Tokyo, Tokyo, Japan*

Contact E-mail Address: k-niimi@umin.ac.jp
Introduction: Endoscopic submucosal dissection (ESD) has been widely accepted as an effective treatment for gastrointestinal tumors. However, ESD for early gastric cancer (EGC) with ulcer scarring is still technically difficult. Non-exposed endoscopic wall-inversion surgery (NEWS) is an advanced method of endoscopic full-thickness resection (EFTR) without transluminal communication, applying ESD technique.
Aims & Methods: The aim of this study is to evaluate the clinical efficacy and safety of NEWS for gastric tumors. Between July 2011 and April 2015, 19 patients (7 females, 12 males; mean age 66.4 years, range 49-79 years) underwent NEWS for gastric tumors. After marking around a tumor on both the mucosal and serosal surfaces and submucosal injection of sodium hyaluronate, circumferential seromyotomy and sero-muscular suturing were made laparoscopically, followed by circumferential muco-submucosal incision endoscopically. The resected specimen was perorally retrieved. Clinical data was analyzed to identify factors that impact the NEWS procedure.
Results: The mean tumor size and resected specimen were 23.3 mm (range, 7-45 mm) and 33.6 mm (range, 20-50 mm), respectively. All lesions were successfully resected in an en-bloc fashion. The mean operation time was 213.5 minutes (range, 140-397 minutes), and the median estimated blood loss was 0 g (range, 0-250 g). Patients started oral intake on mean postoperative day 2 (range, 2-3), and the mean length of postoperative hospital stay was 8 days (range, 6-13 days). There were no severe postoperative complications (hemorrhage, anastomosis insufficiency, or infection). Histopathological examination of the tumors showed 17 GISTs, 1 schwannoma and 1 early gastric cancer. No tumor residual or recurrences was confirmed by performing gastroscopy during follow-up (range, 0-34 months). Resected size ($P = 0.0599$) and blood loss ($P = 0.0474$) were associated with the duration of procedure time.
Conclusion: NEWS is an effective and safe full-thickness resection with minimum possible margin without contamination and tumor dissemination into the peritoneal cavity. Although the procedure is somewhat complex because of the subtlety of the technique, NEWS could be utilized as a novel treatment option especially for node-negative EGC difficult to resect by ESD, or EGC with possible lymph node metastasis with a combination of sentinel node navigation surgery.

P1493 EFFECT OF CERVICAL ANASTOMOSIS ON QUALITY OF LIFE OF LONG-TERM SURVIVOR AFTER ESOPHAGECTOMY FOR CANCER

L. Saadeh[1], M. Scarpa[1], S. Gisbertz[2], E. Pinto[1], A. Slaman[2], R. Alfieri[1], L. Noteboom[2], M. Cagol[1], M. C. Bellissimo[1], C. Castoro[1], M. van Berge Henegouwen[2]
[1]*Oncological Surgery Unit, Veneto Institute of Oncology (IOV-IRCCS), Padova, Italy,* [2]*Dept. of Surgery, Academic Medical Center, Amsterdam, Netherlands*

Contact E-mail Address: marcoscarpa73@yahoo.it
Introduction: Esophageal cancer still remain nowadays burdened by poor outcome despite recent advances in neoadjuvant therapies and surgery still plays a key role in the treatment. Therefore very few information are known about health-related quality of life (HRQL) in long-term survivor after surgery and more in detail if the anastomosis site can affect it.
Aims & Methods: This multicentric study is aimed to analyze how performing a cervical anastomosis could impact on HRQL of long-term disease-free survivor (>36 months). 54 patients who underwent esophagectomy for esophageal cancer from 2007 to 2011 in two different tertiary referral hospitals have been enrolled during the outpatient clinic follow up from October 2014 and March 2015. 29 patients from the Academic Medical Center of the Amsterdam University (Netherlands) and 25 patients from the Veneto Institute of Oncology in Padova (Italy) filled the validated Dutch and Italian version respectively of the European Organization for Research and Treatment of Cancer (EORTC) questionnaires QLQ-C30 and OG25. Global quality of life and symptoms perceived were the primary endpoints. Data about patients characteristics, cancer and anastomosis site and stage were retrieved. Non parametric statistics was performed.
Results: 54 patients underwent esophagectomy for esophageal cancer, 24 patients (44.4%) underwent cervical esophagogastric anastomosis following esophagectomy and 30 (65.6%) thoracic anastomosis.
Cervical anastomosis showed to be associated with worse dry mouth perception ($p = 0.033$), trouble with taste ($p = 0.032$), swallowing ($p = 0.029$) and coughing ($p = 0.018$). Moreover, the presence of cervical anastomosis was correlated with troubles with nausea and vomiting ($Tau = 0.375$, $p = 0.0003$) and decreased role function scale (RF2) of the QLQ-C30 ($Tau = -0.260$, $p =$ -level 0.011) while the Global Quality of Life scale (QL2) showed no significant differences.
Conclusion: Cervical anastomosis is associated with a higher perception of troubles in coughing, swallowing, taste and dry mouth perception that could be well explained with the gastric tube transposition near to the oropharynx. Despite these findings, no differences were observed in the QL2 scale pointing

out how surviving a cancer and its treatment is the most important predictor of HRQL even on long term survivors and can be well described by the ''hedonic adaptation'' paradox.

P1494 THE PROGNOSTIC VALUE OF A MODIFIED TUMOUR REGRESSION GRADE AFTER NEOADJUVANT CHEMORADIOTHERAPY AND RESECTION OF OESOPHAGEAL CARCINOMA

M. Anderegg[1], S. Lagarde[1], W. Borslap[1], S. Gisbertz[1], S. Meijer[2], M. Hulshof[3], J. Bergman[4], O. Busch[1], H. van Laarhoven[5], M. van Berge Henegouwen[1]
[1]*Surgery,* [2]*Pathology,* [3]*Radiation Oncology,* [4]*Gastroenterology,* [5]*Medical Oncology, Academic Medical Center, Amsterdam, Netherlands*

Contact E-mail Address: m.c.anderegg@amc.nl
Introduction: The tumour regression grade (TRG) is used to define the response to preoperative chemoradiotherapy for oesophageal carcinoma. The objective of this study was to determine whether inclusion of the postoperative pathological nodal status could improve the prognostic value of TRG.
Aims & Methods: All patients who underwent an oesophagectomy after chemoradiotherapy between 2003 and 2013 were included in this retrospective study. Patients were classified according to a modified TRG consisting of the TRG by Mandard et al (TRG 1 = complete response in the oesophagus; TRG > 1 = incomplete/no response) and the postoperative lymph node category (N0 = no lymph node metastases; N+ = at least 1 lymph node metastasis). Based on the TRG by Mandard and this modified TRG Kaplan-Meier survival analyses were performed and compared.
Results: 411 patients underwent neoadjuvant chemoradiotherapy followed by oesophagectomy. After exclusion due to non-specific histology (n = 2), unknown TRG (n = 3), intraoperative detection of distant metastases (n = 3), salvage procedures (n = 17) and in-hospital mortality (n = 15) 371 patients were analysed (289 adenocarcinoma, 82 squamous cell carcinoma). A significantly improved median disease free survival was observed in patients with TRG 1 compared to patients with TRG > 1 (90.3 vs. 30.8 months, P = 0.004). After implementation of the modified TRG significant differences in median disease-free survival were found between the four categories: TRG 1-N0 (n = 76) 90.3 months; TRG 1-N+ (n = 10) 20.8 months; TRG > 1-N0 (n = 146) 81.3 months; TRG > 1-N+ (n = 139) 18.1 months (P < 0.001).
Conclusion: The TRG, determined in the primary tumour, provides insufficient information about the prognosis after chemoradiotherapy followed by resection of oesophageal cancer. It is advisable to use a modified classification in which the postoperative pathological nodal status is considered.

P1495 POSSIBILITIES FOR PYLORODUODENAL STENOSIS DIAGNOSTICS AFTER SEALING OF PERFORATED DUODENAL ULCER

P. M. Kosenko[1], S. A. Vavrinchuk[1]
[1]*Department of Surgery, Far East State Medical University, Khabarovsk, Russian Federation*

Contact E-mail Address: kosenko@inbox.ru
Introduction: Disorders of gastric and duodenal motility are present in 10.0-56.3% of patients with ulcer and in up to 65% cases after its surgical treatment, which makes the issue of timely diagnostics and prevention of post-operational motility disorders very actual.
Aims & Methods: Aims. Improvement of early diagnostics of motor-evacuator disorders after organ-preserving operations on perforated duodenal ulcer (PDU).
Methods: Study subject - 227 patients with PDU operated in the period from 2008 till 2013. First group consisted of 189 (83.2%) patients after PDU sealing and second group consisted of 38 patients (16.7%), who underwent duodenoplasty. Control group consisted of 54 healthy volunteers.
Study method involved peripheral electrogastroenterography (PEGEG) using apparatus Gastroscan-GEM in accordance with the standard method. Statistical processing involved discriminatory analysis (DA) of PEGEG parameters with creation of mathematical models on its base. For automated screening diagnostics of electrophysiological signs of PDS and determination of the degree of its compensation on the basis of the created PDS mathematical model we used original computer software ''System for Decision Making Support in Determination of the Degree of Pyloroduodenal Stenosis Compensation''.
Results: In the 1st group in 63.4% of cases the patients after sealing the PDU were classified into the group of subcompensated PDS, which was caused by the presence of stenosis in the PU sealing area with the disrupted peristalsis activity and initial signs of decompensated gastric motorics.
Post-operational radiological and endoscopic studies have confirmed the presence of the changes typical for the subcompensated stenosis in form of the narrowing of duodenum and enlargement of the stomach (27%), presence of moderate amount of liquid in fasting state (34%) and deformity of duodenal bulb (69.2%).
Signs of severe gastric stasis in this group of the patients manifested in 15.4% of patients and signs of moderately severe gastric stasis manifested in 23.1% of patients.
The performance of intraduodenal revision significantly increased the number of detected combined ulcerative complications and lesions. For example, in 2nd group of the patients pyloroduodenal stenosis was detected during the surgery in 26.3% of cases, ''mirror'' and circular ulcers of duodenum were detected in 18.4% of cases.
After duodenoplasty with correction of stenosis detected during the operation in 26.3% of cases we noted completely opposite distribution of patients with compensated type of motorics of stomach and other gastrointestinal sections with physiological response to stimulation and timely or residual accelerated evacuation of food stimulant from the stomach into the duodenum. This group of patients did not have any clinical manifestations of stenosis and needed no repeated surgical interventions due to stenosis.
Conclusion: Conclusion. The software ''System for Decision Making Support in Determination of the Degree of Pyloroduodenal Stenosis Compensation'' created on the basis of DA of PEGEG parameters and their mathematical models allows us to perform the automated computer screening diagnostics of PDS and to determine the degree of its compensation.

P1496 THE SAFETY PROFILE OF DEEP SEDATION WITH THE COMBINATION OF PROPOFOL AND DEXMEDETOMIDINE HYDROCHLORIDE DURING ENDOSCOPIC SUBMUCOSAL DISSECTION

T. Nonaka[1], K. Kanoshima[1], Y. Inoh[1], H. Iida[1], M. Inamori[2], A. Nakajima[1]
[1]*Department of Gastroenterology and Hepatology, Yokohama City University School of Medicine,* [2]*Office of Postgraduate Medical Education, Yokohama City University Hospital, Yokohama, Japan*

Contact E-mail Address: nonaka_taka@yahoo.co.jp
Introduction: ESD is accepted as a standard treatment for early-stage gastrointestinal neoplasias, however, the most effective and safest sedatives and sedation protocol for ESD have not yet been clearly established. In our hospital, the sedation with the combination of propofol (PF) and dexmedetomidine hydrochloride (DEX) under the charge of anesthesiologists have been introduced as new sedation for gastric and esophageal ESD since August 2013.
Aims & Methods: The aim of this study was to clarify the safety profile of the sedation with the combination of PF and DEX during ESD, and to evaluate the acceptability of the sedation on the elderly patients.
Design: Retrospective cross-sectional study.
Setting: Single tertiary referral center.
Subjects: The present study included consecutive 120 patients undergone ESD for early gastric carcinomas or superficial esophageal carcinomas under the sedation with the combination of PF and DEX at the Yokohama City University Hospital between August 2013 and March 2015. Patients in ASA physical status more than II or patients with a tracheotomy were excluded in this study. The subjects were divided into 2 groups, namely, younger than 80 years patients (younger group) and 80 years or older patients (elderly group).
Interventions: We reviewed medical records of subjects, and compared retrospectively the parameters of the safety of the sedation in the elderly group to those in the younger group.
Outcome Measurements: The clinical patient characteristics (including age, gender, body mass index, underlying disease and ASA physical status), endoscopic findings for gastrointestinal neoplasias (including the lesion localized site and macroscopic type) and histopathological findings after ESD (including invasion depth of the lesion and the resected specimen size) were reviewed. Minimum value of blood oxygen saturation (SpO_2), minimum value of systolic blood pressure (sBP), and minimum value of pulse rate (PR) during ESD were investigated as the safety parameters of the sedation. Furthermore, the safety of the sedation during ESD was also evaluated on the basis of the presence or absence of hypoxemia ($SpO_2 \leq 94\%$), hypotension (sBP $\leq$ 80 mmHg), bradycardia (PR $\leq$ 50 bpm) and serious adverse events defined as cardiopulmonary instability forcing discontinuation of ESD.
Results: During ESD, minimum value of SpO_2 was 97 (median, range 79-100) %, minimum value of sBP was 86.5 (median, range 47-150) mmHg and minimum value of PR was 50 (median, range 32-82) bpm in all cases. The incidence of hypoxemia, hypotension and bradycardia were 14.5%, 35.5% and 60.9%, respectively. There was no incidence of severe adverse events necessitating discontinuance of the procedure. Regarding the comparison between the elderly group and the younger group, there was no statistically significant difference in the safety parameters of the sedation between the two groups.
Conclusion: When using the sedation with a combination of PF and DEX during ESD, it is necessary to pay attention to the occurrence of hypotension and bradycardia. However, those were successfully treated with drugs such as ephedrine or atropine, and no serious adverse event necessitating discontinuation of the procedure was encountered.

P1497 OUTCOME OF OVER 220 INSERTIONS OF "PUSH" PERCUTANEOUS ENDOSCOPIC GASTROSTOMY

V. Kalcher[1], K. Emmanuel[1], G. Spaun[1]
[1]*General and Visceral Surgery, Sisters of Charity Hospital, Linz, Austria*

Contact E-mail Address: veronika.kalcher@bhs.at
Introduction: As the Department of General and Visceral Surgery of the Sisters of Charity Hospital Linz, Austria, is focused on oncology there is a need of supportive care. Especially patients with head and neck cancer, or cancer of the esophagus benefit from permanent or temporary push-PEG. Also patients with chronic ileus due to peritoneal carcinosis benefit from this technique. Our department already studied the difference of pull-through- and push-PEG (1). Aim of this study was to compare the outcome of patients before and after standardization of the push-PEG-intervention.
Aims & Methods: Between 2009 and 2012 a first series of retrospective analysis of all patients (n = 100) who underwent percutaneous endoscopic gastrostomy was performed at our department. A second series of retrospective analysis (n = 123) was done between 2013-2/2015 after standardization of the procedure of push-PEG insertion. Data collection included patients' demographics, comorbidities,

complications graded according to the Clavien Dindo classification, indication, peri-interventional radio- and/or chemotherapy, tube diameter, morbidity and mortality. Further the complications of both series were compared. No antibiotic prophylaxis was used.
Results: All in all there were 223 push-PEGs inserted in our department between 2009-2012 and 2013-2/2015. In 96.4% (215/223) the patients suffered from malignant disease. We studied 45 (20.2%) female and 178 (79.8%) male patients, average age was 62.5 years. Nearly two third (138/223, 61.9%) of our patients received radio- or/and chemotherapy within 4 weeks after the push-PEG insertion. Altogether we noticed complications in 82/223 (36.8%) and classified them according to Clavien Dindo. We documented 26.9% (60/223) Clavien Dindo 1 events, where no further treatment was required. 5.8% of patients (13/223) suffered from Clavien Dindo 3a and higher. Surgical site infections which had to be treated pharmacologically occurred in 0.4% (1/223). In 11/223 cases (4.9%) a reoperation was needed. There were no statistically significant differences regarding the overall complications after standardization (39% vs 33.1%) inclusively dislocation but occlusions occurred significantly more often in series 1 (9% vs 1.6%) and surgical site irritations had a higher incidence in series 2 (9% vs 18.7%). Dilatation of gastrotomy (5/123) in series 2 was related with more complications than the cutting trocar technique (80% vs 33.1%).
Conclusion: After standardization of push-PEG insertion and comparing the two series we will use antibiotic prophylaxis in our next series of push PEG insertions due to the higher surgical site irritation rate, although we noticed only a small number of surgical site infections which had to be treated medically. Complications such as dislocation, leakage and occlusion, is often seen in non compliant patients and so sufficient education of patients is required. Push-PEGs of charriere 18 to 24 and dilation technique are connected with higher leakage, surgical site infection and patient discomfort.

P1498 NOVEL EFFECTS OF SURGICAL FIELD EXPOSURE AND LYMPH NODE DISSECTION ON RECURRENT NERVE PALSY IN PRONE POSITION THORACOSCOPIC ESOPHAGECTOMY

Y. Shirakawa[1], Y. Tsukumo[1], Y. Katsura[1], N. Maeda[1], S. Tanabe[1], K. Sakurama[1], K. Noma[1], T. Fujiwara[1]
[1]*Department of Gastroenterological Surgery, Okayama University, Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama, Japan*

Contact E-mail Address: yasuwr@md.okayama-u.ac.jp
Introduction: Since July 2011, we experienced more than 200 cases of thoracoscopic esophagectomy in the prone position (TEPP). The indication for TEPP was initially limited to cases of early-stage esophageal cancer; however, it has now expanded to cases of advanced stage esophageal cancer. While expanding the indication for TEPP, the prolonged operative time and high incidence of recurrent laryngeal nerve (RLN) palsy are important factors. The incidence of RLN palsy was $<10\%$ in cases of open esophagectomy at our institution, but approximately 20% in cases of thoracoscopic surgery after the expansion of the indication. In most cases, RLN palsy occurs on the left side. RLN palsy after surgery for cases of esophageal cancer can cause dysphagia and difficulty in expectoration, followed by pneumonia as the most serious postoperative complication. Furthermore, RLN palsy may affect the quality of life, causing complications such as difficulty in ingestion.
Aims & Methods: In the present study, we focused on and evaluated the standardization of the exposure of the surgical field and lymph node dissection for shortening the operative time and avoiding left RLN palsy. The control of bleeding and upward/downward traction on the esophagus with rolling of the trachea is important for lymph node dissection around the left RLN. After the tracheal branches of the left tracheoesophageal artery were carefully coagulated and cut, the lymphatic chain around the left RLN was detached from the trachea. Moreover, the esophagus was transected at the aortic arch level in a relatively early stage. After the oral end of the esophagus was isolated upward as high as possible and pushed behind the right subclavian artery, the anal end of the esophagus was pulled downward with forceps by the surgical assistant with rotation of the trachea to the right side (T-shape exclusion). This exposure created by the assistant facilitated lymph node dissection around the left RLN with a stable and wide surgical field in the left upper mediastinum and adequate nerve tension. In this procedure, we avoided the use of energy devices as much as possible and strived to perform a sharp dissection using surgical scissors.
Results: After the expansion of the indication for TEPP, the operative time and incidence of left RLN palsy increased. However, the standardized lymph node dissection around the left RLN shortened the thoracic operative time (from 280.9 min to 255.0 min, $p < 0.001$) and decreased the incidence of left RLN palsy (from 20.0% to 13.0%).
Conclusion: These clinical outcomes are because of an improved technical stability, owing to the achieved standardized operative field, regardless of the patient's body type.
Disclosure of Interest: None declared

P1500 THE REALITIES OF VIRTUAL COLONOSCOPY IN RECOGNITION OF CONSTIPATION SYNDROME

A. A. Eleev[1], O. Y. Karpukhin[1], on behalf of Yusupova
[1]*Department of Surgical Diseases No1, Kazan State Medical University, Kazan, Russian Federation*

Contact E-mail Address: Alim1425@mail.ru
Introduction: During many years, a barium enema was the principal diagnostic tool in establishing structure and location of colon abnormalities within the abdominal cavity in patients with chronic constipation. Virtual colonoscopy (VC) is worthy of a consideration among the modern diagnostic methods. In the past decade, this method initially introduced by D.J. Vining et al. (1994) for a non-invasive diagnostics of colon and rectum diseases became very popular among clinicians and radiologists as a result of rapid advances in information processing technologies and image analysis. VC produces three-dimensional digital images of the colon. The method is based on a plain VC scan of the abdomen without contrast after inflating colon with air.
Aims & Methods: To evaluate an application of VC in diagnostics of colon related forms of chronic costiveness.
To analyse colonic architectonics, twelve patients with decompensated forms of chronic constipation were evaluated with VC scans using Phillips Brilliance 64 Slice VC (collimation -1,5 mm; 50 mAs, 120 kV, total duration of procedure - 5 minutes, equivalent dose - 14mSv). Barium enema was used as control. After retrograde inflation of colon by 1500-2000 ml of air, plain abdominal VC scans were performed in patients in supine position. Colons were inspected for position and structural abnormalities followed by post-processing information handling and 3D rendering using VC software of Extended Brilliance Workspace (Phillips).
Specifics of position and structure of colon, length and width of different colon parts, presence or absence of haustration were studied.
Results: Using VC technology, we were able to diagnose the cases of dolichocolon, dolichosigma and Payr's syndrome. In one clinical observation, VC allowed us to establish a dilatation of the right side of the colon with a reduction of haustraion in it. However in this case, Payr's syndrome was diagnosed only by a barium enema under an erect position of the patient.
Conclusion: VC objectively reflects structural features of the colon, anatomical-topographical relations of its different parts and inflammatory changes in its wall.

P1501 INITIAL EXPERIENCE WITH AN INNOVATIVE NEW MODULAR TRAINING MODEL FOR PROCTOLOGY SUITABLE ALSO FOR FLEXIBLE ENDOSCOPY

F. Reichel[1], R. Ingenpaß[1], A. Zipfel[1], K. E. Grund[1]
[1]*Experimental Surgical Endoscopy, General, Visceral and Transplant Surgery, University Hospital Tuebingen, Tübingen, Germany*

Contact E-mail Address: chir.endo@uni-tuebingen.de
Introduction: Proctological examination is a challenging procedure which requires profound knowledge of anatomy and pathology as well as optimal diagnostic and therapeutic experience in handling of the equipment as well as a good manual dexterity. The usual learning on the patient by ''trial and error'' is not optimal from an ethical point of view, but yet there is a lack of standardized reality-like human training options.
Aims & Methods: A novel hands-on model has been developed for the learning and training of proctology which is designed for a modern didactic concept. Constructed from synthetic materials and animal-free artificial tissues and based on patient data, the phantom matches human anatomy exactly and offers realistic haptics.
Results: Our newly developed simulator enables now a complete interactive proctology examination including colorectal endoscopy. It is based on the animal-free Tuebingen training phantoms for flexible endoscopy with new modular insets but considers the special requirements for procotogical examination. These insets have to be optimized for a reality-like phantom, especially the optical and tactile aspects (elastic pelvic floor, functional and variable sphincter, uterus/prostate etc.).
The trainees of our workshops have the opportunity to perform a complete proctological examination (from digital rectal examination to colonoscopy) in a reality-like clinical setting. The colon of the phantoms consists of several segments, so that in colonoscopy also variations of standard anatomy can be shown. For visual inspection the mucosal vessels in the rectum are shown anatomically correct. For a differentiated training the phantom can be adjusted individually and various pathologies are palpable, visible and comparable.
A specially developed sphincter simulates the different intensities of tonuses from insufficiencies up to stenoses of the anal canal continuously and accurately reproducible. The phantom can be switched easily between male and female phenotype. A replacement of this module allows the presentation of various pathologies within a few minutes (e.g. hemorrhoids, polyps, adenomas, prostate tumors, uterine fibroids). On the basis of pressure sensors, the participant receives an objective acoustic feedback on the tactile methodology of his digital rectal examination.
Conclusion: This innovative model represents an important step towards a reality-like phantom for diagnosis and intervention. It will enable the simulation of a complete proctologic examination, and will enable an effective medical education and training in this previously neglected area.

P1502 A SYSTEMATIC REVIEW OF SEGMENTAL VS SUBTOTAL COLECTOMY AND SUBTOTAL COLECTOMY VS TOTAL PROCTOCOLECTOMY FOR COLONIC CROHN'S DISEASE

I. Angriman[1], **G. Pirozzolo**[1], R. Bardini[1], C. Castoro[2], M. Scarpa[2]
[1]*Dept of Surgical, Gastroenterological and Oncological Sciences, University of Padova,* [2]*Oncological Surgery Unit, Veneto Institute of Oncology (IOV-IRCCS), Padova, Italy*

Contact E-mail Address: marcoscarpa73@yahoo.it
Introduction: Surgical management of colonic Crohn's disease (CD) is still unclear since different procedures can be adopted. The choice of operation is clearly dependent on the extent of colonic disease but the advantage and the disadvantages of increasing the removed colonic portion are still debated since no prospective randomised study has been undertaken yet [1].
Aims & Methods: The aim of the present study is to evaluate the differences in short-term and long-term outcomes of adult patients with colonic CD who underwent either subtotal colectomy and ileorectal anastomosis (STC) or segmental colectomy (SC) or total proctocolectomy and end ileostomy (TPC). Comparative studies published between 1984 and 2012, of STC vs SC and of STC vs TPC were selected. The study end points were overall and surgical recurrence, postoperative morbidity and incidence of permanent stoma. Fixed effect models were used to evaluate the study outcomes.
Results: Eleven studies, consisting of a total of 1412 patients (496 STC, 455 SC and 374 TPC) were included. Analysis of the data suggested that there was no significant difference between STC and SC in term of overall and surgical recurrence of CD. On the contrary, STC showed a higher risk of overall and surgical recurrence of CD than TPC (OR = 3.54 [95%CI: 2.45-5.1], $p < 0.001$; OR = 3.52 [95%CI: 2.27-5.44], $p < 0.001$, respectively). Moreover, SC had a higher risk of postoperative complicationns compared to STC that also had a lower risk of complication than TPC (OR = 2.84 [95%CI: 1.16-6.96, $p < 0.001$; OR = 0.19 [95%CI: 0.09-0.38], $p < 0.001$, respectively). SC resulted to have a lower risk of permanent stoma than STC (OR = 0.46, 95% CI 0.30-0.70).
Conclusion: All the three procedures were equally effective as treatment options for colonic Crohn's disease and the choice of operation remains intrinsecally dependent on the extent of colonic disease. However, patients in the TPC group showed a lower recurrence risk than those in the STC group. Moreover Sc had a higher risk of postoperative complication but a lower risk of permanent stoma. These data should be taken in account when deciding surgical strategies and when informing patients about postoperative risks.

Contact E-mail Address: dr.mwlodarczyk@gmail.com
Introduction: The sex of the physician performing the digital rectal examination (DRE) procedure is one of the parameters influencing patients' comfort and satisfaction. It is postulated that the stress related to DRE during admission to the surgical ward may affect the compliance.
Aims & Methods: The aim of our study was to characterize patients' preferences according to their sex, age, socioeconomic status, and religious beliefs and according to DRE-related variables. All patients admitted to the Department of General and Colorectal Surgery at Medical University of Lodz between January 2015 and April 2015 were asked to complete a questionnaire regarding their sex, age, ethnic background, socioeconomic status, religious practice, and preference for a physician performing the DRE during admission to the surgical ward. The questionnaire was comprised of 2 open and 15 closed questions. Only fully completed questionnaires were included for fruther analysis.
Results: The study involved 300 patients, who agreed to complete the questionnaires - 52% (n = 156) women and 48% (n = 144) men. The most common reason of admission to the hospital was colorectal cancer, reported in 39% (n = 117) patients. Most patients (81%, n = 244) expressed no preference for sex of the physician performing the DRE during admission, while 12% (n = 36) preferred a same-sex physician. Stepwise logistic regression analysis showed that the age (OR 0.96; 95% CI 0.92-0.99), female sex (OR 0.27; 95% CI 0.09-0.81), higher education (OR 14.02; 95% CI 5.01-39.19), comorbidities (OR 16.48; 95% CI 3.75-72.34), and previous DRE experience (OR 18.94; 95% CI 3.52-101.90) were all associated with preference fore a same-sex physician. 41% (n = 124) of patients prefer to be examined by a mature doctor (30-60 year old), 3% (n = 8) by a young doctor (resident), 1% (n = 4) by an elderly physician (over 60 year old), while 55% (n = 164) of patients had no preference for that age of a physician. Physician's sexual preference as important variable was reported by 27% (n = 80) of patients. Different skin color of physician as a problematic factor was noted in 12% (n = 36) of patients.
Conclusion: In our study most patients expressed no preference for sex of the physician performing the DRE during admission to the surgical ward. However, over one-tenth of patients reported such preferences. Most of these patients preferred a same-sex physician. Female sex, lower level of education, no comorbidities, young age of patient, and no previous DRE are all associated with a physcian sex preference. It is important to offer these patients the choice of physcian performing the DRE. Addressing patients' preferences may improve the atmosphere in the clinical environment, reduce stress, and facilitate better treatment.
Disclosure of Interest: None declared

P1504 LAPAROSCOPIC OR OPEN TOTAL MESORECTAL EXCISION FOR RECTAL CANCER: 10-YEAR ONCOLOGIC OUTCOMES OF A PROSPECTIVE COMPARATIVE STUDY

M. E. Allaix[1], G. Giraudo[1], A. G. Ferrarese[1], F. Rebecchi[1], M. Morino[1]
[1]*Department of Surgical Sciences, University of Torino, Torino, Italy*

Contact E-mail Address: meallaix@gmail.com
Introduction: Only few data from studies comparing laparoscopic total mesorectal excision (LTME) and open total mesorectal excision (OTME) for rectal cancer with follow-up longer than 5 years are available.
Aims & Methods: The aim of this study was to compare 10-year oncologic outcomes after LTME and OTME for non-metastatic rectal cancer. This is a single-institution prospective non-randomized study comparing LTME and OTME for rectal cancer. Statistical analyses were performed on an "intention-to-treat" basis and by actual treatment. Overall survival (OS) and disease-free survival (DFS) were compared by using the Kaplan-Meier method. A multivariate analysis was performed to identify predictors of poor survival.
Results: Similar 10-year OS and DFS after LTME and OTME were observed: 72.1% vs. 69.1% (P = 0.491) and 64.7% vs. 68.1% (P = 0.784), respectively. Conversion to OTME did not adversely affect OS and DFS. Stage-by-stage comparison showed no significant differences between LTME and OTME. No significant differences were observed in local recurrence rates between the two groups (6.1% vs. 14.1%, P = 0.155). Median time until local recurrence was 21.5 (range, 12-56) months after LTME and 20 (6-64) months after OTME (P = 0.499). Poor tumor differentiation, lymphovascular invasion and a lymph node ratio of 0.25 or more were the independent predictors of poorer OS and DFS. A distal margin ≤1 cm and lymphovascular invasion were associated with higher risk of local recurrence in patients undergoing anterior resection.
Conclusion: LTME has similar 10-year long-term oncologic outcomes to OTME in non-metastatic rectal cancer patients.

P1505 NEW TECHNIQUE OF BALLOON-OVERTUBE- AND FLUOROSCOPY-ASSISTED DIRECT PERCUTANEOUS ENDOSCOPIC JEJUNOSTOMY FOR PATIENTS WITH SURGICALLY ALTERED UPPER GI TRACT ANATOMY

P. T. Kröner[1,2], I. Jovanovic[1], M. C. Phillips[3], K. R. Kyanam Kabir Baig[1], S. P. Sugandha[1], K. Mönkemüller[1]
[1]*Basil I. Hirschowitz Endoscopic Center of Excellence, Gastroenterology, University of Alabama at Birmingham, Birmingham,* [2]*Internal Medicine, Mt. Sinai St. Luke's Roosevelt Hospital, New York,* [3]*Department of Anesthesiology, University of Alabama at Birmingham, Birmingham, United States*

Contact E-mail Address: klaus1@uab.edu
Introduction: Experience using direct percutaneous endoscopic jejunostomy (DPEJ) in patients with surgically altered upper gastrointestinal (GI) tract anatomy is limited to case reports and small series. By using the pull-through method of jejunostomy placement, perforation of the small bowel at the various anastomoses or strictures may occur. The present study describes a new method of DPEJ in patients with surgically-altered upper GI tract.
Aims & Methods: The aim was to report on the efficacy and safety of a novel overtube- and fluoroscopy-assisted DPEJ technique in patients with surgically deranged upper GI tract anatomy.
This was an observational, retrospective, single-arm study conducted at a tertiary care hospital during a 24-month period. Technique: Deep enteroscopy was performed by using the standard push-pull-technique with the patient under general anesthesia and in supine position. Careful attention was paid to clearly define the efferent jejunal limb. The new DPEJ technique focuses on three key components: (i) use of balloon-assisted overtube; (ii) use of fluoroscopy; (iii) leaving the overtube in place during the entire procedure (and also for subsequent DPEJ removal). After a suitable site was identified, DPEJ placement was performed using the Ponsky-method (pull-type-percutaneous gastrostomy tube technique) using a 20 Fr PEG-kit. The overtube was left in place during the entire

procedure, in order to safely allow for the passage of the PEG through the anastomoses, kinks and potential stenosis of the altered anatomy. Leaving the overtube in place also allowed for post-insertion inspection of the PEG-button.
Results: The study included 24 patients with complex post-surgical anatomy (13 female, 11 male, mean age 53 years, age range 28-78). In 14 patients previous endoscopic or radiologic attempts at providing enteral feedings had failed. The patient's upper GI anatomy was the following: gastric bypass (n = 4), Whipple's (n = 5), Billroth II (n = 7), Ivor-Lewis (n = 3), gastric sleeve with leak (n = 3), several anastomosis with undefined, complex post-surgical status (n = 2). The technical success was 90%. In two patients transillumination was not obtainable and placement failed. The mean distance of DPEJ was 75 cm (range 45 to 120 cm) past the gastrojejunal anastomosis. The mean procedure time was 36 minutes (range 20-115). There were no major adverse events associated with the procedure.
Conclusion: DBE-DPEJ using fluoroscopic assistance seems an efficacious, safe and successful approach for patients requiring jejunal enteral feeding. To the best of our knowledge this is the largest study using DPEJ in patients with complex surgically altered upper GI tract anatomy. The novel technique using overtube- and fluoroscopy was efficacious, safe and successful. Future comparative studies are now warranted.

P1506 ASSESSMENT OF MMP-2/-9 EXPRESSION BY FLUORESCENCE ENDOSCOPY FOR EVALUATION OF WOUND HEALING IN A MURINE MODEL OF INTESTINAL ANASTOMOSIS

P.-A. Neumann[1], P. Lenz[2], V. Twardy[1], V. Krüger[1], C. Geyer[3], F. Wötzel[4], A. Faust[5], E. Rijcken[1]
[1]*Department of Surgery,* [2]*Palliative Care,* [3]*Clinical radiology,* [4]*Department of Pathology,* [5]*European Institute for molecular imaging, University of Muenster, Muenster, Germany*

Contact E-mail Address: Paneumann@uni-muenster.de
Introduction: Disturbance of intestinal mucosal wound-closure leads to insufficient anastomotic healing and is associated with considerable morbidity following colorectal resections. Matrix-metalloproteinases play a crucial role in regulation of mucosal wound closure. Especially in the early phase, they can be used as markers for evaluation of the healing process.
Aims & Methods: Evaluation of fluorescence endoscopy for detection of MMP-2/-9 during intestinal anastomotic healing. Correlation of the MMP-2/-9 expression with an endosopic healing score for prediction of anastomotic healing.
A total of 24 Balb/c mice have been used as a model of intestinal anastomotic healing. Following incision of the upper rectum an end-end anastomosis has been performed and endoscopically analyzed on postoperative days 1, 3, and 5 (POD1, POD3, POD5). Mucosal healing was assessed by conventional white-light endoscopy (WLE). For detection of MMP-2/-9 in the anastomotic tissue fluorescence endoscopy was used (FE) following *i.v.*-administration of a Cy5.5-labeled MMP-2/-9 specific tracer 24h prior to endoscopy. Endoscopic analysis was complemented by *ex vivo* quantification of the fluorescent signal using the *MS-FX PRO Optical Imaging System* following removal of the anastomosis.
Results: The use of WLE/FE allowed evaluation of anastomotic healing and visialization of mucosal MMP *in vivo*. In 14 of 24 cases disturbed anastomotic healing was detected. During the healing process the content of mucosal MMP gradually increased from POD1 to POD3 (SNR: $16,3 \pm 2,2$ vs. $24,8 \pm 8,5$, $P = 0.021$) as well as from POD3 to POD5 (SNR: $24,8 \pm 8,5$ vs. $51,8 \pm 13,7$, $P = 0.002$). Areas with defective anastomotic healing showed significantly higher uptake of the tracer *in vivo* as well as *ex vivo* (SNR (Signal-to-noise ratio): $19,9 \pm 8,2$ vs. $40,8 \pm 18,9$, $P = 0,004$).
Conclusion: During disturbed anastomotic healing increased expression of MMP-2/-9 was observed in the anastomotic tissue. Fluorescence endoscopy for detection of MMP-2/-9 during the healing process can be a promising tool for early identification of anastomoses at risk.

Contact E-mail Address: dr.mwlodarczyk@gmail.com
Introduction: Rectovaginal fistula (RVF) is chronic and serious condition with significant influence on patient's quality of life. Due to difficult surgical techniques and various etiologies, treatment of RVF remains a challenge and demands individual approach to the patient. Thus, low rates of long-term positive outcomes are reported and recurrences are frequent.
Aims & Methods: The study aimed at evaluating the outcomes of surgical treatment of RVF depending on the etiology. A retrospective analysis was performed on 94 females who underwent surgical treatment of RVF and related complications at our institution from January 2003 to December 2014. 82 of them were available for follow-up. The study data were retrieved from the hospital medical records, surgical protocols, laboratory test results, and imaging examinations. Data from patients who underwent follow-up in outpatient clinic were also included.
Results: The causes of fistula included: radiation induced (63 patients), inflammatory bowel diseases (IBD) (6), obstetric injury (5), trauma (2), cancer (8) and other (10). Median patients' age varied significantly between groups (obstetric – 31 years; radiation induced – 60 years; IBD – 44 years; trauma – 35 years; cancer – 63 years; others – 38 years). Median follow-up was 3 years. The best surgical outcomes were achieved in the group of patients after obstetric injury (80% healing rate). Satisfactory results were achieved in trauma and others group (75% healing rate). In the group of radiation induced RVF, nearly all patients were managed by fecal diversion and this enabled healing in 10 patients (15,9%) among which 5 undergone restoration of gastrointestinal continuity. In cancer group 2 fistulas were healed (healing rate 25%). In multivariate analysis, patients age below 60, presence of high fistula, no cancer history were independent predictors of fistula healing.
Conclusion: Treatment outcomes depend significantly on RVF etiology and patient-related factors (age, comorbidities). In management of RVF complex approach to the patient is crucial in order to achieve optimal outcomes.

Introduction: Historically appendicitis is tend to be operated as soon as possible in order to prevent future complications, but recent discussions shows, that urgent operation does not always reduce the rate of postoperative complications. Immediate appendectomy can be delayed in some cases.
Aims & Methods: Retrospective, non-randomized, single center, cohort study was performed. During one year period 167 consecutive patients diagnosed with acute appendicitis in which operation was performed and who met the inclusion criteria were included in the study. The study population was divided into two groups according to the time from the onset of the symptoms to the operation. Group I (time to the operation ≤ 24 hours) consisted of 74 patients and Group II (time to the operation ≥ 24 hours) – 93 patients. Primary (postoperative complications) and secondary (length of operation, length of hospital stay and perforation rate at the final pathology report) endpoints were evaluated and compared.
Results: There were no statistically significant difference in the rate of postoperative complications (Clavien-Dindo grading system for the classification of surgical complications) when comparing both groups. In Group I – 21.9% patients (87.5% Grade I) and in Group II – 25.8% patients (83% Grade I) had postoperative complications. Length of operation (in minutes) was similar between the groups (72.97 ± 29.1 (Group I) vs 79.95 ± 35.4 (Group II)). Length of hospital stay (days) was longer in Group II, but no statistically significant difference was found (2.85 ± 2.3 vs 3.34 ± 4.88 accordingly). Perforation rate at the final pathology report was twice higher in Group II (8 (10.8%) vs 17 (18.3%)), but no statistically significant difference was found. Additional analysis comparing different timing (time to the operation $\leq$48 hours vs $\geq$48 hours) in the same patient's cohort was performed. Statistically significant better outcome was found in "$\leq$48 hours" group (complications rate, length of operation and length of stay, perforation rate at the final pathology report).
Conclusion: This study showed shorter length of operation and length of hospital stay, lower rate of perforations in early appendectomy group (≤ 24 hours), but no statistically significance was found. These findings supports earlier reports showing that delayed appendectomy is safe surgical procedure without higher rate of postoperative complications. The appendectomy should be performed as fast as possible ($\leq$48 hours), but the timing of operation can be chosen by responsible surgeon depending on the available personnel and hospital resource.

P1509 TRANSANAL ENDOSCOPIC MICROSURGERY UNDER SPINAL ANESTHESIA: PRELIMINARY RESULTS OF A PILOT STUDY

S. Arolfo[1], A. Arezzo[1], G. Cortese[1], A. Bullano[1], M. E. Allaix[1], E. Galietti[1], M. Morino[1]
[1]*Surgical Sciences, University of Torino, Torino, Italy*

Contact E-mail Address: simone.arolfo@tiscali.it
Introduction: Transanal Endoscopic Microsurgery (TEM) allows a full thickness excision of rectal benign lesions and early rectal cancer with excellent oncologic outcomes compared to Endoscopic Submucosal Dissection (ESD). Today the major advantage advocated by flexible endoscopists is the avoidance of general anesthesia. Combining a minimal-access operation with segmental anesthesia may further enhance the advantages of a real surgical dissection provided by TEM, over ESD that forces to long lasting sedations.
Aims & Methods: The purpose of the study is to assess the feasibility and safety of TEM under epidural anesthesia.
A prospective observational study was conducted with the aim to collect data of patients who underwent TEM under spinal anesthesia. Primary end-points were feasibility and safety; secondary endpoints were post operative pain, heart rate (HR) and non invasive blood pressure (NIBP) at 4, 8, 24 and 48 hours after surgery measured by Visual Analogue Scale (VAS), need of opioids (during and after the operation), post operative nausea or vomiting (PONV) and urinary retention (UR) rate.
Results: 48 patients were included. Median age was 70.5 years and male/female ratio 28/20. No intraoperative complication occurred and median operative time was 60 minutes (range 20-120). 5/48 patients (10,4%) required opioids in the operatory room (fentanyl 50 mcg) and 8/48 (16,7%) in the postoperative time (a single dose of 100 mg tramadol). Median postoperative pain assessed by VAS was 0 (range, 0–3) at 4 h, 0 (range, 0–2) at 8 h, 0 (range, 0–2) at 24 h and 0 (range, 0–1) at 48 h. Median HR was 70, 70, 72,5, 71 bpm and median NIBP

was 130/72,5, 130/75, 125/70, 130/75 at 4, 8, 24 and 48 hours. PONV occurred only in 1/48 patient (2,1%), while 5/48 patients (10,4%) developed urinary retention.
Conclusion: The study proves feasibility and safety of TEM under spinal anesthesia, with reduced impact of side effects. The possibility to avoid general anesthesia opens new opportunities for TEM against flexible endoscopic techniques such as ESD.

Introduction: Endoscopic stenting with a self-expandable metallic stent (SEMS) as a bridge to surgery (BTS) is widely used for acute malignant colonic obstruction (MCO), but recent European Society of Gastrointestinal Endoscopy guidelines discourage this procedure in curable patients. To clarify SEMS feasibility, we conducted a prospective, observational, single-arm, multicenter clinical trial (UMIN000011304) using standardized SEMS placement methods among participating facilities in Japan.
Aims & Methods: Our objective was to estimate the feasibility of SEMS placement as a BTS for MCO. This study was conducted in October 2013. Before start-up, stenting methods considered adequate and standard were discussed and shared among 32 participating facilities. Each patient was treated with a Niti-S Enteral Colonic Uncovered Stent, D-type. Patients with SEMS as BTS were followed up until discharge post-surgery. BTS clinical success was defined as having adequate passage of stool until surgery without stent-related complications and without the need for endoscopic re-intervention or emergency surgery.
Results: A total of 205 consecutive patients were enrolled in this study; 6 were excluded because of loose stenosis, inability to visualize the tumor, respiratory failure, fistula, or benign stricture. The remaining 199 patients comprised the per-protocol cohort. Treatment intent was BTS in 112 patients (56.3%) and palliative in 87 patients (43.7%). 76.8% of the BTS patients had no distant metastasis. Stenting was successful in 99.1% patients (111/112). The clinical success rate was 96.4% (108/112), with 3 persistent colonic obstructions causing failure. The overall preoperative complication rate was 4.5% (5/111). No perforation or stent migration was observed. No emergency surgery was performed for management of complications, and all technical success patients received elective surgery. Median time from SEMS placement to surgery was 20 days (range, 6-159). Open surgery and laparoscopic surgery were performed in 42 (37.8%) and 69 (62.2%) patients, including 7 cases of conversion to open surgery (10.1%), respectively. The tumor was resected in 110 patients. The primary anastomosis rate was 96.4% (107/111). The rate of anastomotic leakage was 2.8% (3/107). The overall stoma creation rate was 4.5% (5/111), including 3 Hartmann operations, 1 diverting stoma, and 1 colostomy without tumor resection. Median duration of hospitalization after surgery was 13 days (range, 6-114). The overall postoperative morbidity rate was 16.2% (18/111). The in-hospital postoperative mortality rate was 0%.
Conclusion: The current study has demonstrated the feasibility of SEMS placement as a BTS for MCO. SEMS placement using shared, standard methods is a safe and effective BTS with acceptable stoma creation and complication rates, allowing elective surgery with a primary anastomosis in most patients.

Introduction: Bianchi's operation, which lengthens intestinal loops while decreasing the luminal diameter to decelerate the intestinal transit time, is sometimes performed in patients with short bowel syndrome with severely dilated bowel loops. We conceived an innovative design concept in which the absorptive area of the small intestine could be increased without changing the caliber of the lumen if a bioscaffold, which might be expected to induce local intestinal regeneration, was interposed longitudinally instead of using staples as in the classic Bianchi's procedure. Small intestinal submucosa (SIS) is a biodegradable, acellular, collagen-rich matrix containing functional growth factors.
Aims & Methods: We investigated SIS-induced small intestine and evaluated it in terms of muscle contractility and other tissue characteristics in the SIS-grafted area when the blood supply was delivered as in the classic Bianchi's procedure. In nine micro-mini-pigs with non-dilated small intestines, the mesentery was separated based on the bifurcated vessels, and the bowel was divided and discontinued as described by Bianchi [1] without the use of surgical staplers. Rather than sewing the edges of the bowel to itself to form two separate loops, the temporary defect that was caused by unstapling was patched by the 3.5×2.0-cm SIS, sutured to the edges of the defect. Next, the two separate conduits that were integrated with SIS were moved in the opposite direction with the mesentery (which contained a single blood supply from one of the bifurcated vessels), and were reconnected in series with the rest of the small intestine as in Bianchi's operation. A muscle strip was obtained and an organ bath technique with electrical field stimulation was applied at the 6-month evaluation. Native small intestine and grafts were investigated morphologically using histology and immunohistochemistry. The enzyme activity of alkaline phosphatase was also measured by absorption spectrometry.
Results: All pigs survived and thrived, and were healthy at the time of functional evaluation. The *in vitro* study revealed that the tissue contracted in response to an acetylcholine agonist and electrical field stimulation. The mucosa was covered with normal epithelium, and regeneration of neural and smooth muscle cells had occurred. The alkaline phosphatase activity in the regenerated area was the same as for the normal tissue.
Conclusion: We obtained good outcomes using the above-described surgical technique with an SIS graft, which may represent a beneficial treatment for patients with short bowel syndrome regardless of their small intestinal diameter. Further investigation in clinical settings is now warranted.

Introduction: Crohn's disease (CD) is a chronic inflammatory disease characterized by defective handling of intestinal bacteria, particularly by the innate immune compartment. Although the underlying cause is unknown, genetic and environmental factors are important. One of the most recognized environmental risk factors is cigarette smoking, which impacts disease risk, prognosis and treatment response. Insight into how cigarette smoking influences innate immunity and gut physiology are now needed.
Aims & Methods: We investigated mucosal immune changes and gastrointestinal (GI) symptoms (using validated GI symptom questionnaires) in non-health care seeking smokers and non-smokers identified in three population-based endoscopy studies, comprising 2554 participants, including a population who had undergone ileocolonoscopy and mucosal biopsy. Tissues were stained with Haematoxylin and Eosin (H&E), and specific immunostains (e.g. CD117). To determine whether smoking was causally linked to mucosal changes and susceptibility to intestinal inflammation we employed a preclinical model of smoke exposure and 2,4,6-Trinitrobenzenesulfonic acid (TNBS)-induced colitis.
Results: Significant changes in the frequency of cells implicated in mucosal defence were observed in the gut of individuals who smoke, most notably in the terminal ileum (TI) and caecum. These changes included expansion of Paneth cells in the terminal ileum ($P < 0.04$), depletion of mast cells in the TI (median count 231 in smokers vs 324 in non-smokers, $P < 0.03$) and depletion of mast cells in the caecum (median count 116 in smokers vs 170 in non-smokers, $P < 0.002$). No significant changes were observed in the transverse or left hemicolon. Smoking was also associated with significantly increased GI symptoms. In particular, there was increased diarrhoea in smokers in comparison with non-smokers (OR = 2.04,1.29-3.21, $P < 0.002$). In preclinical studies mast cells were also depleted in the TI and colon of smoke exposed mice, consistent with the likelihood that the mucosal changes observed in human smokers were causally linked to smoking. Crucially, smoke exposed mice with dysregulated mast cell numbers exhibited heightened susceptibility to experimental colitis induced by TNBS.
Conclusion: Cigarette smoking was associated with altered frequencies of mucosal dwelling cells implicated in host innate immunity, and changes were most apparent in the TI and right hemicolon – the most commonly affected sites in CD. Similar changes were observed in the gut of smoke exposed mice – which was associated with heightened susceptibility to experimentally induced colitis. Together these data provide new insight into the links between smoking, innate immunity and CD.

Contact E-mail Address: jeghia@yahoo.fr
Introduction: The pathophysiology of inflammatory bowel disease (IBD) can result from altered communications between nervous, immune and endocrine systems through chemical messengers. Enterochromaffin (EC) cells are the predominant neuroendocrine cell type in the gut and the main source of Chromogranin A (CgA). CgA is a neuropeptide, which facilitates the neuroendocrine immune communication and has been reported to be increased in IBD patients. Mucosal changes in IBD are characterized by a downregulation of T-regulatory cells (Forkhead Box P3: *FOXP3*), interleukin (*IL*)-10 & transforming growth factor (*TGF*)-β as anti-inflammatory mediators and loss of mucosal healing. Krüppel-like factor 5 (*KLF-5*) has been implicated in mucosal healing in a model of experimental colitis.
Aims & Methods: The aim of this study was to investigate the effect of the lack of CgA using an experimental model of ulcerative colitis (UC) and the correlation between CgA and anti-inflammatory regulators and healing mediators in rectal biopsies from IBD and healthy individuals.
Colitis was induced in CgA-C57BL/6-deficient ($CgA^{-/-}$) mice and wild type ($CgA^{+/+}$) mice by administrating dextran sulfate sodium (DSS 5%) in drinking water for 5 days. Disease activity index (DAI) was evaluated daily and mice were sacrificed on day 5 post-DSS induction to assess the extent of colitis. At sacrifice composite macro- and microscopic scores were evaluated. Myeloperoxidase (*MPO*) activity, *FOXP3*, *IL-10*, *TGF-β*, and *KLF-5*, were quantified in colon and spleen using ELISA or RT-qPCR. Rectal human biopsies were collected from healthy and IBD patients, the correlations between mRNA expression levels of CgA and *FOXP3*, *IL-10*, *KLF-5* were determined.
Results: Delayed onset and DAI were observed in $CgA^{-/-}$ mice as compared to $CgA^{+/+}$ mice after induction of colitis. Macroscopic and histological damage scores and colonic *MPO* activity were significantly decreased in $CgA^{-/-}$ mice as compared to $CgA^{+/+}$ mice. This was correlated with a significant up-regulation of *FOXP3*, *IL-10* and *KLF-5* of mRNA expression levels in the spleen and colonic tissue. However, *TGF-β* mRNA expression levels were not modified. In control mice the mutation did not affect any inflammatory markers studied. Using the mRNA expression levels, in human rectal biopsies, CgA showed a moderately strong negative linear association with *FOXP3* ($r = -0.66$, $P = 0.01$), *KLF-5* ($r = -0.67$, $P = 0.009$) and negative linear relationship with *IL-10* ($r = -0.34$, $P = 0.21$).
Conclusion: These observations suggest that lack of C*g*A in C*g*A-deficient mice reduced the severity of DSS-induced colitis and that C*g*A is critical in the pathogenesis of inflammation in that model of experimental colitis. In human clinical cases, the relationship between C*g*A and anti-inflammatory markers corroborated this observation. These findings reveal new insights into the mechanisms of colonic inflammation, which may ultimately lead to novel therapeutic strategies in human IBD.

P1514 THE PERSISTENCE OF CROHN'S ANAL FISTULAE COULD BE DUE TO THE INTERACTION BETWEEN THE GUT MICROBIOME AND THE IMMUNE SYSTEM

N. A. Yassin[1], H. Al-Hassi[2], S. Adegbola[1], T. Ansari[3], S. Knight[2], P. Sibbons[3], R. Phillips[1], A. Hart[1]
[1]*St Mark's Hospital & Academic Institute,* [2]*APRG, Imperial College London,* [3]*NPIMR, London, London, United Kingdom*

Contact E-mail Address: nayassin@gmail.com
Introduction: An interaction between genetic, microbiological and immunological factors drives Crohn's disease. Bacterial infection probably initiates idiopathic anal fistulae but does not maintain them. There is no evidence that bacterial infection causes the persistence of idiopathic anal fistulae. The aetiological factors behind Crohn's anal fistulae remain unclear. Perhaps an interaction between the gut microbiome and the immune system is implicated. Dendritic cells (DC) express Toll-Like receptors (TLR), which are pattern recognition receptors that are activated by bacterial ligands.
Aims & Methods: We aimed to compare the expression of TLRs and microbiota profiles of Crohn's and idiopathic fistulae. Biopsies were taken from 35 Crohn's and 25 idiopathic fistulae at the time of surgery. DC were identified as HLA-DR-positive and lineage-negative, and characterized by flow cytometry using fresh samples. The expression of TLR2 and 4 was determined. Immunohistochemical techniques determined the expression of TLR2, TLR4 and TLR9 on paraffin-imbedded anal fistula biopsies. DNA was extracted from frozen samples and bacterial 16S rRNA genes were sequenced using a MiSeq sequencer.
Results: TLR2 and 4 were expressed on DC from both Crohn's and idiopathic perianal fistulae using flow cytomtery. There was no significant difference in TLR2 ($p = 0.27$) or TLR4 ($p = 0.45$) expression on CD and idiopathic fistulae. Immunohistochemistry showed equal expression of TLR2 ($p = 0.42$) and TLR4 ($p = 0.11$) on lymphocytes. TLR9 expression was significantly higher in CD fistulae ($p = 0.01$).
Microbiota were classified as common and abundant, infrequent, and rare. The total number of operational taxonomic units (OTUs) observed and the number of species identified in Crohn's fistulae was significantly higher than idiopathic ($p = 0.02$). The most abundant species in the Crohn's group were *Bradyrhizobium pachyrhizi* followed by *Pseudomonas azotoformans* and *Prevotella oris*.
Conclusion: Bacterial products and the local immune response to them are present in perianal fistula tracts. Crohn's anal fistula persistence may be driven by bacterial products rather than live bacteria. This could provide therapeutic treatment targets for Crohn's anal fistulae.

Contact E-mail Address: olena.yakymenko@liu.se
Introduction: Crohn's disease (CD) is characterized by chronic inflammation in the gastrointestinal tract with increased amounts of the pro-inflammatory cytokine TNF-α. Treatment with anti-TNF-α antibodies, e.g. infliximab, is established as an important part of the therapeutic arsenal in severe CD, working, at least in part, via cytotoxic effects on T cells. TNF-a can decrease epithelial barrier function by apoptosis or changes at the tight junctions, however, it is unclear if part of the beneficial effect of anti-TNF-a therapy is due to prevention of this barrier dysfunction.
Aims & Methods: To investigate how infliximab affects uptake of adherent invasive *E. coli* across the colonic mucosa in CD and study mechanisms of transepithelial transport of the adherent invasive *E. coli* HM427 across monolayers of the human Caco-2 epithelial cell line treated with TNF-$\alpha \pm$infliximab.
Methods: Biopsies from macroscopically non-inflamed colon were obtained from CD colitis patients ($n = 6$) before and after a 4-week infliximab treatment. Biopsies from healthy volunteers ($n = 4$) and patients undergoing colon cancer screening ($n = 4$) served as controls. Biopsies were mounted in Ussing chambers, and the radioactivity labeled paracellular probe ^{51}Cr-EDTA and live GFP-incorporated *E. coli* HM427 were added to the mucosal sides of the tissues and passage into the serosal buffer was assessed by g-counting and flow cytometry, respectively. Caco-2 cells were cultured on transwell filters (bacteria transport assay) or 12-well plates (internalization assay) and exposed to either HM427 or the non-invasive *E. coli* HB101 with TNF-$\alpha \pm$infliximab for 24 h. Some monolayers were pre-treated with colchicine or methyl-β-cyclodextrin to stabilize microtubules and disrupt lipid rafts.
Results: Prior to infliximab, transcytosis of HM427 (CD: 2475 bacteria (450-3000) vs controls 1163 (225-1950), $p < 0.05$) and ^{51}Cr-EDTA passage (CD: 2.31 cm/s x 10^{-6} (1.70-6.67) vs controls 1.07 (0.62-1.55 x10^{-6}), $p < 0.05$) was increased in CD colitis. Treatment with infliximab restored transcytosis of HM427 to control group level (CD: 150 (18.8-1069)) and ^{51}Cr-EDTA (CD: 1.82 (0.64-2.95)). Data are presented as median $\pm$ IQR. *In vitro* studies demonstrated that infliximab reduced the TNFα-induced increase in bacterial transcytosis. The TNF-a-induced bacterial transcytosis was decreased by methyl-β-cyclodextrin but not colchicine.
Conclusion: Patients with active CD colitis showed a defect in the barrier to adherent *E. coli*, which was restored by a 4-week treatment with infliximab. The results suggest that TNF-α plays an important role in the barrier dysfunction in CD colitis, facilitating the transcytosis of commensal and pathogenic bacteria that is dependent on lipid rafts. The ability of infliximab to block these effects of TNF-a on epithelial permeability likely contributes to the clinical efficacy of this drug.

Introduction: Angiogenic and lymphangiogenic factors may play an important role in inflammatory bowel disease.
Aims & Methods: To correlate the main angiogenic and lymphangiogenic factors expression in colonic mucosa biopsies with the endoscopic and histological activity in patients with inflammatory bowel disease (IBD).
Prospective study in patients with IBD that underwent a colonoscopy because of medical criteria. Samples of colonic tissue biopsies for histological analyses were obtained. In patients where activity was observed during colonoscopy, samples from affected and non-affected mucosa were also taken. Endoscopic activity was assessed by endoscopic Mayo subscore for ulcerative colitis (UC) and SES-CD for Crohn's disease (CD). Considering histological findings, patients were classified into four groups: Quiescent IBD, mild, moderate and severe lesion. VEGFA, -C, -D, -R1, -R2, -R3 and PlGF expression results were

graded as follows: (++) over 50% of the tissue cells were stained, (+) below 50%, and (-) completely negative. Ang1, Ang2 and Tie2 were assessed as the average density of five hot spots at a magnification of x40. Protein expression was determined by immunohistochemistry.
Results: 82 biopsies from 58 patients with IBD (36 UC and 22 CD) were included. 64% of the patients did not have endoscopic activity, 16% had moderate, 14% mild and 6% severe activity. There were significant ($p < 0.01$) differences in the mean count of Ang1 and Ang2 depending on endoscopic activity. Higher expression of Ang1 and Ang2 was found when the endoscopic activity was severe compared to inactive disease. According to histology, 60% of the patients had quiescent IBD, 20% had moderate lesions, 15% mild and 5% severe lesions. Expression of VEGFD ($p < 0.05$), PlGF ($p < 0.05$) and VEGFR3 ($p < 0.01$), and mean count of Ang1 ($p < 0.05$) and Ang2 ($p < 0.01$) were also significantly different depending on the histological activity. These expressions were increased in parallel with the severity of histological lesions excepting for VEGFD, that was decreased with the severity of the activity. Positive correlations ($p < 0.05$) between histological activity and expression of Ang1 ($r = 0.4$), Ang2 ($r = 0.5$), PlGF ($r = 0.4$), VEGFC ($r = 0.3$), and VEGFR3 ($r = 0.3$), and negative for VEGFD ($r = -0.3$), were demonstrated. On the other hand, positive correlations ($p < 0.05$) between endoscopic activity and expression of Ang1($r = 0.4$), Ang2 ($r = 0.5$), PlGF ($r = 0.4$), and negative for VEGFD ($r = -0.3$), were found. The best area under the Receiver Operator Characteristic (ROC) curve for the diagnosis of histological activity was 0.73 for Ang1 (cut-off at 39.8: 89% sensitivity and 56% specificity).
Conclusion: The expression of VEGFA, -D, -R3, PlGF, and Ang1 and -2 in mucosal biopsies correlates with the histological activity of IBD. Ang-1 and -2 expressions in mucosal samples are markers of histological and endoscopic activity.

Introduction: Several immune-mediated gastrointestinal disorders, including inflammatory bowel disease (IBD), are associated with neuroendocrine cell hyperplasia.
Aims & Methods: We here studied neuroendocrine cells in patients with pouchitis after proctocolectomy with ileal pouch-anal anastomosis for ulcerative colitis (UC). Serial sections from 17 patients with pouchitis and from ileum of 13 IBD patients (5 Crohn's ileitis and 8 UC backwash ileitis) and 11 control subjects were processed for the immunohistochemical detection of CgA and serotonin. Mucosal tryptophan hydroxylase (TpH)-1 and serotonin-selective reuptake transporter (SERT) transcripts were measured by quantitative RT-PCR. We also detected TpH-1 and SERT transcripts in pouchitis biopsies cultured with infliximab or its isotype-matched control human IgG1, while interleukin (IL)-6 and IL-8 were measured by ELISA in culture supernatants.
Results: We observed an increase in CgA-positive cells in both patients affected by pouchitis and those with IBD ileitis compared to control subjects, with no difference between pouchitis and IBD ileitis. No change was found for serotonin-positive enterochromaffin (EC) cells amongst pouchitis and the other two groups, whereas IBD ileitis have higher EC cells than control subjects. we detected an increase in CgA-positive and serotonin-negative cells, calculated by subtracting the number of CgA-positive cells from the number of EC cells, in pouchitis in comparison to IBD ileitis and control subjects. Raised transcripts of mucosal TpH-1, but not SERT, were found in IBD ileitis in comparison to control subjects, without significant difference amongst pouchitis and the other two groups. Although infliximab down-regulated the *ex vivo* production of IL-8, but not IL-6, compared to IgG1, it did not change the expression of TpH-1 and SERT in pouchitis biopsies.
Conclusion: We show hyperplasia of neuroendocrine cells in the mucosa of both pouchitis and IBD ileitis. EC cells and TpH-1 transcripts are increased in the mucosa of IBD ileitis, but not in pouchitis. Hyperplasia of neuroendocrine cells seems to be due to other cell types in pouchitis.

Introduction: Crohn's disease (CD) is an inflammatory bowel disease (IBD) characterized by chronic inflammation of the intestine in humans. The etiology of CD remains unknown, however, the most common hypothesis is that chronic inflammation results from an abnormal inflammatory response against intestinal microbiota in a genetically susceptible host. Several studies have demonstrated that the intestinal mucosa of CD patients is abnormally colonized by adherent-invasive *Escherichia coli* (AIEC) strains. However, to date, no studies have focused on the involvement of such *E. coli* strains in CD patients in Brazil.
Aims & Methods: The aim of this study was to isolate and characterize the *E. coli* strains associated from intestinal mucosa in CD patients in Brazil. Biopsies were performed on 35 subjects: 10 CD patients in active phase, 15 CD patients in remission phase and 10 controls (without intestinal disease).
Results: Although the difference was not significant, the colonization level of the ileal mucosa by adherent bacteria is higher in CD patients than in the control group. Among 270 isolates strains, 241 were identified as *E. coli* strains. Mark from different phylogenetic groups of *E. coli* was carried out by PCR. In controls patients, 47.9% of the strains belong to group A, 2.1% in the B1 group, 6.3% in the B2 group and 43.7% in group D. In CD patients, 36.8% of the strains belong to group A, 30% in the B1 group, 10.9% in the B2 group and 22.3% in group D. In CD patients, a difference between the classification of *E. coli* strains was observed related to disease activity, especially among groups B2 and D. CD patients in active phase (20.2%) harboured 10-fold more *E. coli* belonging to the B2 group compared to CD patients in remission (2.0%) and 2.4-fold less strains of group D (12.8% CD active vs 31.3% CD remission). The adhesion and invasion ability of *E. coli* strains isolated were determined using human intestinal epithelial cells (I-407) and we observed that 26.9% of the isolated strains from CD patients are invasive. For each patient, the *E. coli* strain with the greater capacity of invasion was selected to analyze its ability to survive and multiply in human macrophages (THP-1), and we observed that 76.19% of the selected strains can survive and multiply within human macrophages.
Conclusion: This preliminary study on a small cohort of Brazilian CD patients suggests that the ileal mucosa of CD patients in Brazil is also colonized by *E. coli* strains having adherent and invasive properties.

Introduction: Fistulae represent a frequent complication in Crohn's disease (CD). Surgical resection is often required, as medical treatment outcome with conventional drugs is often insufficient. We have previously demonstrated that epithelial-to-mesenchymal transition (EMT) plays a critical role for fistula development. The T-cell cytokines tumor necrosis factor (TNF), interleukin (IL)-13, IL-17A and IL-22 are highly expressed in transitional cells along fistula tracts in CD patients. Similar to transforming growth factor (TGF) β, TNF is able to induce EMT and the expression of molecules being associated with cell invasiveness and migration. IL-13 has no impact on epithelial cell morphology, but also induces expression of genes being associated with invasive cell growth, such as *SLUG* transcription factor and *β6-integrin*. Here, we analyzed whether the T-cell derived cytokines interferon (IFN) γ, IL-10, IL-17A and IL-22 might be associated with the onset of EMT suggesting a possible role in the pathogenesis of CD-associated fistulae.
Aims & Methods: The effects of IFNγ, IL-17A and IL-22 on EMT development were investigated by stimulating HT29 intestinal epithelial cells (IECs), seeded as hanging drops as an *in vitro* model for EMT (spheroids), for one and seven days, followed by analysis of mRNA expression levels of EMT-associated genes, as well as morphological evaluation. Further, immunohistochemistry visualizing IL-10 was performed using human perianal fistula tissue from seven patients.
Results: Treatment of the HT29 spheroids with IFNγ (100 ng/ml) resulted in a loss of the well-defined globular spheroid shape after day 7. We observed a clear separation of IECs, suggesting the initiation of EMT. This observation was supported by the up-regulation of mRNA levels of the EMT-related transcription factors *SNAIL-1* and *ETS-1*. IL-17A (100 ng/ml) had no effect on cell morphology suggesting that it does not induce EMT in our cell model. On a molecular level, IL-17A had no effect on the mRNA expression of EMT-associated genes, but prevented the TGFβ-induced up-regulation of *SNAIL-1* and *ETS-1*. Similar to IL-17A, treatment with IL-22 (50 ng/ml) did not induce EMT in our spheroid model and did not exert significant effects on the expression of EMT-associated genes. Immunohistochemistry of fistulae tissue derived from CD patients did not reveal a considerable staining for IL-10.
Conclusion: Our data demonstrate that T-cell derived cytokines may play a crucial role in the pathogenesis of CD-associated fistulae. Th1 cell derived IFNγ may be involved in the onset of EMT in IECs, however Th17 cell derived cytokines IL-17A and IL-22 are likely not implicated, and may prevent EMT-associated effects of TGFβ. This observation supports the hypothesis that Th17 cell derived cytokines exert a pivotal role for maintaining intestinal homeostasis. We demonstrated only poor expression of IL-10 in fistulae tissue of CD patients. IL-10 is an antagonist of TNF as well as IL-13, which were previously shown to be highly expressed in the fistula regions. Thus, IL-10 may represent a promising therapeutic agent against fistulae development.

Introduction: Disruption to the epithelial barrier is central to the pathophysiology of IBD (Zeissig et al., 2007, Su et al., 2009). A variety of innate immune mechanisms contribute to the maintenance of the epithelial barrier. When stressed, either by pathogens or by inflammatory cytokine, gut epithelial cells produce IL-8, which acts as a chemo-attractant to circulating polymorphonucleocytes (Eckmann et al., 1993). Farnesoid X receptor (FXR) is a bile acid receptor which promotes gut homeostasis by maintaining the epithelial barrier and exerting anti-inflammatory effects (Gadaleta et al., 2011). The mechanism by which FXR maintains the epithelial barrier is not known.

Aims & Methods: The aim of this study was to assay the effect of FXR agonism on the production of IL-8 by human, gut-derived epithelial cells in response to cytokine stress. HT29 cells were cultured with media containing an FXR agonist (GW4064) or control (DMSO) with or without an FXR antagonist (guggulsterone). Following exposure to the FXR agonist +/- guggulsterone, HT29 cells were stimulated with media containing TNFα. IL-8 was measured both at a protein level, by ELISA, and transcriptional level by RT-PCR.

Results: In the control group, gut epithelial cells produced high levels of IL-8 when exposed to TNFα (6,316 +/- 870 pg/mg). Concomitant treatment with FXR agonist at high dose (GW4064 10μM) completely attenuated this IL-8 response ($p = 0.0004$). Lower doses of FXR agonist (0.1μM and 1μM) had no significant effect on the concentration of IL-8. Guggulsterone was able to reverse the attenuating effect of high dose FXR agonist, with significantly more TNFα-induced IL-8 detected ($p = 0.0005$). Measurement of relative IL-8 gene expression confirmed the findings measured at a protein level (TNFα alone – fold increase ~640 +/- 20, TNFα + FXR agonist – fold change ~0.08 +/- 0.02).

Conclusion: These experiments demonstrate that FXR agonism decreased the IL-8 response of human, gut-derived epithelial cells to TNFα. Gut epithelial IL-8 production is an important innate immune mechanism and this data is in keeping with other studies in demonstrating an immuno-modulatory role for FXR (Vavassori et al., 2009, Haselow et al., 2013). This is a potential mechanism by which FXR may act to maintain epithelial homeostasis.

Introduction: Research of intimate mechanism of anti TNF-alpha led to emphasis on the involvement of this therapy in intestinal epitelial cells apoptosis.

Aims & Methods: We aim to investigate the modifiation of apoptotic ratio after the anti TNF-alpha induction therapy and to correlate the magnitude of that modifiation with the endoscopic response. 27 patients with ulcerative colitis with the indication of anti TNF-alpha therapy admitted consecutively in the Institute of Gastroenterology and Hepatology Insititute Cluj-Napoca was included in the study. We evaluated the apoptotic ratio of intestinal epitelial cells by using TUNNEL method on the biopsy specimens taken before and after the adminstration of anti TNF-alpha therapy. We evaluated at the same time the presence of mucosal healing after the induction therapy.

Results: Determination intestinal epithelium apoptotic rate was performed before and after induction therapy. There is a clear decrease in the rate of intestinal cell apoptosis after the induction therapy compared with biopsies taken before. Thus, the mean apoptotic before initiating TB rate was 74.67% (44-94%), and after initiation of TB was 24.33% (5-45%). The difference between these two values was significant: OR: 50.33 (CI95%: 43.29-57.38), $p < 0.001$. The decrease in apoptotic rate was significantly higher in patients who achieved mucosal healing (median, 62%) compared with those without mucosal healing (median - 39.5%), $p < 0.001$.

Conclusion: Anti TNF-alpha therapy induces apoptosis of intestinal epithelial cells with a significant decrease in the apoptotic ratio at the end of induction therapy, witch correlates very well with the presence of mucosal healing.

Introduction: Crohn's disease (CD) is characterized by an increased level of pro-inflammatory cytokines, which is called systemic inflammation. Previous studies suggest that systemic inflammation can contribute and accelerate brain diseases, and thereby hypothesized that systemic inflammation possibly have effects on the brain. Although in other chronic diseases such as Rheumatoid Arthritis (RA) structural brain changes have been shown, no research have been performed to evaluate the effect of systemic inflammation on the cerebral mechanism in CD patients.

Aims & Methods: The aim of our study was to assess brain involvement in quiescent CD patients with fatigue using quantitative Magnetic Resonance Imaging (MRI) and relate these data to neuropsychological scores. Multiple MRI acquisitions were used to assess cerebral abnormalities in 20 quiescent CD patients with fatigue (defined with at least 6 points out of an 11-point numeric rating scale (NRS)) compared with 17 healthy age and gender matched controls. Furthermore, neuropsychological data was obtained by conducting the Hospital Anxiety and Depression Scale (HADS) and Neuropsychological Inventory (NPI), including the Mini-Mental State Examination (MMSE), the Wechsler Memory Scale (WMS) and a revised form of the Wechsler Adult Intelligence Scale (WAIS-R).

Results: CD patients encountered significantly more depressive symptoms ($p < 0.001$). Results of the NPI showed a reduction of the total score on the WMS ($p = 0.04$), the WAIS-R ($p = 0.001$) and the MMSE ($p = 0.08$) in CD patients compared with healthy controls. Generally, CD patients made more mistakes and more time was needed to complete the tests. Subcortical atrophy was found in the Amygdala, Accumbens, Putamen, Thalamus and the right Caudate, right Hippocampus and right Pallidus ($p < 0.01$). Reduced Glutamate + Glutamine units ($p = 0.02$) and ratios to total Creatine ($p = 0.02$) were found compared with controls. Furthermore significant increased Cerebral Blood Flow (CBF) values ($p < 0.05$) were found in CD patients (53.08 ± 6.14 ml/100g/min) compared with controls (47.60 ± 8.62 ml/100g/min).

Conclusion: To our knowledge, this pilot study is the first one that investigates the changes in the brain due to CD with multiple MRI techniques. Preliminary evidence for structural brain changes is shown, enhancing the hypothesis that systemic inflammation could influence the brain and the association with cognitive tests results. This is the first step in the understanding of the brain involvement in CD patients.

P1523 REDUCED MUCOSA-ASSOCIATED BUTYRICICOCCUS ACTIVITY IN PATIENTS WITH ULCERATIVE COLITIS CORRELATES WITH ABERRANT CLAUDIN-1 EXPRESSION

S. Devriese[1], V. Eeckhaut[2], A. Geirnaert[3], L. Van den Bossche[1], P. Hindryckx[1], T. Van de Wiele[3], F. Van Immerseel[2], R. Ducatelle[2], M. De Vos[1], D. Laukens[1]
[1]*Gastroenterology, Ghent University, Ghent,* [2]*Pathology, Bacteriology and Avian Diseases, Ghent University, Merelbeke,* [3]*Microbial Ecology and Technology, Ghent University, Ghent, Belgium*

Contact E-mail Address: s.devriese@ugent.be

Introduction: *Butyricicoccus* is a butyrate-producing clostridial cluster IV genus whose numbers are reduced in the stool of patients with ulcerative colitis (UC). Conditioned medium of *Butyricicoccus pullicaecorum* 25-3^T (*B. pullicaecorum*) prevents TNFα-induced increase in epithelial permeability *in vitro*.

Aims & Methods: Since butyrate is one of the parameters affecting intestinal epithelial barrier integrity, we further investigated the relationship between the presence of *Butyricicoccus* in colonic mucosa and the expression of tight junction (TJ) complex genes that are partly regulated by butyrate.

Expression of tight junction protein 1 (TJP1), occludin (OCLN), claudin-1 (CLDN1) and *Butyricicoccus* 16S rRNA was analyzed by quantitative real-time PCR in a collection of colonic mucosal biopsies of healthy controls and UC patients with active disease (both $N \pm 10$). CLDN1 expression was also evaluated in ileal lysates of TNF$^{\Delta ARE/WT}$ mice ($N \pm 8$). The effect of butyrate and *B. pullicaecorum* conditioned medium on tight junction gene expression and CLDN1-dependent Notch signalling was investigated *in vitro* in TNFα-stimulated CaCo-2 monolayers and *ex vivo* in inflamed mucosal biopsies of UC patients ($N \pm 5$).

Results: Compared to healthy controls, transcription of TJP1 and OCLN was significantly decreased in inflamed colonic biopsies of UC patients ($P = 0.004$ and 0.041, respectively), whereas CLDN1 mRNA levels were increased ($P < 0.001$). This counterintuitive upregulation of CLDN1 was also observed in TNF$^{\Delta ARE/WT}$ mice compared to their TNF$^{WT/WT}$ littermate controls ($P < 0.001$). *Butyricicoccus* bacteria were present in colonic mucosal biopsies and the number of 16S rRNA transcripts was decreased in active UC patients compared to healthy controls. Interestingly, mucosa-associated *Butyricicoccus* activity negatively correlated with CLDN1 expression (Spearman R = -0.528,

P = 0.0017). In addition, inflammation-induced increase of both CLDN1 protein levels and CLDN1-associated Notch activation could be reversed *in vitro* by butyrate (P = 0.0016). *Ex vivo* stimulation of inflamed UC biopsies with *B. pullicaecorum* conditioned medium normalized CLDN1 mRNA levels and Notch-regulated transcription of HES1 and ATOH1.
Conclusion: *Butyricicoccus* is a mucosa-associated bacterial genus underrepresented in colonic mucosa of patients with active UC whose activity inversely correlates with CLDN1 expression. Butyrate and *B. pullicaecorum* conditioned medium reduce CLDN1 and associated Notch activation, supporting the use of *Butyricicoccus* as a pharmabiotic preserving epithelial TJ integrity.

Contact E-mail Address: sarahk@tlvmc.gov.il
Introduction: CD24, a cell surface glycoprotein, is expressed on immune and intestinal epithelial cells. We have shown that CD24 is important in CRC carcinogenesis (Sagiv, 2008; Shapira, 2011), and that *CD24* SNPs are associated with a late IBD onset and considered protective (Lisiansky, 2014). We hypothesize that CD24 is important in IBD pathogenesis through a combination of immune regulation and alteration of the enteric microbiota composition.
Aims & Methods: Aim: Investigate the role of CD24 in acute and chronic dextran sulphate sodium (DSS)-induced colitis.
Methods: Acute model: *CD24* knockout (KO) and wild-type (WT) C57BL/6J mice were given 2.5-4% DSS in their drinking water for 5 days, followed by 2 days of water. Each group (n = 12) was compared to control animals, which received only water. Mice were sacrificed on day 7 and scored for their disease activity index (DAI). Chronic model: Mice (n = 5/group) were exposed to 3 one-week DSS cycles. Between cycles, mice received water for 2 weeks. The optimal DSS concentration for chronic colitis was determined following various DSS doses (1.5-2.0-2.5%). Colitis severity was assessed clinically and pathologically. High-throughput sequencing of stool 16S rRNA genes was performed (Illumina, Miseq) and enteric microbial populations were characterized using the QIIME software. Specific cytokines were assayed by ELISA.
Results: *CD24* KO mice were more resistant to DSS-induced acute colitis compared to WT even at high DSS concentrations (4%). Colon length of the WT (2.5% DSS) was significantly shorter than the KO mice (6.9 ± 0.4 vs. 4.9 ± 0.2cm, respectively) ($p < 0.001$). DAI scores in the WT were significantly elevated on day 7 (DAI = 9.4 ± 1.2) while no changes were seen in the KO mice. In WT DSS-treated mice (4%), colitis appeared already on day 4 (DAI = 5.1 ± 3.3) with a high (17%) mortality rate (DAI on day 7 = 11.4 ± 1.07) ($p < 0.05$). The optimal DSS concentration in the chronic model was 1.5% (mild inflammation with no death). *CD24* KO mice were significantly less sensitive than the WT. DAI scores at the end of the experiment were 1.0 (KO) and 2.7 (WT) ($p < 0.05$). Colon lengths were reduced by 28.4% in the WT vs. 4.6% in the KO mice ($p < 0.001$). High-throughput sequencing of stool 16S rRNA showed significant differences between the enteric microbial populations. IL-12 levels in the colon were significantly elevated in DSS-treated KO mice compared to WT ($p = 0.02$). Changes in other cytokines, though not significant, were also detected, supporting the involvement of CD24 in the inflammatory response.
Conclusion: 1. *CD24* deficiency protects against colitis induced by acute and chronic exposure to DSS; 2. Microbiota may play a role in this protection; 3. CD24 may be an important player in IBD pathogenesis and serve as a novel target therapy.

P1525 INTESTINAL EPITHELIAL RESPONSE TO FUNGI: IMPLICATIONS FOR THE PATHOGENESIS OF CROHN'S DISEASE

S. Cohen-Kedar[1], L. Baram[1], I. Dotan[1,2]
[1]*Mucosal Immunology Laboratory, The Research Center for Digestive Tract and liver Diseases,* [2]*IBD center, Department of Gastroenterology and Liver Diseases, Tel Aviv Souraski Medical Center, Tel Aviv, Israel*

Contact E-mail Address: sarit.cohenkedar@gmail.com
Introduction: Antibodies directed against fungal cell-wall glycans are associated with Crohn's disease (CD) and may represent loss of tolerance towards intestinal microorganisms. The potential role of fungi and their cell wall glycans in modulating human intestinal immune responses and the cells and receptors recognizing them are still unclear. Intestinal epithelial cells (IECs) are the first to encounter luminal antigens and may play an active role in intestinal immune responses. We recently reported that β-glucans induced chemokine secretion by IEC lines in a Dectin-1 and spleen tyrosine kinase (Syk)-dependent manner.
Aims & Methods: To assess the effects of fungi and fungal glycans on activation of the intestinal mucosa, specifically IECs. IECs were freshly isolated from surgical specimens and mucosal samples were obtained from IBD patients and healthy controls. C-type lectin receptors (CLRs) were detected by immunohistochemistry, flow cytometry, real-time PCR (rt-PCR), Western-blot (WB) and immunofluorescence (IF). Human IEC lines (HT-29 and SW480) were activated by *Candida albicans* and *Saccharomyces cerevisiae*. Chemokine secretion was assessed by ELISA. Syk phosphorylation and microtubule-associated protein 1A/1B-light chain 3 (LC3) activation were assessed by WB and IF.
Results: Expression of the CLRs Dectin-1, Dectin-2, Mincle and DC-SIGN was detected in primary IECs as well as IEC lines. Expression of Dectin-1, Dectin-2 and Mincle was significantly increased in inflamed mucosa from the colon and small bowel of CD patients compared to normal controls [e.g. 18 ± 8 fold increase of Mincle mRNA expression in inflamed colon of CD (n = 7) vs. normal controls (n = 9) p = 0.001]. While IEC lines responded to β-glucan (zymosan or curdlan) activation by pronounced IL-8 and CCL2 secretion (e.g. 8.1 ± 0.6 vs. 0.3 ± 0.01 ng/ml IL-8 in zymosan-treated vs. control HT-29 cells, respectively), their activation by commensal fungal particles of heat-killed (HK)-*S. cerevisiae*, live, HK- or UV-inactivated wild-type *C. albicans*, or live non-hyphal forming *efg1*ΔΔ, *cph1*ΔΔ mutant did not yield significant IL-8 or CCL2 secretion. In contrast, Syk phosophorylation in IECs was similarly induced by β-glucans and fungal particles. Interestingly, exposure of IECs to β-glucans or fungal particles induced activation of the autophagy protein LC3. Furthermore, LC3 activation by HK *C. albicans* was sensitive to Syk inhibitor.
Conclusion: CD-related inflammation is characterized by increased expression of fungi-recognizing receptors. IECs express these receptors and can recognize luminal fungi and the cell wall component β-glucan leading to Syk mediated signaling. The Syk- dependent LC3 activation suggests that autophagy may be involved in IECs' response to fungi and β-glucans. The discordant chemokine secretion in response to commensal fungi and to β-glucans suggests common signaling mediated by receptors additional to Dectin-1. Thus, IECs' response to fungi may play a role in mucosal homeostasis that may be distorted in CD. Defining the mechanisms underlying intestinal immune responses to fungal glycans may enable therapeutic intervention, e.g., inhibition of key signaling mediators such as Syk.

P1526 EXPRESSION OF CLAUDINS IN METAPLASTIC GLANDS IN IBD

S. Čužić[1], M. Bosnar[1], D. Stupin Polančec[1], G. Aralica[2], I. Glojnarić[1], M. Banić[2], V. Eraković Haber[1]
[1]*Fidelta Ltd.,* [2]*KB Dubrava, Zagreb, Croatia*

Contact E-mail Address: snjezana.cuzic@glpg.com
Introduction: One of the characteristics of inflammatory bowel disease (IBD) is gland metaplasia. The aim of the study was to describe changes in claudin expression pattern by metaplastic epithelial cells in patients suffering from Crohn disease (CD) and ulcerative colitis (UC) in comparison to healthy controls.
Aims & Methods: Immunohistochemistry (IHC) for claudins 1, 2, 3, 4 and 8 on formalin-fixed paraffin-embedded (FFPE) tissue samples from resected intestine of IBD patients (8 patients with CD, 5 patients with UC and 7 controls) was performed. The following primary antibodies were used: claudin-1 (AbCam, ab56417, 1:250), claudin-2 (AbCam, ab125293, 1:75), claudin-3 (GeneTex, GTX15102, 1:50), claudin-4 (AbCam, ab53156, 1:1000), claudin-8 (AbCam, ab183738, 1:1000) followed by DAKO EnVision Detection System (Cat.No. K5007). TNFa, IFNg, claudin-1, claudin-2, claudin-3, claudin-4 and claudin-8 mRNA analysis were performed using the same sample tissue as for IHC. RNA was reverse transcribed using random hexamers and a SuperScript III First-Strand synthesis system. RT-qPCR was performed using the TaqMan method and glycerin-aldehyde-3-phosphate (GAPDH) as a housekeeping control.
Results: TNFa and IFNg were increased both in CD and UC samples confirming an inflamed environment. Expression of measured sealing claudins (1, 3, 4, 8) was absent or decreased in metaplastic epithelium. Claudin-1 expression by epithelial cells lining non-metaplastic glands was increased in both patient groups, comparing to healthy mucosa. In contrast, epithelial cells of metaplastic glands did not express claudin-1. Expression of claudin-3 by metaplastic epithelial cells was decreased in comparison to both, glandular epithelium in healthy mucosa and non-metaplastic glands in IBD mucosa. Claudin-4 was expressed along membranes of epithelial cells in healthy mucosa, as well as by epithelial cells of non-metaplastic glands in IBD, whereas epithelial cells of metaplastic glands did not express claudin-4. Claudin-8 in healthy mucosa was expressed mainly by differentiated epithelial cells. Its expression was increased in non-metaplastic epithelium in IBD samples, but was not expressed by epithelial cells of metaplastic glands. In contrast to examined sealing claudins, pore-forming claudin-2, not present along membranes of epithelial cells in healthy colon, was expressed both by epithelial cells of non-metaplastic and metaplastic glands in IBD mucosa. Detected RNA levels clearly reflected changes observed in prevailing non-metaplastic epithelium.
Conclusion: In short, expression of sealing claudins is down regulated in epithelium of metaplastic glands compared to healthy controls and non-metaplastic glands, whereas epithelial cells show claudin-2 positivity both in non-metaplastic and metaplastic glands in IBD. Observed pattern of claudin expression by epithelial cells of metaplastic glands in IBD differs from that reported in colorectal carcinoma.

Introduction: Ulcerative colitis (UC) is an inflammatory bowel disease (IBD) characterized by severe chronic intestinal inflammation with a high impact on the patient's quality of life. Studies suggest that peroxysome proliferator-activated receptor-gamma (PPARγ), highly expressed in colon, is a critical regulator of the inflammatory response and has anti-inflammatory effects. It is a promising new target for the treatment of IBD. AS002 is a novel PPARγ agonist developed for local action in the gut, and would thus be an important addition to the treatment strategy in IBD. In order to study the potential of this compound for IBD treatment, the effects of AS002 were evaluated in the well-established dextran sodium sulfate (DSS) animal model (that shows similarities with human UC), and *ex vivo* in colonic biopsies of patients with UC and controls.

Aims & Methods: Male Balb/c mice (8/group) received 5% DSS dissolved in drinking water for 8 days. Control mice received water. To evaluate preventive effect of AS002, mice received PPARγ agonists (5-ASA (75 mg/kg), rosiglitazone or AS002 (10 and 100 μM)) or vehicle by intrarectal administration 2 days before the induction of colitis (day 0), and each day until day 8. In the curative model, mice received the compounds from day 3-8. At day 8, mice were sacrificed and colon were measured and weighed. Macroscopic damages were evaluated using Wallace's table. Colon samples were taken to measure PPARγ expression by qPCR and to measure the myeloperoxidase level, a protein expressed during inflammation. *Ex vivo*, human colonic biopsies from patients with UC or from normal controls (polyp screening patients) (n = 6 per group) were incubated 1 hour with compounds followed by 3 hours with cell medium only, to better mimic the clinic situation, in order to measure PPARγ activity by assessing mRNA of the PPARγ-responsive gene adipophilin by qPCR. Moreover, metabolism of AS002 in UC biopsies was assessed.

Results: Both AS002 and rosiglitazone increased mRNA expression of adipophilin (mean ± SEM) compared to control wells ($p < 0.05$), in both controls (AS002; 1.02 ± 0.14, Ros; 0.93 ± 0.23, control; 0.33 ± 0.06) and in human UC biopsies (AS002; 0.91 ± 0.21, Ros; 1.0 ± 0.23, control; 0.33 ± 0.1). Lactate dehydrogenase analysis showed that human biopsies were intact and viable after incubation. In DSS colitis, both preventive and curative applications of AS002 showed a significant improvement on colon length, colonic macroscopic damage and myeloperoxidase levels ($p < 0.05$). Rosiglitazone had significant effects only when administrated before DSS treatment ($p < 0.01$), but had no curative effect when given after DSS

Conclusion: AS002, a novel PPARγ agonist with local action in the gut, prevents and reverses acute colitis induced by DSS in mice, a model for UC. The induction of PPARγ expression in colonic biopsies of UC, suggests that AS002 may be used for treatment of UC, and warrants further studies in UC patients.

Introduction: Crohn's disease (CD) has the high incidence of recurrence, impairing quality of life of patients for long period. The precise molecular etiology and the factors underlying the clinical symptoms of CD still remain largely unknown. In this study, we sought out molecules histologically unique to CD to provide novel molecular insight into CD.

Aims & Methods: We compared the distribution of phosphatidylcholine (PC) in the ileum mucosa of CD patients to that of non-CD patients with imaging mass spectrometry (IMS). We further analyzed the expression and localization of lysophosphatidylcholine acyltransferase 3 (LPCAT3) with quantitative RT-PCR (qPCR), immunohistochemical staining, and immunoelectron microscopy. We finally examined whether the secretion of hormone was regulated by LPCAT3 in enteroendocrine cells.

Results: IMS showed the overt accumulation of polyunsaturated fatty acid (PUFA)-containing PC, PC(36:4), PC(38:4), and PC(38:5), in the crypt-rich deep region of ileum mucosa in CD patients ($p < 0.01$ for non-CD patients). qPCR revealed the significant increase of LPCAT3 expression in the ileal mucosa of CD patients ($p < 0.05$ for non-CD patients). Immunohistochemical staining showed that the number of LPCAT3-positive cells was significantly increased in crypt of CD ileum ($p < 0.05$ for non-CD patient), especially in chromogranin A-positive enteroendocrine cells ($p < 0.001$ for non-CD). Immunoelectron microscopy revealed that LPCAT3 was increased on secretory granules of enteroendocrine cells in CD patients. LPCAT3 overexpression significantly enhanced ionomycin-stimulated 5-HT secretion from RIN-14B cells ($p < 0.01$ for control).

Conclusion: LPCAT3, an enzyme synthesizing PUFA-containing PC, was increased in ileal enteroendocrine cells of CD patients, and enhanced Ca^{2+}-depedent 5-HT secretion in a culture model. These findings imply that the enhanced LPCAT3 expression induces 5-HT secretion and exacerbates bowel inflammation in CD ileum, and can propose LPCAT3 as a therapeutic target for symptoms of CD.

Introduction: We have previously reported that NFκB activation in association with specific up-regulation of type 2 receptor for TNF (TNFR2) was observed in the inflamed colonic epithelia and further in colitis-associated cancer (CAC). It has been suggested that prolonged inflammatory bowel diseases (IBD) may promote carcinogenesis in the epithelia, but the role of TNFR2 expression in the setting of CAC has not been elucidated.

Aims & Methods: The aim of this study was to analyze TNFR2 signaling in the colonic epithelial cells in the setting of CAC. A murine colonic epithelial cell line, MOC1, was established by the isolation of 'non-tumor' colonic epithelial cells from wild type mouse (WT) and transformation with SV40 large T antigen to pursue physiological morphology in vitro. For in vivo studies, WT were pre-injected with azoxymethane (AOM) and then administered three times with dextran sodium sulfate (DSS) to induce a model of CAC.

Results: As previously observed in vivo, Western blotting (WB) showed up-regulation of TNFR2 expression in MOC1 cells when stimulated with recombinant (r) IFN-γ. Associated with this, the phosphorylated p65 and IκBα, as well as the protein expression of myosin light chain kinase (MLCK), in these cells were also up-regulated in a rTNF dose-dependent manner. Immunofluorescence and transmission electron microscopies (TEM) revealed that the epithelial NFkB-induced up-regulation of MLCK was associated with induction of the disrupted tight junction (TJ). Such MLCK up-regulation and TJ disruption in MOC1 cells were abrogated by either treatment with anti-TNF mAb (MP6-XT22), TNFR2-specific siRNA or even MLCK inhibitor (ML-7). These results indicate that the epithelial permeability in the context of inflamed colon may be specifically induced by TNFR2 signaling via NFκB activation and MLCK up-regulation in the epithelial cells. Using an animal model of CAC involving AOM and DSS, semi-quantitative PCR revealed that the colonic lamina propria was found to have pro-tumorigenic cytokine production such as IL-1β, IL-6 and MIP-2. Moreover, WB and TEM showed that such up-regulated pro-tumorigenic cytokines in the inflamed colonic tissues were associated with epithelial NFκB activation, TNFR2 and MLCK up-regulations and TJ disruption. Injection with either MP6-XT22 or ML-7 into AOM/DSS-treated mice failed to suppress the severity of colitis. However, these treatments resulted in restored TJ in the colonic epithelial tissues, decreased pro-tumorigenic cytokine production in the colonic lamina propria and reduced CAC development.

Conclusion: Our studies showed that epithelial TNFR2 signaling in the context of IBD may be involved in epithelial permeabilization and pro-tumorigenic cytokine production that result in CAC development. These results suggest that MLCK may be a potential target for the prevention of IBD-associated tumor development in humans.

Introduction: Oleuropein (OLE) is the major secoiridoid of olive tree leaves and its antioxidant and anti-inflammatory activities have been demonstrated in vitro and in vivo animal models.

Aims & Methods: The aim of this study was to investigate the activity of OLE in the colonic mucosa from pts with ulcerative colitis (UC). First, the toxicity, proliferative and antioxidant effects of OLE were assessed in Caco-2 cells using the MTT assay and ELISA (xMark™ Microplate Absorbance Spectrophotometer, Bio-Rad). Cells were treated with different concentrations of OLE for 3 h and then with H2O2. Untreated cells and cells treated with only H2O2 for 1 h stand for negative and positive controls, respectively. Second, biopsies obtained during colonoscopy from 14 pts with active UC (8 M,39-80 yrs, median 59; Mayo score 4-9, median 6) were immediately placed in an organ culture chamber and challenged with or without lipopolysaccaride from *Escherichia coli* (EC-LPS) at 1 μg/mL in the presence or absence of 3mM OLE for 24 h. Levels of cyclooxygenase (COX)-2 and IL-6, IL-8, MCP-1, VEGF, TNFα, IL-1α, IL-1β cytokines were assessed in total protein extracts from treated colonic biopsies and culture supernatant by Western blotting and Biochip Array on Randox Evidence Investigator (Randox Laboratories), respectively.

Results: Treatment with OLE did not show toxicity on Caco-2 cells while significantly improving cell viability when compared with untreated cells (i.e.,

121 ± 16% at 50 mM) or cells treated with only H2O2 (i.e., 67 ± 3% vs 53 ± 6% at 100 mM). In colonic mucosal biopsies from UC pts, levels of COX-2 were significantly lower in samples treated with OLE when compared with untreated (0.67 ± 0.16 a.u. vs 0.84 ± 0.16 a.u., p = 0.03) as well as in samples treated with OLE + ECLPS when compared with those treated with EC-LPS alone (0.80 ± 0.15 a.u. vs 1.06 ± 0.19 a.u., p = 0.003). Accordingly, the level of each of the cytokines IL-6, IL-8, MCP-1, VEGF, TNFα, IL-1α, and IL-1β was significantly lower (p = 0.02 to 0.003) in culture supernatants of colonic samples treated with OLE or OLE + EC-LPS compared with untreated samples or samples treated with EC-LPS alone, respectively.

Conclusion: Non-toxic, proliferative and antioxidant activities of OLE have been demonstrated in epithelial colonic cells. Together with the anti-inflammatory effects exhibited in human ex-vivo experiments, this suggests the possible use of OLE for treatment of UC pts.

Contact E-mail Address: t.holvoet@ugent.be

Introduction: Intestinal fibrosis is a common complication of Crohn's disease. Fibrotic strictures are an important indication for surgery and current therapies are unable to prevent their development. Rho kinase (ROCK) is a key mediator in TGFß-induced activation of myofibroblasts and a promising anti-fibrotic drug target. However, systemic ROCK inhibition is known to cause significant cardiovascular (CV) side effects. Thus, we investigated the effects of AMA0825, a ROCK inhibitor with Localized Activity on the development of intestinal fibrosis.

Aims & Methods: CV effects of AMA0825 were assessed in spontaneous hypertensive rats (SHR). Disease activity, intestinal fibrosis and inflammation were evaluated in chronic DSS-induced colitis and in adoptive T cell transfer in C57BL6 and SCID mice respectively. In vitro effects on the production of fibrotic and inflammatory mediators were measured in human intestinal fibroblasts (HIF), HT29 colonic epithelial cells and THP1 macrophages. mRNA and protein expression was analyzed by qPCR, Luminex bead assays and immunohisto/cytochemistry.

Results: In SHR, AMA0825 had no CV effects at 10 mg/kg *p.o.* In the chronic DSS model daily treatment of mice with AMA0825 (3 mg/kg *p.o.*) did not induce toxicity nor significant differences in weight loss. At sacrifice, the colonic weight/length ratio was significantly reduced (p = 0.03) as well as Trichrome-positive fibrotic tissue in the distal colon of treated mice (p = 0.003). Lower colonic protein levels of pro-fibrotic cytokines IL6, IL13 and TGFb1-2 were observed, and DSS-induced production of matrix metalloproteinase (MMP) 2, 3 and 9 was prevented in treated mice. Interestingly, transcription of COL1A1 and ACTA2 was profoundly reduced, suggesting decreased activation of colonic myofibroblasts, which was confirmed by αSMA immunohistochemical staining. Although local levels of several pro-inflammatory cytokines (CXCL2, KC, IFNG, TNFα and MCP1) were diminished, inflammatory cell infiltration and myeloperoxidase activity remained unaffected by AMA0825 treatment, suggesting a direct anti-fibrotic effect.

The effect of AMA0825 with respect to a known anti-inflammatory agent (mouse anti-TNF IgG1) was evaluated in the adoptive T cell transfer model. Weight loss was not significantly different. AMA0825 did not affect the anti-inflammatory effect of anti-TNF (both on cytokine and histology level). Differences were found with respect to intestinal fibrosis, confirming the direct effect of ROCK inhibition on fibrosis.

In HIFs, AMA0825 dose-dependently inhibited TGFß1-induced formation of actin stress fibers and expression of COL1A1 and ACTA2. TGFb1-induced production of IL6, TGFß1 and MMP 2, 3 and 12 was also abrogated. AMA0825 did not however affect IL8 secretion from TNF-stimulated HT29 cells or LPS-challenged THP1 cells, which is in line with the lack of a profound anti-inflammatory effect in vivo.

Conclusion: Inhibition of ROCK by oral administration of AMA0825 in mice is safe and profoundly diminishes the development of intestinal fibrosis by suppressing pro-fibrotic expression profiles. These effects are mainly due to direct inhibition of myofibroblast formation and activation and less by suppression of inflammation.

Introduction: The risk of colorectal cancer are increasing among the patients with ulcerative colitis.Colitis-associated colorectal cancer (CAC) has been reported to acquire the enhanced malignant potential, resulting in the poorer prognosis than that of sporadic colorectal cancer. However, how CAC have malignant potential remains unknown. We have previously showed that transcription factor Atonal homolog 1 (Atoh1) was phosphorylated by glycogen synthase kinase 3β (GSK-3β), resulting in the proteasomal degradation of Atoh1 in sporadic colon cancer. It was, however, unclear how Atoh1 is stably expressed in CAC.

Aims & Methods: We aimed to elucidate the effect of Atoh1 expression on malignant potential in CAC. We generated the mCherry-Atoh1 gene to visualize protein expression and introduced it in colon cancer cell line, DLD1. Malignant character was assessed by sphere formation, cell cycle, chemoresistance and cell migration. The phosphorylation of Akt and GSK-3β was assessed by Western blot. immunofluorescence was performed human CAC samples (n = 3) to assess the ecpression of Atoh1 and NF-kB p65.

Results: Treatment with TNF-α induced the expression of Atoh1 protein in DlD-1, resulting in the mucinous phenotype. Moreover, stable expression of Atoh1 protein showed cancer stemness such as sphere-forming ability, cell cycle arrest. Furthermore, Atoh1 also showed enhanced malignant potential such as chemoresistance and cell migration. Western blot analysis revealed that TNF-α stabilized Atoh1 protein by suppressing GSK-3β via Akt activation. Accumulation of NF-kB p65 in nuclei with the expression of Atoh1 was shown in human mucinous CAC specimens.

Conclusion: CAC might acquire enhanced malignant potential by which inflammatory signaling might cancel the degradation of Atoh1 protein.

P1533 BUTYRIC ACID ATTENUATES INTESTINAL INFLAMMATION IN MURINE EXPERIMENTAL COLITIS MODELS VIA MILK FAT GLOBULE-EGF FACTOR 8

T. Mishiro[1]
[1]*Gastroenterology, Shimane University, Izumo, Japan*

Contact E-mail Address: tmishiro@med.shimane-u.ac.jp

Introduction: Butyric acid, a short-chain fatty acid, is one of the main metabolites of intestinal microbial fermentation of dietary fiber. It has been shown to play an important role in maintaining the integrity of the intestinal mucosa, and exerts potent anti-inflammatory effects both *in vitro* and *in vivo*. However, the precise mechanisms underlying those effects have not been fully identified. We explored the therapeutic role of butyric acid via milk fat globule-epidermal growth factor 8 (MFG-E8) in a murine experimental colitis model.

Aims & Methods: We exposed colonic epithelial cells to butyric acid, then extracted total RNA and hybridized the samples on microarray chips. To confirm the effects of butyric acid via MFG-E8 on DSS-induced experimental colitis, we gave intrarectal administrations of butyric acid to C57BL/6N (MFG-E8$^{+/+}$) and MFG-E8$^{-/-}$ mice. We also utilized an enzyme linked immunosorbent assay (ELISA) method to evaluate proinflammatory cytokine production in murine colonic samples.

Results: Among the upregulated genes found in the microarray study, MFG-E8 was elevated approximately 5-fold. Furthermore, the acetyl-H3K9 level around the MFG-E8 promoter region was significantly increased by butyric acid exposure in a time-dependent manner. Intrarectal administration of butyric acid during an acute phase of colitis attenuated intestinal inflammatory parameters and inhibited body weight loss only in WT mice but not in MFG-E8$^{-/-}$ mice.

Conclusion: Our novel findings suggest that butyric acid has significant anti-inflammatory effects partly via MFG-E8 on DSS-induced murine experimental colitis.

Introduction: Inflammatory bowel diseases (IBD) result from the chronic dysregulation of the mucosal immune system and the aberrant activation of both the innate and the adaptive immune responses. Interleukin-19 (IL-19) is a member of the IL-10 family of cytokines. The last 10 years from the finding of IL-19, investigations underline the role of IL-19 in the immunological diseases. However, little is known about the exact biological role of IL-19 in IBD.

Aims & Methods: We have used 2,4,6-trinitrobenzene sulfonic acid (TNBS)-induced colitis models to examine the roles of IL-19 in colonic inflammation and thus its possible role in IBD. Using gene-targeting, we generated IL-19-deficient mice. To study the activation of the immune response during colonic inflammation, we used a TNBS-induced colitis model that is associated with the expansion and accumulation of activated T cells in the colon.

Results: We show that IL-19-deficient mice are more susceptible to experimental acute colitis induced by TNBS, evaluated by body weight changes, leukocyte infiltration and epithelial cell damage. Furthermore, TNBS administration to WT mice revealed that the expression of IL-19 mRNA was induced in distal colon on day 1. This increased susceptibility was correlated with increased production of IFN-gamma, IL-12, IL-22, and IL-33 by the distal colon of mice. We next examined the levels of several types of cytokines in lymph node cells. Cells isolated from lymph nodes of IL-19-deficient mice with TNBS-induced colitis produced elevated amounts of IL-1alpha, IL-6, IL-12, IL-17, and IFN-gamma upon stimulation with anti-CD3 and anti-CD28 antibodies in vitro. In contrast, IL-2 and IL-4 levels were markedly decreased in lymph node cells isolated from IL-19-deficient mice with TNBS-induced colitis.
Conclusion: Using this model, our results revealed a crucial role for IL-19 in the control of colonic inflammation. The finding that IL-19 drives pathogenic adaptive immune responses in the colon suggests that the selective targeting of IL-19 may be an effective therapeutic approach in the treatment of human IBD.

Introduction: Environmental factors are believed to contribute to the increased prevalence of Crohn's disease (CD). In response to environmental stimuli, intestinal epithelial cells (IECs) elicit rapid changes in gene expression patterns to maintain epithelial homeostasis. Therefore, the integrality of epithelium and epithelial homeostasis have pivotal roles in improving pathophysiology and clinical outcomes of CD. Recently, microRNAs (miRNAs) have emerged as master regulators of intestinal epithelial homeostasis. However, the biological functions of aberrant expressed miRNAs in CD remain largely elusive. The balance of proliferation and death of IECs is also widely considered as an important factor to maintain the gut epithelial homeostasis. Smad nuclear interacting protein 1 (SNIP1) regulates the stability of cyclin D1 (CCND1) mRNA, which indicates that SNIP1 may play a role in cell proliferation. We therefore examined miRNA level in colon tissues and studied the potential functions of miRNAs that regulate SNIP1 during pathogenesis of CD.
Aims & Methods: To investigate the roles of SNIP1 expression-associated miRNAs in disruption of IECs, miRNAs were assayed in the inflamed colon biopsies of CD patients by microarray. The expressions of miR-124 and SNIP1 mRNA were assessed by quantitative real-time polymerase chain reaction (qRT-PCR), SNIP1 protein level was identified by western blot analysis and immunohistochemistry. Bioinformatics analysis and luciferase reporter assay were used to predict and test the direct binding of miR-124 to the target gene SNIP1, respectively. The effects of upregulation or downregulation of miR-124 on colonic epithelial cell lines were confirmed by CCK-8 assay and cell-cycle analysis. The levels of SNIP1 and CCND1 were determined by qRT-PCR and western blot analysis subsequently. Then we investigated whether overexpression of SNIP1 is sufficient to reverse the inhibitory effect of miR-124 on SNIP1 and downstream CCND1 expressions. The role of miR-124 was further studied in the 2,4,6-trinitrobenzene sulfonic acid (TNBS)–induced colitis mice by intracolonic administration of miR-124 inhibitor.
Results: The expression of miR-124 was significantly upregulated in colon tissues of active CD patients. An inverse correlation between miR-124 and SNIP1 protein levels was observed predominantly. By overexpressing or knocking down miR-124 in HT-29 and Caco-2 colonic epithelial cells, we experimentally validated that miR-124 is a direct regulator of SNIP1 *in vitro*. Overexpression of miR-124 suppressed SNIP1 and CCND1 protein expressions, inhibited cell proliferation, and altered the cell cycle by decreasing S-phase and increasing G1 phase. Forced overexpression of SNIP1 strikingly upregulated SNIP1 and CCND1 protein expressions and partly rescued the inhibitory effect of miR-124 on HT-29 and Caco-2 cells proliferation. *In vivo*, downregulation of miR-124 in the TNBS-induced colitis colon alleviated experimental colitis. Mice treated with anti-miR-124 experienced dramatic decreases of DAI levels and histological scores. Simultaneously, an appreciable improvement of macroscopic inflammation was also observed.
Conclusion: Together, this study presents the first evidence that miR-124 plays a critical role in disturbing epithelial homeostasis through inhibiting SNIP1 expression and subsequently triggering CCND1 degradation in CD.

Introduction: Melatonin has strong anti-inflammatory potentials in the GI tract. On our previous study, melatonin reduces various inflammatory cytokines on colon tissues and accelerates recovery from injured mucosa. We aimed to know the effect of melatonin on intestinal microbiota.
Aims & Methods: We used 3 groups of C57BL/6 mice. Group I: control, Group II: chronic colitis group: 2% DSS for 7 days and followed 2 weeks for recovery and then readministered 2% DSS for 7 days, Group III: chronic colitis with melatonin group: add daily melatonin treatment. Melatonin (10mg/kg) or saline was injected daily by intraperitoneal route. The mice were sacrificed on 28th day. Stool were collected during last 2 days. Genomic DNA from feces was extracted. After amplification of genomic DNA using barcoded primers targeting the V1 to V3 regions of bacterial 16S rRNA genes, pyrosequencing was performed.
Results: Fecal microbial analysis demonstrated that Firmicutes to Bacteroidetes ratio (F/B ratio) is 0.19in Group I, 0.38 in Group II and 0.21 in Group III. Melatonin treatment significantly decreased F/B ratio comparing with DSS colitis group ($p = 0.015$). The increase in bacteroidetes is mainly due to increased bacteroidaceae and prevotellaceae. The decrease in Firmicutes is due to decreased lactobacillaceae and erysipelotrichaceae. On principal coordinates analysis, three groups showed clearly separated each other. A phylogenic tree analysis using MOTHUR showed melatonin treatment group was more close to control Group.
Conclusion: This study showed that DSS induced colitis changed structure of intestinal microbiota. Melatonin treatments on DSS colitis could modulate intestinal microbiota and change them close to control.

Contact E-mail Address: nwilliet@yahoo.fr
Introduction: Patient reported-outcomes (PROs) have emerged as a major therapeutic goal in inflammatory bowel disease (IBD) in both clinical practice and clinical trials.
Aims & Methods: Between January to June 2014, the main PROs questionnaires were completed by patients issued from the French national association of IBD patients (association Francois Aupetit (AFA)): quality of life (QOL) (Short IBD questionnaire [SIBDQ] + the Short-Form-36 [SF-36]), fatigue (Functional Assessment of Chronic Illness Therapy-Fatigue [FACIT-F]), work productivity (and Activity Impairment [WPAI]), disability [IBD disability index], and anxiety/depression (Hospital Anxiety and depression scale [HADS]). Simple and multiple regressions were performed to identify factors associated with PROs.
Results: 1211 patients with IBD (females: 61.2%, median age: 45 years. Crohn's disease: 61.2%) could be analyzed. Median disease duration was 13 years. About one third of IBD patients have moderate to severe disease (Harvey-Bradshaw Index ≥ 8 and Walmsley score ≥ 6) and/or history of surgery (29.6%, n = 359), with a stoma in 8.4% (n = 99) (definitive: 39.4%, n = 39) of patients. Ongoing medications were oral 5-aminosalicylates (33.4%), thiopurines (26.2%) and/or anti-Tumor necrosis factor therapy (32.2%). Half of the population reported a low QOL (SIBDQ < 45: 53.1%), a severe fatigue (FACIT-F < 30: 46.8%), and/or a depression (HAD-D > 7: 48.9%). One third of patients had anxiety (HAD-A > 7: 29.8%) and/or moderate (23.8%) or severe (9.9%) disability. Of the 39.7% patients having a job, absenteeism was rare whereas presenteeism, work impairment and overall work impairment were moderate to severe in about one third of patients. Factors associated with a low QOL, severe fatigue, severe disease disability and/or depression were women, unemployment, severe disease activity and tobacco. Altered QOL was also associated with history of surgery and current use of steroids and/or anti-TNF. Obesity and age at diagnosis greater than 30 years were associated with severe fatigue and severe disability, respectively.
Conclusion: Disease burden is very high in IBD patients, with impaired QOL, disability, fatigue, work impairment and anxiety/depression. This is the first nationwide study addressing this issue and investigating all dimensions of PROs in a large cohort of IBD patients.

Contact E-mail Address: kislakpet99@gmail.com
Introduction: Anaemia is an important extraintestinal manifestation in inflammatory bowel disease (IBD) and it is partly associated to disease activity. Limited data are available on the association between different forms of anaemia and disease outcomes.

Aims & Methods: The aim of this study was to analyze the association between the prevalence of different forms of anaemia and treatment strategy and long-term disease outcomes in the population-based IBD inception cohort from Veszprem province between 1977 and 2012. Data of 506 incident CD patients (male/female: 251/255, age at diagnosis: 31.5 years, SD 13.8 years) and 347 incident UC patients (m/f: 200/147, median age at diagnosis: 36, IQR: 26-50 years) diagnosed between January 1, 1977 and December 31, 2010 were analyzed. Both in- and outpatient records were collected and comprehensively reviewed.
Results: Anaemia (iron deficiency, anaemia of chronic diseases or macrocytic anaemia) was present in 57.5% and 30.2% of CD and UC patients. Anaemia was associated to age at onset ($p_{CD}=0.001$, $p_{UC}=0.026$), location/extent ($p_{CD}=0.016$, $p_{UC}<0.001$), perianal fistulas ($p<0.001$) and complicated behavior ($p=0.002$)/time to behavior change ($p_{LogRank}<0.001$). In contrast, there was no association with gender and smoking status in either CD or UC. Need for steroids and/or azathioprine was significantly associated to anaemia in both CD and UC ($p<0.001$ for all both univariate and logistic regression). In addition, anaemia was associated with the need for anti TNF ($p=0.002$), time to azathioprine ($p_{LogRank}<0.001$, $p_{Cox}<0.001$), need for ($p<0.001$) and time to surgery ($p_{LogRank}<0.001$, $p_{Cox}<0.001$) and time to IBD-related hospitalization ($p<0.001$) in CD. In UC, anaemia, was associated with the need for colectomy ($p=0.004$, OR: 5.57, 95%CI: 1.67-18.54) and time to IBD-related hospitalization ($p<0.001$, $p_{Cox}<0.001$).
Conclusion: Anaemia is an indicator of long-term disease course, including treatment steps, hospitalizations and surgery requirements in both CD and UC.

Contact E-mail Address: kislakpet99@gmail.com
Introduction: Association between extraintestinal manifestations (EIM) and disease activity suggest a common pathogenic link. Limited data are available on the effect of EIMs on the long-term disease course in inflammatory bowel diseases (IBD).
Aims & Methods: The aim of this study was to analyze the association between the presence of EIMs (joint, skin, eyes) and treatment steps and long-term disease outcomes in the population-based inception cohort in the Veszprem province database after 1977. A well-characterized Hungarian cohort of 506 incident cases with Crohn's disease (male/female: 251/255, age at diagnosis: 31.5 years, SD 13.8 years) diagnosed from January 1, 1977 were included and data of 347 incident UC patients diagnosed from January 1, 2002 were analyzed (m/f: 200/147, median age at diagnosis: 36, IQR: 26-50 years, duration: 7, IQR 4-10 years). Follow-up data were collected until December 31, 2012. Both in- and outpatient records were collected and comprehensively reviewed.
Results: EIMs (Joint, skin and eyes) were present in 32.2% of the CD and 17.3% of the UC patients. Presence of EIMs was associated in both CD and UC with female gender ($p_{CD}=0.01$, $p_{UC}=0.07$), with ileocolonic and extensive location ($p_{CD}=0.009$, $p_{UC}=0.003$). In CD, there was an association with smoking ($p<0.001$), but not in UC. No association was found in both CD and UC between the presence of EIMs and need for surgery/colectomy. Presence of EIMs was associated with the need for azathioprine ($p_{CD}<0.001$; $p_{UC}=0.004$) and need for steroids ($p_{CD}<0.001$, $p_{UC}<0.001$) in both diseases, and with need for anti-TNFs in CD ($p<0.001$). In Kaplan-Meier analysis there was an association between the presence of EIMs and time to first UC-related hospitalization ($p=0.002$).
Conclusion:: In IBD, the presence of EIM was associated higher maximum treatment steps during the disease course including need for steroids, azathioprine. In CD, there was an association with anti-TNF therapy while in UC with the need for hospitalization.

Introduction: Crohn's disease patients report varying levels of bodily pain, but the relationship of pain with psychological functioning in response to stress and the coping mechanisms used to deal with their illness is poorly understood. We investigated this issue in a community cohort of Crohn's patients.
Aims & Methods: Consecutive adult Crohn's disease patients were recruited from IBD clinics in 5 tertiary hospitals and from our website call, and filled out their demographics, disease status, Harvey-Bradshaw Index (HBI), SF-36 and SIBDQ questionnaires. Patients also completed 5 social questionnaires: Brief Symptom Inventory (BSI, measures psychological symptoms), Carver's COPE (evaluates coping strategies in disease), Family Assessment Device (FAD, measures family functioning and support), Satisfaction with Life Scale (SWLS), and WPAI. Questions related to pain in HBI, SF-36 and SIBDQ were formulated into 3 sub-scores for analysis of correlations with the social questionnaires, using parametric and nonparametric statistics.
Results: Significant Associations of SF-36 Pain with COPE.

COPE SUBSCALE	no pain	mild pain	severe pain
Self-distraction	5 (1,8)	6 (1,8)	6 (1,8)
Denial	2 (1,8)	2 (1,8)	3 (1,8)
Substance use	2 (1,8)	2 (1,8)	2 (2,8)
Emotional support	4 (2,8)	4 (1,8)	5 (2,8)
Behavioural disengagement	2 (1,8)	2 (1,8)	2 (1,8)
Venting	3 (1,8)	4 (1,8)	4 (2,8)
Planning	5 (2,8)	6 (1,8)	6 (1,8)
Acceptance	ns	ns	ns
Religion	2 (2,8)	2 (1,8)	3 (1,8)
Self-blame	3 (2,8)	4 (1,8)	4 (1,8)

The cohort comprised 439 patients, aged mean (± SD) 39.5 ± 14.6 years; women 60.4%; economic status: low 19.6%, moderate 50.3%, high 26.0%. Mean HBI (± SD) was 4.81 ± 5.05, median (min; max) 4 (0; 27). Pain was reported as follows: HBI – none 41.1%, mild 33.2%, moderate/severe 25.7%; SF-36 - none 15.8%, mild 33.7%, moderate/severe 50.5%; SIBDQ – never 29.4%, not much 38.8%, a lot 31.8%. There was more pain reported by HBI (correlation, $p<.01$) and SF-36 ($p<.05$) in females, and by HBI, SF-36 and SIBDQ (all $p<.001$) in poorer patients. There was more pain revealed by HBI, SF-36 and SIBDQ (all $p<.001$) in patients with a higher BSI-GSI (Global Severity Index), and by HBI, SF-36 and SIBDQ (all $p<.003$) in those with poor family functioning. The amount of pain documented by HBI, SF-36 and SIBDQ (all $p<.001$) correlated with WPAI, for "time missed", "percent impairment", "work impairment", and "activity impairment". There was less pain reported by HBI, SF-36 and SIBDQ (all $p<.003$) in patients with higher SWLS. Pain by SF-36 had significant associations with most COPE subscales [Table, values are median (min,max)], likewise for pain measured by HBI and SIBDQ.
Conclusion: HBI, SF-36 and SIBDQ agreed strongly in their assessment of pain. More pain was associated with high psychological stress, poor family functioning and inability to work. More pain required greater use of coping mechanisms, some of which were negative. Less pain meant greater satisfaction with life. IBD specialists can improve patients' well-being by reducing bodily pain.

Introduction: Inflammatory bowel disease (IBD) is increasing globally but data on natural history of IBD in population-based settings in Asia are limited.
Aims & Methods: IBD cases diagnosed between 2011 and 2013 were prospectively followed-up and changes in disease phenotype, probability of medical therapy and surgery were assessed using Kaplan-Meier analysis.
Results: 403 IBD patients [222 ulcerative colitis (UC); 181 Crohn's disease (CD); median age 37 years] followed-up for 608 person-years and median of 18 months (Interquartile range, IQR: 12-23) were included. Cumulative probability of CD behavior change from inflammatory to stricturing or penetrating disease was 19.8%. Isolated terminal ileal disease was associated with a three-fold increased risk of change in behavior (HR, 3.67; 95% CI, 1.04-13.03). Cumulative probability of immunosuppressants and biologics was 58.1% and 11.3% for CD, and

13.0% and 0.9% for UC, respectively. Perianal CD was associated with an increased risk of biologics in the first year (HR 2.62; 95% CI, 1.04-6.59). Cumulative probability of surgery at one year was 9.4% for CD and 0.9% for UC. Patients with penetrating CD have a greater than five-fold increased risk of surgery (HR 5.94; 95%, CI, 1.91-18.48). At one year, the cumulative probability of colectomy for UC was 1.1% in Asia and 0% in Australia. Cancer was reported in 1.5% of patients. Overall mortality rate was 0.7%.
Conclusion: This prospective population-based study showed that early disease course in IBD patients in Asia was comparable to that of Western patients. Progression to complicated disease behaviour and acceleratedn use of immunosuppressants is common in CD. Early surgical rate for UC is low in Asia. Understanding the natural history of IBD in our population can help optimise therapeutics interventions.

Contact E-mail Address: siewchienng@cuhk.edu.hk
Introduction: The Asia-Pacific Crohn's and Colitis Epidemiologic Study (ACCESS) study determined incidence of adult inflammatory bowel disease (IBD) in Asia-Pacific.
Aims & Methods: Incident cases diagnosed from 2011 to 2013 across 18 centres and 13 countries in Asia and Australia were prospectively enrolled. Endoscopy, pathology and pharmacy records were reviewed for complete case capture. We analysed incidence, demographics and disease phenotype.
Results: 1,106 new IBD patients (2011, n = 419; 2012, n = 687; 131 Australia) were identified [606 ulcerative colitis (UC), 463 Crohn's disease (CD), 37 indeterminate colitis (IC)]. Mean annual incidence for IBD per 100,000 was 1.79 (95% CI, 1.66-1.93) in Asia and 21.83 (95% CI, 18.25 – 25.91) in Australia. The three countries with the highest incidence in Asia was India (7.2; 95% CI, 6.39-8.09), Mainland China (3.64; 95% CI, 2.97-4.42) and Hong Kong (2.98; 95% CI, 2.58-3.44). In Asia, annual incidence for IBD was 0.94 in 2011 and 1.69 in 2012. Mean age of diagnosis was 40 (IQR 27-52) and median time from symptom to diagnosis was 5 months (IQR 1-15). UC:CD in Asia and Australia was 0.67 and 1.51, respectively. There were more male patients (58%). Disease behavior (B1: 85.1%, B2: 26.5%, B3: 6.2%, perianal: 19.8%), location for CD and UC did not differ from previous year. 11.3% of CD were current smokers. Complicated CD was more common in Asia than Australia (45.1% vs 23.3%; $P = .001$). A family history of IBD was less common in Asia (2.3% vs 19.2%; $P < .001$).
Conclusion: This large-scale population-based study shows the incidence of IBD to be lower than the West, but continues to increase in Asia. The ACCESS inception cohort reflects the true incidence of IBD in Asia. Global variation in disease incidence supports environmental influence in disease development.

P1544 THE RISK OF OSTEOPOROSIS IS NOT INCREASED IN MICROSCOPIC COLITIS

S. Wildt[1], M. Hitz[2], S. Becker[3], H. Brockstedt[3], O. Bonderup[3], L. K. Munck[1,4]
[1]*Medical Department, Køge Sygehus, Køge,* [2]*Medical Department, Hvidovre Hospital, Copenhagen,* [3]*Medical Department, Silkeborg Sygehus, Silkeborg,* [4]*Faculty of Health and Medical Sciences, University of Copenhagen, Copenhagen, Denmark*

Contact E-mail Address: siwi@regionsjaelland.dk
Introduction: Patients with microscopic colitis (MC) are often elderly postmenopausal woman and hence have an increased risk of developing osteoporosis. Due to chronic inflammation and relapsing disease patients may be exposed to significant cumulated doses of Budesonide. This may result in systemic effects and compromise bone-quality and –mass, resulting in increased fracture risk. The prevalence of osteopenia and osteoporosis in MC is unknown. The primary purpose of this study was to evaluate bone mineral density (BMD) in patients with MC, and secondary to evaluate the influence of Budesonide on bone mineral status and its effect on adrenal gland function.
Aims & Methods: It was a cross-sectional study including patients with documented MC and disease activity within the last 2 years. Exclusion criteria were prednisolone treatment within the last 6 month, malignancy, other chronic diseases of the gastrointestinal tract, liver, pancreas or small bowel resection. Bone mineral density (BMD) was measured with Dual Energy X-ray Absorptiometry (DXA) in hip and spine. Cumulative budesonide dosage until 3 years before inclusion was extracted from online prescription data, medical charts and patient interview. Adrenalcorticotropic hormone (ACTH) measurements and short ACTH–test were performed. Results were compared with gastrointestinal healthy age and sex-matched controls. Non parametric tests were applied.
Results: Fifty patients, 44 women, with MC participated, (35 with collagenous colitis, 15 with lymphocytic colitis). Median age 67 (range 45-93); median disease duration 28 month (range 2-163); median cumulative budesonide dosage was 1008 mg (range 0-5400). Patients with MC were significantly more often smoker (36%) than the control group (10%) (p = 0,001). No difference in other known risks factors for osteoporosis was detected; sex, age, age of menopause, family history or BMI level. No difference in ACTH levels between patients with MC and controls existed. Short ACTH test was normal in all patients (n = 35).
BMD did not correlate with disease duration/time since MC diagnosis while cumulative budesonide dose was associated with lower BMD in hip (Spearman's rho; p = 0.007) and spine (p = 0.021).

	MC (n = 50)	Controls (n = 49)	P-value
Osteopenia*, n(%)	22 (44%)	15 (31%)	0,23
Osteoporosis§, n(%)	6 (12%)	4 (8%)	0,23
T-Score hip, (median & range)	–0,80(-3,12 – +2,02)	–0,60(-2,3 – +1,0)	0,16
T-Score spine, (median & range)	–0,65(-4,03 – +3,22)	–0,45(-3,0 – +1,8)	0,87
BMD hip (g/cm^2), (median & range)	0,848(0,571 – 1,197)	0,866(0,091 – 1,101)	0,48
BMD spine (g/cm^2), (median & range)	0,952(0,160 – 1,327)	1,021(0,718 – 1,242)	0,77

* Def: -1 < T-score > -2,5§ Def: T-score < -2,5

Conclusion: The risk of osteoporosis in patients with MC is not increased. However the cumulative amount of budesonide is associated with lower BMD - directly or confounded by indication. Supplementation of calcium and D-vitamin is recommended. Long-term budesonide treatment does not affect adrenal gland function and seems safe in patients with MC.

Introduction: Vitamin D deficiency is common in Inflammatory Bowel Diseases (IBD) especially in patients with Crohns disease. The reported prevalence differs between 16-95%. Moreover vitamin D deficiency has been associated with active disease and smoking. The incidence of IBD increases with higher latitude and is more frequently diagnosed in the winter when vitamin D levels are lower. These observations support the importance of vitamin D in IBD.
Aims & Methods: The aims of the study were to determine the prevalence of vitamin D deficiency, seasonal variation and association between vitamin D deficiency and disease activity. Outpatients with an established diagnosis of IBD were recruited as a part of a Norwegian multicenter study. Serum 25OH vitamin D3 was analyzed at the same laboratory. Clinical and epidemiological data were collected by interview or from medical records. Possible associations between vitamin D and relevant variables was investigated with t-test, Chi-square and Pearson correlation coefficient.
Results: A total of 411 patients, CD; n = 231 (56%), UC; n = 180 (44%), agreed to participate in the study. Overall, mean age was 40.8 years and 50.9% of the included were men. There were no significant differences between UC and CD with regard to age and gender. Mean disease duration was 8.8 years in UC and 13.6 years in CD. In UC 57% (102/180) had extensive colitis, while 65% (151/231) of CD patients had small bowel involvement (L1 +L3) and 21% (48/231) colonic disease (L2). 40% (166/411) were on current treatment with anti-TNF. Vitamin D status (25OH) was complete in 408/411 patients, and vitamin D

deficiency (25OH vitamin D < 50 nmol/L) was found in 49% (200/408). In CD 53% were deficient, while the comparable number in UC was 44% (p = 0.07). Very low values (<25 nmol/L) with a potential risk to bone health, were measured in 8% (32/408). Of the included patients, 51.8 vs 48.2% had their 25OH level measured during summer and winter, respectively. Vitamin D levels < 50 nmol/L were more common in the winter than in the summer, 56 vs 43%, respectively (p = 0.01). Mean vitamin D levels between summer and winter were: UC; 59.5 vs 49.3 nmol/L (p = <0.01), CD; 53.5 vs 48.4 nmol/L (p = 0.08). In CD vitamin D deficiency was associated with higher SCDAI score (p < 0.05), but no such association was seen with SCCAI scores in UC (p = 0.13). CRP, calprotectin, gender and smoking were not associated with vitamin D deficiency in either of the two patient groups.
Conclusion: Vitamin D deficiency in this IBD population was common, and most common in CD. UC patients had a greater seasonal variation than CD patients. Increased disease activity was associated with vitamin D deficiency in CD.

Introduction: The ECCO-EpiCom study investigates the differences in the incidence, disease characteristics and therapeutical management of inflammatory bowel diseases (IBD) between Eastern and Western Europe.
Aims & Methods: The aim of this study was to analyze the differences in the surgery and hospitalization rates in the 2011 ECCO-EpiCom inception cohort within the first year after diagnosis. Fourteen European (9 Western and 5 Eastern European centers) and one Australian center with 258 Crohn's disease (CD), 380 ulcerative colitis (UC) and 71 IBD unclassified (IBDU) patients (65% from Western, 25% from Eastern Europe, 10% from Australia; female/male: 326/383; mean age at diagnosis: 40.9 years, SD: 17.3 years) participated in the one-year follow-up. Patients' data regarding disease characteristics, surgical procedures and hospitalizations were registered and entered in the web-based ECCO-EpiCom database every third month during the first 12 months after diagnosis.
Results: In Eastern Europe, significantly more CD patients were hospitalized compared to Western Europe/Australia within the first year after diagnosis (34% vs. 21%, p = 0.02, pLogRank = 0.01). Patients with L3 ± L4 (ileocolonic ± upper GI, $pLogRank_{L3} = 0.007$, $pLogRank_{L3+L4} < 0.00$) and complicated disease behavior ($pLogRank_{B1\ vs\ B2/B3} < 0.001$, $pLogRank_{B2\ vs\ B3} = 0.05$) were more frequently hospitalized. In UC, we did not find a geographic difference in the hospitalization rates during the first year (16% vs. 16%, p = 0.93). In CD, more Eastern European patients underwent a surgical procedure within the first year after diagnosis (pLogRank = 0.001). Of note, this was associated to ileal only location and stenotic behavior ($pLogRank_{B2} = 0.09$, $pLogRank_{L1} = 0.008$). Overall, the disease behavior was the major driver for both hospitalization and surgery ($pLogRank_{hosp} < 0.001$, $pLogRank_{surg} < 0.001$). The majority of the surgical procedures were performed within a short time period after diagnosis. In UC, only 1 patient underwent colectomy.
Conclusion: In Eastern Europe, a significantly higher percentage of CD patients had surgery and were hospitalized compared to Western Europe/Australia within the first year after diagnosis. Disease behavior was the major predictor for both surgery hospitalization. In contrast, both hospitalization rates and risk for colectomy was low in UC.

Introduction: The ECCO-EpiCom study aims to investigate the differences in the incidence, disease characteristics and therapeutical management of inflammatory bowel diseases (IBD) between Eastern and Western Europe.
Aims & Methods: Our aim was to analyze the differences in the therapeutical strategy in the 2011 ECCO-EpiCom inception cohort within the first year after diagnosis. Fourteen European (9 Western and 5 Eastern European centers) and one Australian center with 258 Crohn's disease (CD), 380 ulcerative colitis (UC) and 71 IBD unclassified (IBDU) patients (65% from Western, 25% from Eastern Europe, 10% from Australia; female/male: 326/383; mean age at diagnosis: 40.9 years, SD: 17.3 years) participated in the one-year follow-up. Patients' data regarding disease characteristics and medical therapy were registered and entered in the web-based ECCO-EpiCom database every third month during the first 12 months after diagnosis.
Results: Both in CD and UC, a significant difference was found in the probability of highest treatment steps reached within one year after diagnosis between Eastern and Western Europe and Australia (in CD p = 0.001, and in UC p = 0.003 for the maximum treatment steps at one-year between Eastern Europe and Western Europe/Australia). Overall, the disease behavior (B2 and B3) was the driver for immunosuppressive (IS) therapy (pLogRank < 0.001). In Eastern Europe, the total 5-ASA use was higher in patients with L1 (ileal) localization and B1 (non stricturing-non-penetrating) disease behavior (pLogRank = 0.001), in L3 (ileocolonic) location received earlier and more IS (pLogRank = 0.037). In Western Europe/Australia significantly more CD patients were treated with biological therapy (p = 0.04) compared to Eastern Europe. Overall, penetrating disease behavior was the driver for biological therapy (pLogRank = 0.035). In UC, patients in Western Europe/Australia received more steroids (43% vs. 26%, p = 0.03, pLogRank = 0.01) compared to Eastern Europe, however disease extent was not different. In contrast, time to 5ASA, IS, biological therapy and colectomy was not different between Eastern and Western Europe/Australia. Time to 5-ASA and steroid treatment was dependent on the extent ($pLogRank_{5ASA} = 0.007$ and $pLogRank_{steroid} < 0.001$).
Conclusion: We found a significant difference in the maximum treatment step in both CD and UC during the first year after the diagnosis between Eastern and Western Europe/Australia, with higher exposure to biologicals and lower exposure to 5ASA in CD patients in Western Europe/Australia, while only steroid exposure was different in UC.

P1548 NATIONWIDE PREVALENCE OF INFLAMMATORY BOWEL DISEASES IN HUNGARY. A POPULATION-BASED STUDY BASED ON THE NATIONAL HEALTH INSURANCE FUND DATABASE

Z. Vegh[1], P. A. Golovics[1], P. Fadgyas-Freyler[2], J. Gimesi-Országh[2], Z. Kurti[1], B. D. Lovasz[1], P. L. Lakatos[1]

Contact E-mail Address: kislakpet99@gmail.com
Introduction: Regional studies on inflammatory bowel disease (IBD) suggest an increasing prevalence over time, but no nationwide estimate has been published so far.
Aims & Methods: To estimate the IBD prevalence in 2013 in Hungary overall, by disease, and in specific patient segments. Patients were identified according to international classification codes for ulcerative colitis (UC) and Crohn's disease (CD) in in-patient care, day surgery, non-primary out-patient care and drug prescription databases (2011–2013) of the National Health Insurance Fund (OEP), the only nationwide state-owned health insurance provider in Hungary.
Results: Requiring two or more diagnoses of IBD in non-primary care, a total of 55 039 individuals (men: 44.6%) with physician-diagnosed IBD were alive in Hungary in 2013, corresponding to a prevalence of 0.55% (95% CI, 0.55–0.56). The prevalence of CD 0.20% (95% CI, 0.19–0.20), and UC was 0.34% (95% CI, 0.33–0.34). The prevalence both in men and women was highest in the 20-39 year-olds in CD, while it increased with age in UC, and peaked at ages 60–69 years. Prevalence of actively treated disease (defined as two or more IBD-related visits, plus at least yearly one dispensed prescription of IBD-related drugs in 2011-2013) was 0.31% (95% CI, 0.31–0.32), 0.13% (95% CI, 0.27–0.28) in CD and 0.18% (95% CI, 0.17–0.18) in UC.
Conclusion: The Hungarian IBD prevalence based on nationwide database of the National Health Insurance Fund was higher compared with previous estimates based on the Veszprem IBD cohort. While prevalence estimates were robust across different case definitions, once two or more non-primary out-patient care visits were required, only about 60% of prevalent patients were receiving regular IBD-related medical therapy.

P1549 CHANGES OF THE COLONIC WALL STRUCTURE PRECEDE MUCOSAL HEALING IN PATIENTS WITH ACUTE INFLAMMATORY BOWEL DISEASE UNDERGOING ANTI-INTEGRIN THERAPY – PRELIMINARY RESULTS OF A PROSPECTIVE STUDY

M. Ellrichmann[1], J. Bethge[1], A. Arlt[1], S. Zeissig[1], B. Brandt[1], J. Lankau[1], S. Nikolaus[1], S. Schreiber[1]
[1]*Medical Department I, Interdisciplinary Endoscopy, University Hospital Schleswig-Holstein, Campus Kiel, Kiel, Germany*

Contact E-mail Address: mark.ellrichmann@uksh.de

Introduction: Mucosal healing has become an established endpoint to prove the efficacy of new drugs in the therapy of inflammatory bowel disease (IBD). Vedolizumab (Vedo) blocks the translocation of inflammatory cells from the blood stream to the mucosal compartment by binding to a4β7-integrin. Although mucosal healing has been demonstrated in phase III trials in ulcerative colitis (UC), the endoscopic benefit of anti-integrin therapies seems to be delayed. No data are available that demonstrate Vedo induced mucosal healing in Crohn's disease (CD).

Aims & Methods: Aim: In a subgroup of patients within a larger prospective open label trial we examined the effect of Vedo on endoscopic mucosal healing and mucosal histopathology in comparison to inflammatory changes of the colonic wall structure using high resolution endoscopic ultrasound (EUS) before and 2 weeks after initiation of therapy.

Methods: 10 patients (6m) with acute IBD (6UC; 4CD) and 10 healthy controls (HC) (6m) were examined prior and 2 weeks after initiation of open label Vedo therapy at approved standard dose using a forward-viewing radial echoendoscope (Pentax-Hitachi, Japan). Total wall-thickness (TWT) was measured by EUS in the mid sigmoid. Vascularity of the gut wall was evaluated by dynamic contrast enhanced EUS (dCEUS) (contrast agent SonoVue). Contrast kinetics were quantified as Time to peak intensity (TTP). EUS results were compared to macroscopic IBD scores (Mayo-score for UC; SES-CD-score for CD) and histological inflammation scores (HIS).

Results: In HC TWT was 1.7 ± 0.05mm in comparison to 4.2 ± 0.6mm ($p < 0.001$) in patients with acute IBD. Vedo therapy reduced TWT by 38.1% ($TWT_{14d} = 2.6 \pm 0.4$mm; $p = 0.001$) within 2 weeks in comparison to baseline levels.

TTP in HC was 13.8 ± 1.9s; in acute IBD TTP was accelerated to 6.2 ± 1.6s ($p = 0.0002$). After initiation of Vedo therapy TTP almost normalized within two weeks with $TTP_{14d} = 9.9 \pm 0.8$s ($p = 0.006$) compared to baseline. Prior to therapy there was a strong correlation of TWT and endoscopic activity scores. In contrast to TWT, endoscopic activity scores remained unchanged in all patients ($Mayo_{baseline} = 2.2 \pm 0.2$; $Mayo_{14d} = 2.0 \pm 1.5$; $SES\text{-}CD_{baseline} = 7.2 \pm 0.3$; $SES\text{-}CD_{14d} = 6.5 \pm 0.5$). Throughout the therapy, a positive correlation between TWT and HIS ($r = 0.62$; $p < 0.001$) was observed.

Conclusion: EUS of the colonic wall can precisely quantify the level of inflammation in patients with acute UC and acute CD before and after initiation of VED therapy. Only thickening of the different wall layers and changes in vascularity strongly correlate with HIS as gold standard, whereas endoscopic scores remain unchanged. Therefore, mucosal healing seems to be a late marker to evaluate response to VED therapy and is preceded by normalization of the bowel wall architecture. These results await confirmation in the much larger cohort of Vedo-treated patients that presently enter endoscopic and EUS analysis.

P1550 MULTIDISCIPLINARY APPROACH IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE AND ENTEROPATHIC SPONDILOARTHRITIS: USEFULNESS OF A COMBINED ASSESSMENT IN DIAGNOSTIC DELAY AND OUTCOMES

M. Ascolani[1], P. Conigliaro[2], M. S. Chimenti[2], P. Triggianese[2], L. Novelli[2], S. Onali[1], E. Calabrese[1], C. Petruzziello[1], A. Ruffa[1], R. Perricone[2], F. Pallone[1], L. Biancone[1]

[1]*Systems Medicine,* [2]*Rheumatology Unit, Department Systems Medicine, University "Tor Vergata", Rome, Italy, Rome, Italy*

Contact E-mail Address: biancone@med.uniroma2.it

Introduction: Prevalence of Enteropathic-related Spondyloarthritis (SpAe) in inflammatory bowel disease (IBD) shows marked variations (18-45%) and may be underestimated by gastroenterologists. Joint pain is a frequent (22-33%) and relevant clinical manifestation in IBD patients and its management require rheumatological expertise in conjunction with gastroenterologist.

Aims & Methods: In a prospective, longitudinal study, we aimed to assess, in the context of a combined GastroIntestinal and RHeumAtologic "GI-RHe" Unit, to: (1) evaluate the prevalence of undiagnosed ESpA and other rheumatologic diseases in a cohort of IBD patients; (2) describe the ESpA population and the diagnostic delay; (3) explore impact and outcomes of a combined assessment on therapeutic modifications. For this purpose, from November 2012 to December 2014, 269 IBD patients were referred to the dedicated gastroenterology-rheumatology out-patients clinic because of suspected rheumatologic disease. Clinical and laboratoristic assessment was performed by an experienced rheumatologist. Statistic analyses were made using McNemar's test. Relative risk was calculated to compare the probability of systemic medication intake after the combined visit. Data were expressed as mean ± SD.

Results: Ulcerative Colitis (UC) group included 46 patients (15 male, 31 females; age 47.6 ± 15.2 yrs, UC duration 12 ± 9.7 years,), all with clinically inactive disease (partial Mayo score < 3). Crohn's Disease (CD) group included 86 patients (29 males, 57 females, age 47 ± 13.5 years, CD duration 18± 8yrs), clinically inactive (CDAI < 150) in 49 (89%) patients, mildly active (CDAI 150-220) in 6 (11%) patients. Diagnosis of SpAe was performed in 64 (48.5%) IBD patients, including: 38 (59.4%) peripheral SpA (11.8% type I and 47.6% type II), 13 (20.3%) axial SpA and 13 (20.3%) diagnosis of both peripheral and axial SpA. Clinical and laboratory characteristics in these 64 IBD patients with peripheral SpA were: 23 males and 41 females (age 45.06 ± 12.9 yrs), symptoms duration of 95 ± 113.6 months, ESR 23.09 ± 20.35 (mm/h), CRP 5.36 ± 8.2 (mg/dl), HLAB27 positivity in 4 patients, mean ASDAS-CRP of 2.25 ± 0.96. Diagnosis of Osteoarthritis was made in 34.1% (45) IBD patients, Fibromyalgia in 6% (8), Psoriatic Arthritis in 5.3% (7), Rheumatoid Arthritis in 3.8% (5) and Gout in 2.3% (3) of patients. Among these 132 IBD patients with arthralgias, rheumatologic assessment diagnosed new rheumatologic diseases in 68 patients: 45.6% in UC and 44.2% in CD patients. After rheumatological assessment, a higher percentage of IBD patients were treated with disease-modifying anti-rheumatic drugs (after vs before combined visit: 44.7% vs 31.8%; $p = 0.04$, RR 1.3) and/or with anti-COX2 (28% vs 8,3%, $p < 0.0001$; RR 1.7). The use of anti-TNFs significantly increased after combined visit (29.5% vs 16.6%, $p = 0.001$; RR 1.4).

Conclusion: Multidisciplinary care facilitated the diagnosis and the management of rheumatic disorders in IBD patients with a more comprehensive treatment approach, thus leading to an earlier diagnosis and proper treatment of chronic and debilitating inflammatory arthritis.

Introduction: Thrombocytes play an important role in haemostatic and inflammatory processes. Recently, an increasing number of reports have described the contribution of thrombocytes to the pathogenesis of inflammatory bowel disease (IBD). Studies confirmed that thrombocytes of IBD patients remain activated even in remission. The aetiology of this phenomenon, however still remains unclear.

Aims & Methods: Aim is to determine whether biological therapy with infliximab influences the aggregability of thrombocytes in patients with Crohn's disease (CD) and ulcerative colitis (UC) in clinical and laboratory remission and whether there is any significant difference between the aggregability of thrombocytes in IBD patients treated with infliximab in comparison with IBD patients treated with 5-amminosalicylates (5-ASA) and/or azathioprine.

Method: CD, UC and healthy control subjects were studied. 55 patients (average age 34 yrs, 31F and 24M) in total with IBD met the criteria of this study - 18 CD patients treated with infliximab (CD-BT group), 17 UC patients treated with infliximab (UC-BT group), 10 CD patients and 10 UC patients treated with 5-ASA and/or azathioprine (CD-CT group; UC-CT group). For control group 16 healthy volunteers matching criteria were examined. All patients were in laboratory and clinical remission based on clinical indexes of activity and laboratory results. Blood samples after processing were examined on optical light transmission aggregometer using high and low concentrations of agonist (11μM, 1,1μM, 0,55μM epinephrine; 0,2μg/ml, 0,5μg/ml, 2,0μg/ml collagen, 1,0μM a 3,0μM adenosine diphosphate). The results were compared with healthy control group.

Results: For statistical analysis, the Mann–Whitney test was used. Compared with controls, aggregation of thrombocytes was significantly higher by low concentrations of collagen - 0,5μg/ml and 0,2μg/ml; using 0,5μg/ml of collagen in groups UC–BT ($p = 0{,}024$), UC-CT ($p = 0{,}003$); by concentrations 0,2μg/ml in groups CD-BT ($p = 0{,}007$), CD-CT ($p = 0{,}032$), UC-BT ($p = 0{,}029$), UC-CT ($p = 0{,}002$). Significantly higher aggregation was measured when using low concentrations of ADP- 1,0μM, in comparison to controls; in groups CD-BT ($p = 0{,}006$), UC-BT ($p = 0{,}001$) and CD-CT ($p = 0{,}003$). Using low concentrations of epinephrine (1,1μM) lead to significantly higher aggregation in group UC-BT ($p = 0{,}018$) and UC-CT ($p = 0{,}006$) in comparison to controls. CD-BT compared with CD-CT did not show any significant difference in aggregation of thrombocytes by using any of our concentrations of agonists. Significantly higher aggregation when compared UC-BT with UC-CT using concentration 1,0μM ADP ($p = 0{,}014$) was observed.

Conclusion: Our study confirmed that IBD patients, even in clinical and laboratory remission, present with activated thrombocytes in circulation. Biological therapy with infliximab does not significantly affect the activation of thrombocytes in comparison to conventional therapy with 5-ASA and/or azathioprine.

Contact E-mail Address: ms@buhlmannlabs.ch

Introduction: Calprotectin is a multifunctional protein that plays an important role in the diagnosis and follow-up of inflammatory bowel disease (IBD). High levels of calprotectin in stool samples are associated with inflammation of the intestinal tract. We evaluated the analytical performance of a new particle enhanced turbidimetric immunoassay (PETIA) on the clinical chemistry analyser BS-380 (MINDRAY) including linearity, security zone, precision and correlation to BÜHLMANN fCAL® ELISA.

Aims & Methods: The new latex based turbidimetric calprotectin assay BÜHLMANN fCAL® turbo from BÜHLMANN Laboratories AG, Switzerland applies particles coated with anti-human calprotectin (MRP8/14) antibodies: the agglutination is proportional to the calprotectin concentration.

Calprotectin levels are measured in extracts of human stool samples collected with the BÜHLMANN CALEX® Cap Device.
For linearity study serial dilutions were analysed and theoretical values were calculated from measured values of undiluted specimen. The intra-assay precision was performed with 5 different stool extracts containing different calprotectin concentrations in the range from 30 to 1300 µg/g. The inter-assay precision was evaluated by measuring the same samples over a period of 20 days (2 runs per day in 2 replicates). Extracts of 60 fecal patient samples were analysed on the BS-380 and compared with the results generated with the BÜHLMANN fCAL® ELISA.
Results: The assay has been tested to be linear in the range from 12.5 to 4500 µg/g calprotectin in stool. The obtained recovery values were between 96 and 105%. Security zone: Samples up to 8'000 µg/g results in concentrations above the upper assay limit of 2000 µg/g. The intra- and inter-assay precision (CV) were ≤ 10%. Passing and Bablok regression analysis revealed an intercept of -6.5 (-16 to 5) µg/g (95% CI), a slope of 0.91 (0.87 to 0.96) (95% CI), and a regression coefficient (r) of 0.97, suggesting that the new PETIA method showed a good correlation compared to matched ELISA assay.
Conclusion: The new latex turbidimetric procedure for determining calprotectin is an attractive alternative to ELISA allowing random access and full automation of fecal calprotectin quantitation. Moreover, it represents an accurate and precise method to determine calprotectin levels in fecal extracts.

P1553 BODY COMPOSITION PROFILE IS ASSOCIATED WITH ANTI-TNF RESPONSE IN CROHN'S DISEASE PATIENTS

N. S. Ding[1,1], G. Malietzis[2], T. Ganeshanathan[1], M. Yip[1], L. Penez[1], S. Gabe[1], P. F. C. Lung[3], J. T. Jenkins[2], A. Hart[1]

Introduction: Despite the well-established benefits of the administration of biological therapy in Crohn's disease (CD) patients, primary non-response (PNR) and loss of response (LOR) rates remain a major issue [i]. Variation in body composition (BC) in CD patients is an emerging prognostic factor of poor response to treatment. Visceral obesity is characterized by excess of intra-abdominal adipose tissue accumulation while muscle depletion is characterized by a reduced muscle mass (myopenia) and increased infiltration by inter-and intramuscular fat (myosteatosis).
Aims & Methods: This study aims to evaluate the role of Computer Tomography (CT) defined BC parameters on PNR and LOR to anti-TNF therapy for Crohn's disease.
Patients who were commenced on anti-TNF therapy (adalimumab or infliximab) from Jan 2007 - June 2014 and had a pretreatment CT available for analysis were included. PNR was defined by global assessment (clinical and biochemical) of lack of improvement within 6 months of commencement of anti-TNF therapy. LOR was defined as cessation of their anti-TNF in view of clinical deterioration as assessed by their gastroenterologist. CT image analysis *Slice-O-Matic* V4.3 software (Tomovision, Montreal, Canada) was performed as described previously [ii] In brief, total skeletal muscle and visceral adipose tissue (VAT) surface area (cm^2) were evaluated on a single image at the third lumbar vertebrae (L3). The sum of skeletal cross-sectional muscle areas and VAT were normalised for stature (m^2). Mean Muscle Attenuation [MA] was reported for the whole muscle area at the third lumbar vertebra level. Reduced skeletal muscle index (myopenia) and low MA (myosteatosis) were defined using the sex-specific lower quartile as the cut-off value. Increased VAT index (visceral obesity) was also calculated by using the sex-specific upper quartile.
Results: 49 patients of whom 24 (49%) were male with 33 (67%) receiving infliximab and 16 (32%) having adalimumab were included in the analysis. The median age was 39 years (IQR 29-50). PNR was present in 11 (22%) patients. Patients with visceral obesity were more likely to have PNR [OR 7.42 95%(1.12-49.24) p = 0.038]. From the patients that had PNR, 28% had visceral obesity. LOR was present in 18 (37%) patients. Patients with myosteatosis were more likely to have LOR [OR 4.01 95%(1.05-15.22) p = 0.042]. From the patients that had LOR, 44% had myosteatosis. None of the other factors (myopenia, age, gender and type of anti-TNF) were associated with LOR or PNR.
Conclusion: For patients with CD, certain BC profiles may have prognostic effect on the response to medical treatment. Visceral obesity prior to anti-TNF therapy was associated with PNR while myosteatosis was associated with LOR. CT BC-based assessment may identify patients at high-risk of PNR or LOR, which will allow early optimisation of patients undergoing anti- TNF treatments. Muscle depletion is a common feature of all chronic pathologies and may represent a modifiable risk factor in Crohn's patients.

Contact E-mail Address: nayassin@gmail.com
Introduction: Magnetic Resonance Imaging (MRI) is the gold standard assessment tool, which is used in the assessment of fistulising perianal Crohn's disease as an adjunct to clinical assessment. The use of anti-TNF therapy for the treatment of these fistulae relies heavily on clinical and radiological assessments in order to assess response. It is difficult to predict response based on MRI images as they are difficult to interpret. Having a three-dimensional (3-D) fistula model and being able to quantify the changes in the fistula volume would be more beneficial than relying on complex and subjective MRI reports.
Aims & Methods: We aim to use computer software and MRI segmentation to design 3D models of Crohn's anal fistula tracts, measure baseline and 3 years post-biologics treatment fistula volumes and compare with clinical and MRI healing at 3 years.
An initial pilot was conducted where ten MRI images of high and low volume, simple or complex Crohn's perianal fistulae were selected. The surgeon identified baseline and 1-year post-biologics treatment scans. A radiologist was blinded to the selection process. Three-Dimensional fistula models were independently created by the surgeon and radiologist using the previously validated surgical computer software. Thirty-eight patients were selected and volumes were measured at baseline and 3-years post biological therapy.
Three-dimensional fistula volumes were compared. Kappa statistics were used to assess correlation between the healing categories for the three assessment techniques: volume measurements, clinical healing and MRI healing. Binary logistical regression analysis was used to assess predictors of healing as assessed by changes in 3-D anal fistula volumes.
Results: A change in baseline and post-treatment volumes was observed. The three assessment tools were clinical healing, radiological healing and change in 3-D anal fistula volumes. Healing categories were: healed, improved, no change and worse. The agreement between each pair of assessment techniques were measured using Kappa values. There was fair agreement between 3-D volumes and MRI healing (K = 0.34; 95% CI = 0.11,0.57). Poor agreement was noted between 3-D volumes and clinical healing (K = 0.05; 95% CI = -0.15,0.25) and the agreement was also poor for clinical and MRI healing (K = 0.10; 95% CI = -0.12,0.32).
On univariable and multivariable binary logistical regressional analysis, the single independent factor predictive of 3-D volume change was the duration of the disease (p = 0.045). An increased duration of disease was associated with a reduced likelihood of an improvement in volumes (OR = 0.57; 95% CI = 0.33, 0.9) and a five-year increase in the duration of the disease was associated with the odds of improvement being almost twice as low.
Conclusion: MRI volume measurements of 3D Crohn's fistula models provide an accurate assessment tool. The measurement of perianal fistulae volumes is more is useful than using MRI reports alone as it gives a quantitative measure that can be used to assess the efficacy of therapy. Patients with a long duration of disease are less likely to heal. Serial fistula volume measurements should be used for monitoring the response to biological therapy for perianal Crohn's fistula patients.

Introduction: While there is improving standardization of the macroscopic description of colonoscopic findings in Crohn's disease (CD), it is not the case in the Upper Gastrointestinal (UGI) tract. This limits the ability to implicate clinical significance of UGI findings in CD.
Aims & Methods: We empirically applied the Simple Endoscopic Score for CD (SES-CD) in the UGI tract for the first time, and aimed to assess its utility and significance in pediatric CD.
We used prospectively recorded data of pediatric CD patients collected for the ongoing ImageKids study. SES-CD items were scored in real time during upper endoscopy at each of the UGI segments, including esophagus, body, antrum and duodenum; thus the calculated total SES-CD UGI score ranged from 0 to 48. Demographics, clinical findings, biochemical results and physician global assessment (PGA) were also recorded.
Results: 94 children (52 male; mean age 11.4 years ±3.0; range 3.3-17.3 years). Mean wPCDAI 17.2 (±14.3; range 0-52.5). 44% had UGI SES-CD score ≥1 the majority of whom had endoscopic abnormality in the duodenum (32%) with the least frequent finding being esophageal involvement (9%). Median UGI SES-CD was 0 ± 3; range 0-17 (Graph 1). Distribution of scored features per region is demonstrated in Graph 2. Narrowing was not identified in any region. Patients with perianal CD had higher UGI SES-CD score [Median (IQR) 3 (±5) vs 0

(±3); p = 0.01]. There was a poor but significant correlation of UGI SES-CD with ESR and wPCDAI (r = 0.2, r = 0.2 P = < 0.05).
Conclusion: UGI findings were present in almost half of patients in this cohort. UGI SES-CD is an easily reported objective scoring system which may standardize reporting of endoscopic features of UGI CD.

Introduction: Inflammatory Bowel Disease (IBD), which is characterized by chronic inflammation and relapse course, is associated with increasing cardiovascular risks. Although underlying exact mechanism of this relationship is not clearly understood, substantial studies upon chronic inflammatory disorders including rheumatoid arthritis and systemic lupus erythematosus suggested that chronic inflammation plays a crucial role on the development of cardiovascular disease induced by atherosclerosis.
Therefore, non-invasive imaging methods such as carotid intima media thickness (CIMT), flow mediated dilatation and carotid femoral pulse wave velocity, have been utilized to assess the subclinical atherosclerosis. In addition, epicardial adipose tissue (EAT), which is correlated with atherosclerotic coronary artery diseases, can be evaluated easily by a basic imaging method called transthoracic echocardiography. On the other hand, the lack of strict similarity between patients and controls according to cardiovascular disease risk factors revealed conflicting results in patients with IBD compared with healthy control that were evaluated by CIMT.
Aims & Methods: The aim of this study was to evaluate CIMT and EAT in highly selected patients with IBD and healthy controls with regard to cardiovascular risk factors and put forward whether measuring EAT can be used to detect atherosclerosis.
50 patients with IBD (10 Crohn Disease (CD) and 40 Ulcerative Colitis (UC)) and 34 healthy volunteers matched for age and gender were enrolled to the study, 18 to 50 years old. Diagnosis was established according to clinical, endoscopic and histopathological criteria. Exclusion criteria for both groups were history of coronary, peripheral artery, or cerebrovascular diseases, inflammatory disorders other than IBD, chronic renal failure, total colectomy for IBD and cardiovascular risk factors including diabetes mellitus, hypertension, hyperlipidemia, and smoking.
On the day of assessment, detailed medical history and physical examination were performed. In addition, blood samples for laboratory evaluation were also obtained. CIMT and EAT was performed by the same physician blinded to the study groups.
Results: No significant differences observed between IBD group and control with respect to demographic features (Table 1). CIMT and EAT were significantly higher in the IBD group compared to the control group (0.01 and 0.001, respectively). EAT was correlated with CIMT in the IBD group (r = 0.544, p = 0.001).
Table 1: Characteristics and Values of CIMT and EAT of Study Population

Parameters	IBD	Control	*p*-value
Age (yr)	32.5 ± 7.7	31.4 ± 6.4	> 0.05
Gender (M:F)	28:22	16:18	> 0.05
BMI (kg/m^2)	24.1 ± 3.8	24.6 ± 3.2	> 0.05
ESR (mm/h)	23.6 ± 21.5	6.4 ± 5.7	< 0.001
CRP (mg/dl)	21.2 ± 41	4.2 ± 2.6	< 0.05
EAT (mm)	0.452 ± 0.211	0.233 ± 0.110	< 0.001
CIMT (mm)	0.530 ± 0.153	0.416 ± 0.176	< 0.01

Conclusion: This study suggests that patients with IBD without cardiovascular risk factors have increased risk of early atherosclerosis. In addition, both CIMT and EAT are functional imaging methods to detect atherosclerosis in patients with IBD. EAT may be used as an additional diagnostic tool to detect early atherosclerosis in clinical practice.

Introduction: In case of loss of response (LOR) to anti-TNF agents in inflammatory bowel disease (IBD) patients, interventions, such as dose increase and shorten the interval, lead only to a transient improvement and a majority of patients will eventually loss response. Patients could also be successfully switched within class following antibodies development. However, the LOR in some patients is due to a non anti-TNF driven pathway of inflammation. A functional in vitro test (CD-62L shedding) measuring TNF functional blockade should help us identify those specific situations.
Aims & Methods: An in vitro test was used to predict the response to the drug: the shedding of the L-selectin (CD62L) quantified by flow cytometry on the surface of granulocytes before and after the anti-TNF-agent administration. In a subgroup of patients trough level of the drug (TL) and antibodies against the drug (ADA) have been performed in order to compare both tests. The treatment strategy during the 2 years of the study was blinded to the results of the CD62L shedding, TL and ADA and followed clinical symptoms-based interventions or switch by IBD specialists.
Results: From June 2012 to May 2015, 33 IBD treated with anti-TNF agents at Bern University Hospital were followed prospectively (clinicians blinded) to correlated clinical outcome with their response profile tested at baseline. The 22 responders (R) and 11 non responders (NR) had similar clinical characteristics. During a mean follow up of 25 months (range 7- 41; 77 patient-years follow up), 25 medico- surgical events occurred (3 adverse events (AE), 1 CMV colitis, 16 flares treated with medication, 3 intestinal resections and 2 operations of fistula) 9 in R and 16 in NR, which means 14% vs. 60% (p< .001) of the patient-year follow up. The mean calprotectin during follow up (about 1 measurement per patient year available) was 119 (+/-139 SD) for R and 310 (+/-226 SD) for NR. ADA and TL measurement could be performed in 15 patients (45%; 9 R and 6 NR). Only 2 patients developed ADA (one in each group). There was no significant difference in trough levels between R and NR (2.8 vs. 4.8; p = 0.4) and 62% had a therapeutic level (>1.5). Patients stable without need for intervention were 16/21 (84%; 1 AE) in R vs. 1/9 (2 AE) in NR (p < 0.001). In the NR group all the dose optimization failed, whereas in the responders group, interventions that would have been suggested on the basis of TL and ADA have not been performed (clinicians blinded), but were finally not required, based on the favorable clinical outcome.
Conclusion: Testing the in vitro functional blockade of TNF alpha (CD62L shedding) in anti-TNF treated IBD patients seem to be a better long-term predictor than trough levels and antibodies against the drug measurements. This could minimize interventions and therefore reduce costs and risk of adverse events.

P1558 FECAL CALPROTECTIN AND LACTOFERRIN AS PREDICTORS OF POSTOPERATIVE ENDOSCOPIC RECURRENCE IN CROHN'S DISEASE

P. Andrade[1], S. Lopes[1], E. Rodrigues-Pinto[1], J. Afonso[2], F. Magro[1], G. Macedo[1]

Contact E-mail Address: anapatriciarandrade@gmail.com
Introduction: Endoscopic recurrence after surgery for Crohn's disease (CD) is high, with important prognostic value. Endoscopy, the current gold-standard method for assessing postoperative endoscopic recurrence, is an invasive procedure with a limited acceptance by patients. Furthermore, a significant percentage of patients remain asymptomatic despite endoscopic recurrence.
Aims & Methods: To assess the role of fecal calprotectin and lactoferrin in monitoring postoperative recurrence in CD.
CD patients who previously undergone ileocolectomy were proposed for endoscopic revaluation between 2010 and 2014. Endoscopic recurrence was defined as a modified Rutgeerts score ≥ i2b. Stool samples for quantification of fecal calprotectin and lactoferrin were collected the day before preparation for colonoscopy.
Results: We included 99 patients with a mean age of 45 ± 14 years. The mean time between surgery and ileocolonoscopy was 105 ± 97 months. Thirty-four patients had endoscopic recurrence. The Harvey-Bradshaw index did not correlate significantly with the endoscopic score (p = 0.575) or with calprotectin (p = 0.352) and lactoferrin (p = 0.16) levels. The mean value of fecal calprotectin (417.2 ± 484.2 vs. 100.5 ± 201.4 μg/g, p < 0.001) and lactoferrin (39.3 ± 38.9 vs. 15.4 ± 40.3 μg/g, p < 0.001) was significantly higher in patients with endoscopic recurrence. The cut-off of 50 μg/g for calprotectin allowed distinguishing between patients with and without endoscopic recurrence [sensitivity 94%, specificity 55%, positive predictive value (PPV) 52% and negative predictive value (NPV) 95%]. The cut-off 7.25 μg/g for lactoferrin allowed distinguishing between patients with and without endoscopic recurrence (sensitivity 85%, specificity 75%, PPV 64% and NPV 90%). Fecal calprotectin and lactoferrin

showed a significant correlation in patients with endoscopic recurrence ($K = 0.729$; $p < 0.001$).
Conclusion: Fecal calprotectin and lactoferrin have high diagnostic accuracy to detect postoperative endoscopic recurrence in CD, and significantly correlate with endoscopic scores, thus having an increasing impact as an alternative method to colonoscopy.

P1559 NITRIC OXIDE AS PREDICTOR OF STEROID-RESISTANCE IN ACUTE FULMINANT COLITIS

P. M. Hellström[1], M. A. Halim[1], T. Ljung[1], M. Holst[1], D.-L. Webb[1]
[1]*Medical Sciences, Uppsala University, UPPSALA, Sweden*

Contact E-mail Address: Per.Hellstrom@medsci.uu.se
Introduction: Nitric oxide (NO) is up-regulated by the induction of nitric oxide synthase (iNOS) in inflammatory bowel disease. NO gas can be used as a marker of inflammatory activity in the gastrointestinal tract. In parallel, the NO oxidation products plasma nitrite and nitrate (NOx) can reflect ongoing inflammatory activity. We analyzed rectal NO before and after three days, as well as plasma NOx in patients on glucocorticosteroid (GC) therapy in hospitalized patients. The aim of the study was to evaluate the relationship of rectal luminal NO and circulating plasma NOx in acute fulminant colitis to the outcome as therapeutic response or colectomy.
Aims & Methods: Fifty patients with median age 41 (range 20-78) years, hospitalized due to acute fulminant colitis and received treatment with high-dose GCs. Luminal nitric oxide was analyzed with chemiluminescence with the use of a Foley catheter balloon before onset of therapy and day 3 of treatment. NOx was measured by nitrite/nitrate colorimetric assay. NO levels and plasma NOx were compared to clinical disease activity index and C-reactive protein (CRP).
Results: Thirty-two responded to GC treatment whereas 18 did not, resulting in colectomy. The responders had higher luminal NO than non-responders (day 1: 12525 ± 2600, day 3: 15590 ± 4157 ppb) vs non-responders (day 1: 2874 ± 1283, day 3: 1137 ± 297 ppb) ($p < 0.0114$). Using an optimal cut-off NO level of 2250 ppb, sensitivity and specificity was 86% and 81% for colectomy ($p < 0.0001$). The area under the curve was 0.88 and likelihood ratio 4.8. Similarly, plasma NOx was higher in responders vs non-responders (day 1: 6.2 ± 0.3 vs 3.9 ± 0.4 umol/L) ($p < 0.0001$). Using plasma NOx, we found a corresponding cut-off at 5 umol/L with sensitivity 87% and specificity 87%. The area under the curve was 0.88 and likelihood ratio 6.7. Luminal NO was also correlated to plasma NOx ($r = 0.33$, $p = 0.0205$). In the responder group, CRP levels decreased (day 1: 22.31 ± 2.95, day 3: 15.69 ± 3.57 mg/L), whereas among non-responders CRP levels increased (day 1: 45.83 ± 11.10, day 3: 76.35 ± 16.96 mg/L) ($p < 0.0167$). Kaplan-Meier analysis showed that patients with baseline NO levels lower than 2250 ppb were at a significantly higher risk of colectomy within one month from onset of GCS treatment ($p < 0.0001$). Twelve out of 18 (67%) in patients with day 1 NO $<$2250 ppb were colectomized, the corresponding number of patients with NO $>$2250 ppb was 3 out of 32 (9%). In a similar manner, using plasma NOx $<$5 uml/L for analysis, we found 13 (72%) to be colectomized, and with $>$5 umol/L only two (6%).
Conclusion: NO and its oxidation product NOx are useful biomarkers of inflammatory activity in the gut. However, with more intense inflammation and mucosal damage, less NO is elaborated. Luminal NO and its downstream oxidation product NOx can be used as a sensitive biomarker to predict steroid-resistance in the acute fulminant colitis.

Contact E-mail Address: ppavlidis@nhs.net
Introduction: A poor response to anti-TNFα treatment in patients with Crohn's disease (CD) is not infrequent. As new biologics targeting other immune pathways become available, early prognostic markers of anti-TNFα treatment failure are needed to inform treatment decisions. Faecal calprotectin (fcal) has been shown to be an excellent surrogate marker of intestinal inflammation [1] and a useful prognostic marker of relapse in CD [2], correlating well with endoscopic disease activity scores [3]. Furthermore, a recently published study of gene expression profiling to detect prognostic markers of early response to anti-TNFα therapy, identified the two genes coding for the calprotectin subunits (S100A8, S100A9) to be among the most highly expressed gene transcripts in non-responders [4].
Aims & Methods: We hypothesised that a faecal calprotectin measurement after anti-TNFα induction would predict the response to these treatments at 6 months. We analysed results from a prospectively-kept database for CD patients, who commenced infliximab (IFX) or adalimumab (ADA) therapy at standard induction regimens and doses for active, inflammatory disease. As part of routine clinical practice, serial fcal measurements were obtained at pre-defined interval (before and after induction: IFX 8-12 weeks; ADA 6-8 weeks – i.e. after the third dose of anti-TNF, but before the fourth). Remission was assessed at 6 months and defined by Harvey Bradshaw Index (HBI $<$ 5). Fcal was measured using a commercially available ELISA kit (Buhlmann). Continuous variables are presented as medians followed by interquartile range.
Results: 26 patients had serial fcal at the set time points (16 IFX; ADA 10; median age: 32yrs, disease duration: 5yrs (3, 8), location: 17 ileocolonic, 8 colonic and 1 ileal]. At 6 months, 16/26 (62%) patients were in remission. Those in remission at 6 months were found to have significantly lower fcal post-induction [72 (40, 135) vs. 259 (159, 550)]. A cut-off of fcal $>$175mcg/g returned a 70% sensitivity and 94% specificity for predicting non- responders (likehood ratio: 11.2, area under curve: 0.94, $p = 0.0002$). HBI and fcal levels before anti-TNFα induction did not differ between the two groups (responders, non responders HBI 11 vs. 12.5, $p = 0.73$, fcal 804 vs 868, $p = 0.47$, respectively).
Conclusion: Fcal measurement after the third dose of anti-TNFα is a highly-accurate predictor of non-response. This early measurement could be used to identify patients who would benefit from an alternative treatment strategy.

Contact E-mail Address: ppavlidis@nhs.net
Introduction: Intestinal graft versus host disease (iGvHD) is a common complication of haematopoetic stem cell transplantation (HSCT) associated with significant morbidity and mortality. Gastroenterologists are frequently consulted to assist with the diagnosis, which is based on histological findings. Endoscopic evaluation practice varies between units with some favouring symptom guided investigations and others advocating lower gi endoscopy with rectosigmoid biopsies as the approach with the highest sensitivity.
Aims & Methods: In this study we describe the diagnostic efficacy of upper versus lower gi endoscopy (and biopsy sampling) in supporting the diagnosis of iGvHD. Post HSCT patients with symptoms suggestive of iGvHD who underwent simultaneous upper and lower gi endoscopy in one centre over the last 3 years were identified through prospectively kept electronic patient records. All of them had biopsies taken during procedure from relevant areas (duodenum, terminal ileum, right colon, L colon/rectosigmoid). Continuous variables are presented as medians followed by interquartile range. Categorical comparisons were performed using chi-square test. Predictive values are followed by 95% confidence intervals.
Results: We identified 32 eligible patients [median age: 50 (33, 60), female: male ratio 1:1). Presenting gi symptoms included diarrhoea: 29/32 (88%), anorexia/weight loss: 14/32 (44%), nausea/vomiting: 11/32 (34%), abdominal pain/bloating: 4/32 (13%), rectal bleeding: 3/32 (10%). The median time post HSCT was 107 (55, 178) with 15 patients presenting in $<$100 and 17 in $>$100 days post liver transplantation. There were 8/15 (53%) patients diagnosed with acute GvHD and 10/17 (59%) with chronic GvHD affecting the gut. There was no difference in the gi segments involved in acute and chronic forms of iGvHD, with 18/18 patients having left colon/rectosigmoid, 14/18 (77%) right colon, 8/18 (44%) terminal ileal and 3/18 (16%) duodenal involvement. Duodenal biopsies were positive in only 3/8 (38%) patients with small bowel involvement based on a positive terminal ileal biopsy. The negative predictive value of duodenal biopsies for the diagnosis of iGvHD was 68% (53, 81).
Conclusion: iGvHD in either acute or chronic form appears to always affect the rectosigmoid/left colon. A flexible sigmoidoscopy with biopsies should suffice to rule in or out the diagnosis. Duodenal biopsies do not appear to provide any additional diagnostic benefit in the context of iGvHD investigation.

P1562 DID THE 2009 ECCO GUIDELINES INFLUENCE SCREENING FOR INFECTIONS IN PATIENTS STARTING BIOLOGIC THERAPY?

R. N. Patel[1], S. Stevens[1], N. Stafford[1], L. Evans[1], G. Smith[1]
[1]*Gastroenterology, Charing Cross Hospital, London, United Kingdom*

Contact E-mail Address: rajan.patel@nhs.net
Introduction: In response to concerns regarding the safety of immunomodulator therapy, the European Crohn's and Colitis Organisation (ECCO) published consensus guidelines in 2009 on screening for preventable infections. Investigations for hepatitis B virus (HBV), human immunodeficiency virus (HIV), tuberculosis (TB) +/- hepatitis C virus (HCV) are all recommended prior to initiating biologics.
Aims & Methods: We aimed to assess the proportion of patients being screened in routine clinical practice pre and post publication of the ECCO opportunistic infection (OI) guidelines. A retrospective review of inflammatory bowel disease patients treated with biologic therapy until February 2015 at Imperial College Healthcare NHS Trust was performed.
Results: 187 patients (42.2% male) were prescribed biologic therapy (124 infliximab, 58 adalimumab, 5 certolizumab) between 2001 and 2015. Median age at

initiation was 37 years (range 17 - 87 years). 60.4% were receiving concomitant immunosuppressive, 43.3% had prior surgery and 21.9% had fistula.
Testing for HepB sAg (33.9% vs. 69.4%), HepC Ab (32.2% vs. 76.4%), HIV Ab (23.5% vs. 72.2%) and TB Elispot (9.6% vs. 65.3%) all significantly increased after the publication of ECCO OI guidelines ($p < 0.001$). HepB sAb testing (9.6% vs. 26.4%, $p = 0.002$) also increased but there was no significant change in testing for HepB cAb (8.7% vs. 6.9%, $p = 0.67$). Chest radiographs (CXR) were performed in 87% and 86.1% of patients pre and post guidelines, respectively ($p = 0.87$).

Table 1: Influence of ECCO Guidelines (2009) on screening for infections in patients starting biologic therapy

	All, n (%)	Pre ECCO, n (%)	Post ECCO, n (%)	p value
Hep B sAg	89 (47.6)	39 (33.9)	50 (69.4)	<0.001
HepB cAb	15 (8)	10 (8.7)	5 (6.9)	0.67
HepB sAb	30 (16)	11 (9.6)	19 (26.4)	0.002
Hep C Ab	92 (49.2)	37 (32.2)	55 (76.4)	<0.001
HIV Ab	79 (42.2)	27 (23.5)	52 (72.2)	<0.001
TB Elispot	58 (31)	11 (9.6)	47 (65.3)	<0.001
CXR	162 (86.6)	100 (87)	62 (86.1)	0.87

Conclusion: Screening for infections prior to starting biologic therapy has got considerably better since the introduction of the first ECCO OI 2009 consensus guidelines, but remains substandard. Shortfalls in the assessment of hepatitis B virus infection and vaccination status with HepB cAb and sAb is concerning. The publication of the second ECCO OI evidence-based consensus in 2014 along with a practical checklist for the prevention of infections may trigger further improvements.

P1563 CLINICAL ROLE, OPTIMAL TIMING AND FREQUENCY OF MEASUREMENT OF SERUM INFLIXIMAB LEVELS AND ANTI-INFLIXIMAB ANTIBODY TITERS IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE

R. Bor[1], K. Farkas[1], A. Bálint[1], Á. Milassin[1], M. Rutka[1], M. Matuz[2], F. Nagy[1], A. Fábián[1], Z. Szepes[1], T. Molnár[1]

Introduction: The introduction of biological treatment has made a major breakthrough in the management of inflammatory bowel disease (IBD). However, a substantial number of patients show only partial response, and in approximately 40% of initially responders loses its effect. The cessation of therapy or the switching to another biological drug currently depends mainly on the clinical judgement. Serum infliximab (IFX) and anti-infliximab antibody (ATI) levels are objective parameters, that may have a great role in the therapeutic decisions, but the optimal timing and frequency of their measurements are still not clearly defined.

Aims & Methods: Our aim was to assess the optimal timing and frequency of sampling for measurement of serum IFX and ATI levels during biological therapy. 34 IBD patients receiving maintenance IFX therapy were prospectively enrolled: 17 patients were in complete remission (responder group) and 17 patients showed inadequate response including partial and loss of response or the need for dose escalation. Blood samples were collected before and two and six weeks after the administration of IFX.

Results: Our results confirmed that the expression of ATI in the circulation is transient. Using the three points' measurements the ATI expression showed significant difference between the responder and inadequate responder group (5.9% vs 41.2%; $p = 0.039$), however, single sampling of the ATI was insufficient for predicting the therapeutic response. On the contrary, the mean value of week 0 serum IFX levels were significantly higher in the responder group (3.35 ± 1.65 vs.1.41 ± 1.20; $p < 0.001$) without further difference on the second and sixth week. 79.4% of patients could have been categorized correctly based on the cut-off value of serum IFX level 2.246 μg/ml at week 0. However, prediction of therapeutic response was substantially improved when IFX and ATI levels were measured three times simultaneously (91.2%)

Conclusion: Our results suggest that the simultaneous measurement of serum IFX levels and ATI titers not only at week 0, but also at week 2 and week 6 after the administration significantly increase the diagnostic accuracy for the therapeutic decision in uncertainly responded patients and can serve as a highly precise tool for the evaluation of therapeutic response in the questionable situations.

P1564 ULTRASONOGRAPHY PROVIDES A VALID ALTERNATIVE TO MAGNETIC RESONANCE ENTEROGRAPHY IN CROHN'S DISEASE

Introduction: Objective measures of disease activity in Crohn's Disease (CD) are necessary[1], but no gold standard exists for evaluation of inflammation in the small intestine.[2] Magnetic Resonance Enterography (MRE) is usually recommended over ultrasonography (US).[3] However, US is inexpensive, easily repeatable, and patient friendly. Prior studies comparing MRE and US have mainly focused on whether inflammation was present or not rather than on grading disease severity.[4]

Aims & Methods: Our aim is to compare objective measures of severity of small intestinal inflammation in Crohn's Disease (CD) assessed with bowel ultrasonography (US) and magnetic resonance imaging (MRE) and to correlate these to established clinical and biochemical biomarkers.
We included 20 patients with moderate to severe CD. MRE and US were performed less than one week apart applying standard protocols estimating maximum bowel wall thickness, length of disease involvement, and vascular pattern. Clinical scores, blood samples, and fecal markers were obtained at scan time.

Results: For the most affected segments the two methods showed good agreement for bowel wall thickness (US: median 7.0 mm (range: 4-11) and MRE: median 6.5 mm (range 3-14) mm, Spearman's $rho = .81$, $p < 0.001$) and length of involvement (US: median 10 cm (range: 3-57) and MRE: median 12 cm (range 1-70), $rho = 0.62$, $p < 0.05$). 95% limits of agreement were 0.5 mm (range -3 to 4) for thickness and 1.3 cm (range -11 to 14) for length. Inter rater variability between US and MRE ranged from $kappa = 0.54$ to 0.64 for thickness and $kappa = 0.46$ to 0.64 for length of inflamed segments. Data from both methods showed only weak correlation with CRP, f-calprotectin and clinical indices.

Conclusion: US is a valid and inexpensive alternative to MRE for assessing maximum length of inflammation and bowel wall thickness in CD. Objective structural findings may improve classification of disease severity in addition to existing clinical markers.

Introduction: Peyer's patches (PPs) are aggregates of lymphoid follicles mainly located in distal ileum and play a major role in mucosal immunity as an inductive site. Because gut flora or food antigens interact with PPs and are involved in the pathogenesis of ulcerative colitis (UC), it is speculated that immune responses in PPs play an important role in determination of the clinical course of UC patients. Using narrow-band imaging with magnifying endoscopy (NBI-ME), we recently reported that patients with UC have altered PPs. However, clinical significance of alterations in PPs is unapparent. In this study, we aimed to evaluate the relationship between clinical course and NBI-ME images of PPs in UC patients.

Aims & Methods: Fifty UC patients with clinical remission (partial Mayo score ≤ 2) who underwent total colonoscopy were enrolled from April 2009 to March 2013. NBI-ME images of PPs were collected, and changes in the villi were evaluated by "villi index" as the sum of three categories: irregular formation, hyperemia, and altered vascular network pattern (Hiyama S. et al,

Digestion 2013). Patients were divided into two groups based on "villi index": low (L) type = 0 or 1, and high (H) type = 2 or 3, and sustained clinical remission rate within 2 years after colonoscopy was evaluated. Temporal alteration of PPs images was also analyzed among 14 patients who underwent second PPs observation within 2 years after the first colonoscopy.
Results: UC patients included 24 men and 26 women, and mean age was 45.4 (17-75) years. Fifty-eight percent (29/50) of the patients had L type-PPs, while 42% (21/50) had H type. Age, gender, disease duration, endoscopic score and extent of disease involvement were not associated with the alteration in PPs. The sustained clinical remission rate of patients with L type-PPs was significantly higher than that of patients with H type-PPs [76% (22/29) v.s. 38% (8/21); $p < 0.01$]. There was no relation between sustained clinical remission rate and other clinical factors except older age (≥40). Multivariate analysis revealed that L type-PPs was an independent factor for sustained clinical remission (odds ratio: 7.7, 95% confidence interval 1.92 to 40.7; $p < 0.01$). Among 14 patients with repeated observation of PPs [mean interval: 19 (8-24) months], the type of PPs (L or H type) were unchanged at the time of first and second colonoscopy in 12 patients (86%).
Conclusion: UC patients with severe endoscopic alterations in PPs are at high risk of relapse, and the feature of PPs rarely altered in short interval. Observation of PPs using NBI-ME may be a useful method to predict clinical course of UC.

P1566 THE PREDICTIVE FACTOR REGARDING RELAPSE IN PATIENTS WITH ULCERATIVE COLITIS AFTER ACHIEVING ENDOSCOPIC MUCOSAL HEALING

S. Nishimura[1], Y. Takuya[1], K. Yamakawa[1], K. Watanabe[1], S. Yazumi[1]
[1]*Division of Gastroenterology and Hepatology, Digestive Disease Center, Kitano Hospital, Osaka city, Japan*

Contact E-mail Address: s-nishimura@kitano-hp.or.jp
Introduction: Endoscopic mucosal healing (MH) has been proposed as the therapeutic goal in the treatment of patients with ulcerative colitis (UC). Despite achieving endoscopic MH, however, relapse of UC was found.
Aims & Methods: To validate risk factors of UC-relapse is useful for establishing therapeutic strategy in maintenance of remission and MH. The aim of this study is to evaluate the predictive factor for relapse in patients with UC after achieving endoscopic MH. From April 2010 to February 2015, 298 patients with UC who had been treated at Kitano hospital were analyzed, retrospectively. Clinical and endoscopic activities were evaluated with Lichtiger index and Mayo score, respectively. Endoscopic MH was defined as Mayo score of less than one. The relapse of UC was defined as any recurrence of UC-related symptoms. Cumulative relapse rate after achieving MH was evaluated and we analyzed the predictive factors for relapse in UC patients after achieving endoscopic MH by Cox regression analysis.
Results: Of 298 UC patients, total 88 patients (29.5%) could achieve endoscopic MH. In 21 of 88 patients with endoscopic MH (23.9%), the relapse of UC was found. The median time at relapse of UC was 1.2 years after achieving MH. Based on Kaplan-Meier analysis, the cumulative relapse rate at 1, 3 and 5 years after achieving MH were 12.1%, 29.8% and 36.2%, respectively. The cumulative relapse rate of Mayo-1 group tends to be high compared to that of Mayo-0 group (23.1% (Mayo-0) and 45.9% (Mayo-1) at 5 years, respectively), although there was no significant difference of cumulative relapse rate between Mayo-0 and Mayo-1 group ($p = 0.312$). Moreover, Cox regression analysis demonstrated that the use of immunomodulator was predictive factor for relapse in UC patients after achieving endoscopic MH ($p = 0.035$).
Conclusion: Our data suggest that, even if achieving endoscopic MH, we should keep the maintenance treatment deliberately in UC patients required the treatment with immunomodulator.

Introduction: Adalimumab (ADA) has been widely used in patients with moderate to severe Inflammatory Bowel Disease (IBD) to induce and maintain remission.However, a proportion of patients experience primary treatment failure and some lose response over time.
Aims & Methods: We wished to examine the correlation between ADA drug trough, antibody(Ab) levels and clinical activity defined by clinical and biochemical parameters. Patients receiving ADA, between 18 and 80 years were recruited from the IBD service. Clinical and physical parameters including weight and height, Harvey-Bradshaw Index (HBI), Partial Mayo Score (PMS), CRP and additional medication use were recorded. Two serum samples were collected from each patient ≤48 hours prior to their next scheduled ADA dose. ADA trough and Ab levels were measured by ELISA using commercially available Abs (MP Biomedical). ADA and Ab concentration were normalized to a standard curve using exogenous ADA and HRP-conjugated goat anti-human λ chain Ab (Serotec) respectively.A low trough level of < 0.63μg/ml and -ve Ab level of < 0.43μg/ml were determined using the mean concentration +- 3SD in patients and controls.A HBI of > 5 and PMS of > 3 were defined as clinically active disease.
Results: In total, 42 patients were included; mean age 44 (ranges 27-70), 52% (n = 22were male. In all, 36% (n = 15) had Ulcerative Colitis (UC) and 64% (n = 27) had Crohn's Disease (CD). The mean height and weight were 169 cm and 75kg, 38% (n = 17) were overweight BMI > 25 and 12% (n = 5) were obese BMI > 30. The mean duration of therapy was 3 years and 2.4% (n = 1) were on concomitant immunosuppressants. All patients were receiving 40mg subcutaneously with the majority on fortnightly dosing, 71% (n = 30). The mean HBI score and PMS were 2.5 and 0.4 respectively. In total, 17% (n = 7) had clinically active disease and the mean CRP was 5.5mg/dl(0-51). In all, 4.8% (n = 2) had low trough levels while 64% (n = 27) had a high ADA Ab level. Neither of the 2 patients with a low trough level had clinically active disease and only 1 had a significant Ab level. Neither Ab status nor mean Ab level correlated with disease activity, biochemical activity, dosing schedule or obesity. Similarly, low trough level or mean drug level did not vary according to these parameters (Table 1). One explanation for this finding could be that this study includes patients who are responders and are well maintained on ADA. In addition, very few had a low trough level (n = 2) presumably because 12 of our patients had already been escalated to a shorter dosing interval. Future observation of this cohort as well as a prospective study for patients commencing ADA may show correlation between trough level, Ab status and long-term outcome.
Conclusion: In our cohort, there seems to be a lack of correlation between ADA Ab and trough levels, with neither being predictive of clinical activity.

Introduction: Thiopurine-related drug response in treatment of patients with Crohn's disease (CD) is still incompletely understood. Thus, therapeutic monitoring of thioguanine nucleotides (TGN) and methylthioinosine derivatives (MMPR) has been suggested to improve thiopurine therapy, however with limited success. The comprehensive assessment of thiopurine metabolite pattern instead of determination of total TGN and MMPR levels has been suggested to be beneficial for prediction of thiopurine response.
Aims & Methods: To evaluate the association between eleven thiopurine metabolites and mucosal healing in patients with CD.
Patients with CD on maintenance treatment with azathioprine (AZA) and a stable dose for at least 4 weeks were eligible. We established a novel highly sensitive liquid chromatography-tandem mass spectrometry method for simultaneous quantitation of eleven thiopurine metabolites including mono-, di-, and triphosphates of thioguanosine (TGMP, TGDP, TGTP), methylthioinosine (meTIMP, meTIDP, meTITP), methylthioguanosine (meTGMP, meTGDP, meTGTP), and thioinosine (TIMP, TIDP, TITP). Furthermore, thiopurine S-methyltransferase (TPMT) activity in red blood cell concentrations (RBC) was determined. Blood collection was performed on day of the ileocolonoscopy. Mucosal healing was defined as the absence of any ulcerated lesions on colonic and (neo-) terminal ileal mucosa.
Results: In total 101 patients (f/m = 54/47, median age: 25 years) were included. The median AZA dosage was 2.12 mg/kg/d (range: 0.28-3.13 mg/kg/d) which was stable for median 26 months (range: 1-111 months) before blood collection. Patients without achievement of mucosal healing (non-responder, n = 60) showed significantly lower concentrations of meTIDP (p = 0.04) and meTITP (p = 0.02) in RBC. After stratification of patients in normal and intermediate metabolizers for TPMT the association between non-response and lower RBC concentrations of meTIDP (p = 0.008) and meTITP (p = 0.004) held true in patients with normal TPMT activities (n = 91). No significant differences between

Abstract number: P1567

responders and non-responders were found for the isolated thioguanosine phosphate levels (TGMP, TGDP, TGTP).
Conclusion: There was no significant correlation of isolated thioguanosine phosphate levels (e.g. TGDP, TGTP) and mucosal healing. Lower concentrations of methylthioinosine levels in non-responders support the impact of the TPMT metabolizer phenotype regarding thiopurine response.

P1570 HAEMATOLOGICAL AND INFLAMMATORY MARKERS FOR NON-INVASIVE DIAGNOSIS OF CROHN'S COLITIS

S. Galea[1], N. Azzopardi[1], P. Ellul[1], G. Balzan[1]
[1]*Medicine, Mater Dei Hospital Malta, Msida, Malta*

Contact E-mail Address: stephanieagalea@gmail.com
Introduction: Red Cell Distribution Width (RDW) is associated with active inflammatory bowel disease, as shown in recent studies. [1] RDW is cost-effective, readily available and may be used as a rapid, non-invasive tool in diagnosing disease activity. In our study, results show that C-Reactive Protein (CRP) and Erythrocyte Sedimentation rate (ESR) have low sensitivities (54% and 55%) and specificities (71% and 90%) in detecting Crohn's disease (CD) activity. [2] We then used RDW, platelet count, ESR and CRP to create a risk score which may be used to predict disease activity in CD.
Aims & Methods: Serum samples of CRP, ESR, platelet count and RDW in CD patients were collected on the day of colonoscopy and compared with CD activity according to endoscopic findings and histology results. A total of 308 endoscopic procedures on 161 CD patients were performed over a 48 month period. 89 of these patients were male with a median age of 40.2 years (9-85 years). Disease activity was determined according to endoscopic and histologic findings at colonoscopy. A risk score for disease activity was then created by awarding 1 point to each elevated marker (CRP > 10mg/L, ESR > 14mm1stHr, platelet count > 400,000 and RDW > 14.9%) and the sensitivity and specificity for each marker was calculated. Independent sample t-test was calculated in order to determine the statistical significance of elevated biomarkers in active colitis.
Results: Confirmation of active colitis was present in 191 colonoscopies (62%) at endoscopy and as reported by histology results. RDW, platelet counts, ESR and CRP were significantly elevated in patients with active CD (independent samples t test $p < 0.005$) when compared with patients with quiescent disease.
Table 1: shows the sensitivities and specificities for each biomarker as calculated in the risk score for active disease

Serum Biomarker	Sensitivity (%)	Specificity (%)
RDW	43%	73%
Platelet count	21%	93%
ESR	68%	40%
CRP	44%	64%

90% of patients with a score of 4 ($n = 10$) and 89% of patients with a score of 3 ($n = 37$) had histologically active disease at endoscopy. Meanwhile, 66.6% of patients with a score of 2 ($n = 72$), 53% of patients with a score of 1 ($n = 91$) and 54% of patients with a score of 0 had active disease at endoscopy. There was a statistically significant difference ($p < 0.0001$) between the mean risk score in histologically quiescent disease (mean 0.9145, $n = 117$) and the mean risk score in histologically active disease (mean 1.461, $n = 191$).
Conclusion: RDW when used as a single biomarker has a low sensitivity in detecting active CD. However, the presence of three or more elevated biomarkers should arouse suspicion of ongoing inflammation.

Introduction: Adalimumab (ADM; Humira®) is a human monoclonal antibody targeting tumour necrosis factor alpha (TNFα) used in the treatment of inflammatory bowel disease (IBD). It has been shown that ADM serum concentrations are associated with clinical outcome and that some patients develop antibodies towards ADM. Therapeutic Drug Monitoring (TDM) as well as determination of the anti-drug antibody response is therefore recommended. A number of TDM assays are currently available, but often lack specificity due to the use of non-specific, polyclonal antibodies (pAb) to detect TNFα-bound ADM.
Aims & Methods: Aim 1) To generate and characterize a panel of ADM specific monoclonal antibodies (MA-ADM); 2) to select MA-ADM suitable to be used in ADM assay; 3) to study the effect of neutralizing and non-neutralizing antibodies in the ADM assay; 4) to apply the ADM assay on serum samples derived from a cohort of ADM treated patients.
Methods Using hybridoma technology, two panels of MA-ADM were generated and characterized. MA-ADM were screened for reactivity towards infliximab, golimumab and human IgG using ELISA. The neutralizing capacity of the ADM-specific MA was determined by incubation of ADM with a two-fold excess of MA-ADM followed by measuring the residual binding (capacity) of ADM to TNFα using a goat anti-human IgG conjugate. A competition experiment in which an excess of cold MA over conjugated MA was used to perform epitope binning. MA were subsequently evaluated for their ability to detect ADM in the assay using ADM spiked buffer and serum samples. After selection of one MA, the impact of (non-)neutralizing antibodies on the determination of ADM in this MA-based assay was investigated. ADM concentrations in 96 serum samples of ADM treated patients were determined using the assay.
Results: Thirty-two MA-ADM were generated of which 11 were adalimumab specific. Four MA revealed a neutralizing capacity between 78-95% and five less than 11%. Epitope binning revealed at least 9 non-identical epitopes. MA-ADM40D8 was selected as a conjugate to determine adalimumab in a TNFα coated solid-phase ELISA (MA-based ELISA). The four neutralizing antibodies could completely hamper the determination of ADM in the MA-based ELISA while the non-neutralizing antibodies had no effect on ADM determination. The MA-based ELISA demonstrated good linearity of ADM dose-response curve and good intra-/inter-assay precision with a mean coefficient of variation of 5% and 9%, respectively. ADM concentrations ranging from 0.2 to 23.8µg/ml were measured in the cohort.
Conclusion: In this study, 11 highly specific monoclonal antibodies towards ADM were generated of which four revealed neutralizing properties. A MA-based ADM ELISA was established with good accuracy and precision. This assay, together with the previously described anti-drug antibody assay using MA-ADM6A10 as calibrator are valuable tools that can be used in routine monitoring of adalimumab-treated patients.

Introduction: The monoclonal antibody infliximab (IFX; Remicade®), which targets the pro-inflammatory cytokine tumour necrosis factor-alpha (TNFα), has revolutionized the treatment of patients with inflammatory bowel disease by inducing remission and mucosal healing. Therapeutic drug monitoring has been widely accepted as a tool to enhance the efficiency of IFX therapy. Recently, two biosimilars of infliximab received market authorization under trade names Remsima and Inflectra. Several assays are available to perform infliximab monitoring, but lack the speed to implement treatment algorithms immediately. In addition, available commercial infliximab assays require sample analysis in batch to reduce cost/sample.
Aims & Methods: To develop rapid assays for the quantification of infliximab concentrations using IFX-specific monoclonal antibodies (MA). Besides a sensitive, specific and quantitative read-out, an ideal point-of-care assay has a benchtop size, low cost, fast turn-around time and is easy-to-handle. In addition, data should be easily transferrable to electronic patient files.
1) A fiber-optic surface plasmon resonance assay was developed using a MA/MA sandwich approach. Surface plasmon waves are generated at the interface of an optical fiber/gold layer, which allow real time sensing of interactions between biomolecules at the surface. MA-IFX20G2 was covalently immobilized to a gold-sputtered fiber surface to capture IFX. MA-IFX3D5 was conjugated to gold nanoparticles and was used to detect bound IFX. 2) A lateral flow-based immunoassay was developed using TNFα as capture antigen and MA-IFX6B7 for the detection of IFX bound to TNFα. Conjugated gold nanoparticles were used for signal enhancement. A colorimetric signal was generated and read with a portable lateral flow test reader.
Results: 1) The fiber-optic surface plasmon resonance platform demonstrated a dose-response relationship with good reproducibility in the 0.7 to 75 ng/mL range (n = 6). 2) The lateral flow-based immunoassay revealed dose-response curves with good reproducibility in the 2.5 to 80 ng/mL range (n = 3). Both systems allowed at least a 1:200 serum dilution, a turn-around time less than 20 min and an easy transmission of data.
Conclusion: This work demonstrates the potential of two rapid assays for the determination of infliximab concentrations, a fiber-optic surface plasmon resonance MA/MA sandwich immunoassay and a lateral-flow based immunoassay. Both assays showed to sensitively detect infliximab, are currently applied on clinical samples and benchmarked to the clinically validated infliximab ELISA. The availability of these assays will allow a fast implementation of quantitative infliximab monitoring in a hospital/infusion center setting.

P1573 THERAPEUTIC DEPLETION OF MYELOID LINEAGE LEUCOCYTES IN PATIENTS WITH ULCERATIVE COLITIS: DEMOGRAPHIC FEATURES OF NON-RESPONDERS AND RESPONDERS TO THIS NON-PHARMACOLOGICAL TREATMENT OPTION

T. Tanaka[1], T. Iiboshi[1], H. Goishi[1], M. Akagi[1], T. Kajihara[1], T. Miura[1]
[1]*Gastroenterology, Akitsu Prefectural Hospital, Hiroshima, Japan*

Contact E-mail Address: tomotaka@c.do-up.com

Introduction: Patients with active inflammatory bowel disease (IBD) have elevated myeloid lineage leucocytes, notably elevated CD14(+)CD16(+) monocyte phenotype, which is a major source of tumour necrosis factor-α (Belge, et al. *J Immunol* 2002). Hence selective depletion of elevated and activated leucocytes by adsorptive granulocyte/monocyte apheresis (GMA) with an Adacolumn is expected to alleviate inflammation and promote remission or at least enhance drug efficacy. However, studies in ulcerative colitis (UC) have reported contrasting efficacy, from an 85% (Suzuki, et al. *Gastroenterology* 2005) to a statistically insignificant level (Sands, et al. *Gastroenterology* 2008). Patients' demographic variables in the aforementioned studies were different.

Aims & Methods: In 143 UC patients we looked for clinical and endoscopic features, which could indentify a patient as a potential responder or otherwise as a non-responder to GMA. Seventy-three patients were steroid naive, and 70 were steroid dependent. Patients received up to 11 GMA sessions over 10 weeks. At entry and week 12, patients were clinically and endoscopically evaluated, allowing each patient to serve as her or his own control. Clinical activity index (CAI) $\leq$4 at week 12 was defined as response to GMA. Biopsies from colonoscopically detectable inflamed mucosa were processed to see the impact of GMA on leucocytes within the mucosa.

Results: At entry, the average CAI was 12.8, range 10-17. Ninety-two patients (64.3%) responded to GMA, 52 of 73 steroid naïve (71.2%) and 40 of 70 steroid dependent patients (57.1%). On average remission was sustained for 8.6 months in steroid naïve patients and for 10.4 months in steroid dependent cohort. Upon relapse, the majority of patients responded well to a second course of GMA. Over 1200 biopsies were processed. Infiltrating leucocytes were mostly neutrophils and monocytes. There was a marked reduction of infiltrating leucocytes in responders. Patients who had extensive deep UC lesions together with loss of the mucosal tissue at the lesion sites were identified as non-responders. Patients with the first UC episode were identified as the best responders (100%) followed by steroid naive patients. Additionally, a short duration of active UC marked a patient as a likely responder.

Conclusion: Depleting elevated myeloid lineage leucocytes was associated with efficacy in UC patients, most notably first episode and steroid naïve cases who attained a favourable future clinical course. GMA was more effective if applied immediately after a relapse than after a lag time. In general, GMA is very much favoured by patients for its safety profile and for being a non-drug therapeutic intervention. Patients with extensive deep ulcers, with long duration of UC and exposure to multiple pharmacologicals are unlikely to benefit from GMA.

P1574 ENTEROSCOPIC AND MR FINDINGS OF SMALL INTESTINE IN CROHN'S DISEASE

T. Fujii[1], K. Takenaka[1], Y. Kitazume[2], M. Kimura[1], T. Iwamoto[1], K. Matsuoka[1], M. Nagahori[1], K. Ohtsuka[1], M. Watanabe[1]

Contact E-mail Address: tfujii.gast@tmd.ac.jp

Introduction: Crohn's disease (CD) is a lifelong inflammatory bowel disease. Evaluating the extent and severity of the disease is critical to determine appropriate therapeutic strategies in patients with CD. MR enterography can examine not only intra-luminal changes, but also extra-luminal abnormalities without ionizing radiation and anesthesia, which makes it appropriate for frequent examinations in CD. We developed novel MR enterocolonography (MREC) to simultaneously evaluate both small and large bowel lesions in patients with CD and recently reported its excellent correlation with endoscopy. Balloon-assisted enteroscopy (BAE) and MR procedure can assess the deep small intestine[1)] but clinical significance of small intestinal lesions is uncertain.

Aims & Methods: The aim of this study is to evaluate the correlation between endoscopic and MR findings in deep small intestine and to identify findings of the two modalities to predict patients' prognosis. This is a retrospective cohort study. We performed MREC and BAE in 90 patients for assessing the small intestinal lesions. Modified SES-CD and MaRIA scores were used to evaluate the correlation between BAE and MREC. We also assessed the correlation between small intestinal CD lesions and patients' prognosis (Recurrence: Aggravation of symptoms that need to change treatment. Surgery: Operation related with CD except for anal fistula).

Results: In BAE, the CD lesions were detected in the terminal ileum (57.0%) and proximal ileum (60.2%) at a similar rate. The sensitivity and specificity of MREC for ulcerative lesions in the small intestine (MaRIA $\geq$ 11) were 82% and 89%, respectively, and those for stenotic lesions were 50% and 90%, respectively, using BAE as the reference. Multivariable analysis showed that the presence of active lesions in small intestine with MREC (MaRIA $\geq$ 11) was an independent risk factor for recurrence (P = 0.005, Relative Risk 2.98 (95%CI 1.398-6.350)). Ulceration detected on BAE or stenosis detected with MREC were not a significant risk factor for recurrence. The Kaplan-Meier method showed that the patients with active lesions detected with MREC had a significantly higher cumulative rate of recurrence (more than 50% within 1 year) than those without active small intestinal lesions. Multivariable analysis showed that the detection of stenosis in small intestine with MREC was an independent risk factor for surgery (P = 0.005, Relative Risk 5.83 (95%CI 1.706-19.937)). The detection of ulceration on BAE or the presence of active lesions with MREC were not a significant risk factor for surgery. The patients with stenosis detected with MREC had a significantly higher cumulative rate of surgery (over 40% within one year) than those without stenosis.

Conclusion: Although BAE assesses small intestinal lesions more accurately than MREC, it can be an alternative examination to predict recurrence and surgery. Futhermore, prognosis was different depending on if the patient has an inflammatory lesion or stenotic lesion. Thus, it is important to separately consider inflammatory lesions and intestinal damage to assess prognosis of CD patients.

Introduction: Background: Capsule endoscopy (VCE) and magnetic resonance enterography (MRE) are the prime modalities for the evaluation of the small bowel Crohn's disease (CD). Bowel inflammation on contrast-enhanced MRE can be quantified using the Magnetic Resonance Index of Activity (MaRIA). Clermont score is a novel diagnostic index based on diffusion-weighted (DW)-MRI that does not require administration of intravenous contrast material. The accuracy of both MRE indices was validated against ileocolonoscopic activity indices. Mucosal inflammation on VCE is quantified using the Lewis score (LS). In our previous study, MaRIA score was significantly correlated with LS in the distal small bowel. The Clermont score was never previously correlated with a VCE-based activity index.

Aims & Methods: The aim of this study was to correlate the quantitative assessment of the inflammatory activity by the Clermont score and the Lewis score in the distal small bowel.

Methods: Patients with known SBCD in steroid free clinical remission or with mild symptoms (CDAI < 220) for at least 3 months were prospectively recruited and underwent MRE, followed by Agile patency capsule. If patency was proven, VCE was performed. LS, MaRIA and Clermont scores were calculated for the distal SB. C-reactive protein (CRP) and fecal calprotectin (FC) levels were obtained and evaluated for their association with the clinical scores.

Results: All indices were calculated for 44 patients. Active disease was demonstrated in the distal SB in 62% of the patients by VCE and 72% by MRE (p = 0.4). Both MR-based indices significantly correlated with LS, however the correlation was somewhat stronger for the Clermont index (r = 0.56, p = 0.001 and r = 0.517, p = 0.001, respectively). A very strong correlation between the Clermont and MARIA score was demonstrated (r = 0.99, p = 0.0001). Fecal calprotectin levels equally correlated with Clermont and MaRIA score (r = 0.49, p = 0.001 and r = 0.50, p = 0.001, respectively), while CRP levels did not demonstrate a significant correlation with MR-derived indices.

Conclusion: There was a significant correlation between the capsule endoscopy and both MRE-derived activity indices. A strong correlation between contrast-enhanced and diffusion-weighted MRE indices was demonstrated. Diffusion-weighted MRI allows for an accurate assessment of the small bowel inflammation in CD patients while avoiding intravenous gadolinium injection.

Introduction: Inflammatory bowel diseases (IBDs) including Crohn's disease (CD) and ulcerative colitis (UC) are chronic, immune-mediated diseases which are known to adversely affect quality of life and cause disability. Recently, the inflammatory bowel disease-disability index (IBD-DI) has been validated as a useful tool to measure disability[1]. Previous studies have shown that high level of anxiety and depression was associated with reduction of health-related quality of life (HRQOL) in IBD. However, the relationship between psychological factors (anxiety and depression) and IBD-related disability has yet to be explored.

Aims & Methods: We hypothesize that psychological factors (anxiety and depression) are associated with disability in patients with IBD from Singapore.

Aims:

1. Determine the association between anxiety and depression, and IBD-related disability

2. Determine the other predictors associated with IBD-related disability
3. Determine the correlation between IBD-DI and health-related quality of life
We conducted a cross-sectional, prospective study of patients presenting to our IBD center. A total of 165 IBD patients were recruited into the study. Anxiety and depression were assessed by the Hospital Anxiety and Depression Scale (HADS), with scores ranging from 0 (no anxiety) to 21 (severe anxiety) for the HADS-Anxiety (HADS-A), and from 0 (no depression) to 21 (severe depression) for the HADS-Depression (HADS-D). IBD-related disability was measured by the IBD-DI, with scores ranging from −80 (maximum degree of disability) to 22 (no disability). Health-related QOL was measured using the Inflammatory Bowel Disease Questionnaire (IBDQ). Clinical and demographic data were obtained from our electronic medical records. Univariate analysis and multiple linear regression analysis were performed to identify predictors associated with IBD-related disability.
Results: From November 2014 to April 2015, one hundred and sixty four patients completed the questionnaire. Eighty seven patients had UC and seventy seven had CD. The prevalence of anxiety and depression in our study population were 24.4%(40/164) and 13.4%(22/164) respectively. Patients with lower scores on IBD-DI (i.e. more disabled) had higher scores on HADS-A (Spearman's correlation coefficient, r_s -0.631, $p < 0.01$) and HADS-D (r_s -0.645, $p < 0.01$) (i.e. more anxious and depressed). Univariate analysis showed that older age, ethnicity, smoking status, older age at diagnosis of IBD, use of steroids within 3 months, use of azathioprine, prior hospitalization, anxiety and depression symptoms correlated with IBD-DI. Multivariate regression analysis revealed that being a non-smoker, and older age at diagnosis of IBD predicted lesser disability, whereas use of steroids within 3 months, anxiety and depression symptoms predicted greater IBD-related disability. IBD-DI positively correlated with IBDQ (r_s 0.835, $p < 0.01$).
Conclusion: Our study demonstrated that psychological factors (anxiety and depression) are associated with IBD-related disability. Patients with IBD should be screened for anxiety and depression and appropriate management instituted for better outcome.

P1577 ROLE OF CONTRAST-ENHANCED ULTRASOUND (CEUS) IN ASSESSMENT OF INFLAMMATORY ACTIVITY IN PATIENTS WITH SMALL BOWEL CROHN'S DISEASE

W. Cheng[1], G. Liu[1]
[1]*Department of Medical Ultrasound, The Sixth Affiliated Hospital of Sun Yat-sen University (Guangdong Gastrointestinal Hospital), Guangzhou, China*

Contact E-mail Address: jessica.cheng.sysu@foxmail.com
Introduction: Patients suffering from Crohn's disease (CD) often undergo several imaging studies, subjecting the mostly young patients to ionizing. Contrast enhanced ultrasound for capillary microvascular assessment might be a new diagnostic tool for identifying the activity of inflammation by ultrasound techniques.
Aims & Methods: Aims: To evaluate the clinical value of several quantitative parameters of CEUS, including peak intensity (PI), rise time (RT), time to peak (TTP) in assessing CD inflammatory activity, compared with the power Doppler image and enhancement pattern of CEUS.
Methods: We prospectively evaluated 55 consecutive patients with histologically proven CD. Ultrasound (US) was performed by an experienced radiologist applying baseline US, power Doppler imaging (PDI) and CEUS. After the injection of 2ml ultrasound contrast agent (SonoVue), the dynamic cine sequences were recorded as digital raw data for 120 seconds. Then we perform a quantitative analysis using TIC retrospectively. Quantitative analysis was firstly performed by the software within the ultrasound device, quantitative parameter, PI was obtained. Then the same clips were analysed by Sonoliver, which provided RT and TTP values. The concentration of hs-CRP was set as the gold standard. Quantitative results in patients with active and inactive inflammatory were compared using t-test and receiver operating characteristic curve (ROC) analysis. Cutoff values were determined using ROC analysis, and sensitivity, specificity, accuracy and Youden indices were calculated. Limberg classification of PDI and the enhancement patterns of CEUS were also compared and analyzed.
Results: The population with active inflammatory was 39, while the one with inactive inflammatory was 16. Determined by Limberg classification, 35 of the patients were with inflammatory activity, showed a sensitivity of 0.74, specificity of 0.75, accuracy of 0.75, Youden index of 0.49; Determined by the enhancement patterns of CEUS, 44 of the patients were with inflammatory activity, showed a sensitivity of 0.87, specificity of 0.38, accuracy of 0.73, Youden index of 0.25. Quantitative analysis showed a higher peak intensity (>19dB), a shorter rise time (≤6.2s), and a shorter time to peak (≤8.7s) in patients with active inflamation than in those with inactive inflammation ($P<0.05$). Peak intensity showed a higher efficiency in assessing inflammatory activity of CD according to the comparison of ROC with enhancement patterns of CEUS ($P<0.05$).
Conclusion: Power Doppler imaging, qualitative and quantitative analysis of CEUS can be used to identify the activity in CD, while the lateral was more objective.

P1578 EVALUATION OF PATIENT-REPORTED OUTCOMES FROM THE CROHN'S DISEASE ACTIVITY INDEX TO DEFINE REMISSION IN THE GEMINI 2 STUDY

W. J. Sandborn[1], S. Vermeire[2], B. E. Sands[3], B. G. Feagan[4], M. Shetzline[5], J. Xu[5], R. Mody[5], A. Parikh[5], B. Abhyankar[6]
[1]*University of California San Diego, La Jolla, United States,* [2]*University Hospital Gasthuisberg, Leuven, Belgium,* [3]*Icahn School of Medicine at Mount Sinai, New York, United States,* [4]*Robarts Clinical Trials, Robarts Research Institute, University of Western Ontario, London, Canada,* [5]*Takeda Pharmaceuticals International Co, Cambridge, United States,* [6]*Takeda Development Centre Europe Ltd, London, United Kingdom*

Introduction: Clinical trials in Crohn's disease (CD) are evolving towards including patient-reported outcomes (PROs) to evaluate drug efficacy; however, no validated PROs are available.
Aims & Methods: In post hoc analyses of data from the placebo (PBO)-controlled GEMINI 2 study,[1] we evaluated the use of the PRO components of the CD Activity Index (CDAI) to define vedolizumab (VDZ)-induced remission. Patients (pts) with moderately to severely active CD (CDAI 220-450) who responded to 6 weeks (wks) of VDZ induction therapy were re-randomised to maintenance therapy with PBO or VDZ for 46 wks. PRO components of the CDAI (stool frequency [SF], abdominal pain [AP], and general wellbeing [GWB]) were evaluated alone and in combination (PRO-2 [SF and AP] and PRO-3 [SF, AP, and GWB]) at wks 0, 6, and 52. Contributions of PROs to baseline and mean change from baseline CDAI total scores were analysed. The sensitivity of PRO-based definitions of remission (PRO-2 [SF ≤3 and AP ≤1]; PRO-2 ≤75; and PRO-3 ≤80) to detect clinical remission (CDAI ≤150), their agreement with CDAI ≤150, and the percentage of GEMINI 2 pts who met PRO-based entry criteria (SF ≥4 and/or AP ≥2) were evaluated.
Results: The SF, AP, and GWB subscores contributed 25%, 21%, and 31%, respectively, to the mean baseline CDAI score. PRO-2 and PRO-3 accounted for, respectively, 53% and 91% of the mean change from baseline CDAI score at wk 6, and 47% and 82% at wk 52. PRO-2 (SF ≤3 and AP ≤1), PRO-2 ≤75, and PRO-3 ≤80 detected clinical remission with a sensitivity of, respectively, 67%, 76%, and 57% at wk 6, and 74%, 95%, and 77% at wk 52. PRO-3 ≤80 had the best agreement with CDAI remission at wk 6 and PRO-2 ≤75 had the best agreement at wk 52 (**Table**). PRO-based entry criteria of SF ≥4 and/or AP ≥2 were met by 86% of GEMINI 2 pts.
Table: Definitions of Remission

Definition of remission	Wk 6			Wk 52		
	PBO (n = 148) Pts (%)	VDZ (n = 220)	Agreement with CDAI ≤150[a]	VDZ/PBO[b] (n = 153) Pts (%)	VDZ/VDZ[c] (n = 154)	Agreement with CDAI ≤150[a]
CDAI ≤150	7	15	1.00	22	39	1.00
PRO-2 (SF ≤3 & AP ≤1)	15	20	0.45	18	33	0.74
PRO-2 ≤75	21	29	0.37	23	38	0.84
PRO-3 ≤80	6	13	0.55	19	32	0.80

[a] Determined by kappa statistics; kappa agreement: <0, less than chance; 0.01-0.20, slight; 0.21-0.40, fair; 0.41-0.60, moderate; 0.61-0.80, substantial; 0.81-0.99, almost perfect.[b] Received VDZ during induction and PBO during maintenance.[c] Received VDZ during induction and VDZ every 8 wks during maintenance.

Conclusion: The PRO components of the CDAI contributed most to baseline and treatment-induced changes in CDAI score. Different PRO-based definitions of remission (PRO-2 ≤75 or PRO-3 ≤80) had the best agreement with clinical remission at wks 6 and 52. Interpretations of these post hoc analyses are limited, but applying the cut-offs used here to other datasets could clarify the reliability and clinical meaningfulness of PROs as outcome measures.

Contact E-mail Address: xroblin@aol.com

Introduction: Several studies and meta-analyses have shown a correlation between infliximab trough levels (TLI) and clinical remission. Isolated cut-off points vary according to the techniques used. No study has been carried out to determine whether the variations in this therapeutic cut-off depend on the analysis criterion (remission, mucosal healing, etc.). The aim of our study was to compare whether there were similarities in this threshold for clinical remission or biomarkers assessment in IBD.

Aims & Methods: we included in a monocentric observational study including all consecutive BD patients treated with IFX between 2010 and 2013 and followed up in the gastroenterology service. The TLI measurements (ELISA technique, Theradiag) were performed immediately prior to an infusion of IFX (5mg/kg) simultaneously with the CRP (mg/L) and faecal calprotectin (µg/g of stools). The CDAI or partial Mayo scores were reported for all the patients. Exclusion criteria were primary non-responders to IFX, patients previously treated with another anti-TNF agent, and patients optimised at a dose other than 5 mg/kg/8W as well as those suffering exclusively from anoperineal CD. Clinical remission was defined for CD by a CDAI score of < 150 and for UC by a partial Mayo score of < 3. Normal CRP was defined as CRP < 5 mg/L in patients having a high CRP level at the start of treatment. Faecal calprotectin was defined as normal for a level below 250 µg/g of stools. The TLI cut-off was investigated using a ROC curve analysis to isolate a threshold associated with clinical remission, and normal CRP and calprotectin levels.

Results: 213 patients (131 with CD; mean age: 38+/- 16.2 years; M:F sex ratio: 0.8; mean duration of IFX treatment: 14.9+/-6.3 months) were included. 145 patients were in clinical remission. Mean TLI were significantly higher during remission (2.6 *vs.* 1.2 µg/ml; $p < 0.01$). The optimal cut-off associated with clinical remission was 2.1µg/ml (sensitivity: 78%; specificity: 76%). Of the 140 patients who had high CRP levels at the start of treatment, 85 showed normal CRP and clinical remission. The mean TLI were significantly higher when normal CPR levels associated with clinical remission observed (3.5 *vs.* 1.6 µg/ml; $p < 0.01$). The optimal cut-off associated with normal CRP associated with clinical remission was 2.9 µg/ml (sensitivity: 69%; specificity: 66%). 121 patients showed normal faecal calprotectin associated with clinical remission. The mean TLI were significantly higher in presence of normal faecal calprotectin levels associated with clinical remission (4.9 *vs.* 1.7 µg/ml; $p < 0.001$). The optimal cut-off associated with normal faecal calprotectin was 3.9 µg/ml (sensitivity: 74%; specificity: 80%).

Conclusion: The TLI to target varies depending on the treatment objective chosen in IBD patients. The therapeutic level required for obtaining deep remission defined by clinical and biomarker remission, is higher than the level required to achieve clinical remission only.

P1580 FEASIBILITY AND VALUE OF STOOL ANTI-TNF MEASUREMENT IN IBD PATIENT IN LOOSE OF RESPONSE: A PRELIMINARY STUDY

X. Roblin[1], J. M. Phelip[2], S. Paul[3]
[1]*Gastroenterology, University,* [2]*Gastroenterology,* [3]*Immunology, CHU Saint Etienne, Saint Etienne, France*

Contact E-mail Address: xroblin@aol.com

Introduction: In a preliminary study including 11 patients with severe UC on IFX induction treatment, the authors found an association between faecal IFX levels, a drop in circulating IFX trough levels (TLI) and treatment non-response. To our knowledge, no studies have been carried out on faecal anti-TNF levels (IFX and ADA) in cases of loss of therapeutic response in UC and CD patients. The aim of this preliminary study was to assess the feasibility of this test in determining faecal anti-TNF levels (IFX and ADA) in the two types of IBD and to investigate whether this correlates with clinical or endoscopic activity.

Aims & Methods: Retrospective study were including from a clinical database and from biological collection data, the first 36 IBD patients with faecal calprotectin levels above of 1800µg/g stools. Faecal anti-TNF assays were conducted on all of these patients and compared with the results of 6 IBD patients with a faecal calprotectin level below 500µg/g (below 500µg/g in 3 cases and below 100µg/g in the other 3 cases). At the same time, we analysed trough levels of anti –TNF and antibodies. All measurements were obtained just before infusion or injection of anti TNF drugs. Exclusion criteria were severe acute colitis and patients under anti TNF therapy under induction regimen.

Results: 42 samples were analysed (20 CD, 22 cases on IFX treatment). The 36 patients with faecal calprotectin levels > 1800 µg/g exhibited clinical activity. An anti-TNF (> 0.2µg/ml of stools) was reported in 7 cases. In 5 cases, the patient was treated with IFX (22.7%) and in two cases with ADA (10%) (p: NS). Anti-TNF was found to be present in stools in 5 cases of UC (22.7%) and in two cases of colonic Crohn's disease (10%) (p: NS). A positive anti-TNF threshold of stools was only isolated in cases where calprotectin was over 1800µg/g (19.4%). No correlation to clinical activity or response to optimisation was reported among patients with or without faecal anti-TNF. Circulating anti-TNF levels at the time of the measurement were higher for IFX and ADA in the presence of feacal anti-TNF. In the 7 cases showing faecal anti-TNF, an endoscopy detected ulcers in the colonic mucosa (100%) as compared with 5/29 colonic diseases showing ulcers in the absence of faecal anti-TNF (14%, $p < 0.05$).

Conclusion: Excluding severe colitis and induction regimen, feacal anti-TNF can be detected in cases of CD as well as UC, irrespective of the anti-TNF used. The presence of colonic ulcers appears to be a pre-condition of intestinal leaks which inversely have no effect in these cases on circulating anti-TNF levels. Large-scale prospective studies would better determine the potential value of this new parameter in IBD patients.

P1581 THE USE OF FECAL CALPROTECTIN IN MONITORING OF INFLAMMATORY BOWEL DISEASE ACTIVITY IN PREGNANCY

Y. Uspenskaya[1], E. Gitel[1]
[1]*I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation*

Contact E-mail Address: jusp@mail.ru

Introduction: Pregnant patients with inflammatory bowel disease (IBD) constitute a high-risk group for an unsuccessful pregnancy outcome when experiencing a period of high disease activity (recurrent miscarriage, premature delivery, underweight fetus). In this connection, it has been recognized that it necessary to manage the disease over the course of the pregnancy in order to ensure a successful gestation period. At the same time, the fact that the patient is pregnant significantly limits the number of options for objective and safe diagnostic methods. Measuring fecal calprotectin is a non-invasive way of determining IBD activity. However, its diagnostic utility for pregnant patients has not yet been determined.

Aims & Methods: The aim was to determine the diagnostic utility of fecal calprotectin in determining IBD activity during pregnancy.

To the prospective cohort study were included 14 pregnant women with IBD (12 – ulcerative colitis (UC), 2 – Crohn's disease (CD)). All patients underwent clinical laboratory testing over the course of the pregnancy during which non-specific inflammatory markers and fecal calprotectin were measured, and a clinical activity index (CAI) was determined.

Results: 7 patients from the study group experienced a flare-up of the disease over the course of the pregnancy. In cases of active IBD, the average value of calprotectin was at 292.57 ± 145.2 µg/g, and in cases of non-active UC and CD - $22{,}94 \pm 12{,}94$ µg/g. The calprotectin value during high IBD activity correlated with levels of C-reactive protein. In 3 observed cases, a higher level of calprotectin preceded the appearance of clinical symptoms of UC. Lower calprotectin levels correlated with less active IBD as the UC flare-up subsided. However, values of calprotectin measurements stayed elevated longer relative to the clinical signs and normalization of IBD (5 ± 2.2 weeks), indicating that it was necessary to continue treatment. At the same time, calprotectin levels were not linked with IBD activity after birth and thus cannot be used to predict the course of the disease during the postnatal period.

Conclusion: The initial findings suggest that fecal calprotectin is useful in determining IBD activity and in selecting a treatment method during pregnancy.

Contact E-mail Address: szepes.zoltan@med.u-szeged.hu

Introduction: The incidence of inflammatory bowel disease (IBD) is still increasing in Asia and Eastern Europe. Disease phenotype may differ when compared the East and the West. However, limited studies have reported on the frequency of upper gastrointestinal (GI) involvement in patients with Crohn's disease (CD)

in non-Western countries. In this prospective, international, multicenter study we compared the prevalence of macroscopic and microscopic upper GI manifestations and *Helicobacter pylori* positivity in asymptomatic CD patients in Asia and Eastern Europe in comparison with sex- and age-matched non-IBD controls.
Aims & Methods: Consecutive asymptomatic CD patients were prospectively recruited for upper GI endoscopy between 2013 and 2015 in Hong Kong and in Hungary. Endoscopy and biopsy findings were recorded and histology was performed to assess for *Helicobacter pylori* and microscopic signs characteristic for CD.
Results: One hundred and seventy-one CD patients (91 Hong Kong; 80 Hungary; 71.3% male; median age, 38.5 years) and 122 controls (39 Hong Kong; 83 Hungary) were included. Significant differences were revealed between Chinese and Hungarian CD patients regarding to smoking status and history of appendectomy. Upper GI involvement of CD patients was significantly higher in Szeged (15 vs. 4.4%, $p = 0.018$). No difference was revealed between the two populations in locations and behaviour of CD, and the rate of surgery. There was no difference in the presence of macroscopic inflammation (30.8% vs. 38.7%), microscopic inflammation (84% vs. 80%). Gastroduodenal erosions (17.6% vs. 10%) and *Helicobacter pylori* positivity (13% vs. 3%; $p = 0.001$) was significantly higher in Hungarian CD patients. Granulomas were detected in 1% in Hong Kong and 7.5% in Hungary ($p = 0.001$). Two CD cases (2.5%) in Hungary were diagnosed with celiac disease. Overall CD subjects had a significantly lower *Helicobacter pylori* positivity as compared to controls (8.2% vs 15.5%; $p = 0.010$).
Conclusion: The rate of upper GI lesions in CD patients in Asia was lower to that of Hungary. CD patients had a significantly lower *Helicobacter pylori* positivity rate as compared to controls. The convincingly high frequency of macroscopic and especially microscopic inflammation observed in our study justifies the need of upper GI endoscopy in asymptomatic CD patients independently of ethnicity.

P1583 ADHERENCE TO TOPICAL THERAPY IN ULCERATIVE COLITIS

M. R. Shuvo[1], **P. A. Hendy**[1,2], L. Penez[2], A. Hart[1,2]
[1]*Imperial College,* [2]*Gastroenterology, St Mark's Hospital, London, United Kingdom*

Contact E-mail Address: philiphendy14@gmail.com
Introduction: 5-aminosalicylic acid (5-ASA) is the mainstay of treatment for mild-to-moderate ulcerative colitis (UC) for both induction and maintenance of remission. Topical/rectal therapies (both 5-ASA and steroid) are included in national and society treatment guidelines due to their rapid onset of action and local effects. It is known that patient adherence to oral 5-ASA therapy is poor (around 50%) but there are no published studies examining adherence to topical therapies in UC. The aims of this questionnaire-based study were to establish the rate of non-adherence to topical therapy in UC and to ascertain patient reported reasons for and demographic factors associated with non-adherence.
Aims & Methods: A structured interview was conducted with patients with known UC and themes related to causes of non-adherence to rectal therapy were identified. A pilot questionnaire was developed based on the themes identified from the structured interview. 10 consecutive patients with UC completed the pilot questionnaire and gave their feedback on the questionnaire via a structured feedback form. The final study questionnaire, developed to incorporate patient feedback from the pilot study, was then given to consecutive patients with a confirmed diagnosis of UC in a teaching hospital gastroenterology outpatient clinic. The study questionnaire collected data on patient demographics (including: gender, age, ethnicity, co-habitation, marital status, occupation) and disease and medication history. Common reasons for non-adherence were also recorded (identified in the structured interview and pilot study, and included: difficulty remembering to take it every day, competing priorities and awkward route of administration).
Results: 122 patients, 59 male and 63 female, were recruited with a median age of 47 years. 82% of UC patients had been offered rectal therapy at some point. 7% of respondents had been offered rectal therapy but did not commence treatment. 93 patients had used rectal therapy of which 53% discontinued early. 35% of these patients stopped the medication because it was too difficult to remember to take it every night; however, 94% of these patients would have continued to take the medication if there was an option to take it every second or third night. There was a trend towards significance for male gender in non-adherence to rectal therapy ($p = 0.07$) but other examined factors were not found to be statistically significant.
Conclusion: 53% of patients did not take rectal therapy for the recommended duration, of which 35% cited difficulties remembering daily application of therapy as a major factor for stopping. Perhaps when prescribing topical therapy the clinician should emphasise that it is not an 'all or nothing' treatment and that pragmatism in frequency of application is reasonable, and indeed important to improve adherence.
Although the majority of patients with UC have been offered topical therapy at some point, 18% of patients have not. Clinicians should bear this in mind when considering escalation of therapy in UC, as globally increased use of topical therapy could doubtless reduce the need for escalation to immunosuppressant medications.

P1584 A RANDOMIZED, SINGLE-BLIND, SINGLE-DOSE, THREE-ARM, PARALLEL GROUP STUDY IN HEALTHY SUBJECTS DEMONSTRATING PHARMACOKINETIC EQUIVALENCE OF PROPOSED BIOSIMILAR ABP 501 WITH ADALIMUMAB

P. Kaur[1], V. Chow[2], N. Zhang[1], R. Markus[1]
[1]*Biosimilars, Amgen Inc., Thousand Oaks, CA,* [2]*Qualitative Pharmacology, Amgen Inc., Seatttle, WA, United States*

Contact E-mail Address: pkaur@amgen.com
Introduction: Adalimumab is a recombinant IgG1 monoclonal antibody that binds to TNFα blocking its interaction with p55 and p75 cell surface receptors. ABP 501 is a proposed biosimilar candidate to adalimumab; it contains a fully human recombinant monoclonal antibody with the same amino acid sequence. Evidence from analytical comparisons indicates that ABP 501 is highly similar to adalimumab. This report describes the results of a phase 1 pharmacokinetic (PK) equivalence study comparing ABP 501 with adalimumab.
Aims Methods: This was a single-blind, single-dose, parallel-group study in healthy men and women, 18 to 45 years of age with a body mass index of 18 to 30 kg/m^2. Subjects were randomized to receive 40-mg subcutaneous (SC) injection of ABP 501 or adalimumab reference products sourced from the EU and the US. The primary objective was demonstration of PK equivalence of ABP 501 relative to adalimumab EU and adalimumab US based on area under the serum concentration-time curve from time 0 extrapolated to infinity (AUC_{inf}) and the maximum observed serum concentration (C_{max}). Pre-specified equivalence criterion for the primary PK parameters was for the 90% confidence interval (CI) for geometric means (GM) ratio to fall within 0.80 to 1.25. Secondary endpoints included the safety, tolerability, and immunogenicity after a single dose.
Results: Pharmacokinetics: A total of 67 subjects received ABP 501, 67 received adalimumab EU, and 69 received adalimumab US. After a single dose, the adjusted least square (LS) GM of C_{max} and AUC_{inf} for ABP 501 were 3.22 μg/mL and 2140 μg.h/mL. The adjusted LS GM of C_{max} and AUC_{inf} for adalimumab EU were 3.37 μg/mL and 2050 μg.h/mL and that for adalimumab US were 3.11 μg/mL and 1920 μg.h/mL. The ratios of adjusted LS GM (90% CIs) between ABP 501 and adalimumab EU for C_{max} and AUC_{inf} were 0.96 (0.89, 1.03), and 1.04 (0.94, 1.17) and that for ABP 501 and adalimumab US were 1.04 (0.96, 1.12), and 1.11 (1.00, 1.24). The ratios of adjusted LS GM (90% CIs) for C_{max} and AUC_{inf} between adalimumab EU and adalimumab US were 0.92 (0.86, 0.99) and 0.94 (0.84, 1.04). The 90% CIs of these ratios were fully contained within 0.80 to 1.25, confirming PK equivalence between ABP 501 and adalimumab reference products, as well as between adalimumab EU and adalimumab US.
Safety: There were no deaths, treatment-related serious adverse events, or treatment-related adverse events leading to discontinuation from the study. The most frequently reported treatment-related AEs included headache, nausea, nasopharyngitis, and oropharyngeal pain.
Immunogenicity: No pre-existing anti-drug antibodies (ADA) were detected at baseline. Subjects developing binding antibodies in each group were – ABP 501: 36 (54%), adalimumab EU: 45 (67%) and adalimumab US: 38 (55%). Subjects developing neutralizing antibodies were – ABP 501: 12 (18%), adalimumab EU: 14 (21%) and adalimumab US: 15 (22%).
Conclusion: Results of this phase 1 study demonstrated PK equivalence of ABP 501 following a single 40-mg SC injection relative to that of adalimumab EU and adalimumab US, as well as PK equivalence between adalimumab EU and adalimumab US. Safety was comparable and ADA rates were similar in all three treatment groups.

Contact E-mail Address: axel.dignass@fdk.info
Introduction: Current medical treatment options for patients with steroid-dependent, active ulcerative colitis (UC) with insufficient response or intolerance to immunosuppressants (IS) and/or biologicals are limited.
Aims & Methods: This study was an uncontrolled, open-label, multicenter trial conducted in the UK, France and Germany (ART, NCT01481142). Consecutive eligible patients (18-75 years, steroid-dependent active UC with a Rachmilewitz (CAI) index $\geq$6 and an Endoscopic Activity Index (EAI) $\geq$4, and insufficient response or intolerance to IS and/or biologicals) were included. Patients received at least 5 weekly GMA apheresis. Evaluation visits were planned at Week 12, 24 and 48. The primary endpoint was the remission rate (CAI $\leq$4) at Week 12 in the Intention-to-treat (ITT) population. We report interim safety results observed at 48 weeks after baseline.
Results: The safety population comprised 85 subjects having received at least one apheresis treatment. 8 (11.1%) subjects withdrew from the study because of AEs; none of those were considered related to study treatment. 61/85 patients (71.8%) experienced at least 1 AE up to 2 weeks after the date of the last apheresis treatment. 30 (41.7%) experienced at least 1 AE through week 48. 6 (7.1%) of the 85 subjects experienced serious AEs (SAEs) up to 2 weeks after

the date of the last apheresis treatment. 15 (20.8%) of 72 subjects followed up through to week 48 experienced SAEs. None of the SAEs were considered to be related to study treatment. Headache was the most prominent adverse event (21.2% of patients).
Conclusion: We describe interim safety results from a cohort of steroid-dependent moderate to severe active UC patients with failure or intolerance to IS and/or biologicals treated with GMA apheresis induction therapy. While sustained clinical benefit was reported earlier in 46.4% of the patients at Week 24 and in 39.3% at Week 48, no new safety signals were found. GMA apheresis may be an effective and safe alternative treatment option in patients with UC even failing or intolerant to IS and TNF-inhibitors.

P1586 THE FIRST JAK1-SELECTIVE INHIBITOR, FILGOTINIB, DISPLAYS SIMILAR MOLECULAR ACTIVITY IN THE GUT OF MICE WITH DSS-INDUCED COLITIS AND IN CULTURES OF COLON BIOPSIES FROM INFLAMMATORY BOWEL DISEASE PATIENTS

C. Delachaume[1], V. De Vriendt[2], D. Laukens[3], B. Vayssière[1], D. Merciris[1], S. De Vos[2], M.-C. Ceccotti[1], C. David[1], L. Perret[1], M. De Vos[3], R. Brys[2], **R. Galien**[1]
[1]*GALAPAGOS SASU, Romainville, France,* [2]*GALAPAGOS NV, Mechelen,* [3]*Gent University Hospital, Gent, Belgium*

Contact E-mail Address: rene.galien@glpg.com
Introduction: Filgotinib (known as GLPG0634) is a JAK inhibitor that has been shown to be selective for JAK1 over the 3 other family members (JAK2, JAK3 and TYK2) in biochemical and/or human whole blood assays. Filgotinib is currently being assessed as a treatment for Crohn's disease (CD) in a Phase 2 study. It has been shown to be particularly efficacious in arthritis as well as colitis mouse models. Here, we report that in mouse and human colon after treatment with filgotinib *in vivo* or *ex vivo*, respectively, the same signaling mechanisms are impacted, suggesting common JAK1 inhibition-related effects.
Aims & Methods: Chronic colitis was induced by adding 4% dextran sodium sulfate (DSS) to drinking water of Balb/c mice that were administered 30 mg/kg filgotinib QD during the 16 days of the study. Disease activity index (DAI) was evaluated daily by measuring weight loss, rectal bleeding, and stool consistency. Histological scoring of disease was based on an evaluation of severity and extent of inflammation and epithelial damage. Immune cell infiltration as well as STAT activation in mouse gut was analyzed by immunohistochemistry. Gene expression analysis in the colon mucosa was performed using qPCR. Inflamed colon biopsies from IBD patients were cultured for 18 or 24 hours in the presence of 5 μM GLPG0634 and gene expression as well as STAT phosphorylation were analyzed using qPCR and 5-Plex STAT kit Luminex, respectively.
Results: DAI revealed the strong protection against experimental colitis conferred by filgotinib. This was confirmed by histological assessment, which showed lower disease severity (54%), as well as reduced inflammatory cell infiltration in colon tissue from filgotinib-treated mice compared to controls. Colons from DSS-treated mice displayed higher STAT3 phosphorylation levels, which were prevented by treatment with filgotinib. Of interest, the expression of genes that activate (IL-6) or are induced by the JAK1 pathway (MX1, MX2) followed the same regulation as pSTAT3, suggesting a relationship between these readouts and a role of the pathway in the disease. Remarkably, the same repression of IL-6 and MX1 expression, as well as STAT3 phosphorylation by filgotinib were observed in cultured colon biopsies from IBD patients.
Conclusion: Taken together, these new data provide further mechanistic understanding for the pronounced efficacy of JAK1 inhibition in the pre-clinical mouse DSS-induced colitis model, with the efficacy observed at the macroscopic, histologic and molecular levels correlating with the inhibition of STAT3 phosphorylation in the colon. The striking concordance between molecular signatures related to JAK1 inhibition in experimental colitis and in a human colon biopsy model further stresses the importance of the JAK1 pathway in the etiology of IBD. These data suggest that filgotinib may be beneficial in treating CD patients and support its evaluation in a clinical study.

P1587 MAINTENANCE OF CLINICAL REMISSION IN CROHN'S DISEASE PATIENTS AFTER DISCONTINUATION OF ANTITNF AGENTS: RESULTS FROM A SINGLE CENTRE COHORT

R. Monterubbianesi[1], C. Papi[2], A. Kohn[1]
[1]*Gastroenterology, AO San Camillo Forlanini,* [2]*Gastroenterology, AO San Filippo Neri, Rome, Italy*

Contact E-mail Address: rita.monterubbianesi@gmail.com
Introduction: Introduction of antiTNF agents led to significative progresses in the treatment of Inflammatory Bowel Disease (IBD) and their complications, widening our possibilities of therapeutical approach. However we still don't know whether and when stopping the biological treatment in patients that are in clinical remission.
Aims & Methods: Aim of our study was to assess the rate of clinical remission in a cohort of Crohn's disease (CD) patients who discontinued antiTNF therapy because of clinical benefit and to evaluate if the mucosa healing is associated to a better outcome. A secondary objective was to assess response and tolerance to antiTNF re-treatment in relapsers.
Methods: Consecutive patients followed in a referral center for IBD, affected by CD and who received an antiTNF agent, infliximab(IFX) or adalimumab (ADA) for a period ≥12 months and discontinued the drug because in clinical remission were included. All patients had an endoscopy performed before and after the treatment with antiTNF. Demographic, clinical and endoscopic characteristics of patients were collected. Relapse was defined as need for rescue therapy (corticosteroids or new cycle of antiTNF) or surgery. Efficacy and tolerance of re-treatment with antiTNF for the relapse was evaluated.
Results: Between 516 patients treated with antiTNF agents from 1999 to 2011 in our Centre, 58 patients were included. 47 received IFX and 11 ADA. Median duration of treatment was 19 months. Median IFX infusions: 11. Median ADA administrations: 47. A concomitant treatment with immunosuppressant therapy (ISS) was seen in 66% of patients. When biological teatment was discontinued, 84% of patients were on ISS. Mucosal healing was achieved in 39 patients (67%). Kaplan-Meier curves showed a cumulative probability of a disease free course at 1 year of 69%. After 2 years from stopping antiTNF 48% of patients presented a flare of disease and probability of relapse after 5 years was 65%. In the univariate analysis no variables resulted related to the probability of mantenaince clinical remission. 30 patients received a new cycle of antiTNF: 63% obtained remission, 26% lost response after some months and 10% experience an acute reaction.
Conclusion: In our cohort of CD patients treated with antiTNF at least for 1 year, who discontinued the treatment because in clinical remission, the probability to maintain clinical benefit at 2 years was 52%. The rate of relapse was higher in the first 2 years from withdrawal. Mucosa healing did not predict sustained clinical remission. Re-treatment with antiTNF for relapsers was well tolerated and effective in the majority of patients. Discontinuation of antiTNF therapy does not seem a success strategy in the most of patients and future multicentric prospective studies on predictive factors are needed to identify patients with a higher risk of relapse.
Disclosure of Interest: None declared

P1588 LONG-TERM EFFICACY OF GRANULOCYTE-MONOCYTE-APHERESIS IN ULCERATIVE COLITIS ELDERLY PATIENTS. THE ITALIAN REGISTRY OF THERAPEUTIC APHERESIS

R. Sacco[1], V. D'Ovidio[2], A. Romano[1], M. Bertini[1], G. Federici[1], M. Bertoni[1], S. Metrangolo[1], G. Parisi[1], V. Mismas[1], E. Tumino[1], G. Bresci[1], P. Vernia[2]

Contact E-mail Address: saccorodolfo@hotmail.com
Introduction: Granulocyte-monocyte-apheresis (GMA) is effective in the treatment of ulcerative colitis (UC). Thanks to its favorable safety profile, the use of this technique could be particularly suitable for elderly patients. However, information on the efficacy of GMA in this population is still scant.
Aims & Methods: This observational study investigates the efficacy of GMA in elderly patients included in the Italian Registry of Therapeutic Apheresis.
Data of elderly (>65 years) patients with mild/moderate UC treated with a standard protocol of GMA (5 sessions in 5 weeks) were evaluated. Clinical evaluations were performed at 3, 12 and 24 months since the end of GMA session. The following parameters were assessed: incidence of clinical remission (CAI [Colits Active Index] <4); erythrocyte sedimentation rate (ESR); c-reactive protein (CRP); white cells blood count (WBC). Endoscopical evaluations were performed at a 3-month follow-up: the incidence of endoscopical remission (EAI [endoscopical activity index] 0/1) was assessed.
Results: Data for 74 patients (51 males, median age 68 years; CAI 7.12) were available; 62 patients were either steroid-resistant or steroid-dependent. The proportion of patients with remission of disease was 64% at 3 months, 62% at 12 months and 60% at 24 months. At 24 months, all other efficacy parameters had improved from baseline: CAI (7.12 vs 3.2), ESR (34.82 vs 12.8 mm/h), CRP (4.45 vs 0.80 mg/dl) and WBC (8.11 vs 6.12) ($p < 0.001$ for all comparisons).
Endoscopic data were available for 32 patients. The incidence of mucosal healing was 44%; all patients with mucosal healing presented a clinical remission over the entire follow-up period.
No major adverse events were reported during GMA sessions.
Conclusion: Data collected on a sample of elderly patients included in the Italian Registry of therapeutic apheresis show that GMA is a safe and effective procedure over a long-term follow-up also in this population. Mucosal healing appears strongly associated with clinical remission.

P1589 COST-EFFECTIVENESS OF VEDOLIZUMAB COMPARED WITH INFLIXIMAB, ADALIMUMAB, AND GOLIMUMAB FOR TREATMENT OF MODERATELY-TO-SEVERELY ACTIVE ULCERATIVE COLITIS IN THE UNITED KINGDOM

M. Wilson[1], M. Kerrigan[2], M. Smyth[3], A. Bergman[4], H. Chevrou-Severac[4], **R. Selby**[5]
[1]*RTI Health Solutions, Research Triangle Park, United States,* [2]*PHMR Limited,* [3]*Takeda Development Centre Europe Ltd, London, United Kingdom,* [4]*Takeda Pharmaceuticals GmbH, Zurich, Switzerland,* [5]*Takeda UK Ltd., Bucks, United Kingdom*

Contact E-mail Address: mwilson@rti.org
Introduction: The objective of this study is to examine the clinical and economic impact of vedolizumab (VDZ) compared with infliximab (IFX), adalimumab (ADA), and golimumab (GOL) in the treatment of moderately-to-severely active ulcerative colitis (UC) in the United Kingdom (UK).
Aims & Methods: A Markov decision analytic model in Microsoft Excel was used to compare VDZ with other biologic treatments (IFX, ADA, and GOL) for the treatment of UC patients in the UK. Due to a lack of data in comparable patient populations, this analysis was conducted in anti-tumor necrosis factor (TNF)-naïve patients only. Efficacy data were obtained from a network meta-analysis of Phase III clinical trials, using placebo as the common comparator. Other inputs (e.g., unit costs, adverse event disutilities, probability of surgery, mortality) were obtained from published literature. Costs are presented in 2014 British pounds. Outcomes included quality-adjusted life-years (QALY), time spent in clinical response, and time spent in clinical remission. Time horizons included 10-year (base case) and lifetime (scenario) horizons, with costs and outcomes discounted by 3.5% per year. Incremental cost-effectiveness ratios (ICER) were presented for VDZ compared with other biologics. Univariate and multivariate probabilistic sensitivity analyses were conducted to assess model robustness to parameter uncertainty.
Results: Over the base-case (10-year) time horizon, the model predicted that anti-TNF-naïve patients on VDZ accrued more QALY than patients on other biologics: 5.898 QALY vs 5.818, 5.760, and 5.790 QALY for IFX, ADA, and GOL, respectively. The incremental results over a 10-year horizon suggests that VDZ is a cost-effective treatment compared with ADA (ICER of £6,634/QALY), and VDZ is dominant compared with IFX and GOL. Patients on VDZ spent more time in clinical response (2.93 years vs 2.55 years for IFX, ADA, and GOL, respectively) and clinical remission (1.38 years vs 1.08, 0.99, and 1.04 years) than patients on any other biologic. VDZ was found to be dominant compared with all other biologics over a lifetime horizon. Sensitivity analyses suggest that results are most sensitive to treatment response and transition probabilities. However, VDZ remained cost-effective irrespective of variation in any of the input parameters.
Conclusion: Our model predicted that treatment with VDZ improves QALY, increases time in remission and response, and is a cost-effective treatment option for anti-TNF-naïve patients with moderately-to-severely active UC compared with all other biologics tested. VDZ may also be a cost-saving treatment strategy as well.

Contact E-mail Address: mwilson@rti.org
Introduction: The objective of this study is to examine the clinical and economic impact of vedolizumab (VDZ) compared with conventional therapy (CT) in the treatment of moderately-to-severely active ulcerative colitis (UC) in the United Kingdom (UK) based on results of the GEMINI 1 trial.
Aims & Methods: A Markov decision analytic model in Microsoft Excel was used to compare VDZ with CT (aminosalicylates, corticosteroids, immunomodulators) for the treatment of UC patients in the UK. We considered three populations: the overall intent-to-treat (ITT) population; anti-tumour necrosis factor (TNF)-naïve patients; and patients who previously failed anti-TNF therapy from the GEMINI 1 trial. Population characteristics, efficacy data, and UC health-state utility data were obtained from the GEMINI 1 trial. Other inputs (e.g., unit costs, adverse event disutilities, probability of surgery, mortality) were obtained from published literature. Costs are presented in 2014 British pounds. Outcomes included quality-adjusted life-years (QALY), time spent in clinical response, and time spent in clinical remission. Time horizons included 10-year (base-case) and lifetime (scenario) horizons, with costs and outcomes discounted by 3.5% per year. Incremental cost-effectiveness ratios (ICER) were presented for VDZ compared with CT. Univariate and multivariate probabilistic sensitivity analyses were conducted to assess model robustness to parameter uncertainty, and a scenario analysis was explored using efficacy data from a network meta-analysis.
Results: Over the base-case (10-year) time horizon, the model predicted that patients on VDZ accrued more QALY than patients on CT: 5.551 QALY vs 5.397 QALY in the ITT population (ICER = £33,297/QALY); 5.597 vs 5.403 QALY for anti-TNF- naïve patients (ICER = £24,657/QALY; network meta-analysis results: utilities 5.898 for VDZ vs 5.555 for CT and ICER = £4,862/QALY); and 5.463 vs 5.373 QALY for anti-TNF- failure patients (£64,999/QALY). Patients on VDZ spent more time in clinical response (e.g., 0.99 years vs 0.27 years for the ITT population) and clinical remission (0.64 years vs 0.13 years) than patients on CT. Scenario analyses with a lifetime horizon showed VDZ to be even more cost-effective (ITT population ICER = £20,599/QALY). Sensitivity analyses suggest that results are most sensitive to treatment response and transition probabilities.
Conclusion: Our model predicted that treatment with VDZ improves QALY, increases time in remission and response, and is a cost-effective treatment option for both anti-TNF naïve and anti-TNF failure patients with moderately-to-severely active UC compared with CT over both 10-year and lifetime horizons.

P1591 REMICADE AT HOME: AN ALTERNATIVE SETTING OF INFLIXIMAB THERAPY FOR PATIENTS WITH CROHN'S DISEASE

S. Kuin[1], S. Stolte[1], G. d'Haens[1], **M. Löwenberg**[1]
[1]*Department of Gastroenterology and Hepatology, Academic Medical Center, Amsterdam, Netherlands*

Contact E-mail Address: m.lowenberg@amc.uva.nl
Introduction: Remicade (infliximab) is an anti-Tumor Necrosis Factor (TNF) agent that is frequently used as induction and maintenance treatment for patients with Crohn's disease (CD). Remicade is administered intravenously and is usually given at 6-8 weekly infusion intervals. As a consequence, patients have to come to the infusion clinic, which is a time consuming effort.
Aims & Methods: The aim was to evaluate if Remicade infusions at home could serve as a useful alternative, and whether this is safe. A pilot study was conducted in which CD patients received Remicade infusions at home for the duration of one year. Patients had to be in clinical remission (HBI $\leq$ 4 points) receiving Remicade maintenance treatment. Data collected from questionnaires were assessed to evaluate satisfaction and experience of the participants. Patients were asked to rate on a scale from 1 to 10 (1 = very unlikely, 10 = very likely) if they would recommend Remicade at home to other CD patients. Costs were analyzed and compared to Remicade treatment at the infusion clinic. All data were analyzed using IBM SPSS 21.0 software.
Results: In total, 36 patients were contacted of which 13 patients (36%) wanted to participate. Of the participants, 54% were female and 46% male, with a mean age of 39,8 years. Five patients discontinued home administration before the end of the year (2 because of stringent infusion planning during working hours, and in 3 patients Remicade treatment was stopped). In total, 59 Remicade infusions were administered at home with a median dose of 369 mg (dose range: 300 to 700 mg). No severe adverse events were reported. Differences in costs between Remicade infusions at home and in the hospital were based on costs of home care nurses and infusion unit costs. Drug costs of Remicade were equal in both settings. The mean costs of one Remicade infusion at home was €230 compared to €284 for one Remicade infusion at the infusion clinic (excluding drug costs), which means a cost saving of €54 per infusion when Remicade is administered at home. Ten out of 13 patients (77%) returned the completed questionnaires. Most of the patients would recommend Remicade at home to other patients: 20% scored 3 points, 20% 6 points, 20% 7 points, and the remaining 40% scored 8 points. Seven out of 13 patients (54%) would recommend the possibility of infusions in the evening hours or during weekends.
Conclusion: We here show that about one third of patients wanted to participate. Most patients were satisfied as indicated by a score of 6 or higher in 80% of participants who were asked if they would recommend Remicade at home to other CD patients. Five out of 13 patients stopped before the end of the 1 year follow-up period (2 patients because of logistic reasons, and in 3 patients Remicade treatment was stopped). Home administration was €54 cheaper per infusion as compared to Remicade infusions at the infusion clinic. Future studies should demonstrate the benefits for the patients and possible cost savings of Remicade infusions at home, in order to evaluate whether this alternative setting can be recommended for daily practice.

P1592 OUTCOME OF THIOPURINE INTOLERANCE IN INFLAMMATORY BOWEL DISEASE

S. R. Fernandes[1], L. Correia[1], J. Velosa[1]
[1]*Gastrenterologia e Hepatologia, Hospital Santa Maria - Centro Hospitalar Lisboa Norte, Lisboa, Portugal*

Contact E-mail Address: samuelrmfernandes@gmail.com
Introduction: Thiopurines are frequently used to maintain remission in patients with moderately to severe Ulcerative Colitis and Crohn's Disease. Up to 2/3 of patients will present side effects and about 15% will be intolerant to thiopurine therapy.
Aims & Methods: To evaluate the impact of thiopurine intolerance on various clinical outcomes in patients with inflammatory bowel disease (IBD). Single center, observational study, including patients with IBD under thiopurine therapy. Two cohorts were defined (patients intolerant and not intolerant to thiopurines). Outcomes included need of multiple steroid cycles (≥ 3), multiple surgeries (≥ 2), number of hospital admissions and need and response to anti-TNF therapy. Statistical analysis was performed using SPSS v21.0.
Results: From 523 patients under thiopurine therapy, 61 (11.7%) were intolerant. Multiple steroid cycles (39.3% versus 40.7%, $p = 0.844$), number of hospitalizations (4.22 versus 4.25 $p = 0.96$) and multiple surgeries (9.8% versus 5.9% $p = 0.24$) occurred equally in both groups. Although time until anti-TNF therapy did not differ between groups (109 versus 101 months, $p = 0.655$) the rate of utilization was superior in intolerant patients (68.9% versus 42.6%, $p \leq 0.001$). Need for intensification of anti-TNF was not statistically different between groups (23.3 versus 33.6 $p = 0.274$), but occurred sooner in intolerant patients (26.9 versus 37.0 months, $p = 0.019$). Despite not statistically significant, the percentage of patients not responding to therapy escalation was superior in intolerant patients (80.0% versus 39.0%, $p = 0.08$). These findings were independent of IBD subtype or anti-TNF used.
Conclusion: In our series, the percentage of patients intolerant to thiopurines was in accordance to the published literature. Although intolerance was not associated with a rise in steroid utilization, admissions or surgeries, this group required more anti-TNF therapy and demonstrated worse clinical response.

P1593 ANTI-TNF-ALPHA-INDUCED LUPUS-LIKE-SYNDROM AND ANTI-TNF-ALPHA-INDUCED LUPUS IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE

S. Preuss[1], J. C. Preiss[1], B. Siegmund[1], **J. Maul**[1]
[1]*Medical Department, Division of Gastroenterology, Infectiology and Rheumatology, Charité – Universitätsmedizin Berlin, Germany, Berlin, Germany*

Contact E-mail Address: sandra.preuss@charite.de
Introduction: Drug-induced autoimmunity with elevated autoimmune antibodies, especially elevated ANA titres, is a common phenomenon in anti-TNF-alpha therapy of patients with inflammatory bowel disease (IBD). However, progression to anti-TNF-alpha-induced lupus-like syndrome (LLS) or even anti-TNF-alpha-induced lupus (ATIL) is uncommon. Yet, establishing this diagnosis is difficult since LLS or ATIL mostly manifests with arthralgia that is also frequent as extraintestinal IBD manifestation. Furthermore, there is no common definition for LLS and ATIL and the terms are often synonymously used in publications.
Aims & Methods: Our objective aims to describe precisely the characteristics of LLS and ATIL patients for proposing/discussing clear diagnostic criteria for anti-TNF-alpha-induced LLS and ATIL and to investigate the prognosis of patients with LLS or ATIL. For statistical analysis, a Mann-Withney test or a Spearman correlation was performed.
Results: So far, we have data from 18 patients with LLS or ATIL (10 female, 8 male; median age 41.5 (range 25-74); Crohńs disease (CD) $n = 13$, ulcerative colitis (UC) $n = 5$; Infliximab (IFX) $n = 10$; Adalimumab (ADA) $n = 8$. Median duration of IFX or ADA therapy until LLS or ATIL was 238 days (7-1825).
ANA titre was significantly lower before onset of LLS or ATIL (median ANA titre 1:320, $<$1:160-1:1280; $p = 0.0024$). When LLS or ATIL was present, the median ANA titre was 1:1280 ($<$1:160-1:20480), median anti-dsDNA level was 41.1 U/ml (10.8-104.3 U/ml) and median CLIFT (Crithidia luciliae immunofluorescence test) titre was $<$1:10 ($<$1:10-1:80). There was neither a correlation of ANA titres with dsDNA levels ($r = 0.341$) nor of dsDNA levels with CLIFT titres ($r = -0.065$). Almost all patients (16/18; except one patient with ANA titre of 1:320 and one patient with an ANA titre of $<$1:160) had ANA titres equal or above 1:640 with manifestation of LLS or ATIL.
Eleven patients had arthralgia as predominant symptom whereas 6 patients presented with arthritis (arthralgia + joint swelling). Other symptoms besides arthralgia or arthritis were rare (skin lesions $n = 3$; fever $n = 2$; myalgia $n = 2$; elevated liver function test $n = 2$). Mean total duration of anti-TNF-alpha therapy was 10 months (2-72 months). None of the patients fulfilled the ACR criteria for systemic lupus erythematosus.
Nine patients switched to another anti-TNF-alpha therapy (IFX to ADA $n = 4$; ADA to IFX $n = 4$; IFX to Golimumab $n = 1$) after cessation of symptoms and reduction of ANA titres below 1:1280. Four patients (IFX $n = 3$; ADA $n = 1$) experienced a recurrence of LLS or ATIL. The median ANA titre in these patients at the time point of recurrence was 1:1280 (1:640-1:2560).
Conclusion: In conclusion, in our cohort, almost all patients presented with arthralgia or arthritis and ANA titres equal or above 1:1280 at onset of LLS or ATIL.
Currently, we are investigating the prognosis of patients with LLS or ATIL with respect to failure of anti-TNF-alpha-therapy, worsening of disease, hospitalization and need for surgery in a case-control study.

Contact E-mail Address: shpark78@amc.seoul.kr
Introduction: CT-P13 is a biosimilar to innovator infliximab (INX) that has been approved by the European Medicines Agency in 2013. In observational study of CT-P13 which is ongoing at 15 study centers in South Korea, the efficacy of CT-P13 was assessed in 92 naïve patients of Infliximab with moderate-to-severe IBD patients (39 active Crohn's disease (CD) and 53 active Ulcerative Colitis (UC)).
Aims & Methods: The objective is to compare response and remission rates of CT-P13 in observational study to historical data of INX.
Retrieved relevant references from public domains are SONIC (Colombel JF. 2010)[1] and ACT I/II (Rutgeerts P. 2005)[2]. Efficacy endpoints were assessed using Crohn's Disease Activity Index (CDAI) in patients with moderate to severe active CD and using the Mayo Scoring System (MSS) in patients with moderate to severe active UC disease. Non-inferiority (NI) margin was defined to preserve 50% of effectiveness of INX. NI test was performed at 5% one-sided significance level. NI of CT-P13 is concluded if the bound of the 95% one-sided confidence interval for the difference of response and remission between CT-P13 and INX is larger than the pre-specified NI margin.
Results: SONIC[1] and ACT I/II[2] were used to determine NI margin for the CD and UC, respectively. The response and remission rates in the observational study of CT-P13 were within the NI margin and showed the earlier effectiveness in CD and UC naïve patients of Infliximab.
Conclusion: The early response and remission rates up to week 14 in the observation study of CT-P13 are comparable with historical data of INX.

P1595 HOW MUCH DOES OUR INFLAMMATORY BOWEL DISEASE PATIENTS ADHERE TO THE THERAPY?

S. Campos[1], A. Oliveira[1], P. Freire[1], M. Ferreira[1], S. Mendes[1], M. Silva[1], F. Portela[1], C. Sofia[1]
[1]*Centro Hospitalar Universitário de Coimbra, Coimbra, Portugal*

Contact E-mail Address: saratcampos@gmail.com
Introduction: Inflammatory Bowel Disease (IBD) often requires chronic therapy to reduce the risk of recurrence and possibly colorectal cancer. The adherence to therapy is therefore crucial to its success.
Aims & Methods: We aimed to assess adherence to therapy in IBD per os; determine potential predictors of "non compliance".
Results: We distributed 150 questionnaires regarding therapy adherence (Morisky medication adherence scale), beliefs in therapeutics (Questionnaire about the Beliefs in Therapy), therapeutic complexity (Questionnaire about the Therapeutics Complexity) and psychological factors (Hospital Anxiety and Depression Scale - HADS) to outpatients with IBD followed in a Gastroenterology department of a tertiary hospital. They were complemented in 139 cases (female sex-56%; mean age-40 years Crohn's disease-82, Ulcerative Colitis-57). We documented "non-adherence" to therapy per os (defined as Morisky questionnaire score <7) in 28.7% patients - 25% > 5ASA per os and 27% > azathioprine. The majority of "non-compliance" were intentional type - "I decided to reduce the medication for IBD because I feel worse when I take it" or "I stop taking medication when I feel the disease controlled". The complexity of the therapeutic regimen ($p = 0.003$), in particular the number of daily doses ($p = 0.012$), "ambivalence" (beliefs in the necessity of therapy score > 12/beliefs in concerns about the therapy score > 12) ($p = 0.038$) and depression (score HADS-D > 8) ($p = 0.046$) were associated with the "non-adherence" to therapy per os. Sex, age, disease time, disease type, bowel surgery or

previous hospitalizations, absenteeism and anxiety (score HADS-A > 7) had no impact on "non-compliance".
Conclusion: Non-adherence to therapy per os assumes a particular aspect in IBD. Optimizing the discussion about the concepts and concerns of patients to overcome perceptual barriers regarding medication, simplifying therapeutic schemes and timely manage behavioral changes may alleviate the negative aspects of the clinical course inherent to non- adherence.
Disclosure of Interest: None declared

P1596 INFLAMMATORY BOWEL DISEASE: ADHERENCE TO IMMUNOSUPRESSION IN THE ERA OF BIOLOGICAL THERAPY

S. Campos[1], A. Oliveira[1], P. Freire[1], M. Ferreira[1], S. Mendes[1], M. Silva[1], F. Portela[1], C. Sofia[1]
[1]*Centro Hospitalar Universitário de Coimbra, Coimbra, Portugal*

Contact E-mail Address: saratcampos@gmail.com
Introduction: Adherence to therapy is crucial for the impact in the disease prognosis and the implications in health costs. In Inflammatory Bowel Disease (IBD), infliximab is one of fundamental drug in the therapeutic approach, but its association with azathioprine provides greater efficacy. However, outside clinical trials, research on the adherence to the monotherapy with immunosuppression versus combined therapy with infliximab is scarce. Infliximab, with its administration features, determines particular conditions of adherence, but the same is not possible with azathioprine.
Aims & Methods: We aimed to assess adherence to azathioprine when combined with biological therapy; and determine potential predictors of "non-compliance".
Results: We distributed questionnaires regarding therapy adherence (Morisky medication adherence scale eight items) to 64 outpatients with IBD under azathioprine in a Gastroenterology department of a tertiary hospital, and 59 (93%) were completed. Female sex-58%; mean age-37 years; Crohn's disease-43, Ulcerative Colitis-16; 27 with combined therapeutic with infliximab. Adherence to immunosuppressive therapy (defined as the Morisky questionnaire score > 6) was similar in patients with and without infliximab (monotherapy with azathioprine-69% vs combined therapy-78%; p = 0.554). Overall, the "non-adherence" to immunosuppressants was greater in patients: male gender (p = 0.044); skeptics/indifferent about the need of therapy to control IBD (Questionnaire about Beliefs in Therapy) (p = 0.005), particularly about uncertainty about "life without drugs would be impossible". Age, disease type, previous bowel surgery, smoking, marital status, employment, academic, anxiety/depression (Hospital Anxiety and Depression Scale) and therapeutic complexity showed no increased risk for "non-compliance".
Conclusion: One in four patients with IBD do not adhere to immunosuppressants, but this rate does not seem to increase with the association with biological agents. Male and skepticism/indifference about the need for therapy for IBD, constituted risk factors for "non-compliance" with immunosuppression.

P1597 MANAGEMENT OF ABDOMINAL PHLEGMON IN ANTI-TNF NAÏVE CROHN'S DISEASE PATIENTS

S. O'Donnell[1], T. Chawla[2], G. C. Nguyen[1], M. Silverberg[1], A. H. Steinhart[1], K. Croitoru[1]
[1]*Gastroenterology,* [2]*Radiology, Mount Sinai Hospital, Toronto, Canada*

Introduction: An abdominal phlegmon is an inflammatory mass that can develop in Crohn's disease (CD), typically in the setting of stricturing and/or penetrating disease. The question of whether anti-TNF therapy is of benefit in treating CD patients presenting with phlegmon has not been well addressed.
Aims & Methods: In this retrospective study we aim to determine the efficacy of anti-TNF therapy in preventing surgery in the setting of an abdominal phlegmon complicating CD. Cases seen at single tertiary care IBD centre were identified using a radiology database searching for the words "Crohn's", "phlegmon" and "abscess". Exclusion criteria included a lack of follow up at the same institution, any underlying cause for phlegmon other than CD, postoperative complications resulting in a phlegmon, prior anti-TNF use or cases with > 2 prior resections.
Results: 59 cases were identified. All cases received antibiotic therapy and, of the 33 with an abscess, 22 underwent percutaneous drainage. The cohort was divided into 3 groups according to initial management: antibiotics with no additional therapy (n = 6), antibiotics followed by surgical resection (n = 45), antibiotics followed by anti-TNF therapy (n = 8). There were no major differences in clinical characteristics between the 3 groups at presentation.
45 cases underwent a surgical resection as a first line therapy following standard therapy with antibiotics +/- percutaneous drainage of an abscess. The median time from phlegmon diagnosis to surgery was 2 months (IQR 0-6 months). 8 cases received an anti-TNF as a first line therapy on top of standard therapy with antibiotics +/- percutaneous drainage of an abscess. The median time to commencement of an anti-TNF therapy was 7 months (IQR 0-38 months). There was just one abscess recurrence during follow up. This was in a case initially treated with surgical resection – this recurred at 11 months and after antibiotics and percutaneous drainage of an abscess an anti-TNF was commenced.
A second line intervention was more common in the anti-TNF treated group:12 of the 45 cases in the original surgical group later went on to receive an anti-TNF while 6 of the 8 originally treated with an anti-TNF went on to have surgery, (χ^2 p = 0.008). In a survival analysis, the time to an anti-TNF was significantly longer in the surgical group than the time to surgery in the group originally treated with an anti-TNF [126 months (95% CI 124-128) versus 32 (95% CI 20-44), p = 0.003]. In a cox regression analysis, receiving an anti-TNF prior to surgery was the only factor associated with a delay to surgery, see table.

	HR (95% CI)	P value
Anti-TNF therapy prior to surgery	0.15 (0.05-0.43)	< 0.0001
Phlegmon Resolution on Imaging	0.48 (0.22-1.04)	p = 0.063
Prior Surgery	1.47 (0.68-3.22)	p = 0.33

We did not see a difference in the rate of complications in those who received an anti-TNF prior to surgery nor was there a difference in the length of small bowel resected.
Conclusion: Anti-TNF can be safely used in the management of CD cases presenting with an abdominal phlegmon after antibiotic therapy and drainage of abscess where applicable. However, most cases will ultimately require surgery. Anti-TNF therapy may prolong the time to surgery but does not prevent surgery. Therefore we would propose an algorithm, where if possible, surgery is used first line to delay the need to use an anti-TNF.

Introduction: The advent of anti-TNF agents has advanced therapeutic goals to encompass not only clinical response and remission but also to include mucosal healing (MH). From 2006, we have undergone balloon-assisted enteroscopy to evaluate mucosal lesion of Crohn's disease patients. We have reported the development of immunoassay for antibody to infliximab (ATI) and anti-adalimumab antibody (AAA). In this study, we assess the factors predicting mucosal healing among patients with Crohn's disease treated with anti-TNF agents.

Abstract number: P594 Table 1: Non-Inferiority test results using historical data of INX at early time point

Indication	Category	INX			CT-P13 at Week14[1]	
		Historical data	n/N (%)	NI margin[2]	n/N (%)[3]	The bound of one-sided 95% CI [4]
CD	Response	SONIC-Week10(5mg INX)	104/169(61.5)	-0.119	34/39(87.2)	0.133
		SONIC-Week10(5mg INX + AZA)	129/169(76.3)	-0.010		
CD	Remission	SONIC-Week10(5mg INX)	80/169(47.3)	-0.097	27/39(69.2)	0.066
		SONIC-Week10(5mg INX + AZA)	101/169(59.8)	-0.058		
UC	Response	ACT I-Week8(5mg INX)	84/121(69.4)	-0.168	40/53(75.5)	-0.072
		ACT II-Week8(5mg INX)	78/121(64.5)	-0.024		
UC	Remission	ACT I-Week8(5mg INX)	47/121(38.8)	-0.132	26/53(49.1)	-0.046
		ACT II-Week8(5mg INX)	41/121(33.9)	0.005		

[1] Including two CD patients with baseline CDAI < 220 identified through clinical data reviews.
[2] Margin is defined as the 50% of INX effect size obtained through meta-analysis conservatively.
[3] Last observation carried forward (LOCF) imputation was used.
[4] The bound of the 95% one-sided confidence interval for the difference of response and remission between CT-P13 and INX

Furthermore, the association with mucosal lesion and trough levels of anti-TNF agent and concentrations of anti-drug antibody were investigated.
Aims & Methods: We reviewed the medical charts of patients with Crohn's disease under anti-TNF maintenance therapy who underwent balloon-assiseted enteroscopy between January 2006 and August 2014. Mucosal lesion was scored using the modified Rutgeerts score (MRS) (Imaeda H *et al. J Gastroenterol* 2013). MH was defined as when MRS was 0 or 1. The levels of anti-TNF agents and antibody to anti-TNF agents were measured. Cut-off values of each parameters were set as previously reported (Imaeda H *et al. J Gastroenterol* 2013).
Results: 84 patients were enrolled. MH was obtained in 31 patients (37%), on the other hand 49 patients (58%) had active mucosal lesions (Non-MH). Four patients (5%) had re-appearance of mucosal lesion although once confirmed MH. Anti-drug antibody was positive for all of these patients. Multivariate analysis revealed shorter disease duration and lower C-reactive protein at 2 to 4 weeks after starting anti-TNF agents were the factors predicting mucosal healing. During maintenance therapy, C-reactive protein and serum albumin levels are important clinical markers for the prediction of MH. No patients obtained MH if trough levels of anti-TNF agents are below cut-off values.
Conclusion: Lower C-reactive protein at 2 to 4 weeks after starting anti-TNF agents were the factor predicting mucosal healing. If the concentration of anti-TNF agents were below cut-off levels, mucosal healing is not achieved. Re-exacerbation of mucosal lesions suggests the appearance of anti-drug antibody.

P1599 ANTI-TNF ANTIBODY INDUCED PSORIASIFORM SKIN LESIONS IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE; AN IRISH COHORT STUDY

S. Kirthi[1,2], M. Hussey[1,2], A.-M. Tobin[1], F. Scaldaferri[3], M. Pistone[3], D. McNamara[1,2]
[1]*Trinitry Academic Gastroenterology Group(TAGG), Trinity Collge Dublin,* [2]*Department of Gastroenterology, Tallaght Hospital, Dublin, Ireland,* [3]*Centre for Research and Cure of Inflammatory Bowel Disease UOC, Institue of Medical Pathology Catholic University of the Sacred Heart, Rome, Italy*

Contact E-mail Address: ShivashiniKirthi@physicians.ie
Introduction: Introduction:TNF-α inhibitors have been widely used for the treatment of Inflammatory Bowel Disease (IBD). Studies have suggested an association between anti-TNFα and reactive psoriasis. This association appears paradoxical as TNF is a pivotal molecule in the pathophysiology of psoriatic skin lesions and anti-TNFα agents have been approved for treatment of psoriasis.
Aims & Methods: Aim: To determine the prevalence of psoriasis in an IBD cohort with reference to clinical characteristics and anti-TNFα use.
Methods:A retrospective cohort study design. Patients with a diagnosis of psoriasis and IBD were identified from a database at Tallaght Hospital from 2000 to 2015. Demographic and clinical data were recorded including diagnosis, age, gender, smoking status, anti-TNF α therapy. Prevalence rates of concomitant and reactive psoriasis were calculated and compared using a students T-test. A p value of <0.05 was considered significant.
Results: In total, 1384 IBD patients were identified; female 49% (n = 682), ever smoked 19% (n = 261), 30% (n = 403) anti-TNF α therapy, 59% (n = 237) and 41% (n = 166) on Infliximab and Adalimumab respectively, 35% (n = 483)had Ulcerative Colitis (UC) and 65% had (n = 901) with Crohn's disease(CD). A higher number, 21% (n = 189) of the CD group smoked compared to 15% (n = 72) in the UC cohort, p = 0.0001, 95% CI 0.15-0.21. The overall prevalence rate of IBD and psoriasis was 2.4% (n = 33). Of the 33 patients with psoriasis, mean age 46 years (range 18-66), 24% (n = 8) had reactive psoriasis, ie. psoriasiform lesions occurring after commencement anti-TNFα therapy. The prevalence rate of psoriasis in the non-biologic and biologic cohort were similar 2.5% (25 of 981) and 2% (8 of 403) respectively. Overall, psoriasis occurred more frequently in patients with UC (5.2%), Odds Ratio (OR) = 6, p < 0.001, 95% CI = 2.72-13.61. However, subjects with CD were more likely to develop reactive psoriasis, OR = 34.5, p = 0.0013, 95% CI 3.99-297.99. Of note, there was a trend towards higher rates of reactive psoriasis in Adalimumab users which was 3.6% (6 of 166) vs. 0.8% (2 of 237), OR = 4.4 (P = 0.07). However, overall relatively more CD patients, 44% vs. 31% with UC were prescribed Adalimumab, p = 0.02, 95% CI 0.02-0.25. In addition, in our cohort, smoking was not associated with any form of psoriasis in IBD, OR = 1.39, p = 0.06
Conclusion: In our large study, the prevalence rate of reactive psoriasis was similar to the background rate of psoriasis in the overall IBD cohort (2.0% vs 2.4%). However, our overall rate of reactive psoriasis was lower than previously reported (5%) [1] and could reflect the retrospective study design. Although it remains a possibility, especially as both are autoimmune TNFα mediated diseases, that our findings reflect the natural history of the two diseases. A 2% prevalence rate represents a common adverse event that clinicians should be aware of and our data suggests an increased rate of CD in particular which may reflect smoking status in this group. Psoriasis is common in IBD patients. There is an increasing awareness of the phenomenon of reactive psoriasis in patients with biologics. However, further work to better elucidate the pathophysiology is required.

Contact E-mail Address: stefan.lindgren@med.lu.se
Introduction: Inflammatory bowel diseases (IBD) are chronic with different character and intermittent or more rarely continuous inflammatory activity. The activity ranges from mild to severe. The response to treatment varies and the choice of treatment is still partly arbitrary. Some patients represent a particular problem due to lack of response or intolerance to conventional treatment.
Aims & Methods: 136 patients, 54 with ulcerative colitis (UC), 81 with Crohńs disease (CD) and 1 with indeterminate colitis (IC) were included in a registry covering the majority of patients treated with Granulocyte/Monocyte Adsorption (GMA) in Sweden. The disease activity was mainly mild or moderate. The inclusion criteria were intolerance to conventional treatment in 39 patients, refractory disease in 28, contraindications to conventional therapies in 16, other indication in 25 and unspecified in 45. In 17 patients there was more than one indication for inclusion. Included patients will be followed for 12 months after the last GMA session. Monitoring includes symptoms (short health scale), activity indices (HBI, UCDAI, SCCAI) and fecal calprotectin. The patients received 5-10 GMA sessions 1-2 times weekly and the clinical activity was assessed at baseline, after complete course, 3 month after complete course and 12 month after complete course. Here we present data from the first 3 months of follow-up, based on intention to treat.
Results: Overall, patients reported improved well being. In parallel activity indices and fecal calprotectin levels decreased. The treatment tolerance was high and no adverse events were documented.
Conclusion: GMA treatment improves patient status up to 3 months after completed course. GMA offers an alternative to patients refractory or intolerant to conventional treatment. The long-term benefits of GMA will be documented during the ongoing follow-up in the directory.

Introduction: The OPTIMUM observational study was set up in France in 2011. The purpose of this study is to describe the progression and methods of therapeutic management of mild to moderate ulcerative colitis (UC) and to assess remission rate and duration as well as the predictive factors for relapse.
Aims & Methods: This observational study included patients aged 18 years and above experiencing a mild to moderate UC flare-up. The patient's data were recorded in an electronic CRF during consultations conducted as part of regular monitoring. At each visit, a questionnaire regarding treatment compliance was completed by the patient (the Modified Morisky Adherence Scale: MMAS-8) and the activity was assessed by ulcerative colitis clinical score (UCCS). From June 2011 to June 2012, 812 patients (51% female, average age of 45 ± 15 years) were included in the observational study by 130 gastroenterologists.
A follow-up period of three years is planned. A descriptive analysis of the data at two years is presented here. It was agreed that an annual visit would be defined by an interval of ± 100 days.
Results: In August 2014, the one-year and the two-year visit data were available for 559 (69%) and 393 (48%) of the patients, respectively. Ninety patients (11%) stopped the study prematurely; this was primarily due to a colectomy for 10 patients, a change in diagnosis for 4 patients, 1 death related to malignant thymoma and 28 cases lost to follow-up. According to the UCCS, 437 patients (78%) were in remission (score of 0 to 2) during the first year and 317 (81%) at two years. UC treatment was on-going in 474 patients (85%) at 1 year and in 327 patients (83%) at 2 years (Table 1).
Table 1: UC treatment at each visit

Treatments	5-ASA	Corticosteroïd	Immunosuppressant	Anti-TNF α
1 year n(%)	359 (76)	86 (18)	81 (17)	21 (4)
2 year n(%)	253 (77)	46 (14)	59 (18)	20(6)

The MMAS-8 questionnaire was completed by 370 patients (78%) and 213 patients (65%) at one year and two years, respectively. Compliance was good (score = 8) in 104 patients (28%) at one year and 83 patients (39%) at two years. At least one relapse of UC over the year was reported in 183 patients (33%) at one year and in 119 patients (30%) at two years. Patients with poor compliance have an increased risk of recurrence OR 1.8 (95% IC [1.23–2.62]). Colorectal

cancer or dysplasia was reported in three patients. At least one adverse event was reported in 20 patients (3%) and 4 were recorded as serious AEs.
Conclusion: After two years' follow-up of the OPTIMUM cohort, oral 5-ASAs remain the most commonly prescribed treatment. The relapse rate was around 30% each year and about 80% of patients were in remission at 1 and 2 years. Poor compliance was associated with a higher risk of relapse.

P1602 DOSE ESCALATION AND HEALTHCARE RESOURCE USE AMONG ULCERATIVE COLITIS PATIENTS TREATED WITH ADALIMUMAB IN ENGLAND

C. M. Black[1], E. McCann[2], E. Yu[3], M. Nixon[3], **S. Kachroo**[1]
[1]*Merck, Whitehouse Station, United States,* [2]*Merck, Hoddesdon,* [3]*IMS Health, London, United Kingdom*

Contact E-mail Address: Sumesh.Kachroo@Merck.com
Introduction: Studies focusing on dose escalation of bioloigcs therapies are limited. Therefore, understanding treatment patterns (with a focus on dose increase) and any attendant increase in resource utilization becomes important from a societal perspective.
Aims & Methods: The objective of this study was to describe the real-world use of adalimumab (ADA) for maintenance treatment of ulcerative colitis (UC) and associated healthcare resource use and costs in hospitals in England. A longitudinal, retrospective cohort study was conducted using the Hospital Treatment Insights database, which links pseudonymised patient data with hospital pharmacy dispensing. Included patients were adults with UC who received ≥240mg of ADA in the induction phase and had ≥3 dispenses of ADA in the maintenance phase. Patients were grouped into cohorts according to whether they received ADA 40mg every other week or dose-escalated to ADA 40mg every week in the maintenance phase. Healthcare resource use considered prescriptions and inpatient, outpatient, and emergency department visits with associated costs evaluated via the 2013-14 Payment by Results tariff.
Results: One hundred and ninety-one patients (median age 40.0 years, 42.9% male) had sufficient dispensing data to determine a completed induction phase and to establish a pattern of maintenance dosing. Eight-three patients (43.5%) dose-escalated by ≥100% (median ADA dose after escalation was 107mg) and median time to dose escalation was 139 days. Further analysis revealed that 105 patients (55.0%) dose-escalated by ≥50% and 120 patients (62.8%) by ≥30%. Of the patients who dose-escalated by ≥100%, subsequent de-escalation of ≥50% occurred in 56 patients (67.5%) with a median time to de-escalation of 21.0 days. The median duration of adalimumab treatment in all patients was 1.1 years from the index dose, with a longer duration observed in patients who dose-escalated (1.4 years versus 0.9 years for patients who did not). The mean cost associated with all-cause healthcare resource use was £13,892 in the 12 months post-index ADA dose. All-cause costs were higher for patients who dose-escalated than for patients who did not (£14,596 and £13,351, respectively). Healthcare resource use specifically related to UC was associated with a mean cost of £11,494 in the 12 months post-index period; the dose-escalated cohort had higher costs than the cohort that did not dose-escalate (£11,751 and £11,296, respectively). Prescriptions accounted for the majority of costs (£11,090 in all patients, £11,423 and £10,834 in the dose-escalated cohort and the cohort that did not dose-escalate, respectively). Costs in females were found to be significantly lower than in males (mean difference £1709.65, $p = 0.0281$).
Conclusion: The proportion of UC patients who dose escalate from ADA 40mg every other week to ADA 40mg every week in maintenance is higher than previously reported in the UK Inflammatory Bowel Disease Audit[1]. This finding and the impact that dose escalation has on costs may have implications for healthcare professionals and budget holders in the English healthcare system.

Contact E-mail Address: sumesh.kachroo@merck.com
Introduction: Thiopurine immunomodulators are recommended for moderate to severe ulcerative colitis (UC) patients. No prior study has comprehensively evaluated their effectiveness in disease control in real world clinical practice.
Aims & Methods: This analysis is to describe disease control among moderate to severe UC patients who were biologics naïve and treated with thiopurines. Patients with moderate to severe active UC (Mayo score $>=6$), aged $>=18$ years who were biologics naïve and received thiopurines during the 12 months prior to the enrollment date were recruited from 46 hospitals across the following 11 European countries. Patients who underwent colectomy procedure or ileo-anal Jpouch reconstruction were excluded. Medical charts for the 12 months prior to the enrollment date were reviewed to collect clinical data and patient-completed questionnaires were used to collect information on satisfaction with UC treatment, quality of life and level of disease control. The primary endpoint was disease control, defined as full Mayo score ≤2 with no individual sub-score > 1 (remission) and no corticosteroid use in the two months prior to enrollment or, if no endoscopy, partial Mayo score ≤2 with no individual sub-score > 1 and no corticosteroid use in the two months prior to enrollment. Descriptive and multivariate analyses were performed to summarize patients' disease control status and evaluate factors associated with this outcome. This post hoc analysis was limited to patients who received thiopurines for at least 4 months in the 12-months prior to enrollment.
Results: A total of 103 patients were included in this post hoc analysis. Patients' mean age was 44.3 years (SD = 15.4) and 66% were male. The median duration of UC was 7.6 years (IQR 3.6-12.2). Extent of UC included 12.7% proctitis, 29.4% left-sided, and 55.8% extensive colitis. At the enrollment date, the percentages of patients receiving thiopurines, aminosalicylates, corticosteroids and other types of immunosuppressants were 94.2%, 75.7%, 18.4% and 1.0%, respectively and the mean Mayo score was 5.08 (SD = 2.9). Eighty-nine percent of patients did not achieve disease control. Specifically, 84% of patients were not in remission at the enrollment date and 30% were treated with corticosteroids in the previous 2 months. Overall, 49.5% of patients were not satisfied with current UC therapies, and 74.4% still had uncontrolled UC according to endoscopy results, indicating active inflammation. The correlation coefficient between perceived severity and clinical measures of disease status by full or partial Mayo score was 0.5.
Conclusion: The majority of biologics naïve UC patients were not under control and half of patients were dissatisfied with their UC treatment. There was a significant gap between disease control perceived by patients and control measured objectively. Tighter disease control and step-up in therapy should be considered in UC patients who do not achieve full disease control while on standard medications.

Introduction: Ulcerative colitis (UC) is a chronic inflammatory disorder that can interfere with patient's ability to have full personal and professional lives. UC often requires long-term therapy with multiple medications resulting in a high burden of disease on patients.
Aims & Methods: This study is to describe the impact on Quality of Life (QoL) and work productivity among moderate to severe UC patients who were biologics naïve and treated with conventional therapies. Biologic naïve patients with moderate to severe UC (Mayo score ≥ 6), ≥ 18 years who received conventional therapies during the 12 months prior to enrollment were recruited from 11 European countries. Patients who underwent colectomy or ileo-anal J-pouch reconstruction were excluded. Patients were classified with controlled or uncontrolled disease; controlled disease being clinical Mayo score ≤2, no subscore > 1, and no corticosteroids in the two months prior to enrollment or, if no endoscopy, partial Mayo score ≤2 and no corticosteroids in the two months prior to enrollment. Medical charts for the 12 months prior to enrollment were reviewed to collect clinical data. Patients completed EQ-5D-5L plus a visual analogue scale (VAS, 0-100), Quality of Life in Inflammatory Bowel Disease (SIBDQ) and Work Productivity Activity Impairment: UC (WPAI:UC) questionnaires. QoL and work productivity loss between controlled and uncontrolled patients were compared using chi-square and t-test.
Results: A total of 250 patients were included and 218 (86%) had un-controlled UC. Patients' mean (SD) age was 46.6 years (16.3) and 59% were male. The median duration of UC was 6.9 years (IQR 2.3-14.4). Extent of UC included 21.6% proctitis, 28.4% left-sided, and 49.6% extensive colitis. At the enrollment date, the percentages of patients receiving thiopurines, aminosalicylates, corticosteroids and other types of immunosuppressants were 63.2%, 75.2%, 23.6% and 3.6%, respectively. The mean (SD) of EQ-5D-5L VAS score of 78.4 (14.9) among patients in controlled disease was significantly higher than for patients in uncontrolled disease 69.5 (19.4), ($p = 0.02$). Patients in controlled disease had numerically better scores in SIBDQ than the patients in uncontrolled disease, but not significantly different. The mean (SD) global score in SIBDQ for patients with controlled and uncontrolled UC was 5.1 (1.3) and 4.8 (1.3), respectively. WPAI: UC questionnaire indicated that 40.7% patients were not working. The mean percentages (SD) of patients reporting work time missed, impairment while working and overall work impairment were 12.3 (27.3), 20.5 (25.9), 26.5 (32.2), respectively. The mean percentage (SD) of impairment of non-work activity for patients with controlled and uncontrolled UC were 17.1 (25.5) and 27.4 (28.6) ($p = 0.02$) respectively.

Conclusion: Overall, uncontrolled UC patients experienced a significant lower QoL and a higher percentage productivity loss than controlled UC patients. Since only 32 (14%) patients were in the controlled UC group, more studies are needed to test the differences.

Contact E-mail Address: molnar.tamas@med.u-szeged.hu
Introduction: CT-P13 is the first biosimilar to infliximab that has been approved for the same indications than infliximab in June 2014 in Hungary. Studies examining whether CT-P13 is similar to that of reference infliximab will have a high importance.
Aims & Methods: The aim of this study was to examine the efficacy of CT-P13 induction therapy on mucosal healing in patients with ulcerative colitis (UC). Patients diagnosed with UC, who received CT-P13 induction therapy from June 2014 at three Hungarian IBD center, were prospectively enrolled. Medical records analyzed included patients' characteristics, previous history of infliximab administration, response to CT-P13, concomitant medications, and adverse drug reaction. Serum activity markers, trough levels and antibody titers have been measured. Sigmoideoscopy was performed at the end of the induction therapy within week 6 to 10. Mucosal healing was defined as Mayo endoscopic subscore of 0 or 1. Complete mucosal healing was defied as Mayo endoscopic subscore of 0.
Results: Thirty-eight UC patients who underwent CT-P13 induction therapy were enrolled in the study. Male-female ratio was 22:16. Mean age at diagnosis was 33.2 years (range 17-65). Indication of the therapy was acute, severe flare up and chronic, refractory activity in 16 and 22 patients. Mean value of Mayo endoscopic subscore was 2.7 points at the beginning of the study. Clinical response and remission at week 14 were achieved in 92% of the patients. Sigmoideoscopy revealed mucosal healing in 25 patients; complete mucosal healing in 12 patients at week 14. Endoscopic Mayo subscore decreased significantly at week 14 compared to week 0 ($p > 0.001$). None of the examined laboratory and clinical parameters predicted to the outcome of the therapy on mucosal healing at week 14. Trough levels of infliximab correlated with mucosal healing.
Conclusion: This was the first study examining the efficacy of CT-P13 induction therapy on mucosal healing in UC. CT-P13 induction therapy showed clinical response and remission in more than 90% of the UC patients. Mucosal healing was revealed in 65.8% of the patients after the induction therapy. Our results indicate that the induction with CT-P13 can result mucosal healing in a high proportion of the patients.

P1606 CLINICAL AND QUALITY ATTRIBUTE CONSISTENCY FOR A GLYCOSYLATED MONOCOLONAL ANTIBODY THERAPY (ADALIMUMAB)

T. Albuquerque[1], A. Varga[1], B. Huang[1], M. Naill[1], P. Tebbey[1]
[1]*AbbVie, Inc., North Chicago, United States*

Contact E-mail Address: paul.tebbey@abbvie.com
Introduction: To illustrate the structural consistency of adalimumab (D2E7), we present a series of quality attributes from >500 drug substance batches produced from 4 facilities and 5 production scales from 2001-2013. In parallel, the clinical performance of adalimumab in Crohn's Disease (CD) and Ulcerative Colitis (UC) trials displays consistency through time. Collectively, the data challenge the concept related to biologic therapy variability.
Aims & Methods: A series of structural quality attributes from over 500 adalimumab drug substance batches produced from 4 facilities and 5 production scales were assessed. Structural quality attributes analyzed include charge isoforms containing 0/1/2 C-terminal lysines and other acidic species, oligosaccharides on a conserved N-linked glycosylation site, and TNFa binding. An analysis of clinical response [clinical remission defined by Crohn's Disease Activity Index (CDAI) in CD, and partial Mayo score in UC] observed with adalimumab treatment in patients with Inflammatory Bowel Disease (IBD) facilitated comparison over time.
Results: Manufacturing changes for adalimumab primarily targeted scale increases, improvements in process robustness, and control across manufacturing sites. Charge microheterogeneity of adalimumab has been consistent as measured by proportion of lysines species over the product's history. Glycosylation patterns contribute to the unique structural signature of mAbs, influence function and are considered important product QAs when determining comparability. Identity and quantity of oligosaccharides on the conserved N-linked glycosylation site of adalimumab was evaluated on batches manufactured each year. Relative quantity of the agalactosyl fucosylated biantennary oligosaccharide forms of adalimumab has remained consistent through time, as have proportions of galactose-containing fucosylated biantennary oligosaccharides and detectable high mannose glycoforms. Concurrent to the molecule's structural consistency, potency of antibody for ligand binding was maintained through time. In parallel, the performance of adalimumab in IBD clinical trials that were performed to support regulatory approvals and commitments displayed consistency through time for patients having at least 3 years of adalimumab exposure in ADHERE (CD) or ULTRA3 (UC) (**Table**).
Table: Long-term Remission[a] in Crohn's Disease (CD) and Ulcerative Colitis (UC) for Patients Who Had at Least 3 Years of Adalimumab (D2E7) Exposure

	3 months	6 months	12 months	24 months	36 months
Crohn's Disease, N ± 256	64.8	65.1	65.0	70.4	68.7
Ulcerative Colitis, N ± 346	68.3	68.2	71.4	75.1	76.6

[a]Clinical remission for CD is defined by CDAI < 150; clinical remission for UC is defined by partial Mayo score as a decrease in partial Mayo score of ≥2 points from Baseline AND a decrease in partial Mayo score of ≥30% from Baseline AND a decrease in the rectal bleeding subscore ≥1 from Baseline.
Conclusion: Adalimumab has demonstrated a highly consistent quality attribute profile, exhibiting minimal variability through over 500 batches produced over 12 years, globally aligned and maintained across multiple sites and process scales. The consistency of the structural attributes of adalimumab provides the foundation for consistency in clinical performance. Collectively, these data contribute to the ongoing scientific debate on criteria necessary to establish and maintain biosimilarity.

P1607 ETROLIZUMAB TREATMENT INCREASES BLOOD LEVELS OF CD3, TREG AND TH17 CELLS MEASURED THROUGH EPIGENETIC ACTIVATION OF THE CD3, FOXP3 AND IL-17 LOCI

F. Fuh[1], E. Raschke[2], A. Chai[1], C. Looney[1], T. O. Kleen[2], S. Vermeire[3], S. O'Byrne[1], **T. Ramirez Montagut**[1]

Introduction: Identification of blood biomarkers reflecting GI pathology and disease modification upon treatment is challenging. We assessed the effect of etrolizumab, an anti-$\beta 7$ integrin mAB, on peripheral blood lymphocytes in ulcerative colitis patients (UC pts). We utilized a novel approach to quantify the number of CD3+ lymphocytes and those committed to Treg or Th17 lineage by measuring epigenetic activation of the CD3, FoxP3, and IL-17 loci. Epigenetic activation at all 3 loci has been previously shown to correlate with the respective immune cell content. Importantly, different epigenetic activation patterns have been shown within the FoxP3 gene exclusively in Treg cells and not in FoxP3+ effector T-cells.
Aims & Methods: Immune cell content in peripheral blood samples from healthy controls and UC pts was determined by measuring the presence of epigenetic activation at the respective loci in relation to epigenetic activation of the GAPDH locus, which determines the total cell number. Demethylation of a particular DNA CpG motif can be detected through a demethylation-specific qPCR analysis that quantifies the presence of epigenetically active loci.
Results: Biomarker data was analyzed in 42 anti-TNF-naïve (aTNF-naïve) and 62 anti-TNF-experienced (aTNF-experienced) pts from the placebo-controlled phase 2 study of etrolizumab in pts with moderate to severe UC (EUCALYPTUS). No differences in T cell (CD3+), Treg (FoxP3), and Th17 (IL-17) content were observed at baseline for the 3 treatment arms (placebo, etrolizumab 100 mg, etrolizumab 300 mg). However, compared with healthy controls (n = 60), UC pts showed generally reduced T cell and Treg values. Additionally, aTNF-experienced pts demonstrated lower median T cell and Treg values at baseline compared with aTNF-naïve pts (CD3+ T cells 21.3% vs 25.5%, $P = 0.008$; Treg 1.01% vs 1.35%, $P = 0.01$, respectively). Over the course of the study, peripheral levels of all 3 cell types were relatively stable in the placebo group, whereas etrolizumab-treated pts showed a trend towards an increase in all 3 cell types. The median increase of CD3+, Treg and Th17 cells in the 300 mg group was greater compared with placebo at day 29 ($P \leq 0.05$). After induction with etrolizumab, trends in increases of CD3+, Treg and Th17 cells were associated with clinical remission, however statistical significance was observed only at day 29 for the 300 mg group ($P \leq 0.05$ for CD3 and FoxP3). The median increase in CD3+ T cells appeared more profound in remitters who were aTNF-experienced than in those who were aTNF-naive (2.9-fold and 1.27-fold, respectively, at day 71). Interestingly, different levels of Treg cells at baseline appeared to be associated with an increased likelihood of remission: increased levels in the aTNF-naïve pts and decreased levels in aTNF-experienced pts.
Conclusion: UC pts have lower peripheral blood T cell and Treg levels compared with healthy donors, especially aTNF-experienced pts. Upon treatment with etrolizumab, all tested T cell types in peripheral blood increased with more pronounced increases seen in pts who achieved clinical remission. Finally, levels of Treg at baseline may be associated with clinical remission upon etrolizumab treatment.

P1608 INTENSIVE VERSUS DAILY GRANULOCYTE AND MONOCYTE APHERESIS AS FIRST-LINE THERAPY IN PATIENTS WITH ULCERATIVE COLITIS WHO WISHED TO AVOID PHARMACOLOGICS

T. Ohmori[1]
[1]*Department of Gastroenterology, Ohmori Clinic, Ageo, Japan*

Contact E-mail Address: toshihideo@gmail.com

Introduction: At our clinic, we receive patients with ulcerative colitis (UC) who wish to avoid hospitalization and therefore require treatment in an outpatient setting. Additionally, with the availability of granulocyte/monocyte apheresis (GMA, Adacolumn), most patients favour this non-pharmacologic intervention as the first-line treatment to avoid pharmacologicals. Therefore, we initiate GMA therapy for patients with UC before any drug-based medication.

Aims & Methods: GMA was applied as the first-line therapy for remission induction in consecutive patients with moderate to severe UC according to the Mayo score for ulcerative colitis. All patients had come to our clinic soon after a relapse, and none needed immediate hospitalisation. In under age cases consent from one of the patient's parents who had accompanied the patient to our clinic was sought. Patients received either daily GMA (dGMA) up to 11 sessions, or received 2 to 3 GMA sessions per week (ndGMA), up to 11 sessions. In all cases, safety including haematology and efficacy was determined prior to each GMA session and final evaluation was done one week following the last session.

Results: Twenty-one consecutive patients, average age 35 years, range 14-64 years were treated. Eleven patients had left-sided colitis, and 10 had pan colitis. Patients received either dGMA (n = 11) or ndGMA (n = 10). In the dGMA group, the average number of GMA sessions was 10.8 within 12.8 days. The corresponding values in the ndGMA group were 10.8 sessions and 23.9 days. The average Mayo score at entry was 8.4 in the dGMA group and 8.6 in the ndGMA group. At the final assessment, the Mayo score had decreased to 3.0 in the dGMA group and to 2.4 in the ndGMA group. A small number of patients with extensive deep ulcers did not respond to GMA. No statistically significant differences was found between the two groups in terms of the Mayo score. In these patients, in spite of daily GMA or up to 3 sessions per week, no significant abnormality was observed in the haematological data and no other serious adverse event related to GMA was observed.

Conclusion: Applying GMA immediately following a clinical relapse is a favourable factor for efficacy. Further, prior to GMA, colonoscopy is essential to avoid futile use of GMA in patients who may not respond. The findings in these 21 patients represent routine clinical practice during which GMA therapy was applied for the treatment of patients with an active flare of UC. The GMA treatment frequency we applied is very much more intensive than routine weekly GMA most hitherto studies have reported. The treatment was well tolerated by the patients without any safety concern. However, GMA is very much favoured by patients for its good safety profile, as well as for being a non-pharmacologic intervention.

Introduction: Methotrexate (MTX has been utilized for treatment of inflammatory bowel disease (IBD) or decades. However, its clinical utility is limited by safety and tolerability concerns. Long-term retrospective safety data from large cohorts is sparse. The aim of our study was to describe the safety and tolerability of MTX in a multicenter European retrospective referral center cohort.

Aims & Methods: Consecutive patients treated with MTX for IBD were included. The main outcomes included prevalence of adverse effects requiring dose modification or drug discontinuation.

Results: A total of 216 IBD (CD-182 (84.3%) patients were treated with MTX between July 1992 and January 2012. The clinical and demographic characteristics of the included patients were as follows: age at diagnosis –33 ± 14.6 years, males- 47.2%: duration of disease before onset of MTX therapy- 7 ± 8.1 years, current smokers-23.9%. The induction administration route was oral in 38%, and subcutaneous or intramuscular in 62% of patients. The maintenance administration route was oral in 46.3%, and subcutaneous or intramuscular in 53.7% of patients. The mean weekly dose was 21.1 ± 6.1 mg for induction, and 18.3± 6.4 mg for maintenance treatment. The mean duration of maintenance treatment was 22.4+ 26.7 months. Concomitant treatment was received by 114 (54.6%) of the patients; 66 (30.6%) received concomitant anti-TNFs, 21 (9.7%)- AZA. Corticosteroids were required at least once by 95 (44%) of the patients.

At least 1 adverse effect was experienced by 67 (31.13%) of the patients, leading to reduction in 30 (14%) and temporary discontinuation 6 (2.8%) of the patients. MTX discontinuation was required by 38 (17.8%) of the patients. The reason for modification was gastrointestinal intolerance in in 7.5% hepatotoxicity in 7%, and hematological abnormalities in 1% of the patients. Hospitalization for an adverse effect was required for 14 (6.5%) patients Infectious complications were documented in 34 (15.9%) of the patients during the course of the treatment. Nausea was reported by 20 (9.4%) patients and required medical treatment (metoclopramide or odansetron) in 6 of them. Malignancy was diagnosed in 3 patients. Two deaths occurred during MTX treatment from unrelated causes (1 from urothelial carcinoma and another patient from renal failure and arrhythmia)

Conclusion: MTX treatment in IBD patients is associated with a favorable long-term tolerability and safety profile.

Introduction: Methotrexate (MTX) has been utilized for the treatment of Crohn's disease (CD) for decades. Nevertheless, clinical trials as well as retrospective series provide equivocal evidence regarding the efficacy of MTX in CD.

The aims of this study were to describe the efficacy of MTX for maintenance of remission in CD and to identify the factors associated with MTX failure in a multicenter European referral center cohort.

Aims & Methods: Consecutive patients treated with MTX for CD were included. Patients treated with a combination of TNF-alpha inhibitors and MTX were excluded from the analysis. The main outcome was steroid-free clinical remission, without a need for a concomitant biologic/thiopurine therapy or need for Crohn's related surgery.

Results: A total of 182 CD patients were treated with MTX between July 1992 and January 2012; 66 patients were excluded from the analysis due to a concomitant treatment with a TNF alpha inhibitor. The clinical and demographic characteristics of the included patients were as follows: age at diagnosis – 33 ± 14.6 years, males- 44.8%: duration of disease before onset of MTX therapy- 7 ± 8.7 years, current smokers-19.3%; 24.3% had a stenotic and 25.2% -a penetrating phenotype; 43.1% had a history of anti-TNF treatment. The induction administration route was oral in 34.6%, and subcutaneous or intramuscular in 63.4% of patients. The maintenance administration route was oral in 47.1%, and subcutaneous or intramuscular in 52.9% of patients. The mean weekly dose was 22.1 ± 5.6 mg for induction, and 18.8± 5.1 mg for maintenance treatment. Steroid-free remission was achieved in 39/118 (33.1%) patients and was maintained for 27 ± 28.8 months. The mean time to achieve remission was 2.9 ± 3.5 months. On multivariate analysis, oral induction route (OR: 0.23, p = 0.03) and previous anti-TNF therapy (OR: 0.16, p = 0.013) were associated with a risk of therapeutic failure, while non-smoking (OR: 4.7, p = 0.049) was protective. Neither weekly dose nor route of maintenance MTX administration were associated with a likelihood of achieving remission.

Conclusion: MTX treatment achieves durable clinical remission in a third of CD patients, and should be considered a viable treatment option. The likelihood of clinical remission is lower in smokers, patients with a history of anti-TNF treatment and when oral induction treatment is used.

P1611 EVIDENCE BASED PRESCRIBING TRENDS IN CROHN'S DISEASE IN THE UK: NATIONAL POPULATION-BASED STUDY

V. Chhaya[1], S. Saxena[2], C. Alexakis[1], E. Cecil[2], V. Subramanian[3], V. Curcin[4], A. Majeed[2], R. Pollok[1]
[1]*Gastroenterology, St George's University Hospital,* [2]*Primary Care and Public Health, Imperial College, London,* [3]*Gastroenterology, St James' University Hospital, Leeds,* [4]*Primary Care and Public Health Sciences, King's College London, London, United Kingdom*

Contact E-mail Address: richard.pollok@nhs.net
Introduction: Over the past twenty years the research base has improved sufficiently to enable evidence based guidelines to specify indications for optimal use for 5-aminosalicylic acids (5-ASAs), steroids and thiopurines (TPs).
Aims & Methods: Our aim was to determine trends in Crohn's disease (CD) related prescribing patterns of oral and topical 5-ASAs, steroids and TP over the past 20 years.
We constructed an incident cohort of patients with CD diagnosed between 1990 and 2009 using the Clinical Practice Research Datalink (CRPD). We divided our cohort to compare patterns between era: era 1 (1990–1993), era 2 (1994–1997), era 3 (1998–2001), era 4 (2002–2005) and era 5 (2006–2009). We evaluated trends in prescribing by calculating the proportion (number of patients receiving a prescription/number of patients diagnosed in the era) of patients, adjusted for age and sex, receiving at least one prescription for each oral or topical 5-ASAs, oral or topical steroids and TPs (azathioprine and mercaptopurine) within 1 year from the time of diagnosis. We evaluated trends based on the publication of key research during the study period. χ^2 test for trend was used to compare proportions between groups.
Results: There were 6997 patients who met our inclusion criteria. The proportion of patients with at least one prescription for oral 5-ASAs within a year of diagnosis increased from 32.7% to 47.3% ($p < 0.001$) between era 1 and era 5 but plateaued after era 3 (era 3 vs era 5, $p = 0.59$) which coincided with a publication by Hanauer *et al* [1]. The use topical 5-ASAs was stable at just below 5% ($p = 0.48$) between era 1 and era 5, respectively. Oral steroid prescriptions have been the mainstay of treatment in CD [2] and increased from 51.7% to 61.3% (era 1 vs era 5, $p < 0.001$), but plateaued after era 3 (era 3 vs era 4, $p = 0.98$) in keeping with a meta-analysis [3]. Topical steroid use within 1 years of diagnosis declined from 13.2% to 5.4% ($p < 0.001$). There was an increase in TP prescriptions between era 1 and era 5 from 14.0% to 47.1% ($p < 0.001$) which was supported by evidence published in 1995 [5].
Conclusion: 5-ASA use remains common despite the lack of evidence base in CD, although this stabilised after era 3. Topical therapies in CD are on the decline or at low levels, but steroid use remained high throughout the study period. TP use has increased in keeping with current evidence and guidance but it is conceivable that more patients should be maintained on these agents.

Introduction: Over the past twenty years the research base has improved sufficiently to enable evidence based guidelines to specify indications for optimal use for 5-aminosalicylic acids (5-ASAs), steroids and thiopurines (TPs).
Aims & Methods: Our aim was to determine trends in ulcerative colitis (UC) related prescribing patterns of oral and topical 5-ASAs, steroids and TP over the past 20 years.
We constructed an incident cohort of patients with UC diagnosed between 1990 and 2009 using the Clinical Practice Research Datalink (CRPD), a validated research database representing an 8% sample of the UK population. We divided our cohort to compare patterns between era: era 1 (1990–1993), era 2 (1994–1997), era 3 (1998–2001), era 4 (2002–2005) and era 5 (2006–2009). We evaluated trends in prescribing by calculating the proportion (number of patients receiving a prescription/number of patients diagnosed in the era) of patients, adjusted for age and sex, receiving at least one prescription for each oral or topical 5-ASAs, oral or topical steroids and TPs (azathioprine and mercaptopurine) within 1 year from the time of diagnosis. We evaluated trends based on the publication of key research during the study period. χ^2 test for trend was used to compare proportions between groups.
Results: There were 16512 patients who met our inclusion criteria. The proportion of patients with at least one oral 5-ASA prescription within a year of diagnosis increased from 33.1% to 44.6% ($p < 0.001$) between era 1 and era 5 in keeping with a study published by Sutherland *et al* [1] although its use plateaued from era 3 onward (era 3 vs era 5, $p = 0.26$) (figure 1). Topical 5-ASAs use, increased from 23.1% to 49.9% ($p < 0.001$) between era 1 and era 5 in keeping with evidence published by Marshall *et al* [2]. Topical steroid use decreased from 49.2% to 36.8% between era 1 and era 5 ($p < 0.001$) which was in keeping with supporting evidence [2]. Oral steroid prescriptions rose steadily from 19.6% to 39.7% between era 1 and era 5 ($p < 0.001$). This was despite an increase in TP users from 4.6% to 20.8% ($p < 0.001$) between era 1 and era 5 in keeping with study performed by Hawthorne *et al* [3].
Conclusion: Oral 5-ASA use increased in UC but unexpectedly stabilised after era 3 which was not anticipated as we expected a larger number to receive these drugs. Topical 5-ASAs, considered first line for mild proctitis or left sided colitis, increased whilst topical steroid use decreased during the study period. Steroid use in UC has continued to increase despite improvements in medical therapy such as increasing TP use during the study period which was in keeping with current research and guidance.

Introduction: Previously we reported greater improvement in both fLac&fCal levels observed in UC pts who demonstrated clinical response & endoscopic healing in PURSUIT SC induction golimumab (GLM) study[1].
Aims & Methods: To assess the association of fecal inflammatory markers, lactoferrin (fLac) & calprotectin (fCal), with Mayo endoscopy subscores using data from this study. The Ph3 portion of PURSUIT-SC was a multicenter, rand, PBO-controlled dble-blind study conducted to evaluate safety & efficacy of induction therapy with SC GLM. Pts with Mayo scores of 6-12 inclusive, including endoscopic subscore ≥ 2 were rand to PBO/PBO, GLM 200 mg/100 mg, or GLM400 mg/200 mg at Wks 0 & 2. Mucosal healing was assessed at Wk6 using Mayo endoscopy subscore. Stool samples were collected for fLac & fCal Wk0 thru Wk6. Assays for fLac & fCal concentrations were performed using validated methods. The area under a ROC curve(AUC) was used to assess the association of baseline & Wk6 fLac & fCal with Mayo endoscopy subscores of 0 (defining normal or inactive disease) & subscores of 0 or 1(defining endoscopic healing in this study)at Wk6. Various cut offs of fLac & fCal concentrations were explored to determine the balance of sensitivity&specificity for endoscopy subscores of 0 or 0 or 1.
Results: Mayo endoscopy subscores of 0 or 1 were associated with the lowest concentrations of fLac & fCal (Table). Baseline fLac & fCal were poor predictors for endoscopic healing at Wk6 (AUCs < 0.63). Area under the ROC curve analysis showed that fLac & fCal at Wk6 are fair surrogate markers for normal/inactive endoscopic disease activity (endoscopy subscore of 0) at Wk6 with AUCs of 0.77 & 0.79, resp. Similar AUCs were observed for endoscopy subscores of 0 or 1. Cutoffs of fLac $< 50\mu g/ml$ & fCal $< 250mg/kg$ at Wk6 offered reasonable sensitivity & specificity(fLac 0.74,0.67 & fCal 0.79,0.70) for normal/inactive endoscopic disease activity at Wk6. In contrast, cutoffs of fLac $< 100\mu g/ml$ & fCal $< 500mg/kg$ at Wk6 offered similarly reasonable sensitivity & specificity (fLac 0.73,0.63 & fCal 0.74,0.64) for endoscopy subscores of 0 or 1.
Table: Fecal Inflammatory Marker Concentrations and Mayo Endoscopy Subscores at Wk 6

	PBON Median (IQ range)	Combined GLMN Median (IQ range)	PBON Median (IQ range)	Combined GLMN Median (IQ range)
	FLac (μg/mL)		**FCal(mg/kg)**	
Endoscopy scores				
0	1029.8 (7.7-72.9)	523.5 (0.6-53.2)	10127 (53-502)	5242 (14 -159)
1	6235.9 (5.4-156.9)	17135.4 (4.9-145.3)	62252 (47-706)	171182 (40-577)
2	119157.0 (50.4-442.2)	168146.6 (40.5-441.7)	119672 (268-1564)	168559 (258-1083)
3	59364.0 (70.4-794.1)	117304.4 (94.1-707.6)	59945 (527-2024)	1171159 (532-2544)

Conclusion: At Wk6, Mayo endoscopy subscores were positively associated with levels of fLac & fCal. Cut-offs of fLac $< 50\mu g/ml$ & fCal $< 250mg/kg$ at Wk6 demonstrated reasonable sensitivity & specificity for normal/endoscopic disease activity. Overall these data suggest that fecal inflammatory marker levels might be useful surrogates for endoscopic improvement.

Introduction: In the PURSUIT maintenance (M) trial, continuous clinical response (CCR) was associated with achievement of conventional endpoints, including endoscopic healing in patients with active ulcerative colitis (UC).[1] We characterize the association of components of the Partial Mayo score, including stool frequency (PRO1), rectal bleeding (PRO2), and their combination (PRO1 + 2), with CCR in PURSUIT-M.
Aims & Methods: Patients who responded to golimumab induction at week 6 and were randomized to placebo or golimumab 50 or 100 mg every 4 weeks (Q4W) were included. UC disease activity was assessed using the Mayo score at weeks 30 and 54, PRO1 and PRO2 (averaged over 3 days before visit) Q4W, and Physician Global Assessment (PGA) Q4W. CCR was defined as response maintained through week 54; loss of response was confirmed by endoscopy.[2] Logistic regression of imputed data (last observation carried forward) was used to evaluate the association of subscores with CCR at weeks 30 and 54 in PURSUIT-M. Missing data were not imputed. Area under ROC curves (AUC) were calculated for each Mayo score component; comparisons were made using the DeLong method.[3]
Results: The AUCs for each Mayo score component at weeks 30 and 54 to predict CCR are summarized in the **Table**. Sensitivity analysis excluding patients with missing Mayo subscore data at >2 visits showed similar results.
Conclusion: Stool frequency and rectal bleeding combined (PRO1 + 2) and endoscopy subscore each showed comparable accuracy with Partial Mayo score in the ability to predict CCR. PRO1 + 2 can thus be used to monitor patients' UC symptoms remotely and may provide a useful tool to assess for maintenance of CCR in daily clinical practice.

P1615 THE EFFECT OF C2, FACTOR B AND C3 DEFICIENCIES ON STEM CELL MOBILIZATION AND INFLAMMATION IN A MURINE MODEL OF CHRONIC COLITIS: IMPLICATIONS FOR FUTURE THERAPY

Introduction: Ulcerative colitis (UC) is a chronic inflammatory disease of complex etiology. There is a great need for developing new effective methods to treat UC. The strategy based on the use of drugs modifying complement system (CS) cascade is a new promising therapeutic option allowing for control of stem cell mobilization (1) and inflammatory process in the intestine (2). In the current study we investigated the role of C2, factor B (fB) and C3 in mobilization of various stem cell populations, such as very small embryonic-like stem cells (VSEL-SCs), hematopoietic stem cells (HSCs), clonogenic progenitors and intestinal epithelial stem cells. We also evaluated the clinical response compared with the level of intestinal damage.

Aims & Methods: A well-established murine dextran sulfate sodium (DSS) model of chronic UC was used to study stem cell mobilization and intestinal inflammation in wild type (WT) C57BL/6, C2.fB deficient (C2.fB-/-) and C3 deficient (C3-/-) mice. Briefly, UC was induced by oral administration of 5% DSS in drinking water for 5 days, followed by the consumption of tap water for the next 11 days. The severity of DSS-induced colitis was evaluated daily based on calculation of the disease activity index (DAI). On day 16 the animals were sacrificed for detailed analysis. Flow cytometry, colony-forming unit (CFU) assay and real-time PCR were performed to study the mobilization of selected stem cell populations into peripheral blood. The level of intestinal damage was evaluated by standard histological and immunohistochemical methods.
Results: In the used model of chronic colitis we observed the mobilization into periheral blood of all examined populations of stem cells. The number of mobilized VSELs, HSCs, clonogenic progenitors and cells expressing markers of intestinal epithelial stem cells was higher in C3-/-mice and lower in C2.fB-/- than in WTmice. More severe inflammation was observed in C2.fB-/- mice than in WT mice. Although the stem cell mobilization in C3-/-mice was higher than in WT mice no significant reduction of inflammation in the large intestine was observed in these animals. As noticed, both C3-/- and C2.fB-/- mice exhibited a higher histological colonic damage than WT colitis mice.
Conclusion: We have determined for the first time the role of C2, fB and C3 deficiency in stem cell mobilization and inflammatory process in experimental model of chronic colitis. Pharmacological inhibition of C2 and fB should not be considered as a therapeutic approach for UC treatment. C3 inhibitors might be considered as a part of complex UC therapy due to beneficial effect on stem cell mobilization, but shall not be used alone because the lack of C3 has no effect on tissue repair.

Introduction: The intestinal mucus forms a hydrophobic barrier against colonic microbiota[1]; a defective mucosal barrier has been suggested as an underlying cause of ulcerative colitis (UC)[2]. We propose that the key pathogenetic feature of UC is an intrinsically low mucus phosphatidylcholine (PC) content[3, 4]. What remains unclear is how PC accumulates in mucus under physiological conditions, and how this process fails in UC and induces an inflammatory phenotype.
Aims & Methods: We determined the transport of PC across polarized CaCo2 cells. Genetic animal models of UC were generated by intestinal specific knockout mice of kindlin 1 and 2. They were examined in regard to their microarchitecture, PC secretion capacity, the mucus PC content and the functional capacity of microbiota penetration and induction of inflammation as well as the mucosal protection by oral PC supplementation. Finally, mucosal microarchitecture, PC transport and its mucus concentration was evaluated with biopsy specimens of human UC.
Results: We identified a novel paracellular transport route specific to choline-containing phospholipids that are driven by an electrochemical gradient across tight junctions (TJs) to form a hydrophobic mucosal barrier via mucin binding. Interfering with this pathway blocked luminal PC secretion, and mice with lateral TJ disruption due to intestinal kindlin 1 and 2 deletion developed a UC phenotype. The same TJ disturbance was observed in human UC: lateral TJ disruption impaired mucosal PC secretion, and PC-deficient mucus had reduced hydrophobicity that allowed gut microbiota penetration, which consequently induced mucosal inflammation. This was mitigated when the hydrophobic barrier was reestablished by PC supplementation, which is an innovative treatment option for UC.
Conclusion: Disruption of PC paracellular translocation across the TJ barrier is an attractive hypothesis to explain the pathogenesis of UC.

Introduction: A significant number of patients with inflammatory bowel disease (IBD) treated with infliximab (IFX) require dose intensification due to secondary loss of response (LOR). Due to both economic and safety concerns, such IFX regimen cannot be maintained in the long-term. The aim of this study was to investigate the long-term efficacy of dose de-escalation in patients under optimized IFX regimen, who achieved deep remission, and with TRI > 8 μg/mL.
Aims & Methods: We have included in this prospective study, all adult patients with IBD and followed in the Gastroenterology department. All included patients were treated with IFX at 10mg/kg every 8 weeks for secondary loss of response. These patients were in deep remission for at least 4 months. Deep remission was defined as a CDAI < 150 with fecal calprotectin < 250 μg/g of stool for Crohn's disease (CD) and a total Mayo score <3 with an endoscopic Mayo score <2 for ulcerative colitis (UC). If TRI using an Lisatracker (Theradiag) were > 8 μg/mL following two consecutive IFX infusions, patients were included in this prospective, single-center, observational, longitudinal study after giving their signed consent. All patients with concomitant use of an immunomodulator agent were excluded. Patients had a minimum follow-up of one year. For dose de-escalation, IFX dose was decreased by 1 mg/kg at each infusion to a dose to 5 mg/kg or to get a TRI between 3 and 7 μg/mL. Thereafter, this dose was maintained during follow-up.
Results: We have included 20 patients with a median follow-up of 8 months (6-12) (CD 12, sex ratio M/F: 1, median age at inclusion 30 (21-40), median age at diagnosis 24 (16-35), duration of IFX 10 mg/kg = 12 months (8-14)). All the patients had at the inclusion a TRI > 8 μg/mL and 5% (one patient) of the patients a CRP > 5 mg/L. A decrease of IFX dose until having TRI between 3 and 7 μg/mL and with persistence of a deep remission was obtained in 18 patients. IFX dose used when stopping the de-escelation were 5 mg/kg for one patient, 6mg/kg for 4 patients, 7 mg/kg for 10 patients, and 8 mg/kg for 3 patients (Figure 1a). The average CDAI rates were comparable before and in the follow-

CP=cutpoint; SE=standard error.*Comparison of subscore with the Partial Mayo score regarding the ability to predict CCR.

up after therapeutic de-escelation as the Mayo score, the endoscopic score and the fecal calprotectin levels. Only two patients had a clinical relapse during de-escalation at an IFX dose of 8 mg/kg with TRI > 8 μg/mL. In these two patients, at the moment of LOR, TRI were in our therapeutic definition range. The other 18 patients were followed with a median of 8 months (6-12) after stopping the de-escalation according to TRI (between 3 and 7 μg/mL) for all patients. All these patients remained in deep remission as previously defined. TRI remained stable between 3 and 7 μg/mL during follow-up for all patients. So de-escalation was associated with maintenance of deep remission for 90% of cases with a follow-up of 8 months.

Conclusion: Therapeutic de-escalation is possible in patients with deep remission and with high suboptimal TRI as defined previously [6]. De-escalation to obtain therapeutic TRI is feasible and has no impact on clinical or endoscopic scores and on biomarkers as CRP or fecal calprotectin in 90% of cases without increase of immunogenecity. Finally, therapeutic strategies based on de-escalation is highly interesting in term of health economics.

P1618 RATES OF COLECTOMY IN ULCERATIVE COLITIS THROUGH TIME IN A LATIN-AMERICAN IBD UNIT

A. M. Sambuelli[1], A. H. Gil[1], S. M. Negreira[1], A. Cabanne[2], S. Goncalves[1], M. I. Bellicoso[1], S. P. Huernos[1], P. Chavero[1], C. Carraro[1], P. R. Tirado[1]
[1]*IBD Section - Medicine,* [2]*Pathology, Bonorino Udaondo Gastroenterology Hospital, Ciudad de Buenos Aires, Argentina*

Contact E-mail Address: alicia.sambuelli@gmail.com

Introduction: Ulcerative colitis (UC) is a chronic relapsing disease that carries the risk of potential severe complications and disability. Ileal pouch anal anastomosis (IPAA) was postulated as a suitable curative alternative for unresponsive UC, but a substantial proportion of patients present short-term and long-term complications. Thus, several factors could change the natural history of UC decreasing surgical rates (a rapid diagnosis, information to patients, tight control, treatment algorithms at right time). We designed an IBD specific electronic system functiong as a network for a reference IBD Unit working from 1990 in Buenos Aires.

Aims & Methods: We aimed: 1) to evaluate colectomy rates of UC with disease onset in this century compared with those patients with debut in that last decade of century XX (dated at time of our IBD unit creation). 2) to study the major demographic characteristics associated with surgery. Data were obtained from the software created 2 decades ago (in improvement process), where information were recorded and coded. Data revision and entry from diverse sources of medical reports was carried out. We included all UC patients assisted in our unit in such periods with available information to define colectomy prevalence (survival times) age at UC onset, disease extent, complications. We compared by survival analysis colectomy rates of UC with disease onset from 1990 to 1999 with the rates of patients that started the disease from the 2000 or later.

Results: We inform results of surgical rates (categorized in the two mentioned time periods) of a cohort of 1903 UC patients (Female 996, M 907), mean age (mean ± SD) at disease debut 33.45 ± 15.3, disease extent (Montreal classification) E1: 25,2%, E2: 30.5%, E3: 44.3%. **Group 1:** UC onset from January 1990 to end of December of 1999 (n 884) **Group 2:** UC debut from January 2000 to current time (n: 1019). Mean ages at onset and gender were similar in both periods. Main results about surgery requirement: colectomy rates in UC with disease onset in this century (group 2) were significant lower compared with the historical patients of **group 1**. Cumulative probabilities of surgery at 1, 2, 3, 4, 5, 7 and 10 years for **Group 1** were 4.4%, 8.8%, 13.0%, 14.0%, 16.0%, 18.3%, 22.0% and for **Group 2:** 3.6%, 6.2%, 7.8%, 9.1%,10.3%, 12.7%, 16.1% (Log rank test: $p < 0.006$). The colonic involvement (E3, E2, E1) was significant more extensive in patients who required colectomy (82.7%, 16.2%, 1.1%) compared with UC responsive to medical treatment (37.6%, 33.0%, 29.4%) $p < 0.0001$ (Chi square) for all disease groups of UC extent. The median age of UC onset was lower in patients requiring surgery: 27.5 (QR 20-42) vs. 30.0 (QR 22-43) $p < 0.012$ (Kruskal Wallis Anova test). The more frequent cause of surgery was a severe flare in hospitalized patients.

Conclusion: Colectomy rates in UC showed a significant decrease in the current century compared with last decade of past century. As we are a reference IBD unit, these data could reflect a regional trend in the management. Colectomized patients showed more extensive compromise and younger UC onset, confirming the relevance of opportune algorithms for control and treatment of the risk groups.

Introduction: While it is known that exposure to anti-TNF in Crohn's disease causes a unique histologic fibrosis, the effects of anti-TNF on the histology of colorectal resection specimens in patients with ulcerative colitis (UC) has not been documented. We sought to determine whether preoperative exposure to anti-TNF affects histological measures of fibrosis which may be also be a potential factor in adverse anastomosis complications following ileal pouch anal anastomosis (IPAA) surgery.

Aims & Methods: We performed a retrospective study of patients with UC who underwent IPAA at our institution between 2003 and 2013. Individuals who received anti-TNF as maintenance therapy (i.e. >3 doses of anti-TNF) and who received their last dose in <180 days from the first stage of IPAA were selected. The control group was comprised of UC patients not exposed to anti-TNF pre-operatively, matched 1:1 by age, sex, BMI, disease duration, albumin, and post-operative leak outcome. Hematoxylin-eosin and trichrome slides from the most distal, full-thickness section of colorectum from each total colectomy specimen were evaluated. Blinded assessment of the degree of fibrosis in large bowel layers was performed. Fibrosis was scored on a scale of 1 to 4 for each layer. The histology analysis was performed by a single observer using a semi-quantitative pictorial scale. McNemar's test and paired t-test for categorical and continuous variables, were performed.

Results: 765 UC IPAA patients were reviewed. 138 patients met the inclusion criteria. Histological fibrosis in 69 patients from the therapy group was compared to 69 patients from the matched control group. There were no statistically significant differences in the level of fibrosis in any of the bowel layers individually nor in the combined fibrosis does score in all layer together (Table 1).

Table 1

	Control (n = 69)	Anti TNF Treated Group* (n = 69)	p Value
Fibrosis in Lamina propria, n (%)			0.18
1	25 (37.9)	26 (40.0)	
2	21 (31.8)	21 (32.3)	
3	5 (7.6)	11 (16.9)	
4	15 (22.7)	7 (10.8)	
Fibrosis in submucosa, n (%)	9 (13.6)	6 (9.2)	0.29
1	14 (21.2)	16 (24.6)	
2	27 (40.9)	23 (35.4)	
3	16 (24.2)	20 (30.8)	
4			
Fibrosis above muscularis propria (%)			0.36
	5 (7.8)	0 (0)	
1	9 (14.1)	13 (20.0)	
2	27 (42.2)	22 (33.9)	
3	23 (35.9)	30 (46.2)	
4			
Fibrosis in subserosa, n (%)			0.71
1	26 (40.6)	22 (33.9)	
2	23 (35.9)	22 (33.9)	
3	9 (14.1)	14 (21.5)	
4	6 (9.4)	7 (10.8)	

*Anti TNF Treated Group- Maintenance therapy, >3 infusions/doses within 180 day before Stage 1.

Conclusion: Resection specimens from UC patients treated with maintenance anti-TNF therapy who underwent IPAA surgery showed no significant differences in the degree of histologic fibrosis compared to a matched control group.

Introduction: Endoscopic resection of superficial neoplasms in inflammatory bowel diseases (IBD) is appropriate if a complete resection can be achieved. However, EMR is ineffective for large non-polypoid neoplasms, especially in IBD due to the submucosal fibrosis, and no data are available on the efficacy of endoscopic submucosal dissection (ESD).
Aims & Methods: To assess ESD feasibility and efficacy for large non-polypoid neoplasms in IBD patients. Study design was: prospective multicenter case series conducted in a Italian and Japanese center. Consecutive patients with long-standing ulcerative colitis and a superficial non-polypoid neoplasm, >20 mm within the colitic mucosa were included. Neoplasm was characterization and delineation by chromoscopy and narrow band imaging. ESD performed according to the standard technique. Main outcomes were: feasibility, safety, curative resection rates.
Results: Nine patients with 10 neoplasms were included (7 and 3 in the Italian and Japanese center, respectively). Neoplasms were LST-NG in 5 cases, in the left colon in 7, had median size of 33 mm, associated with scar in 5. Delineation of neoplasm margins was difficult in 5 cases due to subtle elevations extending beyond gross edges and pit and capillary patterns suggestive of non-neoplastic tissue. Margins were profiled by acetic acid in 3 cases. Submucosal fibrosis was present in 9 cases.
ESD was en bloc and R0 in 8 (80%) cases (Video). SM fibrosis was present in 9 lesions: in all 5 lesions which underwent previous resection or biopsies, and in 4 naïve cases. A curative resection was achieved in 7 (70%) cases.
No endoscopic invisible dysplasia or cancer was found during the follow-up (median 24 months, range 6-72) at the resection site and elsewhere within the colitic mucosa.
Conclusion: ESD achieves curative resections in IBD patients but the procedure is difficult due to the high prevalence of submucosal fibrosis. Patients need to be accurately evaluated before resection and adhere to strict long-term follow-ups.

Introduction: There is increasing use of biologic therapy in ulcerative colitis (UC). As a result there is concern regarding the impact of biologics on operative outcomes. This study examines the exposure and impact of biologics and corticosteroids on postoperative outcomes for patients undergoing an ileal pouch anal anastamosis (IPAA) over an 11 year period at a single institution.
Aims & Methods: A retrospective chart review was performed for subjects with UC who underwent IPAA between 2002 and 2013. Inpatient and outpatient charts were reviewed for demographic data, clinical data, anti-TNF therapy, steroid and immunosuppressant use, and surgical outcomes. Early complications were defined as occurring within 30 days of IPAA construction and late complications were defined as within 12 months following ileostomy closure. Pearson Chi-square and Student's t-test was used; multivariate logistic regression analysis was performed to identify significant factors associated with postoperative complication.
Results: 758 patients underwent IPAA. 57.5% (n=437) of patients were female. At the time of first surgery the median age was 36 with a median BMI of 25 (range 22-28.4). Mean preoperative disease duration was 5.3 years (range 2.4 – 10.6y). 16.2% (n=106) of IPAA were performed laparoscopically. The reconstructive IPAA procedure was performed in 2- (n=460) and 3- (n=285) stages and the remainders were performed in non-traditional staged operations. 88 patients had anti-TNF exposure within 180 days of surgery whereas 128 patients had immunosuppressant use within 90 days of surgery. 54.3% of patients (n=369) had systemic corticosteroids (>15mg/day) within 30 days prior to surgery. Of these, 286 patients had high dose (>30mg/day via intravenous) corticosteroids within 7 days of their first surgery. Early complications consisted of pelvic abscess (n=135.17.8%), small bowel obstruction (n=134.17.7%), wound infection (n=108.14.3%), and deep vein thrombosis (n=33, 4.4%). Late complications consisted of anal stricture (n=55, 7.3%), pouch fistula (n=26, 3.4%), and functional pouch failure (n=7, 0.9%). The overall pouch leak rate was 92 (12.1%). There was one death. The median length of stay was 9 days. Exposure to biologics was not significantly associated with post-operative complications (OR 0.81, CI 0.54-1.23) whereas a 3 stage procedure (OR1.61, CI 1.17–2.54), and use of high dose corticosteroids within 7 days of surgery (OR 1.59, CI 1.11–2.27) were significantly associated with increased complications.
Conclusion: The use of high-dose steroids preoperatively increases the risk for developing post-operative complication. However, the use of biologics was not shown to be associated with early or late complications following IPAA surgery for UC.

Introduction: Ileal-pouch anal anastomosis (IPAA) has been the standard treatment of choice for patients with ulcerative colitis (UC) who require surgery. Although patients' quality of life after IPAA is largely satisfactory, some suffer from pouchitis. Also, the development of carcinoma in the ileal pouch or the remnant rectal mucosa has been concerned.
Aims & Methods: The aim of this study was to investigate the frequency of pouchitis and to assess the results of surveillance pouchoscopy. One hundred three patients with UC who underwent IPAA in the University of Tokyo hospital were included. Out of 103, ninety-three patients who received pouchoscopy were retrospectively investigated. The background data were obtained by reviewing patients' charts. The diagnosis of pouchitis was made according to modified pouchitis disease activity index, which was determined by clinical and endoscopic scores. The cumulative pouchitis rate was calculated by Kaplan Meier curve, and risk factors for the development of pouchitis were investigated by the Cox regression test. Pathological reports were also reviewed for assessing the development of dysplasia and cancer after IPAA.
Results: A total of 572 pouchoscopies were performed in 93 patients. The cumulative pouchitis rate was 4.5%, 12.5%, and 27.6% at 1, 5, and 10 year after IPAA. The presence of immune-related extraintestinal manifestations was an independent risk factor for the development of pouchitis (Hazard ratio 3.82, 95% CI 1.33-10.45, p=0.014). Although low-grade dysplasia was detected in a biopsy specimen from the ileal pouch with pouchitis in a patient, subsequent pouchoscopies were negative for dysplasia. None developed high-grade dysplasia or invasive cancer.
Conclusion: Pouchitis developed in 4.5%, 12.5%, and 27.6% after 1, 5, and 10 years. The presence of immune-related extra-intestinal manifestation is an independent risk factor for the development of pouchitis. The development of carcinoma in the ileal pouch or the remnant rectum after IPAA is considered minimal.

Introduction: Among immunocompromised patients who respond to the HBV vaccine, clinically significant HBV infection has been documented in those who do not maintain anti-HBs concentrations > 10 IU/l.
Aims & Methods: 1) To understand the kinetics of the anti-HBs titers over time in IBD patients who have initially responded to the vaccination. 2) To identify predictive factors of negativization of anti-HBs titers over time.
This multicenter study included IBD patients vaccinated in the COMVI-B trial (EUDRA CT number: 2010-023947-14), where patients with negative HBV serology and without previous vaccination against HBV were randomized 1:1 to receive Fendrix® or double doses of Engerix® at months 0, 1, 2 and 6. Patients with anti-HBs > 10 IU/L 2 months after the 4th dose were followed-up. Anti-HBs titers were then measured at 6 and 12 months. When anti-HBs titers were < 10 IU/L during the follow-up, they were considered negatives. Long-term maintenance of positive anti-HBs titers was estimated using Kaplan-Meier curves. Cox-regression analysis was performed to identify potential predictive factors for losing anti-HBs protective titers during follow-up.
Results: 118 patients were included. Fifty percent of patients received each of the vaccines (Engerix® or Fendrix®). There were no differences in the main characteristics (age, anti-HBs concentration after complete vaccination or IBD treatment) between the study groups (Engerix® or Fendrix®). The cumulative incidence of negativization of the anti-HBs titers was 14% after 6 months and 22% after 12 months of follow-up. The incidence rate of negativization of the anti-HBs titers was 23.5% per patient-years of follow-up. In the multivariate

analysis (adjusted by the patient's age and the treatment with thiopurines or anti-TNF drugs), to have had anti-HBs ≥100 IU/L (vs. < 100 UI/L) after the vaccination was the only factor that was associated with a lower probability of negativization of anti-HBs titers during the follow-up (HR = 0.07, 95%CI = 0.02-0.2, p < 0.0001). The type of vaccine administered was not associated with the risk of negativization of anti-HBs titers.
Conclusion: A high proportion of IBD patients with protective anti-HBs titers after vaccination loose them over time (approximately, 25% of patients per year of follow-up). The risk of loosing protective anti-HBs titers is dramatically increased in patients achieving anti-HBs below 100 IU/L after the vaccination. Thus, anti-HBs > 100 IU/L should be the threshold to consider HBV vaccination success in IBD patients.

P1624 EFFICACY OF CONCOMITANT MESALAMINE SUPPOSITORY IN PATIENTS WITH ACTIVE ULCERATIVE COLITIS WHO SHOWED INADEQUATE RESPONSE TO AN ORAL 5-AMINOSALICYLIC ACID PREPARATION: A PROSPECTIVE STUDY

N. Yoshimura[1], R. Tanaka[1], M. Sako[1], M. Takazoe[1]
[1]*Department of Internal Medicine, Division of IBD, Tokyo Yamate Medical Centre, Tokyo, Japan*

Contact E-mail Address: ynaokun@yahoo.co.jp
Introduction: Hitherto, oral 5-aminosalicylic acid (5-ASA) preparations have been widely administered as first-line mediation for inducing and maintaining remission in patients with mildly to moderately active ulcerative colitis (UC). Further, for distal UC, topical preparations as enema or suppository have been applied. However, patients who do not respond well to an oral 5-ASA preparation alone should benefit from concomitant mesalamine suppository.
Aims & Methods: We were interested to evaluate the efficacy of concomitant Pentasa suppository for inducing remission in patients who had active UC including the rectum while on an oral 5-ASA preparation. In a single-centre prospective setting, 192 consecutive patients with mildly to moderately active UC with rectal inflammation while on oral 5-ASA preparations for at least 4 weeks were included. All patients received concomitant Pentasa 1g suppository rectally once a day for 4 weeks together with the ongoing oral 5-ASA preparations. No patient received corticosteroid or immunosuppressant. At week 4, clinical efficacy for Pentasa suppository was evaluated by applying the UC-Disease Activity Index (UC-DAI), including the 3 sub-scores. Clinical remission was defined as the bleeding sub-score = 0, and a decrease of ≥ 3 in the UC-DAI, while clinical response meant a decrease of ≥ 1 in the UC-DAI.
Results: At week 4, the average UC-DAI fell from 3.2 ± 0.7 at entry to 1.4 ± 1.7 (n = 192, P < 0.001). Of the 192 patients, 90 (46.9%) achieved clinical remission, and 43 (22.4%) achieved response level. The bleeding sub-score fell from 1.0 ± 0.2 to 0.4 ± 0.5 (P < 0.001). Regarding the response rate vs extent of UC, the UC-DAI fell from 3.2 ± 0.7 to 1.4 ± 1.7 in patients with proctitis (n = 171, P < 0.001) and from 3.1 ± 0.5 to 1.3 ± 1.5 in patients with left-sided colitis (n = 20, P < 0.001). One patient with pancolitis worsened. Further, by concomitant Pentasa suppository, the bleeding sub-score in patients who did not respond well to oral 5-ASA preparations alone (n = 129) fell from 1.0 ± 0.1 to 0.3 ± 0.5 (P < 0.001); in sulphasalazine-treated subgroup (n = 49, mean dose 3.7 ± 1.0g/day, range 1.5-6.0/day) fell from 1.0 ± 0.1 to 0.3 ± 0.5 (P < 0.001); in Pentasa (n = 20), 2.3 ± 0.8g/day, range1.5-3.0/day fell from 1.0 ± 0.0 to 0.2 ± 0.4 (P < 0.001); in Asacol (n = 60), 3.4 ± 0.4g/day, range 2.4-3.6/day fell from 1.0 ± 0.1 to 0.4 ± 0.6 (P < 0.001), reflecting significant efficacy for concomitant Pentasa suppository in patients who did not respond well to high dose oral 5-ASA preparations alone. No serious adverse event was observed.
Conclusion: This is the first study in Japan that has investigated the efficacy of Pentasa suppository in patients who did not respond well to an oral 5-ASA preparation. Based on the outcomes of the present investigation, we believe that patients with distal UC who have active disease while on an oral 5-ASA preparation alone should benefit from concomitant Pentasa suppository.

P1625 MANAGEMENT OF UC-LIKE CROHN'S DISEASE AFTER IPAA

T. Emmanouil[1], E. Falidas[2], N. Kontoravdis[3], C. Christou[3], P. Evangelides[4], S. Baratsis[3]
[1]*Gastroenterology, Iaso General Hospital,* [2]*Surgery, Iaso General,* [3]*Surgery,* [4]*Anaestesiology, Iaso General Hospital, Athens, Greece*

Contact E-mail Address: marteod1@yahoo.com
Introduction: Crohn's disease (CD) and ulcerative colitis (UC) are the two major types of idiopathic inflammatory bowel disease (IBD) with unknown pathogenesis. Approximately 20% of CD cases involve the colon causing difficulty in differential diagnosis between UC and Crohn's colitis, even in colectomy specimens. Standard surgical management of UC patients is total proctocolectomy (IPAA) but for the subgroup of patients referred to as ulcerative colitis-like Crohn's colitis or indeterminate colitis management remains obscure.
Aims & Methods: To identify features associated with "ulcerative colitis (UC)-like" subgroup of Crohn's colitis and to present treatment options.
Six patients diagnosed as having UC and underwent IPAA from 1983-2013 and subsequently developed CD of the small bowel (ileum or ileal pouch) were identified. Six other patients operated with IPAA for "true" UC were used as controls. UC diagnosis was based on clinical, endoscopic, and pathologic grounds pre-operatively. Demographics were recorded and pathology-endoscopy reports pre-surgically were reviewed and compared with histopathology results from resection specimens for both groups. All patients were followed-up and treated differently according to their symptoms and extent of the disease.
Results: Patients with "UC-like" CD were on average 7 years younger than those with "true" UC (P < 0.01). More active disease in the proximal colon and active inflammation of the ileum were noticed in 4 of 6 "UC-like" CD cases, but in none of the "true" UC cases (P < 0.05). In most "UC-like" CD cases there were many hospital admissions for early or late small bowel obstructions or pouch related fistulas. Crohn's granulomas and transmural inflammation in non-ulcerated areas were absent in both groups. In one patient with severe bowel obstruction stricture resection and anastomosis were performed. Three other patients were faced with seton placement and biologics and in two only a permanent ileostomy was performed with/or without pouch extraction.
Conclusion: UC-like Crohn colitis is highly suspected when pre-surgically it is found more active disease in the proximal colon or inflammatory involvement of the terminal ileum. Additionally, when there is small bowel obstruction or early development of pouch related fistulas post surgery. Under certain circumstances this subgroup of patients can be treated conservatively after IPAA even with preservation of the ileal pouch.

P1626 PREDICTING SURGERY AT THE MOMENT OF DIAGNOSIS OF CROHN'S DISEASE IS POSSIBLE. PROPOSAL OF A PREDICTIVE MODEL

T. Cúrdia Gonçalves[1], M. Costa[2], J. Firmino Machado[3], M. J. Moreira[1], J. Cotter[1,4]
[1]*Gastroenterology Department, Centro Hospitalar do Alto Ave, Guimaraes,* [2]*School of Health Sciences, University of Minho, Braga/Guimarães,* [3]*Unidade de Saúde Pública Porto Ocidental, Porto,* [4]*Life and Health Sciences Research Institute, University of Minho, Braga/Guimarães, Portugal*

Contact E-mail Address: tiagogoncalves@chaa.min-saude.pt
Introduction: It is estimated that 80% of patients with Crohn's Disease (CD) will required a surgery anytime during their lives. However, few studies to determine predictors of surgery at the precise moment of diagnosis have been performed. We aimed to identify predictive factors for surgery at the moment of diagnosis and to propose a predictive model for that outcome, able to guide therapeutic decisions.
Aims & Methods: Unicentric, retrospective, case-control study of CD patients: 71 cases with previous abdominal surgery for CD and 205 non-operated CD controls. Demographic, clinical, laboratorial, and endoscopic data and Montreal classification at the moment of diagnosis were collected. Statistical analysis was performed using SPSS software, version 22.0.
Results: There were no differences between groups regarding gender (p = 0.984) or family history (p = 0,970). Smoking habits were more common in cases (p = 0.003). Concerning Montreal classification, L3 location was more common in cases (p < 0.001) e B1 behaviour was less frequent (p < 0,001); no differences were found on age at diagnosis (p = 0.142), upper gastrointestinal tract involvement (p = 0.122) or perianal disease (p = 0.264). At the moment of diagnosis, while abdominal pain and oral manifestations were more common in cases (p = 0.006 and p = 0.046, respectively), no significant differences were found in the remaining symptoms or extraintestinal manifestations. At the moment of diagnosis, anemia (p < 0,001), leucocytosis (p < 0.001), thrombocytosis (p < 0.001) and increased ESR (p = 0.002) and CPR (p < 0.001) were significantly more frequent in cases. Multivariate analysis established B2 or B3 behaviour (OR = 0.728, p = 0.013), L3 location (OR = 3.01, p = 0.016), haemoglobin value (OR = 0.728, p = 0.013) and leukocyte count (OR = 1.24, p = 0.001) as predictive factors for surgery at the moment of diagnosis. These factors were included in a predictive model for surgery ($P_{(cirurgia)} = 1/(1+e^{-[-1.692+1.1xL3+3.09xB2/B3-0.317xHb(g/dL)+0.214xLeuc(x103n/\mu L)]})$), with a specificity of 93.5%, a sensitivity of 71.4%, a positive predictive value of 76.9%, and a negative predictive value of 91.6%.
Conclusion: At the moment of diagnosis, behaviour and location of CD and haemoglobin and leukocyte values, when integrated in the proposed predictive model, allow, with high specificity, identification of patients potentially requiring surgery. In these patients, the use of more aggressive medical therapies should be considered to avoid or at least defer a surgical outcome.

Contact E-mail Address: marionaserrap@gmail.com
Introduction: Cancer risk in Lynch Syndrome (LS) carriers is variable and may depend upon the involved gene. However, starting at early ages, LS non-affected carriers follow an exhaustive surveillance through colonoscopy in order to detect pre-neoplasic lesions or CRC in early stages. Thus, it is crucial to find a key biomarker that reflects CRC development risk. It has been shown that bacterial communities in the colonic mucosa of CRC patients differ from healthy individuals and intestinal microbiota has been proposed as a

determining agent in the development and progression of CRC along its stages. Recent data from our research group showed that a set of specific phylotypes determined in intestinal biopsy from CRC patients presented a high relatedness with CRC risk.

Aims & Methods: We aimed at defining a microbiological signature in stool sample capable of determining CRC risk in LS carriers.

We designed a preliminary retrospective study to analyze intestinal microbiota in feces of individuals with different profile of CRC risk: LS carriers (n = 30) who had a colonoscopy in the Digestive Department of Hospital Universitari Dr. Josep Trueta.

Detection of specific phylotypes was performed through q-PCR of 16S rDNA bacterial sequences. The quantification of specific bacteria sequences was expressed in q-PCR cycle threshold (Ct). Ratios for the different sequences identified were calculated.

Results: Ratios were calculated for LS carriers with (high-risk group, n = 15) and without (low-risk group, n = 15) adenomatous polyps in their last colonoscopy. Cut-off values were defined (14.02, 24.76, 21.42 and 22 ct values respectively for four bacterial sequences) and specific patterns for 16S rDNA were identified. Low-risk group presented elevated levels of 16S rDNA (Ct values under cut-off) in front of high risk-group that presented low levels. The analytical performance of the CRC risk estimation was 80% and 100% respectively for sensitivity and specificity.

Conclusion: Changes of specific microbiological signatures in feces of LS carriers may depict those carriers harboring lesions. These preliminary results outline a new non-invasive approach to identify high-risk LS carriers. But, the potential of this tool needs validation in larger studies.

Introduction: Colorectal cancer (CRC) is the second leading cause of cancer death in Europe and in United States, and is the most frequently diagnosed cancer in Europe, with over 400,000 new cases and 200,000 deaths in 2008.

These data reflect that preventive measures need to be taken. The most effective and economic measures to reduce CRC incidence and mortality are CRC risk screening test, thus an improvement of the sensitivity from actual screening methods would be helpful. For this reason, we think it is crucial a better understanding of the CRC etiology to find a key biomarker that could be used for CRC screening.

The genetic basis and natural history of CRC are well defined, considering that less than 5% of CRCs are hereditary, and majority are sporadic CRC (patients with no personal or family history of colonic neoplasm). The etiology of this disease is still unknown, although a multifactorial origin in which endogenous and exogenous factors are actively involved in tumor development is suspected. These factors are: age, tobacco, personal history of inflammatory bowel disease, diet, lifestyle, and more recently microbiota.

Lately, it has been shown that bacterial communities in the colonic mucosa of CRC patients differ from healthy individuals and the intestinal microbiota has been proposed as a determining agent in the development and progression of CRC along its stages.

Recent data from our research group showed that a set of specific phylotypes determined in intestinal biopsy from CRC patients presented a high relatedness with CRC risk.

Aims & Methods: We aimed at defining a microbiological signature in stool sample capable of being use as screening test.

We designed a preliminary retrospective study to analyze intestinal microbiota in feces of healthy individuals (n = 15) and CRC patients (n = 15) who had a colonoscopy in the Digestive Department of Hospital Universitari Dr. Josep Trueta.

Detection of specific phylotypes was performed through q-PCR of 16S rDNA bacterial sequences. The quantification of specific bacteria sequences was expressed in q-PCR cycle threshold (Ct). Ratios for the different sequences identified were calculated.

Results: Ratios were calculated for healthy individuals (n = 15) and CRC diagnosed (n = 15) at colonoscopy. Cut-off values were defined (22, 16.56, 22.97 and 19.24 ct values respectively for four bacterial sequences) and specific patterns for 16S rDNA were identified. Healthy group presented elevated levels of 16S rDNA (Ct values under cut-off) in front of CRC group that presented low levels. The analytical performance of the CRC risk estimation was 80% and 100% respectively for sensitivity and specificity.

Conclusion: Changes of specific microbiological signatures in feces depict CRC neoplasia. These preliminary results outline a novel non-invasive approach to screening CRC. The potential of this tool needs validation in larger studies.

Lashkaryov Institute of semiconductor physics, National Academy of Sciences of Ukraine,* [4]*Diagnostic and interventional ultrasound, Clinical hospital "Pheophania",* [5]*LCL «Diaprof», Kyiv, Ukraine*

Introduction: Probiotics have strong potential to develop healthy diets and integrated approach for immunity-related diseases management. The cell wall of probiotic bacteria is a dynamic entity, depending on many components and plays an essential role in many aspects of modulating immune response [1]. The cell wall elasticity impacts on beneficial effects of probiotic strains have not been sufficiently studied.

Aims & Methods: The aim of this study was to investigate the effect of lactic acid bacteria (LAB) and bifidobacteria strains on phagocytic system cells functional activity and immunoregulatory cytokines synthesis *in vitro* in regards to the bacteria surface properties as cell walls elasticity using atomic force microscopy (AFM).

Methods: We conducted experimental studies on Balb/c line mice 18-20 g weight using lyophilized strains of LAB – *L. acidophilus* IMV B-7279, *L. casei* IMV B-7280, *L. delbrueckii* subsp. *bulgaricus* IMV B-7281 and bifidobacteria – *B. animalis* VKL, *B. animalis* VKB. We evaluated the viability of probiotic cultures via monitoring of their growth. We cultivated the macrophages received from the peritoneal cavity of mice by common method individually with the strains of LAB and bifidobacteria. We estimated the impact of LAB and bifidobacteria strains on the functional activity of peritoneal cavity macrophages using the conventional methods of study oxygen-dependent bactericidal activity, nitric oxide production, their effect on the immunoregulatory cytokines. We used AFM scanning to estimate bacteria cell walls elasticity.

Results: All strains had a stimulating effect on the functional activity of macrophages and ability to produce NO/NO_2 *in vitro*. Lactobacilli strains increased the production of IL-12 and IFN-γ *in vitro*. The AFM demonstrated different degree of the cell walls elasticity in various strains of LAB and bifidobacteria. Among lactobacilli the most elastic cell wall was found in *L. delbrueckii* subsp. *bulgaricus IMV B-7281*, and among bifidobacteria – in *B. animalis VKL*, which induced the considerable activation of the phagocytes. Probiotic strains survival in the macrophages depended on the elasticity of bacterial cell walls and on the time of their joint cultivation.

Conclusion: LAB and bifidobacteria strains stimulate immunomodulatory cytokines and active oxygen and nitrogen oxides compounds production in macrophages. Strains with a more elastic cell wall according to AFM data demonstrated higher resistance to intracellular digestion in macrophages and higher level of their activation. AFM might be considered as a fast and accurate method to assess parameters of probiotic strains cell wall to predict their immune-modulatory properties.

Contact E-mail Address: A.Schierenberg@umcutrecht.nl

Introduction: Dutch primary care practice guidelines promote selective use of faeces testing for bacterial and parasitic enteropathogens in patients suspected of gastroenteritis (GE), based on clinical assessment (1). As clinical differentiation between bacteria and parasites is difficult, selective testing may be a source of underdetection of enteropathogens (1).

Aims & Methods: This study quantified the number of undetected patients with one or more enteropathogens in primary care patients suspected of GE as a consequence of the present guideline. In the first week of every month between July 2012 and June 2013 we randomly collected faecal samples of – at least – the first 100 routine primary care patients. A multiplex qPCR assay was performed for all patients for detection of five bacterial (*Salmonella* spp., *Shigella* spp., *Yersinia* spp., *Campylobacter* spp. and *Plesiomonas* spp.), three parasitic pathogens (*Entamoeba histolytica, Giardia lambiae and Cryptosporidium* spp.,) and two potentially pathogenic parasites (*Blastocystis hominis* and *Dientamoeba fragilis*). The identified enteropathogens were compared with the clinical indication for testing (request for bacteria, parasites or both) as provided by the primary care physician (PCP). Potentially pathogenic parasites were analysed separately.

Results: In all 1275 samples were collected. The mean age of included patients was 35 years (SD = 24) and 56% of the patient were female. PCPs tested both bacteria and parasites in 541 (42%) patients. Selective testing was performed in 734 (58%) patients, of which 343 (27%) were tested for bacteria only and 391 (31%) for parasites only. Of the 734 selectively tested patients 39 (36%) of the total 108 patients positive for one or more enteropathogens were undetected due

to the selection made by the PCP. When potentially pathogenic parasites were included, 140 (36%) of the total 402 patients positive for one or more enteropathogens were undetected.
Conclusion: In this study the etiological diagnosis of GE was missed in 36% of the primary care patients due to preselected faecal testing by PCPs. If this underdetection represents clinically relevant underdiagnosis needs to be established.

P1631 SHIGA TOXIN PRODUCING ESCHERICHIA COLI IN GASTROENTERITIS IN PRIMARY CARE

A. Schierenberg[1], M. D. Nipshagen[2], J. M. Alphenaar[2], B. D. L. Broekhuizen[1], P. C. J. Bruijning-Verhagen[1], S. van Delft[3], M. P. D. Deege[2,3], M. E. Kolader[2,3], M. J. M. Bonten[2], N. J. de Wit[1], J. G. Kusters[2]
[1]*Julius Center,* [2]*Medical Microbiology, UMC Utrecht,* [3]*Saltro Diagnostic Center, Utrecht, Netherlands*

Introduction: Gastroenteritis (GE) with Shiga-like toxin producing *Escherichia coli's* (STECs), including enterohaemorrhagic *E. coli* (EHEC), can cause serious complications including haemorrhagic colitis, haemolytic-uremic syndrome and death. Therefore, the Centers for Disease Control and Prevention (CDC) recommend screening of patients with community acquired diarrhoea for STEC. In Europe STEC screening is gradually being introduced in standard care. However, the incidence of GE caused by STEC in European primary care is unknown.
Aims & Methods: The aim of this study was to determine the incidence of STEC in Dutch primary care patients suspected of GE. In the first week of every month between July 2012 and June 2013 we randomly collected – at least – the first 100 faecal samples of patients suspected of GE. The RIDA®GENE *E. coli* Stool Panel I multiplex qPCR (R-Biopharm AG, Germany) was used for detection of Shiga-toxin 1 and 2 genes and the intimin (EAE) gene, after validation with positive (n = 80) and negative (n = 20) control strains, as well as preselected positive and negative stool samples (n = 75 each). The cumulative incidence for STEC with 95% confidence interval (CI) was calculated.
Results: In all 1275 samples were collected. The mean age of included patients was 35 years (SD = 24) and 56% of the patient were female. The RIDA®GENE *E.coli* Stool Panel I kit showed 100% sensitivity and specificity in the validation. STEC was found in 14 patients (1.1%, 95% CI: 0.5-1.7%), of which 6 (0.5%, 95% CI: 0.1-0.9%) were EHEC. STECs were more often detected in summer (June-September) (n = 9, 64%), with a peak incidence in August (n = 5). In none of the STEC positive patients other relevant bacteria or parasites (*Salmonella* spp., *Shigella* spp., *Yersinia* spp., *Campylobacter* spp., *Plesiomonas* spp., *Entamoeba histolytica, Giardia lambiae* and *Cryptosporidium* spp.) were found.
Conclusion: The prevalence of STEC in faecal samples of primary care patients suspected of GE was 1.1%. In all positive samples STEC was the only detected relevant enteropathogen. Although screening on STECs seems most relevant in the summer period, the clinical relevance of STEC infections in primary care needs to be determined before further decisions can be made on future screening.

P1632 ADHERENCE TO GENERAL PRACTICE DIAGNOSTIC GUIDELINES FOR GASTROENTERITIS IN THE NETHERLANDS

A. Schierenberg[1], B. D. L. Broekhuizen[1], M. D. Nipshagen[2], M. B. J. Kommer[1], P. C. J. Bruijning-Verhagen[1], S. van Delft[3], A. C. van de Pol[1], M. J. M. Bonten[2], N. J. de Wit[1]
[1]*Julius Center,* [2]*Medical Microbiology, UMC Utrecht,* [3]*Saltro Diagnostic Center, Utrecht, Netherlands*

Contact E-mail Address: A.Schierenberg@umcutrecht.nl
Introduction: Dutch primary care guidelines for gastroenteritis (GE) advice to reserve diagnostic faeces testing (DFT) for: ill patients with fever, frequent watery or bloody/mucosal stools, patients with comprised immunity or increased transmission risk (1). Compliance with current guidelines is unknown. Laboratories recently replaced traditional culture is by user-friendly and fast molecular PCR-based techniques, with potential impact on testing practices in primary care.
Aims & Methods: To determine the adherence to the Dutch primary care guideline for DFT in patients with GE and evaluate the impact of PCR introduction. A before-after cohort study in 1000 primary care patients receiving DFT was performed. Clinical data were extracted from the electronic medical patient records and a random selection (2 samples, n = 500) was made from the before (conventional DFT, 2010-11) and after period (PCR, 2013). For each episode the GP's reason for DFT was extracted and their management assessed by two researchers on its accordance with the Dutch guideline (1). The proportion of adherence was calculated and group differences of patient characteristics were tested using the chi-square and Mann-Whitney U tests. Multivariate logistic regression was performed investigating the influence of PCR with adjustment for population differences between the periods.
Results: In 88% of the patients a reason for testing was specified, most frequent were symptom duration of > 10 days and a recent visit to the (sub)tropics. Guideline adherence for DFT was 17% overall; 16% under conventional testing and 18% under PCR. Patients tested according to the guideline were significantly older, more often female, had more contacts per episode, comorbidities and acid related disorder drug use (Table 1). The use of PCR did not seem an independent predictor of guideline adherence (OR = 1.2, 95% CI = 0.8-1.8).
Table 1: Patient characteristics and reasons for DFT (numbers are percentages, unless specified otherwise).

Patient Characteristics/ DFT reason	Adherence (17)	Non-adherence (83)	Total
Age, mean (SD)[#]	45,3 (25,1)	32,2 (23,9)	34,5 (24,6)*
Gender, Female[#]	64	55	57*
Contacts per episode, mean (SD) [#]	4 (2,8)	3,7 (2,4)	3,4 (2,5)*
Intestinal comorb.	19	9	11*
Cardiovascular comorb.	13	5	6*
DM	13	4	6*
Acid rel. disorder drug use	43	23	26*
Guideline criteria†: Sick Patient/Immunocomp. patient/Increased transmit. risk			6/9/3
Non-guideline criteria: Duration ≥ 10 days/Recent visit (sub)tropics			26/17
Any reason specified by GP			88

[#]Included in multivariate regression, [†]Reason presence signifies "adherence", *$p < 0.05$.

Conclusion: Adherence to the Dutch primary care guideline for DFT in primary care patients with GE is low and DFT is predominantly driven by motives that are not specified in this guideline. The introduction of PCR testing did not influence guideline adherence. Evaluation of the current guideline regarding DFT is needed to ensure proper management of primary care patient with GE.

P1633 CLOSTRIDIUM DIFFICILE INFECTION IN COUNTY DURHAM HOSPITALS: A CHANGING CLINICAL PROFILE OVER 5 YEARS

F. Rana[1], R. Kirkley[1], S. Brown[2], D. Nayar[3], A. Dhar[1]
[1]*Gastroenterology,* [2]*Pharmacy,* [3]*Microbiology, County Durham & Darlington NHS Foundation Trust, Co. Durham, United Kingdom*

Contact E-mail Address: anjan.dhar@cddft.nhs.uk
Introduction: *Clostridium difficile* infection (CDI) continues to pose a significant challenge to all hospitals in the United Kingdom, despite significant improvements to antibiotic prescribing and new drugs to treat it. Its incidence in the ageing population contributes to significant morbidity and mortality as does its association to patients with multiple co-morbidities[1]. County Durham represented an area of high CDI about a decade ago, and since then significant improvements in the rational use of antibiotics together with a multi-disciplinary approach to hospital acquired infections have resulted in a reduction of the annual incidence of the disease. In this report we describe the changes to clinical practice and outcomes of CDI in this region over a period of 5 years.
Aims & Methods: An annual review of all CDI patients was carried out over two 12 month periods, June 2010- May 2011 and April 2012- October 2013 using a standardised proforma and all cases recorded on the Microbiology and Infection Control Databases. The patients included all hospital attributable cases which are nationally reported as post-48 hour infections. A number of paramters including patient demographics, severity of CDI, antibiotics implicated in the development of CDI, outcomes, mortality and recurrence were studied in both time periods.
Results: The incidence in County Durham in 2008-2009 was one of the highest reported in the North East - 232 cases (74.4/100,000 bed days). By 2010 this incidence fell to 70 cases (23/100,000 bed days). In 2013, 75% of CDI patientes were diagnosed inthe hospital, and 75% were over the age of 75 years. 39/71 patients responded to initial treatment, and the remaining patients needed esclation of treatment. 39% pts died with in 3 months of their diagnosis, with 70% deaths occurring in hospital. Different parameters were studied including mortality and whilst there had been a significant reduction in the over-all incidence of CDI in the region, the mortality remained unchanged (25% in 2010-11 vs 24.7% in 2012-13). The results are as follows:

Parameter	2010-11	2012-13
Mean Age	75.5	76.8
CDI in community	38%	25%
CDI in hospital	62%	75%
Recurrence	7%	17%
28-day Mortality	**25%**	**24.7%**

Conclusion: Most of our CDI cases occur in the elderly, with 75% pts being over the age of 75years. There is a higher recurrence rate in 2012-13 (17%) compared to 2010-11 (7%), which is a cause for concern. Despite improvements in treatment, the all cause 28-day mortality remained unchanged and this is a challenge to healthcare professionals to find better ways of treating elderly patients.

P1634 PROCALCITONIN LEVELS CAN BE USED TO DISCRIMINATE BETWEEN INFLAMMATORY AND NON-INFLAMMATORY DIARRHEA

H. J. Shin[1], S. H. Kang[1], H. Y. Jeong[1], H. S. Moon[1], J. K. Sung[1], S. H. Kim[1], H. Y. Lee[1], B. S. Lee[1], E. S. Lee[1]
[1]*Internal Medicine, Gastroenterology, Chungnam National University Hospital, Daejeon, Korea, Republic Of*

Contact E-mail Address: doctor85@naver.com

Introduction: The objective of this study is to determine if the level of procalcitonin can be used to differentiate between inflammatory diarrhea and non-inflammatory diarrhea in patients with acute infectious diarrhea or acute gastrointestinal infection.

Aims & Methods: This was a retrospective case-control study based on medical records from a single tertiary medical center located in Daejeon, Republic of Korea. The records of 1,176 patients who presented with abdominal pain, fever (≥37.8℃), and diarrhea between March 2011 and February 2015 were reviewed, and 514 patients were selected. The eligible patients had undergone abdominal computed tomography (CT) or colonoscopy within 3 days and blood sampling on the day of admission. The selected patients were divided into two groups on the basis of their abdominal CT or colonoscopy findings: group A, the inflammatory diarrhea group (n = 370), and group B, the non-inflammatory diarrhea group (n = 144). We then compared the clinical and laboratory characteristics of these two groups.

Results: White blood cell (WBC), absolute neutrophil count (ANC), blood urea nitrogen (BUN), C-reactive protein (CRP), and procalcitonin levels were significantly higher in group A (inflammatory diarrhea) patients than group B (non-inflammatory diarrhea) patients (11.05 ± 0.30 vs. 8.76 ± 0.29 ($P < 0.05$), respectively, 9.19 ± 0.26 vs. 6.64 ± 0.27 ($P < 0.05$), respectively, 19.1 ± 0.65 vs. 16.21 ± 1.1 ($P < 0.05$), respectively, 5.52 ± 0.23 vs. 3.06 ± 0.31 ($P < 0.05$), respectively, and 2.47 ± 0.17 vs. 0.58 ± 0.12 ($P < 0.05$), respectively). Multivariate analysis revealed that procalcitonin level on admission was the most important predictor of inflammatory diarrhea (OR 1.321, $P < 0.05$). Receiver operating characteristic analysis results also showed that procalcitonin had the highest area under-the-curve value (0.81; 95% confidence interval 0.79–0.83; $P < 0.05$) for distinguishing inflammatory diarrhea from non-inflammatory diarrhea. At a cut-off level of 0.797 mg/dL, procalcitonin had a sensitivity of 87.03% and a specificity of 68.75%.

Conclusion: Procalcitonin as a diagnostic marker of inflammatory diarrhea was superior to the other inflammatory markers and clinical characteristics we evaluated in this study. A patient's procalcitonin level on admission may aid clinical decision-making, for example initiating empiric antibiotics therapy and/or performing additional clinical tests.

Introduction: An increasing awareness of the etiology of sporadic and outbreak cases of viral gastroenteritis has transformed the traditional dichotomous view that *Norovirus* causes epidemic viral gastroenteritis in older children and adults whereas *Rotavirus* causes diarrhea in infants and young children. We previously reported that 14.3% of adult diarrhea was caused by group A *Rotavirus* infection (*Lancet*, 357, 9272, 2001). Thereafter other viruses such as *Astrovirus*, *Adenovirus*, *Norovirus*, and *Enterovirus* have turned out to be also responsible for gastroenteritis. However acute gastroenteritis seemed to be gradually changed.

Aims & Methods: We recruited consecutive 768 patients (M/F; 387/371, median age; 35) acute sporadic diarrhea in adult, during the four years from 2011-2014. Referring to virus, *Astrovirus*, *Adenovirus*, *Norovirus*, and enteric pathogenic bacteria were examined by conventional stool culture. We used commercially – available immune-chromatography assay kits (QUICKNAVI-NORO™, Otsuka Pharmaceutical Co., Ltd Tokyo, Japan, and BD Rota/Adeno Examan Stick™, Becton and Dickinson Co., Franklin Lakes, NJ) for virus check. Cosinor method was tried to analyze seasonality of infection.

Results: Viral infection was confirmed at the rate of 56.4% (429/760), and bacteria was 24.0%(184/760) in sporadic acute gastroenteritis. Co-infection between virus and bacteria was extraordinary high.

Conclusion: Viral infection is approximated with a cosine curve with a period of 12 months. However Rotavirus and Adenovirus is getting decreased. Norovirus infection is getting increased. Co-infection between virus and virus or virus and bacteria is unexpectedly frequent such as we reported two years ago at this meeting. Campylobacter species are becoming dominant among bacteria pathogens. *Vibrio parahemolyticus* due to raw fish eating was dominant for long time, however during the 4 years we daiganosed only 2 case. We speculate this paradigm shift of intestinal infection appears from induction of Rotavirus vaccination, profile change of intestinal microbiota, and dietary change such as "fish to meat."

Introduction: Intestinal tuberculosis (ITB) is rare but on the rise. The diagnosis is frequently delayed. Clinical presentation tends to be non-specific and often mimics inflammatory bowel disease (IBD), malignancy or less sinister conditions (eg. appendicitis, gastroenteritis). In light of the TB resurgence in urban, high-immigration areas in developed nations, prompt recognition of ITB is vital to avoid complications and death. We present the largest case series of patients with ITB in Europe.

Aims & Methods: Retrospective study of 61 consecutive ITB patients from 2008-2014 at two East London hospitals, identified using the London TB Register. Electronic records were searched for demographics, symptom duration, site of ITB, details of diagnostic confirmation and patient outcomes. Statistical analysis was done using χ^2, Fisher exact & Mann-Whitney U tests ($\alpha = 0.05$).

Results: Male:female ratio was 40:21. Mean age was 34.6 (range 13-82) years. 93% were born outside the UK, mostly from TB-endemic areas (Indian subcontinent: 88%, sub-Saharan Africa: 9%). 3% had confirmed HIV. 25% had previous pulmonary TB. Time from symptom onset to ITB diagnosis varied from < 1 week to 30 years (mean 59.4 weeks).

Main sites of ITB involvement were the small bowel (52%) or ileocaecum (44%). 3% had appendiceal TB. 26% had colonic TB (31% right colon only). Virtually all patients – except the 8% with isolated perianal TB – had cross-sectional imaging; presumptive diagnosis of ITB was made on radiology in 31%. In the other 69%, ITB was confirmed on positive histology and/or microbiology (28/61 each). 8/10 IGRAs performed were positive. 17 patients underwent endoscopy, confirming TB in 76%. Nearly one-third of patients underwent diagnostic surgery (14 had laparoscopy, 5 had laparotomies).

The total cohort was divided into Group A: ITB diagnosed on index visit to our centres with ITB-related complaint (n = 23) and Group B: ITB diagnosed later than index visit (n = 38). Group B were more likely to have previously been administered treatment for other diagnoses ($p = 0.002$), particularly IBD ($p = 0.007$). Group B had higher rates of perianal TB (4/5), strictures (18% v 9%) and obstruction (13% v 0%). 1 patient died in Group B, none in Group A. Unexpectedly, overall Group A appeared to have more severe disease on diagnosis. Group A were more likely to have perforations (17% v 11%) and intra-abdominal collections or intestinal fistulae (35% v 16%). They were also more likely to be hospitalised when ITB diagnosis was made ($p = 0.019$), undergo laparotomy ($p = 0.025$), have more surgical complications (intra-operative perforation, wound dehiscence, adhesions) ($p = 0.04$), and longer length of hospital stay that visit (mean 19.4 v 7 days). Patient delay in presentation to our centres did not influence outcomes between groups (difference in symptom duration pre-index visit, $p > 0.1$).

Conclusion: ITB is curable but morbidity and mortality remains high due to late diagnosis. The differential needs to be considered early in patients with abdominal complaints and high index of suspicion for TB to establish prompt diagnosis and treatment.

P1637 ENDOSCOPIC AND CLINICAL CHARACTERISTICS OF AMEBIC COLITIS IN JAPANESE PATIENTS: WITH SPECIAL REFERENCE TO DISEASE LOCATION

K. Nakayama[1], K. Aoyagi[1], Y. Tomioka[1], T. Watanabe[1], H. Ishibashi[1], K. Abe[1], Y. Kayashima[1], S. Matsuoka[1], H. Sakisaka[1], T. Tanabe[1], S. Sakisaka[1]
[1]*Gastroenterology and Medicine, Fukuoka University Faculty of Medicine, Fukuoka, Japan*

Contact E-mail Address: nakakei@minf.med.fukuoka-u.ac.jp
Introduction: Amebiasis is a major cause of death from parasitic disease worldwide. In the developed countries, however, amebic infection could be overlooked because of a relatively lower incidence as well as nonspecific endoscopic findings, and travelling to endemic areas and sexual contacts are predominant risks for infection. The endoscopic findings include various patterns, possibly making the exact diagnosis difficult.
Aims & Methods: Our aim is to elucidate the endoscopic and clinical characteristics of amebic colitis in Japanese patients. This is a retrospective observational study. Twenty consecutive Japanese patients who were diagnosed as amebic colitis in our hospital were included. Clinical, endoscopic (19 colonoscopy, 1 sigmoidoscopy), parasitological, histological findings, and clinical outcome were reviewed. Sex, age, risk of infection, disease locations, and the presence of concomitant diseases were also recorded.
Results: This study included 20 patients (male 95%, mean age 45.6 years), 80% of which had symptoms (mucous and bloody stool 60%, diarrhea 25%, fever 15%, abdominal pain 15%). Travels to endemic areas and sexual transmission were determined in 60% and 25%, respectively. Colonoscopic findings included aphthous ulcers (75%), superficial ulcers (65%), and inflamed mucosa (62%). Among 19 patients who underwent colonoscopy, the disease location was the right colon alone (proximal to the splenic flexure) 25%, the left colon alone (including rectum) 32%, and both 42%. The age at diagnosis was higher in patients without left colon involvement than in patients with left colon involvement (mean 54.8 vs. 42.3, $p < 0.05$). In 80% of patients parasitological confirmation was demonstrated using mucosal biopsy (55%) and/or stool examination (30%), while in 20% of patients both of them were negative, leading the diagnosis by additional serological tests (20%). Concomitant diseases included inflammatory bowel disease 15%, human immunodeficiency virus (HIV) infection 15%, and pseudomembranous colitis 5%. After all patients received metronidazole (mean 1,470 mg daily for 10-15 days), only one patient had relapse (the retreatment was successful).
Conclusion: Endoscopic diseased segments are often restricted to the right colon, especially in the aged patients with amebic colitis. Thus colonoscopy but not sigmoidoscopy is mandatory when clinical and endoscopic features are suggestive of amebic colitis even in the developed countries. Concomitant infections including HIV should also be considered.

P1638 HIGHER FECAL HEMOGLOBIN DETECTED IN OLDER PATIENTS WITH MORE SEVERE C. DIFFICILE INFECTION

L. Chen[1], S. L. Doyle[1], J. H. Boone[1], D. M. Lyerly[1]
[1]*Research and Development, TechLab Inc., Blacksburg, United States*

Contact E-mail Address: lichen@techlab.com
Introduction: *C. difficile* infection (CDI) rates continue to increase and cause poor outcome for patients over 65 years with comorbid disease. Patients with mild or severe disease may require a different treatment regimen to prevent relapse, while exposing carriers to antibiotics may cause infection. Previous studies have linked higher fecal lactoferrin levels with severe CDI including presence of stool toxin, increased white blood cell count, older age, ribotype 027 infection and poor outcome. Fecal hemoglobin is a biomarker for blood in stool and has been correlated with colorectal cancer and mucosal damage. Hypervirulent strains express toxins that lead to inflammation and bleeding in the lining of the colon. Measuring hemoglobin in stool may provide an additional biomarker for determining mucosal damage. Currently, the levels of fecal hemoglobin in patients with more severe CDI has not been critically evaluated.
Aims & Methods: The levels of fecal hemoglobin in severe CDI was evaluated. Severe CDI was defined in toxin positive samples with lactoferrin levels $\geq$100 μg/g faeces. Stool samples collected from patients suspected of CDI were included. Toxin was detected using tissue culture with neutralization (TC). Presence of toxigenic *C. difficile* was confirmed with a combination of bacterial culture and TC. Lactoferrin (LF) was measured using a commercial quantitative enzyme-linked immunoassay (EIA) and a cutoff of 7.25 μg/g was considered positive. Hemoglobin was detected using a monoclonal-based EIA and results were reported as μg/g. Stool consistency was determined using the Bristol Stool Scale 1 to 7 (liquid).
Results: A total of 209 fecal samples were submitted from patients with a mean age and stool consistency of 55 years and 6, respectively. A total of 16% ($N \pm 34$) had toxigenic CDI and 12% ($N \pm 24$) were positive for stool toxin. In the TC+ group, 85% were positive for LF and 35% had levels over a higher cutoff $\geq$100 μg/g to indicate more severe CDI. The mean hemoglobin levels were higher (770 μg/g vs. 610 μg/g; $p = 0.0085$) for the TC+ vs. TC- groups and for the TC+ $\geq$100 μg/g LF compared to the TC+ $<$ 100 μg/g LF groups (830 vs. 220; $p = 0.0013$). When stratified by age, 67% of TC+ LF $\geq$100 μg/g patients were older than 65 years and had a mean hemoglobin level significantly higher compared to younger patients (1081 vs. 329 μg/g). There was no difference in stool consistency among most of the diagnostic groups except the older patient group with TC+ and $\geq$100 μg/g LF (Bristol stool score 7).
Conclusion: Older patients with severe CDI as defined by the presence of stool toxin and LF over $\geq$100 μg/g had significantly higher levels of fecal hemoglobin. Future studies are needed to evaluate the utility of hemoglobin in stool as an aid in assessing severe CDI.

P1639 DEVELOPMENT OF A CLINICAL RULE TO PREDICT HOSPITAL ONSET-HEALTHCARE FACILITY ACQUIRED CLOSTRIDIUM DIFFICILE INFECTION: THE ERASE & CLEAN OFF CDI STUDY

M. Core[1], T. Smith[1], S. G. Rothrock[1], T. Desmond[1]
[1]*Orlando Health, Orlando, United States*

Contact E-mail Address: meg.core@gmail.com
Introduction: *Clostridium difficile* (CDI) infections have been difficult to control and prevent in hospitalized patients. One possible contributor to stable or increasing CDI rates is that many at-risk patients do not have individual prevention or treatment measures adopted until after CDI develops. A pilot project was performed to develop a prediction rule for patients who develop hospital onset-healthcare facility associated (HO-HCFA) CDI. If a simple rule can be developed to predict this disease, future research may be able to institute prevention strategies in at-risk patients.
Aims & Methods: This study took place at an urban hospital with 237 beds, 12,000 annual admissions and an annual ED census of 80,000 visits. This was a retrospective case-control study of patients $\geq$ 18 years old admitted between January 1, 2012, and December 31, 2013. Clinical features of patients with HO-HCFA were compared to controls who were admitted to the hospital on the same date. Logistic regression and recursive partitioning were used to create models for predicting HO-HCFA based on (1) initial ED and (2) all (ED plus inpatient) features. Receiver operating characteristic curves were compared between rules using the method of Delong (area under the curve [AUC]). Rules with a significantly greater AUC were retained. If the AUC did not differ between rules, those rules with significantly greater sensitivity and specificity (McNemar's test) were retained. If AUC and sensitivity/specificity did not differ, the rule with the least number of clinical variables was retained.
Results: There were 105 patients with HO-HCFA after excluding recurrent cases. There were 210 patients without HO-HCFA that served as controls. Recursive partitioning resulted in the optimum rule with five ED based clinical features predictive of HO-HCFA: **E**rrant immune system - 3 points, **R**esident of assisted living facility – 10 points, **A**lbumin low – 4 points, **S**ixty years old or older – 3 points, **E**pisode of CDI in the past – 12 points, (mnemonic **ERASE)**. A cutoff of $>$ 4 total **ERASE** points yielded a rule that was 65% sensitive (55-74%, 95% CI) and 81% specific (76-86%, 95% CI) for predicting HO-HCFA. Logistic regression (including inpatient plus initial features) resulted in the optimum rule using inpatient plus ED features with eight clinical weighted features associated with HO-HCFA designated by the mnemonic **CLEAN OFF–CDI: C**DI history – 14 points, **L**ives in assisted living facility – 9 points, **E**levated WBC count ($>$ 8800 cells/mm^3) - 3 points, **A**ntibiotic use during admission – 3 points, **N**exium like medicine [proton pump inhibitor] use during admission – 5 points, **O**peration during admission – 4 points, **F**asting blood sugar high (history of diabetes) **-** 2 points, and a **F**aulty immune system – 4 points. A cut off of $>$ 10 points yielded a rule that was 81% sensitive (72-88%, 95% CI) and 81% specific (75-86%, 95% CI) in predicting HO-HCFA.
Conclusion: Clinical prediction rules were created based on ED-based information and inpatient plus initial features to predict which patients will develop HO-HCFA. Prospective validation in larger diverse settings is required to confirm the utility of these rules. If confirmed, these findings may be used in the future to predict who will develop HO-HCFA and institute more comprehensive measures to prevent this disease.

P1640 CLINICAL FEATURES AND OUTCOMES OF CYTOMEGALOVIRUS COLITIS: RETROSPECTIVE REVIEW

M. W. Jung[1], S. J. Shin[1], S. G. Lim[1], K. M. Lee[1]
[1]*Gastroenterology, Ajou University School of Medicine, Suwon, Korea, Republic Of*

Contact E-mail Address: jmw_81@hanmail.net
Introduction: Cytomegalovirus (CMV) colitis occurs predominantly in immune compromised patients. However, cases of severe CMV colitis are also described in the immunocompetent patients. The aim of this study was to investigate the clinical feature and outcome of CMV colitis.
Aims & Methods: We retrospectively reviewed the medical records of 106 patients who were diagnosed with CMV colitis by immunostaining for CMV antibodies or CMV-Polymerase chain reaction (PCR) test, based on the histological examination of tissue, obtained by colonoscopic biopsy or surgical resection.
Results: The patients infected with CMV colitis had comorbidities including cardiovascular disease ($n = 26$, 24.5%), diabetes mellitus ($n = 22$, 20.8%), chronic renal failure or end stage renal disease (ESRD) ($n = 11$, 10.4%), and sepsis ($n = 13$, 12.3%). Forty nine of patients (49/106, 46.2%) had inflammatory bowel disease (IBD). The most common presenting symptom was hematochezia ($n = 45$, 42.5%) and other symptoms were diarrhea ($n = 27$, 25.5%) and abdominal pain ($n = 18$, 17.0%). Sixty of patients (60/106, 56.6%) were treated with antiviral agent (ganciclovir). The mean period of antiviral agent treatment was 15.9 ± 8.7 days. The symptoms of twenty eight patients (28/106, 26.4%) were resolved without antiviral agent treatment. Eleven of patients (11/106, 10.4%) had to undergo colectomy due to worsened condition of colitis

(pan colitis, uncontrolled bleeding, and perforation). The associated risk factors for colectomy were steroid-using patients ($p = 0.021$) and underlying sepsis ($p = 0.005$).
Conclusion: CMV colitis in patients with recent steroid use or with septic condition were associated with poor outcome including colectomy.

P1641 IN PATIENTS WITH CLOSTRIDIUM DIFFICILE ASSOCIATED DIARRHEA IN RUSSIA: IDENTIFICATION OF HYPERVIRULENT STRAIN

N. Zakharova[1], T. Fil[1]
[1]*Department of Therapy and Clinical Pharmacology, North-Western State Medical University Named after I.I. Mechnikov, St. Petersburg, Russia, Saint-Petersburg, Russian Federation*

Contact E-mail Address: nvzakharova@mail.ru
Introduction: *C. difficile* is an etiological factor of antibiotic-associated diarrhea (AAD) in 15–25% of cases. According to published data, outbreaks of nosocomial infection caused by strain *C. difficile* NAP1 (North American pulsed-field type 1) type BI PCR ribotype 027 have been reported in Europe and the USA. This new strain was shown to be resistant to fluoroquinolones and displayed genetic mutations in a toxin regulator gene (tcdC), causing higher expression of toxins A and B; it produced a binary toxin (CDTa+CDTb).
Aims & Methods: To discover the frequency of strain *C. difficile* BI/NAP1/027, during a 10-months period, all cases of AAD and CDI in a multi-specialty hospital were recorded. CDI was diagnosed by the identification of toxins *C. difficile* A and B using the EIA test system "Xpect *C. difficile* Toxin A/B" (Oxoid/Remel, USA) in fecal samples. Then 50 positive diarrheal fecal samples were examined with an automatic PCR real-time multiplex– the GeneXpertDX (Cepheid, USA) to detect genes of cytotoxin B, a binary toxin (cdtA and cdtB genes), and a deletion in the tcdC gene (attributed to BI/NAP1/027).
Results: 130 fecal samples of patients with AAD were collected for the research. 62 patients (47,7% of cases) had a positive toxin assay. During the observation, three CDI outbreaks lasting from 7 till 14 days were declared in the hospital, and some sporadic cases were registered. The average age of the CDI patients was 61 ± 14 years. The average time between the patient's admission and CDI was 10 ± 5.7 days. The duration of the CDI episode was $7{,}5 \pm 3.5$ days. All patients were treated either with metronidazole or vancomycin, or with both medical drugs. More often, this complication developed in the pulmonary (18), surgical (13) and intensive care (10) units. The risk of developing CDI in the early post-surgical period was significantly higher: among 35 patients that were in the early postsurgical period, 26 had a positive fecal test for *C. difficile* toxins (95% CI OR 1.265 – 7.290, $p = 0.013$). Two patients within 6 months prior to this hospitalization had AAD (*C. difficile* assay was not conducted). There was not a single case when pseudomembranous colitis was considered the attributable cause of death. Four patients died during the CDI episode, but the cause of death was another disease. According to the results of the PCR, one case revealed a false positive result from the EIA system «Xpect C.difficile Toxin A/B». The other 49 samples were positive for the cytotoxin B encoding genes. The deletion in the tcdC gene, attributed to strains BI/NAP1/027, and the binary toxin gene were absent in all samples. Thus, the sensitivity of the EIA was 100%, and its specificity was 98%. The follow-up period for all patients after CDI was 9 months. No recurrence of the infection was registered.
Conclusion: During a 10-months observation in a multi-specialty hospital in St.Petersburg, CDI was identified in 47.7% of cases of AAD. There were no cases of the hypervirulent strain BI/NAP1/027 and no deaths due to CDI or recurrent CDI. EIA is shown to be a sensitive and specific test for the diagnosis of CDI.

P1642 CLINICAL STUDY OF 32 PATIENTS WITH ANTIBIOTIC-ASSOCIATED HEMORRHAGIC COLITIS

S. Oka[1], K. Takemoto[1], R. Takenaka[1], H. Tsugeno[1], S. Fujiki[1]
[1]*Digestive Endoscopy Center, Tsuyama Chuo Hospital, Tsuyama, Japan*

Contact E-mail Address: oka.shouhei@gmail.com
Introduction: Antibiotic-associated hemorrhagic colitis causes bloody diarrhea and abdominal pain after taking antibiotics, and reveals characteristic endoscopic findings. Recently, *Klebsiella oxytoca* is described as a cause of antibiotic-associated hemorrhagic colitis.
Aims & Methods: This is a retrospective chart review for patients who visited our hospital. Patients underwent diagnostic colonoscopy, and who received a diagnosis of antibiotic-associated hemorrhagic colitis. Total 32 patients with Antibiotic-Associated Hemorrhagic Colitis were identified among those who visited our institution between October 2000 and April 2015. Demographics and clinical courses of these patients were examined. In addition, we analyzed the prevalence of *Klebsiella oxytoca*.
Results: There were 13 male and 19 female patients, with a median age of 49.7 years old (range: 17-81 years old). Of these patients, 11 patients (34.4%) had underlying clinical conditions: 6 (18.8%) had hypertension, 4 (12.5%) had hyperlipidemia, 2 (6.3%) had diabetes mellitus, 2(6.3%) had chronic liver injury, 1 (3.1%) had nephrotic syndrome. Chief complaints of these all patients were bloody diarrhea and abdominal pain. Causative antibiotics were penicillins in 22 (68.8%) patients, cephalosporins in 4 (12.5%) patients, quinolones in 3 (9.4%) patients, macrolides in 1 (3.1%) patient and Fosfomycin in 1 (3.1%) patient. Duration until onset after taking causative antibiotics were 5.6 ± 2.4 days. Colonoscopy revealed segmental hemorrhagic colitis with rectal sparing in all patients. Colitis was almost localized in the right colon. Endoscopic findings were mucosal edema, mucosal hemorrhage and mucosal redness. In stool culture, 17 (58.6%) of the 29 patients who underwent stool culture were positive for *Klebsiella oxytoca*. All the 32 patients achieved clinical remission with conservative treatment and needed 4.0 ± 1.2 days till. clinical remission.
Conclusion: Antibiotic-associated hemorrhagic colitis was seen in relatively younger population who didn't have underlying clinical conditions. Causative antibiotics were mostly penicillins, cephalosporins and quinolones. Colitis was almost localized in the right colon. *Klebsiella oxytoca* was detected in most patients with antibiotic-associated hemorrhagic colitis.

P1643 THE DETECTION OF COLORECTAL NEOPLASTIC LESIONS IN ASYMPTOMATIC HIV-INFECTED SUBJECTS DURING SCREENING COLONOSCOPY

N. Nagata[1], H. Cho[2], S. Moriyasu[2], K. Watanabe[2], J. Akiyama[1]
[1]*Department of Gastroenterology and Hepatology,* [2]*National Center for Global Health and Medicine, Tokyo, Japan*

Contact E-mail Address: nnagata_ncgm@yahoo.co.jp
Introduction: The incidence of non-AIDS defining cancer has increased with prolongation of life expectancy of HIV-infected patients. Previous studies from western countries have suggested that higher incidence of colonic adenoma in patients with HIV infection compared with the general population. However, little is known about the risk of adenoma in HIV-infected patients compared with the general population in Asia.
Aims & Methods: We conducted a prospective cross-sectional single-center study to determine the prevalence of colonic neoplasm in 200 HIV-infected patients and age- and sex- matched 200 uninfected subjects. All subjects underwent screening colonoscopy. Colorectal neoplasm included adenoma, early or advanced adenocarcinoma, and other tumors. Lifestyle habits, medications, co-morbidities, HIV-related factors and human papillomavirus (HPV) infection were assessed before colonoscopy. To evaluate the effects of HIV infection on colorectal neoplasm, adjusted odds ratio (OR) was estimated by multivariate logistic regression.
Results: Between HIV infected and non-infected subjects, no significant difference was noted in the prevalence of adenoma ($n = 28$ vs 30, $P = 0.78$). Multivariate analysis adjusted by alcohol, smoking, NSAIDs, low-dose aspirin, and diabetes mellitus showed that HIV infection is not associated with increased risk of adenoma (adjusted OR [95%CI], 1.08 [0.60-1.95], $P = 0.80$). Between HIV infected and non-infected subjects, no significant difference ($p > 0.05$) was noted in the prevalence of early adenocarcinoma ($n = 2$ vs $n = 1$), advanced adenocarcinoma ($n = 0$ vs $n = 2$), malignant lymphoma ($n = 1$ vs 0), carcinoid tumor ($n = 0$ vs $n = 1$), and lipoma ($n = 0$ vs $n = 2$). Colorectal Kaposi's sarcoma was more common in HIV-infected patients ($n = 6$ vs 0, $P = 0.03$). Among HIV-infected patients, advancing age was an independent and significant risk factor for adenoma (adjusted OR [95%CI], 1.09 [1.05-1.13], $P < 0.01$). CD4 count, HIV-RNA, history of antiretroviral treatment, and oncogenic HPV infection were not risk factors for adenoma.
Conclusion: HIV infection was not identified as risk for colorectal adenoma and adenocarcinoma in Asian HIV-infected patients. However, it should be noted that 14% of asymptomatic HIV-infected patients had adenoma and its risk increased with age. Thus, HIV-infected patients should not miss screening opportunities for colorectal adenoma as well as other HIV-related malignancies.

P1644 UNDERSTANDING THE EPIDEMIOLOGY AND CLINICAL SIGNIFICANCE OF LATERALLY SPREADING TUMORS: A META-ANALYSIS

R. Bogie[1], M. Veldman[1], L. Snijders[1], B. Winkens[2], C. le Clercq[1], A. Masclee[1], S. Sanduleanu[1]
[1]*Division of Gastroenterology and Hepatology,* [2]*Department of Methodology and Statistics, Maastricht University Medical Center, Maastricht, Netherlands*

Contact E-mail Address: s.sanduleanu@mumc.nl
Introduction: Although the large flat colorectal neoplasms – also known as laterally spreading tumors (LSTs) – are considered to be important contributors to postcolonoscopy colorectal cancers, their frequency and significance for post-polypectomy surveillance are unclear. We performed a meta-analysis to examine the prevalence, and their endoscopic and histopathologic subtypes of LSTs in population-based studies.
Aims & Methods: We conducted a systematic search in PubMed, Cochrane Library and Scopus through all published articles (English language) until October 2014 (PRISMA methodology). Eligible studies were those reporting both population size and total number of patients with at least one LST and/or the total number of detected LSTs. We calculated pooled prevalences (95% confidence intervals (CI)) of LSTs, using random effects models.
Results: Of the 2362 studies identified, 120 were selected, of which 17 were population-based (7 European, 7 Asian, 3 American). The definitions employed for a LST varied considerably across studies: the most common definition used was 'a neoplasm with laterally growing appearance and at least 10 mm in size'. Nine of the 17 studies used the term 'LST', seven 'large flat colorectal lesion' and one an equivalent term (nodule aggregating tumor). Six of the 17 studies included both the population size and the total number of LST patients and were used in the prevalence analysis; pooled estimates for the LST prevalence were 0.67% (**Table**). Five of the 17 studies also reported the total number of patients with at least one neoplasm; pooled estimates showed a LST prevalence of 3.1% (CI: 2.4-3.8%) in these studies. Ten of the 17 studies additionally reported on the proportion of LSTs of all lesions found; pooled estimates of these data showed a LST prevalence of 2.53% (CI: 1.66 – 3.41%). Of all LSTs, 60.8% (CI: 50.7-70.8%) were of granular subtype and 39.2% (CI: 29.2-49.3%) of nongranular subtype. One study reported a predominance of nongranular LSTs.

Histopathology of LSTs included adenomas with low-grade dysplasia (61.3%, CI: 52.1-70.6%), adenomas with high-grade dysplasia (24.5%, CI: 18.3-30.7%), invasive cancer (8.2%, CI: 4.7-11.7%) or hyperplastic polyps (15.9%, CI: 8.5-13.3%). Patients with LSTs were predominantly males (56.8%, CI: 54.1-59.5%); mean age at LST diagnosis was 64.2 years. Overall, substantial heterogeneity was found across studies (maximal I^2: 95%).

Table 1: Pooled data (mixed model). *Number of LSTs derived from figures, only largest lesion per patient mentioned

Author (year)	Number of LST patients	Total number of patients	Prevalence (%) [95% CI]
Zhao (2014)	259	38050	0.68 [0.60, 0.77]
Reinhart* (2013)	354	52521	0.67 [0.61, 0.75]
Martinez (2012)	24	1234	1.94 [1.25, 2.88]
Rotondano (2011)	254	27400	0.93 [0.82, 1.05]
Chiu (2009)	53	12731	0.42 [0.31, 0.54]
Tantau (2008)	14	3856	0.36 [0.20, 0.61]
Total			0.67 [0.50, 0.84]

Conclusion: The prevalence of LSTs in population-based cohorts ranges from 0.36% to 1.95%. Such variability can be partially explained by differences in definitions applied. A universal nomenclature for LSTs is a necessary first step to clarify their biologic behavior and significance for post-polypectomy surveillance.

P1645 HEPATITIS B INFECTION AS A RISK FACTOR FOR ADVANCED COLONRECTAL POLYP AND CANCER

S. Lee[1], J. W. Kim[1], S.-J. Koh[1]
[1]*Internal Medicine, Metropolitan Government Seoul National University Boramae Medical Center, Seoul, Republic of Korea*

Contact E-mail Address: tjgmldl16@naver.com

Introduction: Hepatitis B virus infection cause cirrhosis and hepatocellular carcinoma but is also etiologically linked to several extrahepatic medical condition. Several studies have probed the existence of HBV in some extrahepatic organs and tissues. HBV is also associated with extrahepatic malignancy and may be oncogenic. However, the association of HBV infection and advanced colorectal polyp and cancer has not been investigated.

Aims & Methods: A retrospective case-control study with 130 HBV infection patients(114 CHB infection, 26 LC Patients, 31 HBV treatment) and 130 healthy controls matched for age, sex. First, we investigate each group different incidence of colorectal polyp especially of advanced polyp and cancer. And the associations between advanced colorectal polyp and HBV infection were explored with multivariate logistic regression analysis.

Results: HBV patients had a higher rate of colorectal polyp, advanced colorectal polyp, colon cancer than healthy group (OR: 6.29, 95%CL: 3.651-10.859; OR: 1.31, 95%CL: 1.193~1.446; OR: 1.066, 95% CL: 1.020-1.114). And HBV infection patients had a more polyps and size is larger than healthy group (0.04 ± 0.089 vs 1.81 ± 0.184, $p < 0.001$, 0.084 ± 0.0152, 0.447 ± 0.0423 $p < 0.001$). Of the HBV patients, 111/130 had detectable HBV DNA and HBV DNA detection was a significant risk factor for colon polyp, advanced polyp.($p < 0.001$, OR 56, $p = 0.008$). Furthermore, advanced colorectal polyp and cancer is detected only HBV DNA detection patients (31/111, 8/111). And multiple logistic regression analysis also show association of HBV DNA and advanced colon polyp ($p = 0.004$)

Conclusion: The HBV infection was positively associated with advanced colorectal polyp and colon cancer, especially for HBV DNA detectable patients. But HBV infection treatment was not show association with colorectal polyp. Further prospective studies are warranted to confirm this relationship.

Introduction: Although alcoholic liver disease (ALD) may affect the incidence or progression of colorectal neoplasia through liver metabolism of alcohol, innate immune response, and genetic alterations, little is known about the association between ALD and colorectal neoplasia.

Aims & Methods: The aim of this study was to investigate whether ALD is associated with the increased risk of advanced colonic neoplasm. We analyzed 118 consecutive patients with ALD who underwent colonoscopy between January 2000 and December 2013. For each case, age- (±5 years) and sex-matched controls were identified from patients with non-alcoholic fatty liver disease and healthy controls. Clinical data were retrieved from medical records by evaluating colonoscopic, pathologic, and radiologic findings.

Results: Of the 118 patients with ALD, six (5.1%) had colon cancer and 18 (15.3%) had advanced colonic adenoma. A case-control study showed that the odds for detecting advanced colorectal neoplasm among ALD patients without decompensated liver cirrhosis (LC) were approximately 10.1 times greater than in the age- and gender-matched healthy controls (odds ratio [OR], 10.10; 95% confidence interval [CI], 3.64–28.01; $P < 0.001$). Age was an independent risk factor for detecting advanced colonic neoplasm in patients with ALD (OR, 1.08; 95% CI, 1.03–1.14; $P = 0.002$).

Conclusion: The yield for detecting advanced colonic neoplasm was significantly higher in patients with ALD than in healthy controls. Screening for colorectal neoplasm using colonoscopy is strongly warranted in ALD patients without decompensated LC or those who consider liver transplantation.

P1647 COLORECTAL CANCER IN INFLAMMATORY BOWEL DISEASE- IS SURVEILANCE WORKING?

T. Akbar[1], S. Rahmany[1], R. Harris[1], S. Cotton[1], L. A. McCabe[1], D. A. Lloyd[1], J. N. Gordon[1]
[1]*Royal Hampshire County Hospital, Hampshire Hospitals NHS Foundation Trust, Winchester, United Kingdom*

Introduction: The burden of colorectal cancer (CRC) in inflammatory bowel disease (IBD) is currently unclear. Recent studies suggest the magnitude of risk may be considerably lower than previous estimates raising questions surrounding current surveillance protocols. However, studies that use IBD surveillance cohorts to identify cases may underestimate the burden of disease with substantial number of cases arising in patients that fall outside current surveillance parameters. Our aim was to identify all cases of CRC arising in patients with IBD in a single geographic locality in a recent timeframe and analyse factors affecting diagnosis with particular reference to current UK surveillance recommendations.

Aims & Methods: Patients with IBD who developed CRC in a 5-year period from between 2010 and 2015 were identified from a fully maintained database of all CRC cases diagnosed in our locality. This was cross-referenced with histology reports and endoscopy reports from the same period. Case notes were reviewed with data on demographics, disease, presentation, diagnosis, CRC surveillance, cancer stage and outcomes collected and analysed.

Results: 672 cases of CRC were identified in the study period of which 17 (2.5%) arose in patients with IBD (10 UC: 6CD: 1 IBDU). 16 cases were adenocarcinomas with 1 anal squamous cell carcinoma in a patient with long-standing fistulating perianal Crohn's disease. 6/17 cases (35%) were screen detected in asymptomatic patients undergoing regular surveillance. 4/17 (24%) were interval cancers identified in patients prior to their next scheduled surveillance. The remaining 7/17 (41%) were identified in patients who were not participating in a screening programme. 4 of these cases fell outside current screening parameters with the further 3 cases arising in patients who had ceased surveillance (average age 87; range 84-93). Surveillance in the interval cancers did not adhere to published guidelines in 3 out of 4 cases. 5/6 (83%) screen detected cases were classified as Duke's A or B, compared with 5/11 (45%) of the non-screen detected cases.

Conclusion: The burden of CRC in patients with IBD is significant accounting for 2.5% of all cancers in the study period. Screen detected cancers were identified at an earlier stage than non-screen detected cancers, though 41% of cases arose in patients that would not currently qualify for screening in the UK. Screening did not adhere to guidelines in 75% of interval cancers. These results support the concept of a surveillance programme though reinforce the importance of meticulous high quality colonoscopy and adherence to guidelines to improve outcomes.

Introduction: Screening for colorectal cancer by sigmoidoscopy benefits from the fact that distal findings predict the risk of proximal advanced neoplasms. Not all sigmoidoscopy trials have been observed a reduction in CRC-specific mortality. Major criticism of sigmoidoscopy trials is its lower ability to detect APN respect to colonoscopy. Moreover, proximal tumors may be due to the

serrated pathway. No long data about rate of proximal serrated lesions detected with sigmoidoscopy strategies has been published.
Aims & Methods: To determine the rate of detection of proximal serrated lesions by simulated sigmoidoscopy in a population based multicenter, nationwide, randomized controlled trial.
Methods: Asymptomatic individuals aged 50-69 years were eligible for a randomized controlled trial designed to compare colonoscopy and fecal immunochemical test (Colonprev study). Sigmoidoscopy yield was simulated from results obtained from the colonoscopy group, according to the criteria proposed in the UK Flexible Sigmoidoscopy Trial for colonoscopy referral. The main outcomes were first, rate of detection of proximal serrated lesions defined as sessile serrated polyp or hyperplastic polyp of any size (SP + HP) and secondly, proximal serrated polyp of any size or hyperplastic polyp ≥ 10mm (SP + HP10), both proximal to splenic flexure.
Results: Proximal serrated lesions (SP + HP) were observed in 329 of 5059 (6.5%) individuals, whereas proximal serrated polyp of any size or hyperplastic polyp ≥ 10mm (SP + HP10) were detected only in 88 subjects (1.7%). pSP + HP and pSP + HP10 were detected in 47 subjects (0.9%) and 16 subjects (0.3%), in the sigmoidoscopy simulation (odds ratio for sigmoidoscopy 0.13; 95% CI 0.09-0.18; p < 0.0001 and 0.17; 95% CI 0.1;-0.29, p < 0.0001, respectively. The number of individuals needed to refer for colonoscopy to detect one pSP + HP and one pSP + HP10 was 7 (95% CI 5-9) and 20 (95% CI 12-32), respectively. Sensitivity of sigmoidoscopy for pSP + HP was lower in women, from 14.3% in men aged 60-69 years to 3.9% in women aged 50-59 years. Sigmoidoscopy did not detect any of the 11 and 18 women's, aged 60-69 and 50-59 years, respectively, with a pSP + HP10.
Conclusion: Sigmoidoscopy–based strategies detect fewer individuals with proximal serrated lesions. Performance of sigmoidoscopy was lower in women, especially those aged 50-59 years.

Barcelona,* [5]*Gastroenterology Department, Hospital Clinic, Barcelona, Spain*

Contact E-mail Address: xbessa@hospitaldelmar.cat
Introduction: Screening for colorectal cancer by FIT is based on consecutive rounds to detect precursor lesions or CRC in early stages. Data on consecutive rounds of FIT screening are limited and based mostly on small population studies.
Aims & Methods: We assessed the final data regarding positivity predictive values (PPVs) for high-risk adenomas (HRA), low-risk adenomas (LRA) and CRC among patients with a previous negative result from a FIT.
Methods: Data were collected from 2 rounds of FIT screening in average-risk persons (50 to 70 years old). The PPV for HRA and CRC were compared among the first-round (FR group) participants and second-round (SR group) participants with a previous negative FIT result. We also evaluated those patients participant in the second round not previously participants in first round (first screening in the second round) (FS group). Definitions: HRA: advanced adenoma or three or more adenoma
Results: The rate of positive results from FIT was significantly superior in the first vs. second round screening (6.2% vs. 4.7%, p < 0.0001) and very similar to the FS group (6.4%, p < 0.32, respect to FR). Data comparing all participants in the FR, SR and FS groups who tested FIT positive and were eligible for colonoscopy were compared (4182 vs. 2281 vs 1323 colonoscopy studies performed, respectively). A significant decrease in the PPV was observed for CRC between the FR and SR (6.3% to 3.3%; p < 0.0001) and similar to the FS group (6.3% to 6.7, p < 0.65, respect to FR). A significant decrease in the PPV for HRA were observed between FR vs SR (41.2% to 33.2%; p < 0.0001) but also respect to the FS group (36.0%, p < 0.001, respect to FR). There were no significant differences in stages (I + II vs. III + IV) of CRC detected in the three groups (31.4%, 30.6%, and 22.6, respectively for stage III + IV). Proximal location of colorectal adenocarcinoma was significantly diferent between three groups (18.6%, 29.7% and 27.0%, for FR, SR and FS groups, respectively, p < 0.014).
Conclusion: In our population-based CRC screening program the rate of positive results from FIT decrease after a first round, and PPVs of FIT for HRA and CRC are significantly lower among second-round participants who tested negative in the first round. No differences were observed in CRC stage but a significantly more proximally location of CRC on second round screening for CRC were observed.

Contact E-mail Address: sawada1046@gmail.com
Introduction: Sessile serrated adenomas (SSAs), which are characterized by their preferential locations in the proximal colon and frequent *BRAF* mutation, are thought to be precursor lesions of colorectal cancer with microsatellite instability (MSI) and CpG island methylator phenotype (CIMP), while other serrated lesions including traditional serrated adenomas (TSAs) also exhibit frequent *BRAF* mutation.
Aims & Methods: To clarify the molecular and clinicopathological characteristics of serrated lesions, we assessed DNA methylation of cancer-associated genes in a cohort of *BRAF*-mutant precancerous lesions including hyperplastic polyps, TSAs, and SSAs with or without dysplasia (n = 106) and adjacent normal colon tissues (n = 83) from 94 individuals.
Results: Prevalence of CIMP-positive lesions was significantly lower in sigmoid colon and rectum as compared to other bowel subsites including cecum, ascending, transverse and descending colon (sigmoid-descending colon junction was defined as a demarcation point). In addition, a number of cancer-associated genes showed higher methylation levels in the proximal colon lesions than in the distal colon ones when the sigmoid-descending colon junction was used as a boundary line. In contrast, no significant difference in the methylation levels was observed in the normal background colonic mucosa of the *BRAF*-mutant lesions along the bowel subsites.
Conclusion: Levels of DNA methylation in the *BRAF*-mutant colorectal lesions were strongly associated with their locations and histology, suggesting the presence of distinct carcinogenic pathways. In contrast, no significant difference of methylation in the normal background mucosa indicates the lack of epigenetic field defect (field cancerization).

P1651 MOLECULAR SUBTYPE OF COLORECTAL CANCER IN JAPANESE PATIENTS

T. Yamaguchi[1], T. Iijima[1], R. Wakaume[1], Y. Nakayama[1], M. Amaki[1], S. Natsume[1], K. Takahashi[1], H. Matsumoto[1], D. Nakano[1], M. Miyaki[1]
[1]*Tokyo Metropolitan Cancer and Infectious Diseases Center Komagome Hospital, Tokyo, Japan*

Contact E-mail Address: tatsuro@yamaguchi.email.ne.jp
Introduction: Carcinogenesis of colorectal cancer has been studied in detail. As a result, it has come to be known that colorectal tumors had various genotypes. Recently, some groups have proposed molecular subtyping of colorectal cancer, however, there has not been established classification yet. Among molecular markers, microsatellite instability (MSI), CpG island methylator phenotype (CIMP), and KRAS/BRAF gene mutations are the most important markers. Here, we report a clinicopathologic features based on the molecular subtyping in Japanese colorectal cancer patients.
Aims & Methods: We consecutively selected 576 colorectal cancer patients who underwent surgical resection at the Tokyo Metropolitan Cancer and Infectious Diseases Center Komagome Hospital from January 2008 to December 2010 after obtaining informed consent. Patients with inflammatory bowel disease or a known history of familial adenomatous polyposis and Lynch syndrome were excluded. If patient was resected two or more colorectal tumor, a tumor which was more advanced was selected for analysis.
According to Phipps et al. (*Gastroenterology* 2015), tumor samples were classified into 5 subtypes based on combinations of tumor markers: type 1 (MSI-H, CIMP-positive, positive for *BRAF* mutation, negative for *KRAS* mutation); type 2 (MSS or MSI-L, CIMP-positive, positive for *BRAF* mutation, negative for *KRAS* mutation); type 3 (MSS or MSI-L, non-CIMP, negative for *BRAF* mutation, positive for *KRAS* mutation); type 4 (MSS or MSI-L, non-CIMP, negative for mutations in *BRAF* and *KRAS*); and type 5 (MSI-H, non-CIMP, negative for mutations in *BRAF* and *KRAS*).
Results: Among the 576 colorectal cancer patients that we were able to obtain colorectal cancer and corresponding normal tissues during the study period, the distribution of the 5 types were 1.6% in type 1, 1.0% in type 2, 22.4% in type 3, 46.2% in type 4, and 3.0% in type 5, respectively. Median age were 71 in type 1, 76 in type 2, 68 in type 3, 67 in type 4, and 60 in type 5, respectively. Female were 75% in type 1, 66.7% in type 2, 47.6% in type 3, 39.4% in type 4, and 66.7% in type 5, respectively. In type 1 and type 2, all cases were colon cancer, and in type 3 and type 4, left-side cases were frequencies. While frequencies of poorly differentiated adenocarcinoma and mucinous carcinoma were high in type 1 and type 2, those were low in type 3 and type 4. 3-year survival rate were 71.4% in type1, 25.0% in type 2, 82.1% in type 3, 88.3% in type 4, 100% in type 5, respectively. Most of type 2 patients did not show chemotherapy response, and were poor prognosis.
Conclusion: Each colorectal cancer subtype demonstrated different clinicopathological features.

Introduction: Obesity is a risk factor for colorectal cancer and adenoma but the causal mechanisms have not been fully elucidated. SPARC is a matricellular protein with pleiotropic functions implicated in obesity related metabolic dysfunction. SPARC levels are increased in obesity and are predominantly secreted by adipose tissue in the obese. Its role in obesity-related colorectal carcinogenesis has not been studied.
Aims & Methods: We aim to determine whether the association between obesity and adenoma is related to SPARC levels.
A cross-sectional study was performed. Outpatients (45-70 years) undergoing colonoscopy were recruited in accordance with STROBE guidelines. Clinical, anthropometric data, physical activity levels and venous samples were obtained prior to colonoscopy. Serum SPARC levels were measured using ELISA-based assay (USCN Human Osteonectin Elisa Kit). Correlation analysis and multivariate logistic regression was used to quantify the association between SPARC and BMI, and SPARC and adenoma respectively.
Results: 124 subjects were studied (Table). SPARC levels were modestly correlated with BMI (correlation coefficient 0.31 [0.06-0.53]). SPARC levels were significantly associated with adenoma status (OR 1.84 [1.24-3.15], p = 0.0079) after correcting for potential confounders on multivariate logistic regression.

	Colonoscopy		
VARIABLE	Normal (CONTROL) (n = 94)	Adenoma (CASES) (n = 30)	TOTAL (n = 124)
Age, (yr)	0057.0 (10.0)	0060.0 (7.0)	0058.0 (10.5)
Male Gender, N (%)	47 (50.0)	18 (60.0)	65 (52.4)

Introduction: Various populations of stem cells (SCs) have been the subject of intense research in translational oncology. The number of very small embryonic/epiblast like stem cells (VSEL-SCs - small $CXCR4^+CD34^+CD133^+$ population of Lin^-CD45^- cells) mobilized into peripheral blood (PB) increases in active inflammatory bowel disease (1) and in patients with pancreatic cancer (2). Higher numbers of circulating VSEL-SCs and mesenchymal stem cell (MSCs) were detected in pancreatic cancer patients. This trafficking of bone marrow stem cells (BMSCs) was associated with significantly elevated C5a and C5b-9/MAC levels together with sphingosine – 1 phospate (S1P) concentrations detected in plasma of cancer patients, and seemed to be executed in a SDF-1 independent manner.
Aims & Methods: We became interested if stem cells were also mobilized into peripheral blood in patients with colonic adenomas (CA) and colorectal cancer (CC). Therefore we recruited 19 patients with CA, 19 patients diagnosed with CC and 10 healthy individuals into this study. All patients underwent colonoscopy and were classified according to endoscopic, pathologic and clinical criteria. Peripheral blood samples were collected, and by employing fluorescence-activated cell sorting (FACS) the numbers of i) VSELs-SCs, ii) Mesenchymal SCs (MSC), iii) Endothelial Progenitor Cells (EPC) and iv) Hematopoietic SCs (HSC) were counted and/or isolated. Plasma levels of complement cleavage fragments, activation of coagulation and fibrinolysis, C-reactive protein as well as level of various chemokines were measured by ELISA: C5a, zonulin, plasmin-anti-plasmin (PAP) and thrombin-anti-thrombin (TAT), stromal derived factor - 1 (SDF-1), vascular endothelial growth factor (VEGF) and hepatocyte growth factor (HGF).
Results: In contrast to our previous data showing increase of circulating stem and progenitor cells including VSELs and MSCs, no increase in circulating stem and progenitor cells was found in patients with colorectal adenomas and cancer. While in our previous study mobilization of stem cells correlated with level of C5a, in patients with CC the level of C5a was low. Higher plasma levels of zonulin (marker of intestinal permeability) and HGF were observed in patients with cancer. No statistical difference was observed in PAP, TAT, SDF-1, VEGF and clonogenic assays in both groups of patients.
Conclusion: Mobilization of stem cells into peripheral blood depends on type of malignancy. Lack of mobilization of stem cells in patients with colorectal adenomas and cancer correlated with lack of activation of complement cascade. The role of intestinal permeability requires further investigation.

Introduction: Transforming growth factor β (TGF-β) has paradoxical and context dependent effects on cell survival and proliferation. In normal tissues, TGF-β1 inhibits cell proliferation through binding to type II TGF-β receptor (TGF-βRII) and type I TGF-β receptor (TGF-βRI) and regulating cell cycle by induction of $p21^{Cip1}$. Conversely, in many advanced colorectal cancers, TGF-β1 is overexpressed and promotes migration and proliferation of tumor cells, although TGF-βRII/Smad signaling pathway is usually impaired due to the transcriptional repression or functional deficiency of TGF-βRII. The roles of TGF-β1 in TGF-βRII-dysfunctional colorectal cancer cells are still unknown.
Aims & Methods: We aimed to investigate the roles of TGF-β1 in TGF-βRII-dysfunctional colorectal cancer cells. We used human colorectal cancer cell lines; HCT116, Lovo and LS513, to investigate the ability of TGF-β1 to affect apoptosis and proliferation, and its association with TGF-β receptors. TGF-β1, TGF-βRII or TGF-βRI expression was knocked down by short interfering RNA, and p53 knockdown was performed by short hairpin RNA.
Results: Enzyme-linked immunosorbent assay revealed that TGF-β1 was generated in the supernatant of all cancer cells. Suppression of TGF-β1 in HCT116 (mutant TGF-βRII and wild type of TGF-βRI and p53) cells increased the expression of p53 and $p21^{Cip1}$, and reduced cell survival by increased apoptosis. In p53-deficient HCT116 cells, suppression of TGF-β1 did not affect cell survival. In Lovo (mutant TGF-βRII and wild type of TGF-βRI and p53, same as HCT116) cells, suppression of TGF-β1 also demonstrated the similar effects, whereas in LS513 (wild type of TGF-βRII, TGF-βRI and p53), it did not increase p53 expression. Stimulation with human recombinant TGF-β1 or neutralizing antibody against TGF-β1 did not cause Smad2-phosphorylation or the elevation of p53 expression in HCT116 cells. In LS513, recombinant TGF-β1 induced Smad2 phosphorylation and $p21^{Cip1}$ expression without p53 induction. Suppression of TGF-β1 did not induce significant p53 elevation in LS513 cells. However, suppression of TGF-β1 caused p53 elevation in TGF-βRII deficient LS513 cells. Moreover, suppression of TGF-β1 significantly increased the

expression of TGF-βRI in HCT116 cells. Addition of SB431542, a selective inhibitor of TGF-βRI, suppressed p53 elevation despite of TGF-β1 suppression. Consistently, suppression of TGF-βRI inhibited p53 elevation and cell apoptosis when expression of TGF-β1 was suppressed in HCT116.
Conclusion: These results indicate that in TGF-βRII-dysfunctional colorectal cancer cells, endogenous TGF-β1 has the potential to suppress p53 expression via reduced TGF-βRI expression, leading to resistance to apoptosis.

Introduction: Serrated lesions of the colon comprise of a group of heterogeneous lesions with distinct histological features. The large serrated polyps, in particular, are associated with advanced colonic neoplasia and possibly higher risk of colorectal cancer.[1,2] However, there is a paucity of data on the optimal surveillance interval for patients with different serrated lesions of the colon.
Aims & Methods: We aim to determine the polyp and adenoma detection rate on surveillance colonoscopy in patients with different serrated lesions.
We identified patients who were diagnosed to have serrated lesions during colonoscopy in our hospital between January 2008 and June 2011. Patients with concurrent or past history of colorectal cancer were excluded. Patients were categorized according to their baseline lesions: serrated adenoma (SA), large (≥10mm) serrated polyps (LSP) and medium-sized (5-9mm) hyperplastic polyps (MHP) without concomitant or past history of adenoma. Patients with SA and LSP (SA + LSP group) were grouped together for analysis because of the small number of patients in these groups. The proportion of patients and the time to recurrent colonic polyps/adenoma on surveillance colonoscopy between the two groups (SA + LSP vs MHP) were compared.
Results: 98 patients (24 SA, 9 LSP and 65 MHP) were included for analysis. Surveillance colonoscopy was completed in 65 (66.4%) patients (20 SA, 7 LSP and 38 MHP) with a total of 75 colonoscopy performed. The median age of the patient in the SA + LSP group was significantly older than the MHP group (64.3 years, range 34-86 vs 55.8 years, range: 26-89; $p = 0.023$). The median time of surveillance colonoscopy was 40.7 and 44.3 months in SA + LSP group and MHP group respectively ($p = 0.332$). The proportions of patients with recurrent colonic polyps (including serrated lesions and adenoma) on surveillance colonoscopy were 63.0% and 36.8%, respectively (SA + LSP group vs MHP group) ($p = 0.038$). There was also a significant difference on the time to polyps recurrence between the two group, with a lower rate in the MHP group (Log Rank; $P = 0.006$). The adenoma detection rate on surveillance colonoscopy for SA + LSP group and MHP group were however comparable (29.6% and 28.9%; $p = 0.952$). Amongst those who have recurrent polyps, 41.2% and 35.7% of patients developed serrated lesions in SA + LSP group and MHP group respectively.
Conclusion: Patients with baseline SA and LSP have a significantly higher polyp recurrence rate on surveillance colonoscopy. However, the adenoma detection rate on surveillance colonoscopy was similar. These findings provide new data when deciding on the optimal screening interval for patients with different baseline serrated lesions.

P1656 MECHANISM OF PROKINETICIN RECEPTOR 2 IN COLON CANCER

Y. Ueda[1], T. Goi[1], D. Fujimoto[1], M. Morikawa[1], K. Koneri[1], M. Murakami[1], Y. Hirono[1], A. Yamaguchi[1]
[1]*First Department of Surgery, University of Fukui, Fukui, Japan*

Contact E-mail Address: yukiyukiax5@gmail.com
Introduction: Prokineticin-1 (PROK1) is thought to be involved with cell invasion through the intermediary of prokineticin receptor 2 (PK-R2), that is one of the Prokineticin-1 receptors. We report a function via PROK1-PK-R2 signaling in vitro.
Aims & Methods: 1: Four colon cancer cell lines (DLD1, HCT116, SW620 and HT29) were analyzed for PROK1 and PK-R2 protein expressions. 2: Two colon cancer cell lines (DLD1 and HT116) stimulated with PROK1 protein, were observed for 24 hours using "Olympus Fluoview 10i-w", for the presence of change in cell movement. Furthermore, we measured the moving distance of five cells in non-stimulated group and PROK1 stimulated group, compared using the U test of Mann-Whitney. 3: The expression of PROK1 and PK-R2 protein was assessed in 325 colorectal cancer tissues by immunohistochemical staining using anti-PROK1 antibody and anti-PK-R2 antibody. We investigated the relation between PROK1 and PK-R2 expression and clinicopathological factor. The association of PROK1 and PK-R2 expression with serosal invasion, lymphatic invasion, venous invasion, lymph node metastasis, peritoneal metastasis, and hematogenous metastasis was assessed by cross-tabulation, and statistical significance was determined by the c^2 test. Life-table analysis was performed using Kaplan-Meier technique and outcomes from different groups of patients were compared by the log rank test.
Results: 1: The expression of PROK1 and PK-R2 protein was detected in four colon cancer cell lines. 2: The PROK1 stimulated group, compared to non-stimulated group is a highly deformation of cells, and observed increased motility. The average of the moving distance of the cells of DLD1 was 380.96 pixel in non-stimulated group, in PROK1 stimulated group was 581.50 pixel. The average of the moving distance of the cells of HCT116 was 286.29 pixel in non-stimulated group, in PROK1 stimulated group was 400.90 pixel. Both cell lines showed a significant extension of the moving distance of the cells in PROK1 stimulated group. 3: Group1, positive both PROK1 and PK-R2, was 117 cases. Group2, positive either PROK1 or PK-R2, but not both, was 109 cases. Group3, negative both PROK1 and PK-R2, was 99 cases. According to the clinicopathological examinations, the frequency of Group1 was significantly higher in cases with lymphatic invasion, venous invasion, lymph node metastasis and hematogenous metastasis. The prognosis for patients with Group1 were significantly worse than the other groups.
Conclusion: Colon cancer cell lines stimulated with PROK1 protein, showed enhancement of moving distance and deformation and motility of cells. Signaling cascade thought PROK1/PK-R2 was suggested likely to be involved in metastasis, especially cell invasion.

Introduction: Serrated polyps comprise a heterogeneous group of lesions. The reliable classification and their molecular profile are important to implement a surveillance and screening approach.
Aims & Methods: We aimed to study BRAF and KRAS mutations and CpG island methylator phenotype (CIMP) in the DNA of polyps in order to determine molecular and histological differences and the prognostic value of these markers in patients with serrated polyps. We performed a retrospective study with patients recruited between 2007and 2009 with at least one surveillance colonoscopy. A total of 994 polyps from 313 patients were collected for histological and molecular analysis. We analyzed KRAS and BRAF mutations in the DNA of all these polyps, and CIMP in 404 polyps from 103 patients. Mutation analysis for KRAS (codons 12 and 13) was performed by DNA sequencing and BRAF mutation (V600E) using allelic discrimination. CIMP was examined by MS-MLPA, considering CIMP-positive when 5 out of 8 markers were methylated.
Results: Adenomas were the main lesion (68%, n = 676), being 0.8% of them mutated for BRAF, 11% for KRAS and 1.1% CIMP-positive. A total of 318 (32%) polyps were classified as serrated lesions: 265 (83.3%) were hyperplastic polyps (HPs), 47 (14.8%) sessile serrated polyps (SSP) and 6 (1.9%) traditional serrated adenomas (TSA). Of the serrated polyps, 39.7% of them showed BRAF mutation, 20.3% KRAS mutation and 12.8% CIMP. Considering only serrated polyps, we found BRAF mutation in 39.4% of HPs and in 40.8% of SSP and KRAS mutations in 18.7% of HP and in 28.6% of SSP. There were no differences in the morphology, size and location of the serrated polyps depending on the BRAF mutational status, while KRAS mutation was predominantly present in rectum-sigmoid ($p = 0.014$). Serrated polyps were found in 104 patients at baseline colonoscopy. The mutational status of BRAF did not predict the finding of advanced adenomas or serrated lesions at follow-up. However the presence of somatic mutations in KRAS in serrated polyps at baseline predicts advanced lesions at follow-up. Patients with somatic BRAF mutation in polyps at baseline do not show a higher proportion of advanced adenomas or large (> 1cm) or proximal serrated polyps at follow-up (BRAF mutation: 34.5% vs no-BRAF mutation 45.9%; $p = 0.35$). Regarding KRAS, there is a higher proportion of advanced adenomas or advanced serrated polyps when serrated polyps at baseline showed KRAS mutation (60.9% vs 30.2%; $p = 0.016$).
Conclusion: We found a low frequency of somatic BRAF or KRAS mutations in serrated polyps. The presence of BRAF or KRAS mutation was not associated with location, size or histology in serrated polyps. Patients with KRAS mutations in serrated polyps show a higher risk of new advanced lesions in follow-up colonoscopies.

P1658 THE RELATIONSHIP BETWEEN PROXIMAL COLONIC DISTRIBUTIONS OF ADVANCED POLYPS AND THOSE OF INVASIVE CANCER

S. Kimura[1], M. Tanaka[2]
[1]*Gastroenterology, Aomori Rousai Hospital, Hachinohe,* [2]*Pathology and Laboratory Medicine, Hirosaki Municipal Hospital, Hirosaki, Japan*

Contact E-mail Address: georgiabroad@aomorih.rofuku.go.jp
Introduction: Colorectal polyps with advanced pathology (adenoma with high-grade dysplasia; HGD or intramucosal cancer) are considered to be precursor lesions developing into invasive cancer. In the present study we aimed to evaluate the relationship between the distributions of colorectal polyps with advanced patholgy and those of invasive cancers with a special attention to proximal location.
Aims & Methods: The study included 1064 patients (mean age 66.1+-10.2yr, M:F = 2.07:1) having colorectal polyps with advanced histology which were

colonoscopically resected in our hospital. The percentages of proximal location (proximal to the splenic flexure) of the lesions were assessed with regard to age (younger than 65 yr or 65 yr of age or older), gender (male or female), number (single or multiple), size (less or more than 10mm), shape (polypoid or non-polypoid), and histology (HGD or cancer). 629 patients with invasive colorectal cancer (mean age 70.4+-11.1yr, M:F = 1.41:1) resected by surgery were also investigated the percentages of proximal distribution with regard to age and gender.

Results: The percentages of proximal polyp location were 24.7% of 457 non-elderlys and 36.6% of 607 elderlys ($p < 0.001$), and 29.2% of 718 males and 36.1% of 346 females ($p < 0.05$), disclosing significant proximal shift of the lesions in older and female patients. 29.4% of 930 patients with single lesion and 46.3% of 134 with multiple lesions ($p < 0.005$), revealed proximal extension in those with multiple lesions compared to single lesion. 31.9% of 464 patients with small lesion and 31.2% of 600 with large lesion, demonstrating no difference in distribution according to size. The percentage of proximal location was significantly higher in 221 patients with non-polypid lesion than 843 with polypoid lesion (51.1% vs 26.3%) ($p < 0.0001$). In contrast it was significantly lower in 475 patients with intramucosal cancer than 589 with adenoma of HGD (24.6% vs 35.3%) ($p < 0.005$), disclosing negative association of proximal shift with pathological progress. The percentages of proximal invasive cancer location were 24.2% of 265 non-elderlys and 38.5% of 364 elderlys ($p < 0.001$), and 24.4% of 369 males and 43.8% of 260 females ($p < 0.0001$), respectively. Significant proximal shifts in older and female patients were also observed in those with invasive cancer similar to the patients having pathologically advanced polyps. The logistic regression analysis revealed that older age (OR 1.72; 95%CI, 1.25-2.38, $p < 0.001$), non-polypoid shape (OR 3.56; 95%CI 2.46-5.15, $p < 0.0001$) were independent risk factors of proximal shift in patients with advanced polyps, and older age (OR 1.88; 95%CI, 1.32-2.69, $p < 0.001$), female gender (OR 2.25; 95%CI 1.60-3.17, $p < 0.0001$) in those with invasive cancers.

Conclusion: Proximal shifts in older and female patients were observed in both of those with colorectal advanced polyps and those with invasive cancers. Among risk factors for proximal shift in patients having pathologically advanced polyps non-polypoid appearance was a most significant factor, although number, size, and pathological progress from HGD to cancer were not influencing factors for proximal shift.

P1659 THE GROWTH PATHWAY AND THE PATHOLOGICAL FEATURES OF DEPRESSED-TYPE COLORECTAL CARCINOMAS

S.-E. Kudo[1], Y. Fukami[1], H. Miyachi[1], Y. Kouyama[1], K. Ichimasa[1], S. Matsudaira[1], H. Oikawa[1], Y. Mori[1], M. Misawa[1], T. Kudo[1], T. Hisayuki[1], K. Kodam[1], T. Hayashi[1], K. Wakamura[1], A. Katagiri[1], T. Baba[1], E. Hidaka[1], F. Ishida[1]

[1]*Digestive Disease Center, Northern Yokohama Hospital, Yokohama city, Japan*

Contact E-mail Address: kudos@med.showa-u.ac.jp

Introduction: Advanced colorectal carcinomas were conventionally considered to develop from sessile-type "polyps". And it has been maintained as the mainstream of development of cancers in colorectum.

But recently advances in endoscopic technology and diagnostic ability have revealed the existence of many depressed-type carcinomas, which have a growth pathway different from "*adenoma-carcinoma sequence*".

Aims & Methods: The aim is to clarify the pathological features of depressed-type colorectal carcinomas compared with flat- and sessile-type. A total of 23725 colorectal neoplasms excluding advanced carcinomas were resected endoscopically or surgically in our Center from April 2001 to November 2014. Of these, 961 lesions were T1 carcinomas. According to the morphological/development classification, 226 lesions (23.5%) were depressed-type, 325 lesions (33.8%) were flat-type and 409 lesions (42.6%) were sessile-type. We analyzed the pathological features of these lesions.

Results: The rate of submucosal invasion in all the lesions was 64.0% in depressed-type, 3.7% in flat-type and 3.0% in sessile-type. Within under 5mm in diameter, that was 11.3%, 0.02% and 0.05% respectively. In T1 carcinomas, the rate of lymphovascular permeation was 63.7% in depressed-type, 33.5% in flat-type and 38.6% in sessile-type, that of tumor budding was 68.1%, 45.8% and 52.6%, and that of poorly differentiated adenocarcinoma was 16.4%, 11.1% and 15.2% respectively. Within lesions smaller than 20mm in size, the rate of nodal metastasis was 10.3%, 2.9% and 7.6%, respectively. The rates of these pathological factors and nodal metastasis were significantly higher in the depressed-type lesions. On the other hand, the rate of adenomatous component was 6.6%, 44.0% and 51.1%, respectively. This was significantly lower in depressed-type lesions, suggesting that they emerge directly from the normal epithelium without going through the adenoma stage.

Conclusion: Growing downward even when they are small in size, depressed-type colorectal neoplasms hardly had adenomatous component and harbor higher risk of lymphovascular permeation, tumor budding and nodal metastasis. It suggests that they follow a growth "*De Novo* pathway", different from the "adenoma-carcinoma sequence." Therefore it is important to give a careful consideration to the development and progression of colorectal cancers.

P1660 CLINICAL OUTCOMES OF FOLLOW-UP COLONOSCOPIC SURVEILLANCE FOR PATIENTS WITH SESSILE SERRATED ADENOMAS

S. J. Park[1], H. Yoon[1], I. Jung[1], C. M. Shin[1], Y. S. Park[1], N. Y. Kim[1], D. H. Lee[1]

[1]*Department of Internal medicine, Seoul National University Bundang Hospital, Seongnam-si, Republic of Korea*

Contact E-mail Address: eupark76@naver.com

Introduction: Sessile serrated adenomas (SSAs) are known to be precursors of colorectal cancer (CRC). The proper interval of follow-up colonoscopy for SSAs is still being debated.

Aims & Methods: The purpose of this study was to determine the proper interval of colonoscopic surveillance in patients with SSAs.

This study retrospectively reviewed the medical records of patients who diagnosed as SSAs at colonoscopy and received one or more follow-up colonoscopies. Clinicopathologic characteristics of SSAs detected at initial and follow-up colonoscopies were analyzed.

Results: From 2007 to 2011, 152 SSAs and 8 synchronous adenocarcinomas were identified in 138 patients. The mean age of patient was 56.4 years and 60% were male. SSAs were located in a right colon (proximal to the hepatic flexure) in 68.4%. In 8 synchronous adenocarcinomas, The T stage of 5 cases were pTis, and the others were more than pT1. 2 cases of cancer were treated with colectomy and the others were treated with snare polypectomy. At the first follow-up (the mean interval from initial colonoscopy: 20.2 months) 27 SSAs were identified in 138 patients. 66.7% of SSAs were located in a right colon. At the second follow-up (the mean interval from the first follow-up: 21.4 months), 6 SSAs were identified in 65 patients, 66.7% of SSAs were located in a right colon. At the third and fourth follow-up (the mean interval: 15.9 and 18.2 months), 21 and 11 of each patient received colonoscopy, and no SSAs were detected. The mean size of SSAs at initial, first and second follow-up endoscopy were 7.9 ± 5.1, 9.9 ± 5.6 and 8.5 ± 1.8mm, respectively. The difference of size was not statistically significant (ANOVA, *p-value*: 0.335). The size of SSAs detected with synchronous adenocarcinoma was 9.25 ± 8.75mm and the others were 8.13 ± 5.01mm. The difference of size was not statistically significant (t-test, *p-value*: 0.554). During follow-up colonoscopic surveillance, no cancer was detected.

Conclusion: Biennial colonoscopic surveillance might be enough to detect metachronous CRC in patients with SSAs. During follow-up colonoscopies in patients with SSAs, we should inspect right colon more carefully.

P1662 COLORECTAL SCREENING BY USING TOTAL COLONOSCOPY FOLLOWING FECAL IMMUNOCHEMICAL TESTS IN JAPANESE ALCOHOLIC MEN AND THE DETERMINANTS OF THEIR COLORECTAL NEOPLASIA

T. Mizukami[1], A. Yokoyama[1]

[1]*Internal Medicine, Nho Kurihama Medical and Addiction Center, Yokosuka-city Kanagawa, Japan*

Contact E-mail Address: mi-zukami@violin.ocn.ne.jp

Introduction: Alcohol consumption increases the risk of colorectal adenoma and cancer. The fecal immunochemical test (FIT) is a widespread screening method for colorectal neoplasia. However, appropriate screening methods for high-risk alcoholics have not been evaluated.

Aims & Methods: Total colonoscopic screening was performed in 1006 Japanese alcoholic men (462 FIT-positive and 544 FIT-negative). Advanced neoplasia was defined as neoplasia $\geq$10 mm, villous or tubulovillous adenoma, high-grade adenoma, or carcinoma.

Results: The detection rates of non-advanced adenoma, advanced neoplasia, and intramucosal or invasive carcinoma were 38.7%, 39.4%, and 9.7%, respectively, among the FIT-positive group, and 33.5%, 10.7%, and 2.2%, respectively, among the FIT-negative group. Advanced neoplasia, especially carcinoma, was much more frequently detected in the distal colon than in the proximal colon among the FIT-positive group. The multivariate odds ratios (ORs) (95% confidence interval) for non-advanced adenoma and advanced neoplasia were 2.81 (2.05-3.86) and 9.30 (6.29-13.76), respectively, for the FIT-positive group (vs. negative); 1.67 (1.39-2.01) and 1.82 (1.45-2.30), respectively, according to age (per +10 years); and 1.57 (1.08-2.28) and 1.86 (1.16-3.00), respectively, according to current smoking status (vs. non-smokers). The multivariate OR for advanced neoplasia was significant (1.61 [1.03-2.52]) according to the presence of a markedly enlarged mean corpuscular volume (MCV $\geq$ 106 fl vs. $<$106 fl). Genetic polymorphisms of alcohol dehydrogenase1B and aldehyde dehydrogenase-2 did not affect the risk of colorectal neoplasia.

Conclusion: In conclusion, the detection rate of advanced colorectal neoplasia was extremely high among FIT-positive alcoholics but was high even among FIT-negative alcoholics. An older age, smoking, and an enlarged MCV were predictors of the detection of advanced colorectal neoplasia.

Contact E-mail Address: talatayy@gmail.com

Introduction: Suppressor of cytokine signaling 1 (SOCS1) is a prototype molecule of SOCS family. Alterations in SOCS1 expression have been reported in human cancers and there are some studies suggesting that SOCS1 might act as a tumor suppressor in carcinogenesis. In the present study, we aimed to evaluate the association of SOCS1 promoter -1478CA/del gene polymorphism detected in DNA isolated from tissues of patients with colorectal cancer (CRC) with histopathological characteristics and survival.

Aims & Methods: For the study, we retrospectively enrolled 53 patients with resected colon due to CRC and 23 control subjects with no systemic illness. SOCS1- 1478CA/del gene polymorphism was determined using Polymerase chain reaction -Restriction fragment length polymorphism (PCR-RFLP) methodology. These results were evaluated in relation to histopathological features and survival results and analyzed statistically. A p value equal to or less than 0.05 was considered significant.

Results: Neither control subjects nor CRC group showed a significant association with SOCS1 -1478CA/del gene polymorphism ($p = 0.248$). SOCS1 -1478CA/del gene polymorphism was not significantly associated with histopathological features either. However, in the overall survival (OS) analysis, those patients with del/del allele were found to have a 3.9-fold greater risk of mortality compared to those with CA/CA allele ($p = 0.05$). Progression-free survival (PFS) was also significantly different in such patients ($p = 0.05$).

Conclusion: The present study examining the association of SOCS1 -1478CA/del gene polymorphism with CRC showed that CRC patients with del/del allele had both significantly shorter PFS and OS versus those with CA/CA or CA/del allele.

P1664 WHY ARE WE MISSING SERRATED POLYPOSIS SYNDROME PATIENTS?

Y. J. van Herwaarden[1], P. Dura[1], S. Pape[1], F. M. Nagengast[1], T. M. Bisseling[1], I. D. Nagtegaal[2]
[1]*Gastroenterology & Hepatology, [2]Pathology, Radboudumc, Nijmegen, Netherlands*

Contact E-mail Address: yasmijn.vanherwaarden@radboudumc.nl

Introduction: Serrated polyposis syndrome (SPS) is a new and under recognised colorectal cancer (CRC) predisposition syndrome. Previous studies reported miss-rates of SPS diagnosis varying from 40 to 82% (1,2). Since SPS patients and their first degree relatives have an increased risk of CRC, early recognition is important.

Aims & Methods: We aimed to determine the miss-rate of SPS during follow-up and determine reasons for missed diagnosis. We retrospectively identified patients diagnosed with ≥ 1 colorectal polyp or carcinoma detected at our center between 1986 and 2013 using the nation-wide pathology registry. A cumulative polyp count was scored for adenomatous and serrated polyps per patient. Size and location of serrated polyps were recorded to assess if patients fulfilled the WHO criteria for SPS (2010). Based on the available diagnosis in the patient files, miss-rate and 95% confidence interval (CI) were calculated.

Results: We randomly assessed 4500 patients of which 1804 (40.1%) had ≥ 1 serrated polyp. Nineteen patients fulfilled the WHO criteria with a median number of 24 serrated polyps (range 5-59) and 2 adenomas (range 0-21). In four patients no prior SPS diagnosis was made, leading to a miss-rate of 21.0% (95%CI 2.1-38.1). Duration of follow-up varied from 2 to 16 years in these missed cases. In three out of these four patients familial CRC was diagnosed instead of SPS. These patients were under strict follow-up with surveillance intervals ranging from 1 to 6 years. The diagnosis in the other patient was probably missed because the majority of serrated polyps had been removed before the formulation of the WHO criteria for SPS in 2000 and the pathology reports were not easily available. Of the patients diagnosed with SPS only one had a delay of 2 years before diagnosis, however, the surveillance interval (every 2 years) was adequate. A fifth patient fulfilling the SPS criteria was diagnosed with Lynch syndrome based on a MSH2 mutation, and as such was not marked as a missed case.

Conclusion: The miss-rate for diagnosis of SPS is significant, even during longer follow-up with repeated colonoscopies. Failure to recognize SPS was the result of not systematically applying the WHO criteria or the unavailability of older pathology reports to the clinician. Awareness of this CRC predisposition syndrome needs to be raised to lower the miss-rate of SPS.

P1665 THE MANAGEMENT FOR COLORECTAL DIMINUTIVE ADENOMATOUS POLYPS USING PIT PATTERN CLASSIFICATION

Y. Maeda[1], S.-E. Kudo[1], K. Wakamura[1], H. Miyachi[1], A. Yamauchi[1], M. Misawa[1], Y. Mori[1], T. Kudo[1], K. Kodama[1], T. Hayashi[1], A. Katagiri[1], F. Ishida[1]
[1]*Digestive Disease Center, Showa University Northern Yokohama Hospital, yokohama-shi, Japan*

Contact E-mail Address: yasuharumaeda610@hotmail.com

Introduction: It is now available to estimate histological feature of colorectal lesions using magnifying chromo-endoscopy (pit pattern (PIT) classification). In regard to diminutive (≦5mm) adenomatous polyps (DAPs), it has been reported that the prevalence of advanced histological features was low. However diminutive invasive cancer has been found. We basically permit to left untreat and follow up DAP with type IIIL PIT and resect ones with type IIIs, IV or V PIT in routine colonoscopy.

Aims & Methods: The aim of this retrospective study was to assess our management DAPs using PIT classification. The study subjects were patients over 30 years who were referred for initial total colonoscopy were followed up for more than 3 years between April 2001 and March 2014. Exclusion criteria was patients who had the lesions > 5mm in size and/or with type IIIs, IV, ? PIT left untreated at initial treatment, and those who have a history of familial adenomatous polyposis, Lynch syndrome, Advanced colorectal cancer, Inflammatory bowel disease and cololectomy.

They were classified into three groups according to the findings and treatment of initial colonoscopy: Group A, patients whose DAPs with type IIIL PIT were left untreated as semi-clean colon group.; Group B, patients whose all neoplastic polyps including DAPs were resected as clean colon group.; Group C, patients without any adenomatous polyp as internal control group. As a primary outcome measure, the cumulative incidence of index lesions (ILs) at follow-up colonoscopy analyzed among the three groups. The ILs diagnosed during follow-up colonoscopy was defined as follows: large adenomatous polyp ≧10 mm, high grade dysplasia (intra mucosal cancer), and invasive cancer. We evaluation the incidences of invasive cancers.

Results: A total of 4602 patients were enrolled in our study. 1439 patients classified into Group A, 1112 in Group B, 2051 in Group C. ILs were detected in 136 patients (9.4%) in Group A, 116 (10.4%) in Group B, and 40 (2.0%) in Group C, respectively. Invasive cancers were detected in 12 patients (0.8%) in Group A, 12 (1.1%) in Group B, and 9(0.4%) in Group C, respectively. There was no significant difference between Group A and Group B in incidences of ILs and invasive cancer. In regard to Group C, it was significant lower than Group B and Group C in incidences of them.

Conclusion: Removing DAPs with type IIIL PIT did not decrease an incidence of ILs and invasive cancers, significantly. DAPs with type IIIL PIT could be allow to left untreated and followed up.

P1666 TUMOR LOCATION IN COLORECTAL CANCER (CRC) DETECTED BY CRC SCREENING USING IMMUNOLOGICAL FECAL OCCULT BLOOD TEST (FIT) WITH TWO-DAY METHOD

Y. Saito[1,2], H. Suzuki[3], I. Hyodo[2,3], M. Kaneko[4]
[1]*Ibarakiken Medical Center, [2]Sub-committee for Colorectal Cancer, Ibaraki Prefectural Council for Controlling and Preventing Life Style-related Disease, Mito, [3]Department of Gastroenterology, University of Tsukuba, Tsukuba, [4]Ibaraki Health Service Association, Mito, Japan*

Contact E-mail Address: saitoitsyo@yahoo.co.jp

Introduction: According to the Japanese colorectal cancer (CRC) screening guideline, a 2 days stool sampling method by immunological fecal occult blood test (FIT) is widely accepted for over 40-year-old males and females. On the contrary, the role of flexible sigmoidoscopy in population-based screening has been recognized once again, based on the evidence that the UK Flexible Sigmoidoscopy Screening Trial recently provided high-level evidence that flexible sigmoidoscopy results in a substantial reduction in CRC mortality and incidence.

Aims & Methods: The purpose of this study was to investigate tumor location in colorectal cancer (CRC), which were detected by CRC screening using immunological fecal occult blood test (FIT). For 6 years (from April 2007 to March 2012), 719,079 participants, who were over 40-year-old, were screened for colorectal cancer with one of FITs, the OC-SENSOR (Eiken, Japan). A cut-off value of 100ng/mL was adopted.

Results: Colorectal cancer (CRC), which were detected by 2-day method with FIT, were 1,289 cases in number. The cancer detection rate was 0.0179%. Further examination revealed the proportion of CRC for R/C: 392(30.4%), S/C: 416(32.4%), D/C: 57(4.4%), T/C: 130(10.1%) and A + C/C: 294(22.8%).

Conclusion: Our results by 2-day method with FIT showed that over 1/3 of CRC might be missed on flexible sigmoidoscopy screening. We concluded that CRC screening using FIT with two-day method might be more adequate.

P1667 STUDY ON THE CUT-OFF VALUE OF FIT SCREENING (2007-2012)

Y. Saito[1,2], H. Suzuki[3], I. Hyodo[2,3], M. Kaneko[4]
[1]*Ibarakiken Medical Center,* [2]*Sub-committee for Colorectal Cancer, Ibaraki Prefectural Council for Controlling and Preventing Life Style-related Disease, Mito,* [3]*Department of Gastroenterology, University of Tsukuba, Tsukuba,* [4]*Ibaraki Health Service Association, Mito, Japan*

Contact E-mail Address: saitoitsyo@yahoo.co.jp

Introduction: According to the Japanese colorectal cancer (CRC) screening guideline, a 2 days stool sampling method by immunological fecal occult blood test (FIT) is widely accepted for over 40-year-old males and females. It is demanded that CRC screening is carried out effectively, so one of the effective screening is to decide an appropriate cut-off value.

Aims & Methods: The aims of this study is to analyze the appropriate cut-off value. So the cut-off values were analyzed with positive rate, cancer detection rate, positive predictive value (PPV), invasive cancer detection rate and PPV of the invasive cancer for 719,075 (Males: 299,275 and Females: 419,804) CRC participants (2007-2012) with FIT-2days method. The cut-off value was analyzed in 100, 110, 120, 130, 140, 150, 200ng/mL. The comparative verification with the chi-squared test was used for reference to the cut-off value 100ng/mL.

Results: Positive rates fell significantly both males and females according to increasing cut-off values. Cancer detection rates also fell significantly over 150ng/mL for males and females (males: 0.255%–0.228% and females: 0.126%–0.110%). PPV rose significantly over 140ng/mL for females, and over 130ng/mL for males (males: 2.84%–3.22% and females: 2.10%–2.47%). Invasive cancer detection rates fell significantly at 200ng/mL just for females. PPV of the invasive cancer also rose significantly over 140ng/mL for females, over 130ng/mL for males (males: 1.43%–1.67% and females: 1.16%–1.42%).

Conclusion: As for the cancer detection rate for both males and females with the cut-off value 140ng/mL, there was no difference compared to the cut-off value 100ng/mL. In addition, PPV rose over cut-off value 130ng/mL in males, so we thought cut-off 130ng/mL was an appropriate value by this study. In this study, we targeted CRC examinee over 40 years old. Also we analyzed 50-74 years old, it became an equivalent result.

Introduction: Low-volume PEG-Asc has been proved to be similarly safe and effective as traditional 4 L PEG. However, PEG-Asc produce lots of bubble and endoscopists feel discomfort during colonoscopy. The study on adding antiforming agent such as simethicone with PEG-Asc methods are lacking.

Aims & Methods: The aim of this study was to compare PEG-Asc and PEG-Asc with simethicone in the aspect of bowel preparation quality and compliance of endoscopist. Single center, randomized, observer-blinded study was performed from July 2014 to September 2014. Total 200 out-patients were prospectively enrolled. We used the Boston Bowel Preparation Scale and Bubble score for evaluation of bowel cleansing. To investigate the compliance of endoscopists, a questionnaire for water shooting count and withdrawal time was performed. Also, patients completed questionnaires about the symptoms associated with the preparations to assess their tolerability before the colonoscopy.

Results: One hundred patients received PEG-Asc and 100 patients received PEG-Asc with simethicone. There were no significant differences between 2 groups in the aspect of completion of preparation, cecal intubation time, success rate and overall preparation quality. In consideration of better preparation quality, the PEG-Asc with simethicone group showed superior cleansing results over the PEG-Asc group (6-9 Boston scale score: 100% vs 84%, 3 bubble score: 95% vs 54%, $p < 0.05$). From the perspective of practitioners, PEG-Asc with simethicone group was less suffer from bubble which disturbed the lens. The mean count of water shooting for cleansing lens was significantly lower and withdrawal time of colonoscope was less in PEG-Asc with simethicone group compared to PEG-Asc group (1 vs. 10, 15.02 ± 10.10 vs. 17.83 ± 14.80min, $p < 0.05$). PEG-Asc with simethicone caused fewer gastrointestinal symptoms (ex. abdominal fullness, colicky pain, general discomfort) than PEG-Asc.

Conclusion: According to our data, PEG-Asc plus simethicone has comparably effective and better tolerable for patient and endoscopist. Therefore, a combination of PEG and simethicone appears to be a standard method for bowel preparation.

Introduction: Accumulating data indicate that some microRNAs (miRNAs or miRs) function as tumor suppressors or oncogenes in cancer development. The certain miRNAs (miR-143, -145, -34a, -7) were differently expressed in the samples between the tumor and the paired non-tumorous samples in the same patient in colorectal tumors.

Aims & Methods: We examined the expression of these miRNAs in 131 sporadic exophytic adenomas or early cancers, 52 sporadic flat elevated adenomas or early cancers, and 77 type 2 cancer to clarify the relationship between the expression of the miRNAs and the endoscopic morphological appearance in the colorectal tumors. To validate the function of these miRNAs in cell growth, we used the endogenous or inhibitor miRNA for transfection of the human colon cancer DLD-1 cells.

Results: The expression levels of miR-143, -145, and -34a were significantly reduced in most of the exophytic tumors compared with those in the flat elevated ones. In type 2 cancers, the miRNA expression profile was very similar to that of the exophytic tumors. The expression levels of miR-7 were significantly up-regulated in some flat elevated adenomas compared with those in exophytic adenomas. The cell growth of DLD-1 cells was significantly inhibited in a dose-dependent manner at 48 h after the transfection with endogenous miR-143,-145, or -34a or inhibitor of miR-7.

Conclusion: These findings indicated that the expression of onco-related miRNA associated with the morphological appearance of colorectal tumors and miRNA may be a hopeful candidate as an RNA medicine for the treatment of colorectal tumors.

Introduction: Rectal neuroendocrine tumors measuring ≤ 10 mm in diameter (RNETs ≤ 10 mm) rarely metastasize, thus those are usually treated by endoscopic resection (ER). Recently, lymphovascular invasion (LVI) has been considered to be an important predictor for nodal metastasis after ER [1,2]. However, little is known about the accurate detection rate of LVI in RNETs ≤ 10 mm evaluated by immunohistochemical analysis.

Aims & Methods: The aim of this study is to demonstrate the actual detection rate of LVI in RNETs ≤ 10 mm using D2-40 and Elastica van Gieson (EVG) stain. We retrospectively reviewed 100 consecutive RNETs ≤ 10 mm in 96 patients treated by ER between November 2000 and March 2015 at 5 hospitals in Japan. In addition to HE stain, lymphatic invasion was evaluated using D2-40 stain, and venous invasion was evaluated using EVG stain. The detection rate of LVI using D2-40 and EVG stain was compared with that using HE stain. We analyzed clinical outcomes in 75 patients who were followed for 24 months or more. The study protocol conformed to the ethical guidelines of the Helsinki Declaration, and our institutional review board approved the study.

Results: Of the 96 patients, the median age of patients was 61 years (range 27–84) with a preponderance of male (n = 63). Of the 100 RNETs ≤ 10 mm, 11 were located in the upper rectum and 89 were located in the lower rectum. The median tumor size was 5.0 mm (range 1.0–10.0). R0 resection was achieved in 71 lesions, Rx in 16, and R1 in 13. The median SM depth was 2000 μm (range 400–5500). In all the tumors, the mitotic count was very low, and grading was based on the Ki-67 index. 8 tumors demonstrated a Ki-67 index of 3%–4%; there were 92 Grade 1 RNETs and 8 Grade 2 RNETs. Using HE stain alone, we detected lymphatic invasion in 7.0% and venous invasion in 4.0% patients. Using D2-40 and EVG stain, lymphatic and venous invasion was detected in 19.0% and 47.0% patients, respectively. Finally, the detection rate of LVI using D2-40 and EVG stain was significantly increased compared with that using HE stain (56.0% vs. 9.0%). Among the tumor size > 5mm vs. ≦5mm, the rate of LVI with the size > 5mm was significantly higher (71.4%) than that (47.7%) ≦5mm. Among Grade 1 vs. Grade 2 RNETs, the rate of LVI was 57.6% (53/92) vs. 37.5% (3/8); there was no significant difference observed. During the

median follow-up period of 42 months (range 12.5-184.1 months), no metastasis or recurrence was detected. There were no deaths due to RNETs.
Conclusion: Compared with HE stain, D2-40 and EVG stain proved to significantly increase the detection rate of LVI in RNETs ≤ 10 mm. Therefore, the application of D2-40 and EVG stain is considered to be indispensable for RNETs ≤ 10 mm after ER. Further prospective studies are required to clarify the clinical role of LVI evaluated by D2-40 and EVG.

Contact E-mail Address: rita.vale.rodrigues@gmail.com

Introduction: The purpose of intensive postoperative surveillance programs after curative surgery for colorectal cancer (CRC) is to detect asymptomatic recurrences, with the premise that an important rate will be potentially eligible for curative resection, improving the survival. We have implemented a surveillance program for patients with CRC, AJCC stages II-III, after curative surgery, lasting five years, with periodic clinical assessment, carcinoembryonic antigen (CEA), cancer antigen 19-9 (CA19,9), computed thorax, abdomen and pelvis tomography (CT) and colonoscopy.
Aims & Methods: Primary outcome: rate of surgical treatment of recurrence with curative intent; secondary outcomes: colorectal cancer mortality, time to detection of recurrence, survival after treatment of recurrence with curative intent, clinical characteristics associated with unresectability of recurrence and diagnostic accuracy of the surveillance model. Cohort study, single center. All patients with CRC on the intensive surveillance program between 03/2008 and 01/2015, with at least one determination of any of the methods and a monitoring visit, were included. Statistical analysis was performed with SPSS v20.0, using chi-square test, a multivariate regression model and survival analysis with Kapplan-Meier log-rank test; p value < 0.05 was considered statistically significant.
Results: 404 patients were evaluated; 59.6% male; mean age = 65 ± 10 years; site of tumor: rectum: 50.7%, colon: 49.3%; AJCC classification: stage II: 43.8%, stage III: 56.2%; Average time of follow-up = 37 months (1-79). Recurrence rate: 12.9% (n = 52), mostly detected in the first 3 years (88.4%), due to elevation of tumor markers: 46.2%, CT: 40.4%, colonoscopy: 7.7%, symptoms: 5.8%; Site of recurrence: metastatic: 86.5%, locoregional: 13.5%; Twenty-one patients underwent curative resection. Clinical factors associated with unresectable recurrence were age > = 70 years (p = 0.022), and site of tumor-colon (p = 0.033). CA 19,9 elevation was the only altered surveillance test associated with unresectability (p = 0.024). After recurrence: average time of follow-up = 15 months (1-49), 2-year survival: 95.2% if curative surgery was performed *vs* 59.9% for unresectable recurrence (Kapplan-Meier log-rank, p = 0.016). Overall rate of cancer-specific mortality: 2.2% (n = 9). This surveillance model had good diagnostic accuracy for detection of recurrence (AUC 0.885).
Conclusion: The benefit of this intensive postoperative surveillance program is demonstrated by the number of patients undergoing curative surgery of recurrence (40.3%), with an impact on survival.

P1672 COLORECTAL CANCER STAGE IV AT DIAGNOSIS - THE LAST FRONTIER?

R. V. Rodrigues[1], P. Sousa[1], I. Rosa[1], J. P. Silva[1], A. D. Pereira[1], on behalf of Multidisciplinary Group of Colorectal Cancer, Instituto Português de Oncologia de Lisboa Francisco Gentil, EPE
[1]*Gastroenterology, Instituto Portugues de Oncologia de Lisboa, Franscisco Gentil, Lisboa, Portugal*

Contact E-mail Address: rita.vale.rodrigues@gmail.com

Introduction: Surgical resection with curative intent in patients with metastatic colorectal cancer (mCRC) on diagnosis has impact on survival and should be offered whenever possible. However, preoperative predictors of survival are needed, to better select patients.
Aims & Methods: To evaluate the overall survival (OS) and the treatment morbidity/mortality and to determine possible predictors of surgical resection with curative intent in patients with mCCR on diagnosis. Retrospective, single-center study. Patients with mCRC on diagnosis, assessed in multidisciplinary group between 06/2008 and 12/2013, and whose treatment and follow-up occurred in the same institution were included. Statistical analysis was performed with SPSS v20.0, using chi-square test, T-student test, a multivariate regression model and survival analysis with Kapplan-Meier log-rank test; p value < 0.05 was considered statistically significant.
Results: 181 patients were evaluated, 56.4% male; mean age = 65 years (28-94); Charlson comorbidity Index = 8.78 ± 1.75; average CEA and CA 19.9 on diagnosis: 30.8ng/mL (1-20412) and 34.5ng/mL (1-1516684); site of tumor: colon: 57.5%, rectum: 42.5%. Stage: cM1a: 67.4%, cM1b: 32.6%. Metastatic site: liver: 55.7%, disseminated disease: 28.7%, lung: 7.2%, peritoneum: 5%, lymph nodes: 2.8%, other: 0.6%. Treatment: palliative chemotherapy (CT): 26%, palliative radiotherapy (RT): 5%, symptomatic therapy: 5.5%, palliative surgery +/- CT +/- RT: 38.1%, curative surgery +/- CT +/- RT: 25.4%; Treatment complications: 27.1%. Postoperative mortality: 4.6%. Global OS at 3 and 5 years: 26.4% and 10.7%. The OS at 3 and 5 years was significantly higher in the group of patients who underwent curative surgery: 68.4% and 32.5%, compared with the group of patients with unresectable disease: 10.7% and 2.7%, (Kapplan-Meier log-rank, p < 0.001). Average time of follow-up = 33 months (14-82). The clinical factors associated with unresectable disease were: CEA on diagnosis > = 5 (p < 0.001), age > = 70 years (p = 0.005) and M1b disease (p < 0.001).
Conclusion: This study demonstrates that, even in mCCR, surgical curative resection is associated with prolonged survival. Age > = 70 years and CEA > = 5 at diagnosis are possible predictors of poor prognosis and their prospective validation in a therapeutic decision model could help on the selection of surgical candidates.

Contact E-mail Address: gon22gon@naver.com

Introduction: Recently, rectal neuroendocrine tumors (NETs) are found more frequently on screening colonoscopy. Most of rectal NETs are located in deep mucosa and/or submucosa. Therefore, conventional endoscopic mucosal resection (EMR) has a likelihood of incomplete resection. There are several method of treatment for rectal NETs: conventional EMR, EMR with a cap (EMR-C), EMR with a ligation device (EMR-L), and endoscopic submucosal dissection (ESD). In this study, we compare the effectiveness of EMR-C and ESD in resection of rectal NETs.
Aims & Methods: 118 lesions of 114 patients with rectal NETs which was resected by EMR-C or ESD were included in this study. All patient received EMR-C or ESD at Pusan National University Yangsan Hospital between June 2009 and July 2014. Endoscopic complete resection rate, histologic complete resection rate, procedure time, and adverse events in the EMR-C (n = 63) and ESD (n = 50) groups were analyzed.
Results: Mean (standard deviation [SD]) tumor size was 4.60 (1.63) mm in the EMR-C group and 7.53 (3.04) mm in the ESD group (P < 0.001). Complete resection was performed in all group. Histologic complete resection rate of EMR-C group(92.1%) was significantly greater than that of ESD group (77.4%) (P = 0.041). Mean procedure time was longer in the ESD group (14.03 [7.21] min) than in the EMR-C group (3.81 [1.15] min) (P < 0.001). Histologic complete resection rate was similar in both tumor diameter ≤ 5 mm (EMR-C, 93%; ESD, 100%; P = 0.442)and in cases of 5 mm < tumor diameter ≤ 10 mm (EMR-C, 83%; ESD, 72.0%; P = 0.504).
Conclusion: EMR-C is simple, faster, and more effective in resction of rectal NETs, when compared with ESD, and may be preferable for resection of small rectal NETs.

Introduction: Receptor downregulation is the most prominent regulatory system of receptor tyrosine kinase (RTK) signal attenuation and a critical target for therapy against colorectal cancer that are highly dependent on RTKs including epidermal growth factor (EGF) receptor (EGFR) and erbB2 (HER2). Platinum-containing anti-cancer drugs such as cisplatin are widely used for patients with various types of cancers. We have recently reported that ultraviolet-C (UV-C) irradiation induces the removal of EGFR from cell surface that can protect colon cancer cells from oncogenic stimulation of EGF, resulting in cell cycle arrest by desensitization of EGFR, which exerts oncogenic signaling in colorectal cancer.
Aims & Methods: In this study, we investigated the combination effect of low dose cisplatin and low dose UV-C on cell growth and apoptosis in several human colorectal cancer cells (SW480, DLD-1, HT29 and HCT116) using cell proliferation assay, BrdU incorporation assay, Western blot analysis and fluorescence microscopy study.
Results: The combination inhibited cell cycle and colony formation indicating the suppressive effect on cell proliferation, while either cisplatin or UV-C alone had little effect. We also observed that the combination induced apoptosis in these cells. To clarify its mechanism, we focused on receptor tyrosine kinases (RTK) and found that the combination caused the downregulation of EGFR as well as HER2. In fluorescence microscopy study and quantification analysis for cell surface EGFR, UV-C caused transient internalization of the EGFR but with time EGFR recycled back to the cell surface, while cisplatin did not affect its

localization. Moreover, the combination caused persistent internalization of the EGFR, indicating that cisplatin inhibits the recycling of the internalized EGFR induced by UV-C, which results in the lasting ubiquitination of the EGFR.
Conclusion: These results suggest that the combination use of cisplatin and UV-C synergistically leads anti-cancer effect by down-regulating RTK. Our present findings could provide evidence of a possible combination therapy against human colorectal cancer.

Introduction: In clinicopathological characteristics for rectal neuroendocrine tumors (R-NETs), we have previously reported that venous invasion as well as tumor size and lymphatic invasion has indicated high malignant potential to metastasize to lymph node[1)]. The pathological assessment after initial resection and surveillance method is not established.
Aims & Methods: The purpose of this study is to revaluate the risk factors for lymph node metastasis including our up data, moreover to analysis long-term outcome after treatment go through our strategy. We investigated a total of 304 patients diagnosed R-NETs between January 1979 and May 2013 at cancer institute hospital. We used endoscopic ultrasonography (EUS) to measure tumor diameter and to estimate the depth of invasion. We pursued the initial therapeutic strategy according to clinical malignant potential, and we decided whether or not we achieved complete resection with investigating pathological features. We performed endoscopic treatment for patients with R-NETs based on the following criteria: tumor diameter less than 11 mm, no lymph node metastasis and no invasive lesion to muscularis propria determined by EUS, computed tomography (CT) or magnetic resonance imaging (MRI). If the case didn't meet these criteria, it underwent surgical treatment with radical lymph node dissection. Pathological malignant potential was evaluated especially with mitotic rate and MIB-1 index, lymphovascular invasion (lymphatic or venous invasion). We recommend annually check by colonoscopy and abdominal CT or abdominal ultrasonography to not only recurrence lesions also synchronized colorectal tumors, and we don't have period definition. We evaluated outcome of patients followed up by the above-mentioned strategy and surveillance.
Results: We evaluated 304 R-NETs that was excluded multiple type NETs. In 34 cases with more than 11mm in diameter, 19cases (55.9%) were found lymph node metastasis, the muscularis propria invasive lesion found it 9 of 12 cases (75%). In lymphovascular invasion (lymphatic or venous invasion) there were 20 of 8 cases (34%) found lymph node metastasis, it was significant high frequency. In the feature of central depression found it 7 of 37 cases (19%). There were 118 R-NETs those were identified and Grading, the cases of 113 were classified to Grade1 that lymph node metastasis was found in 9 (8%). In 5 cases were classified to Grade2, and found it was 1 case (20%). In median follow-up period was 60 months (range; 24 to 237) there were no patients with recurrence lesion with any examination after underwent our treatment strategy.
Conclusion: In our hospital, the treatment strategy of R-NETs is getting a good long-term outcome with being enforced of evaluating clinicopathological features. In surveillance method, because R-NETs is a slow growing tumor, we have to recommend maintain periodic examination as much as possible.

P1676 A HUMANIZATION AND AFFINITY MATURATION OF AN ANTI-CD24 MONOCLONAL ANTIBODY TARGETING GASTROINTESTINAL CANCERS

S. Shapira[1], D. Kazanov[1], S. Kraus[1], I. Benhar[2], N. Arber[1]
[1]*Integrated Cancer Prevention Center, Tel Aviv Sourasky Medical Center,* [2]*Department of Molecular Microbiology and Biotechnology The George S. Wise faculty of life sciences, Tel Aviv University, Tel Aviv, Israel*

Introduction: Background: CD24 is a cell-surface heavily glycosylated GPI-anchored mucin-like protein. We have shown that CD24 is a valid target in gastrointestinal (GI) malignancies. Anti-CD24 mAb treatment induces a significant growth inhibition of CRC and PC cells, in a time- and dose-dependent manner *in vitro* and *in vivo* (*Gastro* 2006, *Clin Can Res* 2007, *Can Res* 2008). Affinity maturation is an important process in optimizing therapeutic antibodies. Affinity-matured antibodies can exhibit increased biological efficacy, and allow reduced dosage with less toxic side effects.
Aims & Methods
Aim: To develop mature humanized anti-CD24 monoclonal antibodies (mAbs) and to evaluate their efficacy alone and/or in combination with standard chemotherapy for CRC and PC.
Methods: Edman-degradation, cDNA synthesis, sequence and computational analysis (Ig-blast) were performed to reveal the entire DNA sequence of a murine anti-CD24 mAb (SWA11). Replacement of the Fc with the human IgG1 resulted in a mouse-human chimera. A human donor (Ig-blast) was chosen as a scaffold human Ab for grafting critical sequences of the murine antibody into it leading to the generation of humanized Ab derivatives. Sequence analysis of the CDR loops was the base for library designing. Affinity maturation was performed in two steps; CDR walking (two-step selection) and by using phage display technique
Results: *In vivo* antibody targeting and accumulation within a CD24 positive tumor and its excess clearance was clearly demonstrated using direct imaging. Combinatorial phage-displayed antibody libraries with varying degrees of diversity at randomized positions from which high-affinity antibodies can be selected were created. A chosen matured clone was isolated and showed higher binding strength ($1.8x10^{-8}$), compared to the parental murine and humanized Abs ($3.3x10^{-8}$ and $4.2x10^{-8}$). The matured antibody showed selective recognition and binding to the CD24 antigen, as demonstrated by antigen-based and whole-cell ELISA and FACS analysis. It stability was enhanced following the maturation process, as demonstrated by *in vitro* stability test. The antibody lost only 16% of its activity after 23 days in 37°C. Combined treatment with standard chemotherapeutic agents and natural products, such as monoterpenes (terpinen-4-ol), showed significant reduction in cell viability (90% cell death).
Conclusion: Targeting CD24 may be a promising treatment for GI malignancies in combination with chemotherapy and natural agents. The resulted matured fully humanized anti-CD24 mAb is more effective than the murine parental Ab.

P1677 COLORECTAL CANCER WITH SYNCHRONOUS UNRESECTABLE LIVER METASTASES. WHICH IS THE BEST TREATMENT?

S. Arolfo[1], R. Spadi[2], A. Miegge[1], M. Morino[1]
[1]*Surgical Sciences,* [2]*Medical Sciences, University of Torino, Torino, Italy*

Contact E-mail Address: simone.arolfo@tiscali.it
Introduction: The optimal treatment strategy of patients affected by colorectal cancer with unresectable liver metastases (mets) is at present undefined. There are 2 main therapeutic options:
1) surgical excision of the primary tumour followed by first line CT to downsize liver mets
2) first line-chemotherapy (CT) to stabilize/downsize the disease followed by removal of primary tumor and further post operative CT to downsize liver mets.
Aims & Methods: Aim of the study is to analyze the safety and effectiveness of the therapeutic strategies in a group of patients treated in one Institution.
A retrospective analysis of a prospectively collected database was conducted. All patients affected by colorectal cancer with synchronous unresectable liver mets treated between January 2003 and October 2012 in this Institution were included. Patients more than 80 years old, presenting peritoneal carcinosis or severe medical morbidities and a follow up shorter than 2 years were excluded. Primary endpoint was overall survival in both groups, estimated with Kaplan-Meyer methods; secondary endpoints were rate of liver mets resection after CT, influence of CT regimens and morbidity in both groups.
Results: 148 patients were included, with a median follow up of 45.5 months (range 24.4-126.1). Baseline characteristics were similar in both groups, even if patients older than 65 were more often operated on (60.3% vs 41.2%; $p = 0.01$), while patients with extrahepatic disease were more frequently treated with CT. 85 patients (57.4%), were treated with I line CT (Group 1), whereas 63 (42.6) with surgical excision of primary tumor (Group 2). In group 1, 34/85 patients underwent colorectal resection (6 in the emergency setting, 4 for occlusion and 2 for perforation during CT administration). 42/63 patients in group 2 were treated with CT after surgery of the primary tumor. Overall survival was not significantly different: 16.2% in Group 1 and 17.6% in Group 2 ($p = 0.174$), but statistical significance was reached comparing patients who underwent colorectal resection in both groups with who did not ($p = 0.025$) Rate of liver mets surgery was higher in Group 2: 19/63 (30.2%) vs 17/85 (20.0%) ($p = 0.056$). CT regimen were similar, but anti VEGF and EGFR monoclonal antibodies were more often used in Group 1 (53.8% vs 22.5% $p = 0.014$); CT regimen was more frequently stopped for progressive disease in Group 1 patients (53.8% vs 22.5% $p = 0.014$). Age, Grading, Lymph node ratio < 0.28, post surgical CT, CT suspension, liver mets surgery, and liver mets ablation were identified as prognostic factors at univariate analysis. Only age > 65 and lack of liver mets surgery were confirmed at multivariate analysis. Further multivariate analysis on operated patients in both groups (97 who underwent colorectal resection) and on patients treated with CT in both groups (127) revealed that post surgical CT, low lymph node ratio and age < 65 were predictive of better survival.
Conclusion: With the limits of a retrospective analysis the study shows that both treatment strategies are equally effective. Age > 65 and Lymph node ratio > 0.28 are predictive of worse outcome. Monoclonal antibodies are probably not so useful in this kind of patients.

Introduction: The Czech Republic belongs to the countries with the highest colorectal cancer (CRC) incidence all over the world. In several studies, metabolic syndrome (MS), especially diabetes mellitus type 2 (DM2) and ischemic heart disease (IHD), was found to be associated with development of colorectal neoplasia. There is absence of prospective studies focused on association between these metabolic diseases and colorectal neoplasia in the Czech population.

Aims & Methods: To investigate the prevalence of colorectal neoplasia (advanced adenomas and cancers) in individuals with high metabolic risk factors - DM2 and cardiovascular risk (SCORE > 10%). Prospective, multicenter study is planned to run since January 2013 until December 2015 with 2,000 individuals involved; 1,000 in the target group (metabolic risk) and 1,000 in the control group. All individuals (aged 45–75 years) from the screening population (asymptomatic, without family or personal history of colorectal neoplasia) have been examined by colonoscopy (possibly after positive FIT) at eight high quality colonoscopy centers. All participants underwent blood biochemical tests and filled the questionnaire regarding lifestyle. The interim data are presented, including both crude and adjusted (odds ratio, OR, by logistic regression, including age, sex and previous FIT+) comparisons.

Results: 1344 individuals have been examined until April 2015. Complete data have been recorded in 774 individuals; 433 men (56%) and 341 women (44%); mean age 60 years. There were 379 individuals (49%) enrolled in the target group and 395 (51%) in the control group. There has been higher prevalence of adenomas in the target group (47%; 95% CI 42-52%) in comparison to the control group (31%, 95% CI 27-36%), adjusted OR 1.36, p = 0.08. Similarly, the advanced adenomas prevalence was higher in the target group (18%; 95% CI 14-22%) than in the control group (8%; 95% CI 5-11%), adjusted OR 1.90, p = 0.01. There were no statistically significant differences found in cancer prevalence.

Conclusion: Metabolic risk factors (cardiovascular; diabetes mellitus type 2) are significantly associated with prevalence of advanced colorectal neoplasia in the Czech population. These results may help to identify the colorectal cancer high risk individuals and can be used in personalized CRC screening program modification.

Project was supported by the Czech Ministry of Health grant NT 13673.

P1679 COLORECTAL CANCER SCREENING IN THE CZECH REPUBLIC – IS THE TRANSITION TO POPULATION BASED PROGRAM EFFECTIVE?

S. Suchanek[1], O. Majek[2], O. Ngo[2], T. Grega[1], B. Seifert[3], L. Dusek[2], M. Zavoral[1]
[1]*Department of Gastroenterology, 1st Faculty of Medicine of Charles University and Military University Hospital, Prague,* [2]*Institute of Biostatistics and Analyses, Faculty of Medicine of Masaryk University, Brno,* [3]*Institute of General Practice, 1st Faculty of Medicine of Charles University, Prague, Czech Republic*

Contact E-mail Address: stepan.suchanek@uvn.cz

Introduction: The organized non-population-based National Colorectal Cancer (CRC) Screening Program in the Czech Republic has been running since year 2000. It was focused on asymptomatic individuals aged 50 years with no upper age limit. The target population coverage was continuously increasing and reached the level of 27% in year 2013. In 2014, the transition to population-based setting was realized by personalized mail invitations of program non-participants in specific age range. The preliminary data from the first round are presented.

Aims & Methods: To assess the increase of target population coverage, volume of preventive colonoscopies (FIT+colonoscopy and screening colonoscopy) and colorectal neoplasia detection after initiation of organized targeted invitation (comparison of years 2013 and 2014). All non-participants (no prior colonoscopy in last 5 years and no FOBT in last 3 years; no CRC previously diagnosed) from screening population (aged 50 – 70 years), were invited by mail to immunochemical fecal occult blood test (FIT) or screening colonoscopy. In case of FIT positivity, the colonoscopy was performed. The invitation was centrally organized, using the database of health insurance companies.

Results: In year 2014, there were 1,500,897 individuals (53% of all CRC screening target population) invited to FIT or colonoscopy, with 14% response. According to preliminary results, this resulted in coverage increase by 6 percent points in comparison with year 2013 (33% in year 2014). This has influenced the increase of number of detected adenomas (by 41%) and cancers (by 19%) detection in year 2014 (detailed results in the table) according to the Colonoscopy Registry.

	Year	Colonoscopy (numbers)	Adenomas (numbers)	%	Cancers (numbers)	%
FIT+ colonoscopy	2013	21,973	8,757	39.9%	817	3.7%
	2014	28,655	11,692	40.8%	950	3.3%
Screening colonoscopy	2013	4,965	1,361	27.4%	49	1.0%
	2014	9,258	2,596	28.0%	81	0.9%
All preventive colonoscopies	2013	26,938	10, 118	37.6%	866	3.2%
	2014	37,913	14,288	37.7%	1,031	2.7%

Conclusion: The transition to population-based Colorectal Cancer Screening Program in the Czech Republic was effective. It resulted in the improvement of target population participation followed by increase in colorectal neoplasia detection.

This project was supported by the Czech Ministry of Health grant NT 13673.

P1680 LONG-TERM OUTCOMES AFTER ENDOSCOPIC RESECTION FOR SUBMUCOSAL INVASIVE COLORECTAL CARCINOMA

T. Muramoto[1], K. Ohata[1], Y. Misumi[1], H. Tsunashima[1], E. Sakai[1], M. Takita[1], Y. Matsuyama[1], T. Tashima[1], Y. Minato[1], K. Nonaka[1], N. Matuhashi[1]

Contact E-mail Address: takashi_mura7711@hotmail.com

Introduction: Endoscopic resection (ER) for early colorectal carcinoma has been recently performed more and more often. Only little, however, is known about the long-term outcomes after ER for submucosal (SM) invasive colorectal carcinoma.

Aims & Methods: The aim of this study was to evaluate long-term outcomes after ER for SM invasive colorectal carcinoma. We retrospectively analyzed all consecutive patients with SM colorectal carcinoma that underwent ER at NTT Medical Center Tokyo through January 2000 and December 2012. Our treatment strategy followed the Japanese Society for Cancer of the Colon and Rectum (JSCCR) guideline, in which cases meeting all the following conditions were recommended for ER, because they have a low risk for lymph node metastasis and local recurrence: (i) negative vertical margin, (ii) invasion depth of less than 1000μm, (iii) well and moderately differentiated adenocarcinoma, (iv) no lymphatic or vascular invasion, (v) budding grade 1. The patients were retrospectively divided into the following three groups: patients that underwent ER alone and met the guideline criteria (Group A), patients that underwent ER plus additional surgery because they did not meet the guideline criteria (Group B), and patients that underwent ER alone although they did not meet the guideline criteria (Group C). We collected data on patients' characteristics and pathological features of resected cancers, and investigated the clinical courses.

Results: ER was carried out for 217 SM colorectal carcinomas (134 males, 83 females, mean age 65.4yr). 142 cancers were located in the colon (right colon 68, left colon 74) and 75 were located in the rectum. Macroscopically 88 (41%) and 129 (59%) were protruded and laterally spreading tumors, respectively. Pathologically 136 (63%) and 81 (37%) were well and moderately differentiated adenocarcinomas, respectively. There were 86 cases (40%) in Group A, 108 (50%) in Group B, and 23 (10%) in Group C. The median follow-up periods in Group A, B, and C were 45.3, 47.3 and 58.3 months, respectively. In Group A, there was no case of recurrence during the follow-up period. In Group B, lymphatic metastasis was found in 9 cases (8.3%) at the time of additional surgical resection. The recurrence rate after the additional surgery was 0.9% (1/108). That case developed lymph node metastasis 11 month after ER, and then underwent additional salvage surgery. In Group C, the recurrence rate during the follow-up period was 13% (3/23; $P < 0.01$ compared with Group B). Two cases and one case presented with local recurrence and liver metastasis, respectively. In one local recurrence case, multiple lymph node and liver metastases also developed rapidly after the salvage surgery. Two cases of three died in the 20 and 57 month after the ER. In these two cases, the tumors were pathologically moderately differentiated adenocarcinoma at the time of ER.

Conclusion: Our results suggest that the criteria for additional treatment after ER presented in JSCCR guideline are appropriate. Once tumor recurrence occurs, it is often very difficult to control disease progress. Therefore, in patients failing to meet the guideline criteria, we recommend additional surgery as far as possible, because of the high rate of recurrence.

Introduction: The leucovorin (FOL) and fluorouracil (5-FU) plus oxaliplatin (*l*-OHP; FOLFOX) or FOL and 5-FU plus irinotecan (SN-38; FOLFIRI) are widely used as first-line chemotherapy in the treatment of advanced colorectal cancer (CRC). However, second-line chemotherapy must be abandoned in certain cases due to disease progression, adverse effects or high medical cost in clinical setting. Therefore, the most effective regimen should be selected as first-line chemotherapy. We reported that individualization of first line treatment was possible using the collagen gel droplet-embedded culture drug sensitivity test (CD-DST) (UEGW 2014 P1538).

Aims & Methods: In this prospective study, we explored the overall survival (OS) of the CRC patients treated with individualized first-line chemotherapy based on CD-DST. Between Mar. 2008 and Mar. 2015, we obtained tumor specimens from 108 CRC patients without preoperative chemotherapy. CD-DST was performed and the growth inhibition rate (IR) was determined by incubation for 24 h with 5-FU and *l*-OHP (6.0 and 3.0 μg/ml, respectively) and 5-FU and SN-38 (6.0 and 0.2 μg/ml, respectively). The cumulative distribution of IR values under each condition was evaluated on the basis that the clinical response to FOLFOX and FOLFIRI is equivalent (approximately 50%). [1] All patients were divided into 4 cohorts: FOLFOX and FOLFIRI responders (super responders), FOLFOX responders, FOLFIRI responders, and poor responders. [2] From the point of view that there is no choice other than FOLFOX or FOLFIRI in clinical setting, all patients were divided into 3 cohorts: FOLFOX recommended, FOLFIRI recommended, and both regimens recommended. First-line regimens were selected by the attending physician. OS of the treated CRC patients were evaluated Kaplan-Meier method.

Results: There were 35 patients with unresectable CRC with chemotherapy. [1] In 4 cohorts, the median survival time (MST) of super responders (n18) and poor responders (n13) was 1,128 and 810 days, respectively. [2] In 3 cohorts, FOLFOX was recommended, FOLFIRI was recommended, and both regimens were recommended in 19, 15, and 1 patients, respectively. In first-line treatment, the MST was 960 days in 24 patients with recommended regimen and 430 days in 11patients without recommended regimen ($p = 0.054$). For poor responders, the corresponding MST values were 810 and 244 days ($p = 0.014$).

Conclusion: Individualized first-line therapy with the CD-DST may improve the prognosis of patients with unresectable CRC, especially in poor responders.

Introduction: The assessment of risk factors of cancer recurrence in patients with stage II colon cancer (CC) is crucial for identifying the patients at higher risk of recurrence who are likely to benefit from adjuvant chemotherapy. Although some of these factors have been proposed, the data are controversial and there is still need for new and more reliable predictive factors. Our aim was to study the clinical, histological and molecular features associated with 3-year disease-free survival (DFS) in a series of consecutive patients with stage II CC treated in three regional digestive oncology centers.

Aims & Methods: Clinical and histological data of all patients after curative surgery for stage II CC, treated in three institutions from 2001 until 2009, for whom at least 3-year follow-up data were available, were collected retrospectively. Additionally, histological samples were obtained and prospectively tested for microsatellite instability using fluorescent PCR amplification. Cox proportional hazards regression models were used to compute p values, hazard ratios (HRs), and 95% confidence intervals (CIs).

Results: Among 195 patients studied (median age 76 years, range 23-97 years, men 55%), 37 (18.9%) received adjuvant chemotherapy. Twenty-two patients (11%) had disease recurrence during the 3-year period following diagnosis. No significant association was found between the risk of recurrence and age, sex, degree of tumor differentiation, the presence of venous, lymphatic or perineural invasion at histology, adjuvant chemotherapy or the MSS status. On univariate analysis, obstruction or tumor perforation at diagnosis, T4 tumor status and low (<12) number of lymph nodes examined were clinically significant risk factor for recurrence, while anemia and right colon localization were associated with a lower risk of recurrence. On multivariate analysis, only low number of lymph nodes (HR = 3.81 {95% CI: 1.19-12.19}, $p = 0.02$) and T4 status (HR = 5.49, {95% CI: 1.06-28.43}, $p = 0.04$) were significantly associated with a higher risk of 3-year recurrence.

Conclusion: In our study, only T4 status and low number of lymph nodes were independent prognostic factors for 3-year DFS. In consequence, these patients should be considered for adjuvant chemotherapy.

Disclosure of Interest: None declared

P1683 LONG-TERM OUTCOMES AND PROGNOSTIC FACTORS OF RECURRENCE IN T1 COLORECTAL CARCINOMAS

Y. Kouyama[1], S.-E. Kudo[1], H. Miyachi[1], K. Ichimasa[1], S. Matsudaira[1], Y. J. Kimura[1], H. Oikawa[1], T. Hisayuki[1], K. Wakamura[1], T. Hayashi[1], K. Kodama[1], T. Kudo[1], Y. Mori[1], M. Misawa[1], A. Katagiri[1], T. Baba[1], H. Eiji[1], F. Ishida[1]

[1]*Digestive Disease Center, Showa University Northern Yokohama Hospital, Yokohama, Japan, Yokohama-shi, Japan*

Contact E-mail Address: kouyuta1101@yahoo.co.jp

Introduction: Although the recurrence of T1 colorectal cancers is relatively rare, some cases do develop even after surgery. However, their prognostic factors remain obscure, and there is little evidence regarding long-term outcomes.

Aims & Methods: Our aim is to clarify the prognostic factors for recurrence of T1 colorectal carcinomas, reviewing their long-term outcomes. We analyzed the associations between recurrence and various clinicopathological features (age, gender, tumor size, location, morphology, degree and depth of submucosal invasion, lymphatic infiltration, vascular infiltration, tumor budding, histologic type, and lymph node metastasis) in 792 patients with T1 colorectal carcinomas resected at our unit from April 2001 to December 2012. Patients were followed up until December 2014 over a median follow-up period of 51.4 months. Of these, 544 lesions were resected surgically including additional colectomy after endoscopic resection, and 168 lesions were endoscopic resections only. Cox regression analysis was used to calculate hazard ratios for recurrence or distant metastasis.

Results: One case developed local recurrence in 69.4 months after endoscopic resection. Distant recurrences were found in eight cases, of which five cases were after surgical resections and three cases were after endoscopic resections. Of the nine lesions in total, five cases were rectal carcinomas, and four cases were depressed type of the lesion. As for pathological factors, all cases were submucosal massively invasive carcinoma. Five cases had lymphatic infiltration, and four cases had vascular infiltration. Three cases had poorly differentiated carcinomas. Only the attribution of rectum was revealed to be a significant prognostic factor of recurrence in Cox regression analysis ($p = 0.036$, HR = 4.54).

Conclusion: Even after surgical resections, some lesions develop recurrences. More careful surveillance is recommended, especially for rectal carcinomas.

P1684 ALTERED LEVELS OF CORTISOL IN HAIR IN PATIENTS WITH IRRITABLE BOWEL SYNDROME

A.-K. Norlin[1], S. Walter[2], E. Theodorsson[3], E. Grodzinsky[4,5], M. P. Jones[6], Å. Faresjö[1]

Contact E-mail Address: anna-karin.norlin@liu.se

Introduction: Stress is considered an important component in the pathophysiology of Irritable Bowel Syndrome (IBS). Long term Hypothalamus Pituitary Adrenal (HPA)-axis activity can be studied by measuring cortisol in hair.

Aims & Methods: We investigated whether hair cortisol concentrations (HCC:s) and self-reported stress differentiate IBS patients from non-IBS controls by means of a case control study. Subjects aged 18-65 years, with a known IBS diagnosis and active symptoms, identified in the patient medical register of 10 selected Swedish primary health care centres (PHCs), were invited. The control group comprised other patients at these PHCs, with a similar age and sex distribution, who had sought care for other complaints not associated with gastrointestinal (GI) symptoms and with no earlier GI diagnoses. Hair samples were collected from 381 IBS-patients and 450 non-IBS controls. HCCs were measured using a competitive radioimmunoassay. Questionnaires including self-reported perceived stress (PSS) and Rome III criteria were completed by 296 IBS patients and 375 non-IBS controls. We had access to all participants' medical records and the material was checked thoroughly in both groups. Due to non-completions of questionnaire, steroid treatment, IBS diagnoses in the controls, other GI diagnoses, two old age and one patient's will to drop-out, 169 Rome III-fulfilling IBS patients and 316 patients without gastrointestinal complaints were available for analysis. Due to non-normal distributions, HCCs were log transformed before statistical analysis and also divided into quintiles. Multiple regression analyses were used to adjust for potential confounders among relevant background variables.

Results: IBS patients had significantly ($p = 0.022$) lower HCCs (median = 16.3 pg/mg, IQR = 26.9 pg/mg) compared to controls (median = 22.8 pg/mg, IQR = 29.1 pg/mg). There was also a significant difference ($p = 0.001$) in the distribution of cortisol quintiles between IBS- and non-IBS-patients. The highest proportion of IBS patients (30.2%) were found in the lowest cortisol quintile. The opposite was seen in non-IBS patients, where the smallest proportion (14.2%) was found in the lowest quintile. PSS was higher among IBS-patients with a mean (SD) total score of 25.3 (SD = 8.0) compared to the non-IBS patients 21.4, (SD = 7.5) ($p < 0.0001$). After taking other factors into considerations in multiple regression models of HCCs and PSS, only quintiles of HCCs stayed significantly related to IBS ($p < 0.005$). There was a weak negative correlation between HCCs and PSS in the study group as a whole ($r = -0.109$, $p = 0.019$).

Conclusion: IBS patients had lower HCCs than non-IBS patients and IBS patients were over-represented in the lowest quintile of cortisol. These results could indicate a possible suppression of the HPA-axis activity in a considerable proportion of IBS patients. Self-reported stress was higher in IBS-patients compared to non-IBS patients, but the correlation between HCC and PSS was poor, indicating that they in fact reflect different aspects of stress in IBS.

P1685 INHIBITION OF DEFECATORY URGE PROVOKED BY RECTAL BALLOON DISTENSION FACILITATES COGNITIVE CONTROL IN HEALTHY VOLUNTEERS

D. Zhao[1], M. Corsetti[1], M. Van Gils[2], N. Weltens[1], M. Moeni-Jazani[3], M. Tuk[4], J. Tack[1], L. Warlop[2,3], L. Van Oudenhove[1]

Introduction: A recent study (Tuk et al 2011) showed that as the bladder fills people increasingly inhibit their motor impulse to void, and that this is associated with improved performance on cognitive control tasks requiring inhibition of automatic responses.
Aims & Methods
Aims: To investigate the effect of defecatory urge provoked by rectal distension on cognitive control in healthy subjects.
Methods: Twenty-two healthy volunteers were intubated with a rectal balloon. After a 15-min adaptation period, a stepwise (4mmHg/30sec) isobaric distension procedure was performed using a barostat. Perceived intensity of urge to defecate was rated on a visual analogue scale (VAS) after 15sec in each distension step. Moderate and severe urge thresholds were derived for each subject to define 3 ''urge conditions'': no urge (balloon deflated), moderate urge (VAS $\geq$ 41), and severe urge (VAS $\geq$ 81). Next, during each of the 3 urge conditions (in counterbalanced order), subjects performed the Stroop task as a measure of cognitive control. This task includes 3 types of stimuli, incongruent color naming (color words written in font of a different color), congruent color naming (color words written in font of the same color), or ''word naming'' stimuli (color words written in black), presented 10 times each during each urge condition. In response to the stimuli, subjects needed to press one of 3 keys with colors corresponding to the color of the font (in both color naming trials) or the meaning of the color word (in word naming trials) as quickly as possible. Linear mixed models [3 (urge condition) x 3 (Stroop stimulus) within-subject 2-way ANOVA] were used to analyze reaction times (RT). The urge condition*Stroop stimulus interaction effect was the effect of interest, followed by planned comparisons of the difference in RT between incongruent color naming (task requiring cognitive control over an automatic response) on one hand and congruent color naming and word naming (automatic response tasks) on the other, between Stroop conditions. A larger difference in the no urge compared to the other two conditions would confirm our hypothesis of increased cognitive control during inhibition of defecatory urge.
Results: The difference in RT between incongruent color naming and word naming in the no urge condition (85 $\pm$ 29 msec) was higher than in the moderate (-6 $\pm$ 30) and severe (-7 $\pm$ 35) urge conditions (both $p < .002$). The difference between incongruent color naming and congruent color naming trials in the no urge condition (181 $\pm$ 35 msec) was also numerically higher compared to both the medium (141 $\pm$ 36) and high (158 $\pm$ 42) urge conditions, but these differences were not significant ($p = .23$ & .50, respectively).
Conclusion: In line with earlier findings on voiding urge, inhibition of defecatory urge provoked by rectal balloon distension facilitates cognitive control in healthy volunteers. This may be explained by ''spillover'' of inhibitory processes from one domain to the other due to a common neural mechanism underlying inhibitory processes. Further, these findings provide proof of concept for an influence of gut-brain signals on cognitive processes, which may be relevant for Irritable Bowel Syndrome.

Introduction: An impaired gut barrier leading to visceral hypersensitivity and immune disorders have been described in irritable bowel syndrome (IBS). The ubiquitin-proteasome system (UPS) could be involved in the alteration of the colonic barrier observed in IBS via the degradation of tight junction proteins. We aimed to investigate the role of UPS in gut barrier regulation in two mice models mimicking IBS: the water avoidance stress model (WAS) and a post-inflammatory model (post-TNBS).
Aims & Methods: Both models were performed in C57BL/6 male mice (n = 8-10/group); WAS model was induced by placing mice on a small platform in a tank of water during 1 hour per day during 10 consecutive days. Control mice were placed on the same platform without water. Post-inflammatory model was obtained with an intra-colonic instillation of TNBS (0.5mg) at day 1, before a 28-day follow-up. Colonic permeability, inflammatory response and UPS activities and composition were measured. In additional experiments, mice received injections of a selective proteasome inhibitor (PR-957) or we used knock-out mice for β2i proteasome subunit.
Results: In WAS mice, a significant increase of fecal pellet output (1.5 fold change, $p < 0.05$), of mucosal pro-inflammatory cytokine (IL-1β, TNFa and CXCL-1) mRNA levels and of myeloperoxidase (MPO) activity was found. Colonic permeability also increased (1.5 fold change, $p < 0.05$) while expression of tight junction proteins, occludin and ZO-1, was reduced. While pro-inflammatory cytokine mRNA levels were restored to control levels at day 28 in post-TNBS mice, colonic permeability remained higher (3 fold change, $p < 0.05$) with a significant decrease in claudin-1 expression. In both models (WAS at day 10, post-TNBS at day 28), we observed an increase of proteasome trypsin-like activity and of inducible β2/constitutive β2 subunit expression ratio (1.5 and 3 fold change in WAS and post-TNBS mice, respectively, both $p < 0.05$). Moreover, intestinal hyperpermeability was blunted by i.p. injection of selective proteasome inhibitor (PR-957) in post-TNBS and WAS mice and knock-out mice for β2i subunit exhibited a significant decrease in intestinal permeability and fecal pellet output during WAS.
Conclusion: In conclusion, proteasome system is altered in the colonic mucosa of IBS mice models with an increased trypsin-like activity. Intestinal hyperpermeability was prevented by inhibition of proteasome or deletion of β2i subunit in mice suggesting that UPS may be involved in the occurrence of IBS symptoms.

P1687 ADENOSINE RECEPTORS IN INFLAMMATION ON RAT COLON PREPARATIONS. ARE THEY INVOLVED IN THE ANTI-INFLAMMATORY ACTION OF STW 5?

Introduction: The purine nucleoside adenosine, which is involved in a variety of physiological functions, regulates immune and inflammatory responses and acts as a modulator of gut functions. Although it is present at low concentrations in the extracellular space, stressful conditions, such as inflammation, can markedly increase its extracellular level up to micromolar range. By activation of different receptor subtypes adenosine is able to induce anti-inflammatory or pro-inflammatory impacts. The current study examined the impact of adenosine A2A receptors (A2AR) and adenosine A2B receptors (A2BR) to regulate contractility in untreated and inflamed rat colon preparations using a specific A2AR agonist (CGS 21680) and an A2BR antagonist (PSB-1115) on acute inflammation in rat colon preparations. Further it focused on interactions of the multi-herbal drug STW 5 with A2AR as a possible mechanism of the protective effect of STW 5 in gastrointestinal disorders.
Aims & Methods: Inflammation was induced by intraluminal instillation of 2,4,6-trinitrobenzene sulfonic acid (TNBS). Contractions were measured isometrically in an organ bath set up. Gene expression was determined using RT-PCR. Radio ligand binding assays (competition experiments) were carried out with rat brain homogenates. Morphological changes were estimated after van Gieson staining.
Results: All four adenosine receptor subtypes were expressed in untreated colon preparations. Activation of A1, A2B, and A3 receptor with specific agonists reduced the acetylcholine (ACh, 10μM)-induced contractions, while activation of A2BR enhanced it. After incubation with TNBS morphological damages in colonic mucosa and muscle walls were detectable followed by reduced ACh-contractions. The TNBS-mediated decrease of ACh-contractions as well as the morphological damages were partially normalized by co-incubation of TNBS with CGS 21680 (10μM) or with PSB 1115 (100μM). The same effects with smaller intensity were found for STW 5 (512 μg/ml) in female but not in male colon preparations. These results are in accordance with ligand binding studies indicating that STW 5 interact with the A2AR.
Conclusion: Anti-inflammatory mechanisms and cell protective actions of STW 5 are partly due to the interaction with adenosine receptors. The results give a clear-cut correlation with symptom improvements in clinical trials and therby highlight the relevance of STW 5 as a therapeutic approach in IBS.

Introduction: Psychosocial factors are associated with visceral sensitivity in FD, but in IBS evidence is limited.
Aims & Methods: We aimed to study associations between psychosocial factors and visceral sensitivity parameters in IBS. Two IBS cohorts underwent rectal barostat testing and completed questionnaires on anxiety & depression, GI-specific anxiety, somatization, and abuse history. Cohort 1 (n = 124, Rome II) underwent an ascending method of limits (AML) paradigm returning to operating pressure (OP) between distensions to measure pain threshold and pain referral area. Cohort 2 (n = 127, Rome III criteria) underwent an AML protocol

without returning to OP, random phasic distensions with pain intensity ratings, and assessment of pain ratings during 4h following a 25g lactulose challenge test.

Results: Parameters significantly associated with visceral sensory measures in bivariate analysis were included in 3-step general linear models. The 3 steps and the results are shown in Table 1.

		Step 1 Demographics & Abuse	Step 2 +Anxiety & Depression	Step 3 +Somatization
COHORT 1				
Pain threshold	*Age*	0.007	0.01	0.01
	Female gender			0.04
	Sexual abuse adult	0.001	0.007	0.007
Somatization			0.02	
Pain referral area	*Age*		0.05	0.05
	GI-specific anxiety		0.03	0.2
Somatization			0.04	
COHORT 2				
Pain threshold	*Age*	0.0001	0.002	0.002
	Sexual abuse adult	0.04	0.04	0.05
Somatization			0.5	
Pain intensity ratings (36 mmHg rectal distension)	*Female gender*	0.01	0.007	0.1
	Depression		0.04	0.2
Somatization			0.03	
Lactulose provoced pain	*Female gender*	0.005	0.008	0.3
	Physical abuse child	0.05	0.06	0.3
	GI-specific anxiety		0.03	0.2
Somatization			0.0004	

The effects of GI-specific anxiety on pain referral area (Co.1), the effect of depression on pain intensity ratings and the effects of female gender, childhood physical abuse and GI-specific anxiety on lactulose-provoked pain (Co.2) were mediated through somatization.

Conclusion: Somatization either has an independent effect on visceral sensitivity parameters, or mediates the association between psychosocial factors and these parameters.

Contact E-mail Address: lukas.vanoudenhove@med.kuleuven.be

Introduction: Irritable Bowel Syndrome (IBS) is associated with an increased postprandial symptom response to a 25g lactulose challenge test compared to healthy controls (Le Nevé et al, AJG 2013). Psychosocial morbidity is associated with having a diagnosis of IBS and with increased symptom severity in IBS patients.

Aims & Methods: Our aim was to investigate the relationship between psychosocial status and the time course of the postprandial symptom response to this test. 204 IBS patients (Rome III) consumed a 400-ml liquid breakfast (Nutridrink, 1.5 kcal/ml, 16% proteins, 49% carbohydrates, 35% fat, gluten free, lactose <0.025 g/100 ml) combined with 25g of lactulose after an overnight fast. They completed visual analogue scales (0-20) assessing severity of five gastrointestinal (GI) symptoms (abdominal pain, bloating, nausea, gas, urgency) and overall digestive comfort before breakfast and every 15 minutes up to 240 minutes postprandially. Patients completed validated self-report questionnaires for general anxiety, GI-specific anxiety, depression and somatization. The relationship between these psychological variables and the course of GI symptom scores over time was analyzed using linear mixed models, controlling for comorbid functional dyspepsia. "Time" was included as a categorical within-subject effect, the psychological variables were included as continuous between-subject effect (in separate models to avoid multicollinearity), and the psychological variable-by-time interaction effect was also included. The main effect of the psychological variable and the interaction effect are the effects of interest.

Results: Significant main effects of both general and GI-specific anxiety, depression and somatization, indicating a shift of the intercept of the curve (i.e. at the preprandial time point), were found for digestive comfort (negative association) as well as all GI symptoms (positive association), except for gas, where only both types of anxiety showed a significant main effect. General anxiety-by-time interaction effects were found for pain ($p=0.012$), bloating ($p=0.0039$), and urgency ($p=0.048$). No significant GI-specific anxiety-by-time interaction effects were found for any symptoms. Depression-by-time interaction effects were found for pain ($p=0.046$), bloating ($p=0.0071$), urgency ($p=0.004$), and digestive comfort ($p=0.030$). Somatization-by-time interaction effects were found for bloating ($p=0.027$), and urgency ($p=0.032$). These interaction effects reflect a steeper early postprandial increase of these symptoms (decrease for digestive comfort) and slower recovery to baseline in subjects with higher levels of the respective psychosocial factors.

Conclusion: In IBS, anxiety, depression and somatization are associated with increased symptom responses to a lactulose challenge test (steeper postprandial increase in ratings to a higher maximum and slower recovery), particularly for the symptoms bloating, urgency, and, to a lesser extent, pain. These results indicate that psychosocial morbidity is relevant for symptom reporting in IBS, including symptoms after a standard nutrient challenge test.

P1690 EFFECT OF LINACLOTIDE AS COMPARED TO PLACEBO ON RECTAL SENSORY AND MOTOR RESPONSE TO DISTENSION ASSESSED BY ELECTRONIC BAROSTAT IN HEALTHY SUBJECTS

M. Corsetti[1], G. Pagliaro[1], **J. Tack**[1]
[1]*Targid, Kuleuven, Leuven, Belgium*

Contact E-mail Address: maura.corsetti@med.kuleuven.be

Introduction: Linaclotide has been recently approved for the treatment of IBS with constipation. In animal models, linaclotide was able to inhibit high-threshold afferent responses both in basal and sensitized conditions (1). Whether the reported efficacy of linaclotide in reducing abdominal pain in humans is related to a direct effect on sensory pathways is unknown.

Aims & Methods: To compare the effect of linaclotide and placebo on the rectal sensory and motor response to distension assessed by the barostat in healthy subjects.

After an overnight fast a 700 ml plastic balloon was introduced in the rectum of 10 volunteers (6 females, 32 ± 4 years) and connected to a barostat. A volume- (50 ml/2 min) and a pressure-controlled (4 mmHg/2 min) stepwise, two ramp (300 ml/min, fast and 100 ml/min, slow) and three phasic (up to 8, 16, 24 mm Hg) distensions were performed and the intra-balloon pressure then settled at minimal distending pressure (MDP)+ 2 mm Hg for 30 min before and 120 min after the oral administration of placebo and linaclotide (290 µg) in a randomized, crossover fashion. Distensions were then repeated. Rectal tone, rectal distensibility (slope of the volume-pressure and pressure-volume relationship) and volume and pressure threshold for discomfort were evaluated. During phasic distensions intensity of discomfort and pain were rated on a 100 mm visual analogue scale (VAS) and rectal distensibility calculated as ratio between volume and distending pressure. Data are expressed by mean ± SEM of the delta (Δ) between values after and before the administration of the drug and compared by means of the Wilcoxon test.

Results: The MDP and rectal tone did not differ between treatments. During volume-controlled distension, rectal distensibility (-0.02 ± 0.005 for placebo vs -0.02 ± 0.01 mmHg/ml for linaclotide, $P=0.74$) as well as volume (20 ± 11 vs 5 ± 13 ml, $P=0.19$) and pressure (1.7 ± 5 vs -4.8 ± 3.7 mm Hg, $P=0.26$) thresholds for discomfort did not differ between treatments. During pressure-controlled distension, rectal distensibility (5.5 ± 1.2 vs 2 ± 1.9 ml/mmHg, $P=0.22$) as well as pressure (-1.6 ± 2 vs 1.7 ± 1.7 mmHg, $P=0.41$) and volume (20 ± 16 vs -8 ± 33 ml, $P=0.32$) thresholds for discomfort did not differ between treatments. During fast ramp, rectal distensibility (0.005 ± 0.12 vs -0.25 ± 0.19 mmHg/ml, $P=0.30$) as well as volume (12 ± 10 vs -3.4 ± 22 ml, $P=0.68$) and pressure (-0.58 ± 3.7 vs -10 ± 4.7 mmHg, $P=0.23$) thresholds for discomfort were similar for both arms. During slow ramp, rectal distensibility (-0.30 ± 0.26 vs -0.34 ± 0.25 mmHg/ml, $P=0.49$) as well as volume (19 ± 22 vs 24 ± 18 ml, $P=0.96$) and pressure (-6.6 ± 2 vs -4 ± 3.6 mmHg, $P=0.41$) thresholds for discomfort did not differ between treatments. During phasic distensions up to 24 mmHg, rectal distensibility (-0.005 ± 1.7 vs 1.2 ± 1.5 ml/mmHg, $P=0.99$) as well as VAS scores for discomfort (2 ± 5 vs 12 ± 8 mm, $P=0.08$) and pain (3.6 ± 3 vs 8 ± 6 mm, $P=0.30$) did not differ between treatments. No effect of linaclotide vs placebo was observed also during phasic distensions up to 8 and 16 mmHg (all $P>.10$).

Conclusion: In healthy humans, acute administration of linaclotide does not affect the sensory and motor response to rectal distension. It remains to be evaluated whether linaclotide affects rectal sensitivity in patients with visceral hypersensitivity and whether it affects responses to colonic distension.

P1691 CORTICOTROPIN-RELEASING FACTOR CHANGES THE PHENOTYPE OF MESENTERIC LYMPH NODES DENDRITIC CELLS BY REGULATION ERK1/2 SIGNAL PATHWAY IN IBS

M. Li[1], Y. Hu[2], X. T. Wang[2], B. Lu[2]

Contact E-mail Address: lemon20050928@163.com
Introduction: Our previous research indicated that abnormal immune function of mesenteric lymph nodes dendritic cell (MLNDC) was involved in the pathophysiology of irritable bowel syndrome (IBS). However, little is known of the contribution of Corticotropin-releasing factor (CRF) to intestinal DCs and the involved signal pathway.
Aims & Methods: In this study, we try to investigate the role of CRF in the change of intestinal dendritic cell phenotype and changes in mitogen-activated protein kinase (MAPK) activity in MLNDC.
The mice mesenteric lymph nodes dendritic cells (MLNDCs) were obtained by the technique of magnetic bead sorting. Expression of CRF-R1/R2 on the surface of MLNDCs were determined by double-labeling immunofluorescence and RT-PCR. Then, MLNDCs were exposed to different concentration of CRF, the expression of MHCII and CD80 were tested by the technique of flow cytometry and western blot. IBS rat model was established by combining neonatal maternal separation (NMS) and colorectal distension and undergoing transfection with CRF -targeting siRNA by intracerebroventricular injection. According to experiments, expression of surface molecule MHC-II and CD80 on the surface of MLNDC in both groups was determined by flow cytometric analyses, and Western-blot were used to determine the expression of MHCII?CD80?p-p38?p-ERK1/2 and p-JNK in MLNDC.
Results: Both the CRF receptors (CRFR1 and CRFR2) exist on the surface of MLNDCs. CRF could increase the expression of MHC-II of MLNDCs. In vivo, visceral sensitivity was significantly higher in IBS group while lower in IBS-CRF silencing group. MLNDC from IBS group expressed high level of MHCII, however, MLNDC from IBS-CRF silencing group expressed lowered surface expression of MHCII, the expression of p-ERK1/2 in MLNDC in IBS group were higher than that in control group while significantly reduced in IBS-CRF silencing group ($p < 0.05$). However, there was no substantial difference in the protein expression of p-JNK and p-p38 between groups.
Conclusion: Our findings suggest that CRF could induce the expression of MHCII in MLNDC in IBS, which may involved in the activation of ERK1/2 signal pathway.

Introduction: Background: Sense of coherence (SOC) is defined as a global orientation that expresses the extent to which a person has a pervasive, enduring, though dynamic feeling of confidence that life is comprehensible, manageable, and meaningful (Antonovsky, 1987). SOC is strongly correlated with performance of activities of daily living, global health status and outcome in various medical conditions. In IBS few studies have addressed the importance of SOC for health status and quality of life. As stressful life events are common symptom triggers in IBS, and SOC is associated with successful coping with stressors and better health outcome, we hypothesized that SOC is reduced in an IBS subgroup characterized by high symptom burden and reduced quality of life (QOL).
Aims & Methods
Aim: To assess SOC in a large group of patients with IBS and evaluate the association with GI and psychological symptoms, and disease-specific QOL.
Methods: We included 387 patients with IBS (mean age 37 ± 13 (mean $\pm$ SD) years; 271 females) and 58 healthy controls (31 ± 9 years; 36 females). All subjects completed the SOC scale, and the patients also completed questionnaires to assess the severity of GI (Gastrointestinal Symptom Rating Scale-IBS, GSRS-IBS) and psychological symptoms (Hospital Anxiety and Depression Scale, HAD; Visceral Sensitivity Index, VSI), as well as disease-specific QOL (IBSQOL). The 5th percentile of the total SOC score in the healthy control group was used to define low SOC.
Results: SOC was reduced in IBS vs. control subjects. This was true for the total score and the three domains comprehensibility, manageability and meaningfulness. Within the IBS group SOC was lower in females than in males ($p = 0.009$), but unrelated to age ($p = 0.3$). IBS patients with low SOC (SOC total score < 116;n = 76) reported more severe IBS symptoms (GSRS-IBS) than patients with normal SOC (n = 311): abdominal pain (4.7 ± 1.3 vs. 3.9 ± 1.4; $p < 0.0001$), bloating (5.0 ± 1.3 vs. 4.4 ± 1.4; $p = 0.002$), constipation (3.2 ± 1.8 vs. 2.7 ± 1.7; $p = 0.03$), and diarrhea (4.2 ± 1.3 vs. 3.4 ± 1.4; $p < 0.0001$). They also reported more severe depression (HAD depression: 8.7 ± 3.4 vs. 4.1 ± 3.0; $p < 0.0001$), as well as general (HAD anxiety: 12.5 ± 3.6 vs. 7.0 ± 3.9; $p < 0.0001$) and GI-specific anxiety (VSI: 49 ± 15 vs. 36 ± 16; $p < 0.0001$). Reduced disease-specific QOL was seen for all IBSQOL domains in the low SOC group, and this was especially pronounced for the domains Emotional, Mental Health and Energy (see table).

Table SOC	Low SOC (n = 76)	Normal SOC (n = 311)	p-value
Emotional	33 ± 21	56 ± 22	< 0.0001
Mental health	49 ± 25	76 ± 20	< 0.0001
Sleep	64 ± 24	73 ± 24	
Energy	39 ± 27	61 ± 27	< 0.0001
Physical functioning	61 ± 23	75 ± 21	< 0.0001
Food	54 ± 24	66 ± 21	< 0.0001
Social role	50 ± 24	66 ± 23	< 0.0001
Physical role	40 ± 26	61 ± 30	< 0.0001
Sexual function	57 ± 28	67 ± 25	

Conclusion: A substantial proportion of patients with IBS have reduced sense of coherence, which is associated with more severe symptoms overall as well as reduced quality of life. Low sense of coherence diminishes the ability to mobilize coping resources in response to daily stressors, and therefore helping IBS patients with low sense of coherence to improve their coping skills has the potential to positively affect global health in IBS.

Introduction: Ischemic cerebral stroke is a major cause of death worldwide. In addition to the brain injury, patients are also at risk of a number of comorbidities including cardiac, pulmonary and gastrointestinal (GI) complications as well as infections and sepsis. Bowel dysfunction and constipation greatly reduce the patients' quality of life but, equally important, they represent a major risk factor in sepsis development. Intestinal dysfunction has its roots in defect nervous regulation of motility and secretion, events locally controlled by the enteric nervous system (ENS). Co-morbidity in both central and enteric neurons has been demonstrated in several neuropathologies like Parkinson's disease and prion diseases but is so far unexplored in brain damaging situations like stroke.
Aims & Methods: The aim of the present study is to investigate if the ENS is affected after ischemic cerebral stroke. Forty-one C57BL/6 mice, mean age 11.6 months underwent either left sided permanent occlusion of the middle cerebral artery (pMCAO) (n = 30) or sham operation (n = 11). The pMCAO model results in limited damage to cortical brain tissue. After 6 hours (pMCAO n = 6), 3 days (pMCAO n = 12, sham n = 7) or 7 days (pMCAO n = 12, sham n = 4) mice were sacrificed their GI tracts collected. Histological and immonycytochemical methods were performed to analyze intestinal remodulation, and neuronal density in colon.
Results: Mice subjected to pMCAO display mild symptoms, like transient immobility of the contralateral hind paw. Animal weight and intestinal length was unaltered between pMCAO and sham animals. Morphological and immunocytochemical analysis of the colon revealed normal morphology 6 hours and 7 days after pMCAO compared to sham. After 3 days a thickening of the mucosa was observed in the pMCAO group compared to sham ($p < 0.05$). A significant loss of both myenteric ($p < 0.01$) and submucousal ($p < 0.05$) neurons was noted in the colon after 3 days, present also at 7days in pMCAO animals compared to sham.
Conclusion: pMCAO, an experimental model simulating stroke, results in a loss of enteric, in particular myenteric colon in mice. The loss is obvious 3 days post pMCAO and a 50% loss of myenteric neurons is detected 7 days post stroke. The mechanism behind is elusive but may involve neuroimmune interactions.

Introduction: Psychiatric factors have long been thought to play a primary role together with biologic factors in the onset of irritable bowel syndrome (IBS) because of the interplay between psychosocial stressors and abdominal symptoms'
Aims & Methods: Since psychiatric disorders and pain syndromes are associated to changes in catecholaminergic transmission and these conditions are both related to IBS we investigated whether genetic reduction of both catechol-O-methyltransferase (COMT) and dopamine transporter (DAT) affects gut motility and enteric nervous system (ENS) circuitries. Female DAT and COMT heterozygous ($DAT^{+/-}COMT^{+/-}$) and wild-type ($DAT^{+/+}COMT^{+/+}$) mice (12 ± 2

weeks) were genotyped by PCR. Gastrointestinal transit was assessed 30 minutes after intragastric administration of nonabsorbable fluorescein isothiocyanate labeled dextran. Isolated ileum segments were isometrically mounted in organ baths and changes in muscle tension were recorded following addition of either carbachol (0.001-100 μM), KCl (60 mM) or after electric field stimulation (EFS, 1-40 Hz) and inhibition in non-adrenergic non-cholinergic conditions (EFS = 10 Hz, 1 μM atropine, 1 μM guanethidine, in the absence or presence of 0.1 mM L-NAME). Immunofluorescence staining for the neuronal marker HuC/D, neuronal nitric oxide synthase (nNOS) and the glial marker S100beta was evaluated with confocal microscopy in longitudinal muscle myenteric plexus preparations (LMMPs). To evaluate the integrity of myenteric plexus neurochemical coding, acetylcholinesterase and NADPH-diaphorase activity and GluN1 mRNA levels were studied in LMMPs.
Results: Gastrointestinal transit was delayed in transgenic animals compared to controls (GC 5.1 ± 0.2 vs 5.7 ± 0.2, $p < 0.05$). In $DAT^{+/-}COMT^{+/-}$mouse ileum, both receptor- and KCl-mediated contractions as well as cholinergic and nitrergic responses to electrical field stimulation significantly increased. In the myenteric plexus of $DAT^{+/-}COMT^{+/-}$mice immunoreactivity to S100beta augmented while staining for acetylcholinesterase$^+$ ($-18 \pm 4\%$) and NADPH-diaphorase$^+$ ($-23 \pm 6\%$) diminished. Distribution of nNOS immunopositive neurons changed compared to wild-type animals. A two-fold increase of GluN1 mRNA levels was found in LMMPs obtained from transgenic mice.
Conclusion: Our study provides evidence that changes in catecholaminergic transmission due to genetic-driven COMT and DAT defective activity affects ENS architecture, neurochemical coding and function leading to intestinal dysmotility and possibly to enhanced visceral pain perception, which may underlie the development of a disease with high social and economic impact such as IBS.

Contact E-mail Address: atsimperidis@yahoo.com
Introduction: Although there are some considerations, involving pathological and anatomical data, to clarify the perfusion deficit[1, 2], the underlying etiology of ischaemic colitis (IC) is unclear[3].
Aims & Methods: The aim of this study is the evaluation of laboratory findings, such as haematological tests and lipids, in order to compare the pathophysiology of IC with that of ischaemic cardiovascular disease (CVD).
Laboratory tests were evaluated in 56 cases of IC and the findings were compared with 44 controls with known predisposing factors (including history of thrombosis, atherosclerosis, hypertension, chronic renal insufficiency, diabetes mellitus, irritable bowel syndrome, chronic constipation, history of abdominal aorta aneurysm, history of schock and autoimmune disease) but no evidence of IC. Parameters measured were: Complete blood count, cholesterol, high-density lipoproteins (HDL), low-density lipoproteins (LDL), triglycerides and apolipoproteins B (ApoB).
Results: The absolute lymphocyte count had a tendency to be lower in the IC group ($p = .080$) with lymphopenia ($< 1200/\mu l$) most prevalent ($\chi^2(2) = 7.925$, $p = .019$). The platelet count was higher and the mean platelet volume (MPV) lower in the IC group ($p = .0005$ and $p = .039$, respectively). HDL levels > 40 mg/dl were significantly more common in male patients than in male controls 76.9% vs 35.7% ($\chi^2(1) = 6.034$, $p = .014$), while in females, levels > 50 mg/dl tended to be more prevalent in the IC group, 60.0% vs 28.6% ($\chi^2(1) = 3.548$, $p = .060$). The values of ApoB were lower ($p = .028$) in the same group. No significant results arose from the neutrophils to lymphocytes ratio (N/L) and the rest of the parameters tested, while no difference was observed in the statins' intake between the groups.
Multivariate analysis was performed to determine the effects of HDL and ApoB in IC. Increased HDL levels were associated with an increased likelihood of exhibiting IC (OR 1.119; 95% CI 1.039-1.204) and increased ApoB levels were associated with a reduced probability of IC (OR 0.948; 95% CI 0.916-0.981). (OR: Odds ratio, CI: Confidence intervals)
Conclusion: This study suggests that the pathophysiology of IC seem to be different from that of acute CVD. Platelets in patients with IC seem to function in a different way than in CVD, while they appear to have the inflammatory bowel disease (IBD) profile and they are, possibly, activated. Furthermore, HDL and ApoB predict IC in the opposite way than they do for CVD.

P1696 ENDOSCOPIC FINDINGS ARE SIGNIFICANT FACTOR OF CLINICAL OUTCOME IN ISCHEMIC COLITIS

J. Lee[1], S. W. Kim[2]
[1]*Internal Medicine,* [2]*General Surgery, Chosun University, Gwangju, Korea, Republic Of*

Contact E-mail Address: leejun@chosun.ac.kr
Introduction: Colonic ischemia is the most common form of intestinal ischemic injury and comprises a spectrum that ranges from transient colitis to fulminant universal colitis. The aim of this study was to explore clinical characteristics and endoscopic findings and to investigate prognostic factor of ischemic colitis (IC).
Aims & Methods: We conducted a retrospective study in single tertiary hospital. The medical records of patients who were diagnosed with IC from 2010 to 2014 were reviewed. Their clinical characteristics, laboratory results, radiological, endoscopic, histological evidence were collected and analyzed.
Results: A total 103 patients with IC were identified. Endoscopic findings were presented mucosal gangrene at 20 patients (19.4%), right colon involvement at 21 patients (20.4%) and multi-segment involvement at 64 patients (62.1%). Multivariate analyses showed that mucosal gangrene is independent risk factor of clinical outcomes such as mortality (adjusted odds ratio = 22.7), surgery (adjusted odds ratio = 89.6), ICU admission (adjusted odds ratio = 3.47). Patients were divided into two groups (the presence or absence of mucosal gangrene) Nausea/vomiting, rebound tenderness, and guarding were observed more frequently in mucosal gangrene group ($P = 0.007$, $P < 0.001$, $P < 0.001$, respectively). No differences in other clinical symptoms and signs and laboratory findings, comorbidities were observed between the two groups.
Conclusion: Endoscopic findings of mucosal gangrene in patients with IC are significant factor of clinical outcome. The initial presentations that were clinical symptoms and laboratory findings do not necessarily predict the presence or absence of gangrenous change of IC. Clinicians have to consider prompt colonoscopy for prognosis as well as diagnosis of IC.

P1697 DYSSYNERGIC PATTERN OF DEFECATION IS OBSERVED IN HIGH RESOLUTION ANO-RECTAL MANOMETRY IN PATIENTS WITH INCONTINENCE, CONSTIPATION AND ANAL PAIN

C. Ciriza De Los Ríos[1], F. Canga[1], I. Castel[1], G. Castellano[1]
[1]*Gastroenterology, Hospital 12 DE Octubre, Madrid, Spain*

Contact E-mail Address: constanzacarpa@gmail.com
Introduction: Dyssynergic pattern of defecation has been described in 22% of healthy control with high resolution (HRAM)[1] and in 67% with high definition ano-rectal manometry[2] when bearing-down in the lying position.
Aims & Methods: To determine the percentage of dyssynergic defecation pattern found in ano-rectal HRM in a group of patients. Also, to evaluate if there are any differences in the clinical and manometric parameters between the groups with normal and dyssynergic pattern in the HRM and the result of the balloon expulsion test (BET). Anal sphincter pressures, bearing down maneuver and rectal sensory thresholds were measured in 100 patients with HRAM (Given imaging). We compared data analyzed between the two groups those with normal defecatory pattern and the other with dyssynergic defecation. Also they were compared for the BET (positive: balloon expulsion time in physiological position < 2 minutes).
Results: Patients' characteristic and manometric data are expressed in the table. Dyssynergic pattern was found in 34 (34%) of the patients and in 6 (17.6%) of them the BET was negative. 5 patients in which BET was negative had constipation and 1 anal pain. All the patients with dyssynergic pattern and incontinence had normal BET. There were differences in the anal residual and in the rectal bearing down pressures between the two groups. No other significant differences in the other parameters studied were observed.
Conclusion: Dyssynergic pattern is frequently observed in patients studied with HRAM. Anal canal pressure was higher and rectal pressures lower (more negative gradient and lower defecation index) during simulated evacuation in patients with dyssynergic pattern but only a minority of them had a negative BET.

P1698 EVALUATION OF THE EFFECTIVENESS OF BIOFEEDBACK THERAPY IN THE TREATMENT OF FUNCTIONAL CONSTIPATION AND ENCOPRESIS IN CHILDREN

D. Jarzebicka[1], J. Sieczkowska[1], M. Dadalski[1], J. Kierkuś[1], G. Oracz[1]
[1]*Gastroenterology, Hepatology, Feeding Disorders and Pediatrics, The Children's Memorial Health Institute, Warsaw, Poland*

Contact E-mail Address: dorota.jarzebicka@wp.pl
Introduction: Defecation disorders are one of the most common problems in gastroenterology. It may be caused by the organic disease or more frequently it is a functional problem. The treatment includes fiber rich diet, proper education of patient, pharmacotherapy and in some cases the biofeedback therapy. Biofeedback therapy is helpful therapeutic method for the treatment of functional constipation with pelvic floor dyssynergia and fecal incontinence (encopresis) caused by abnormal function of the anal sphincters.

Aims & Methods: The aim of the study was to assess impact of parameters of anorectal manometry and their changes during biofeedback therapy on clinical outcome in children with constipation and pelvic floor dyssynergia and to evaluate the effectiveness of biofeedback therapy in fecal incontinence (encopresis) in children. Since 2000 to 2014, 44 children (aged 7-18 years, medium 12.5 years) with constipation and pelvic floor dyssynergia and 19 patients (aged 6-18 years, medium 11 years) with symptoms of fecal incontinence caused by improper function of the anal sphincter muscle were retrospectively assessed in this study. All of them had one to four biofeedback series consisted of two to four sessions. In the first group of patients with pelvic floor dyssynergia amplitudes between extremal and basic pressure during defecation maneuver during first and last session as well as difference between them both (amplitude in first session – amplitude in last session) were compared between group with clinical improvement after last session (n = 38) vs. group with no clinical improvement (n = 6). U Mann-Whitney test was used for analysis with $p < 0.05$ regarded as significant. In the second group with encopresis, during manometric recording, the patients were required to squeeze as to prevent defecation while being given visual feedback and verbal guidance on how to reach this goal.
Results: In the first group, there were no significant difference found in amplitude in first session values [mmHg] 94, 65, 115 vs. 112, 55, 170 [median, Q1, Q3]; amplitude in last session values 36, 27, 52 vs. 41, -38, 66; as well as in difference between them both 71, 11, 124 vs. 81, 17, 109 in groups with clinical improvement after last session vs. group with no clinical improvement respectively. In the group with encopresis, the improvement in the anorectal manometry parameters was observed in 17 out of 19 patients. Subjective clinical improvement was reported by 14 out of 19 patients. 2 out of 19 patients were lost for follow up.
Conclusion: Parameters of anorectal manometry and their changes during biofeedback therapies do not contribute to clinical outcome in children with constipation and pelvic floor dyssynergia. Biofeedback therapy is effective treatment for fecal incontinence in children caused by abnormal function of the anal sphincters.
Disclosure of Interest: None declared

P1699 BOTULINUM TOXIN INJECTION – LONG TERM EFFICACY IN THE TREATMENT OF CHRONIC ANAL FISSURE

F. Ávila[1], V. Costa Santos[1], P. Massinha[1], R. Liberal[1], A. C. Rego[1], N. Nunes[1], J. R. Pereira[1], N. Paz[1], R. Quintanilha[2], M. A. Duarte[1]
[1]*Serviço de Gastrenterologia,* [2]*Serviço de Cirurgia Geral, Hospital do Divino Espírito Santo de Ponta Delgada, Ponta Delgada, Portugal*

Contact E-mail Address: filipaavila@gmail.com
Introduction: Chronic anal fissure is a common cause of anal pain. It is more common in young adults, with similar incidence in both sexes. Its location achieves more frequently the posterior anal commissure (90-98%). Botulinum toxin (BT) and the lateral internal sphincterotomy are reserved for refractory cases. BT is minimally invasive and safer, compared to surgery, which carries a significant risk of disturbance in anal continence. BT presents a limited period of action and its long-term effectiveness is not well known.
Aims & Methods
Aims: Evaluate the long-term outcomes and the healing success rate of BT injection in chronic anal fissure.
Methods: Observational and retrospective study, including the patients treated with BT (single injection of 20U or two injection of 10U in intersphincteric space) between 2009 and 2012. Patients were followed up at 1, 6, 12 and 24 months and were assessed for healing of anal fissure. The response was registered as complete with a total healing and relapse.
Results: Ninety-one patients were treated, with an average age of 47 years and mostly were male (54 percent). In 80% of patients the fissure was located in the posterior midline. All the patients had been treated with topical drugs. In the first month, 87% of patients showed a complete healing. The 6 month inspection revealed 3% of recurrence and an increase of healing in 2 patients (86%). The 12 month, 76% of patients had no evidence of fissure, with a relapse rate of 10%. The healing rates at 24 month and relapse were 63% and 11% respectively. The recurrence rate was 24%, and 19% of patients was carried out surgery. The treatment was well tolerated by all patients and there were no complications.
Conclusion: BT has proven to be a safe and effective therapy, with satisfactory results in the long-term treatment.

P1700 THE PUBORECTAL CONTINENCE REFLEX IS NOT MEDIATED BY THE PUDENDAL NERVE AND SEEMS TO SUPPORT FAECAL CONTINENCE DURING AGEING

J. E. Jonker[1], M. M. Van Meegdenburg[1], E. Heineman[2], M. Trzpis[1], P. M. A. Broens[1,2]
[1]*Department of Surgery, Anorectal Physiology Laboratory,* [2]*Department of Surgery, Division of Pediatric Surgery, University of Groningen, University Medical Center Groningen, Groningen, Netherlands*

Contact E-mail Address: p.m.a.broens@umcg.nl
Introduction: We have recently found that conscious and unconscious contractions of the puborectal muscle are required for faecal continence and that unconscious contraction is mediated by the puborectal continence reflex.
Aims & Methods: In this study we aimed to investigate whether the puborectal continence reflex is regulated by the same nerve pathway as conscious contraction of the puborectal muscle. Furthermore, we aimed to find whether unconscious and conscious contractions of the puborectal muscle are influenced by each other, by age and by gender.
We included all adult patients who underwent anorectal function tests between 2010 and 2014 at the UMCG (n = 283). In total, 189 patients were excluded, because of possible generalized nerve damage or operations in the pelvic region, after which 94 patients remained. The patients underwent three different types of anorectal function tests. First, they underwent the anal electrosensitivity test, to investigate sensory condition of the pudendal nerve. Second, they had the anorectal pressure test, to measure conscious contraction of the puborectal muscle. Lastly, they underwent the balloon retention test, to measure unconscious contraction of the puborectal muscle.
Results: We found no correlation between unconscious contraction and anal electrosensitivity ($P = .811$). In contrast, we found a correlation between conscious contraction and anal electrosensitivity ($P = .012$). Furthermore, there was no correlation between conscious and unconscious contraction ($P = .634$). Age had no influence on unconscious, nor on conscious contraction of the puborectal muscle ($P = .080$ and $P = .344$, respectively). Gender had no influence on unconscious contraction ($P = .673$). However, gender did have a significant influence on conscious contraction ($P = < .001$), since men had a significant stronger conscious contraction.
Conclusion: We conclude that the nerve pathway responsible for the puborectal continence reflex is different than the one responsible for conscious contraction of the puborectal muscle. In addition, conscious and unconscious contractions work independently of each other. The puborectal continence reflex and conscious contraction of the puborectal muscle seem to support faecal continence during ageing.
Further clinical studies are necessary to evaluate the exact nerve pathway responsible for the puborectal continence reflex.

P1701 ENDOSCOPIC RADIAL INCISION AND CUTTING METHOD FOR REFRACTORY STRICTURE OF RECTAL ANASTOMOSIS AFTER SURGERY

K. Harada[1], S. Kawano[1], S. Hiraoka[1], Y. Kawahara[1], Y. Kondo[2], H. Okada[1]
[1]*Gastroenterology,* [2]*Gastroenterological Surgery, Okayama University Hospital, Okayama, Japan*

Contact E-mail Address: keita818@cc.okayama-u.ac.jp
Introduction: Benign colorectal strictures occur mainly secondary to surgical resection, the risk is up to 20%. They sometimes cause obstruction and can lead to a low quality of life even if the surgery was successful. The therapeutic options for these strictures are repetitive surgery or endoscopic treatment. The most preferred treatment is endoscopic balloon dilation (EBD) because of its less-invasiveness, safety and effectiveness. However frequent sessions are often required to fully clear the obstruction. The best treatment for benign rectal stricture has not yet been determined. Radial incision and cutting (RIC) method was a first reported by Muto et al. as a new endoscopic therapeutic modality for refractory esophageal benign strictures. RIC is superior to other dilation methods in that it achieves a certain diameter of the lumen and a long patency period. But it has not been applied to any gastrointestinal tract other than the esophagus.
Aims & Methods
Patients: Indications for RIC for rectal anastomotic stricture at our institution were as follows: 1) the stricture caused an obstruction; and 2) ten or more sessions of EBD or mechanical bougie were not effective enough to permit the passage of an ordinary endoscope (about 10 mm in diameter). Institutional review board approval was obtained for this study and written informed consent was obtained from all patients.
RIC method: As previously described, first, the stricture area was incised radially in four or more directions with an insulation-tipped (IT) knife-1 (Olympus Co., Japan). Next, the flaps formed by the radial incisions were sliced off with the IT knife-1.
Results: From January 2012 to January 2015, we experienced 11 patients with a rectal anastomotic stricture through which an endoscope could not pass. Among them, 3 patients matched the indication and we performed total of four sessions of RIC during this period. They were all male, two were in their 60s and the other was in his 50s. All of three patients have undergone laparoscopic-assisted low anterior resection and diverting ileostomy due to advanced rectal cancer for two patients and rectal GIST for the other. Each surgery has been completed successfully and curative. One of them complained about difficulty in defecating after ileostomy closure surgery and two were found the stricture before ileostomy closure by preoperative X-ray contrast enema. RIC was performed for each patient in mannered style. Each procedure was successful to obtain adequate dilatation by only one session. Each patient was discharged 3 days after RIC

Abstract number: P1697

	Normal defecation (n = 66)	Dyssynergic (n = 34)	p-value

BET Positive Negative	66 (100%) 0 (0%)	28 (82.4%) 6 (17.6%)	<0.001

as scheduled without any complications. Although one patient showed restenosis after RIC, that occurred half a year later. He underwent second RIC which resulted in successful again and clinically observed for more than another half a year. The other patients were also course observed for 4 months and 18 months respectively without any complaints even after ileostomy closure surgery.

Conclusion: The RIC method can be the novel option for the refractory rectal anastomotic strictures. We have experienced only a few examples to date, and long-term follow-up results are not yet clear. Further case series were required for assessment.

P1702 THE FREQUENCIES OF BOTH HARD AND SOFT STOOLS ARE MAJOR RISK FACTORS FOR FECAL INCONTINENCE

O. S. Palsson[1], M. van Tilburg[1], W. Whitehead[1], on behalf of Rome IV Questionnaire Development Committee
[1]*Medicine, University of North Carolina, Chapel Hill, United States*

Contact E-mail Address: opalsson@med.unc.edu

Introduction: Both loose/watery stools and hard stools have been identified as population risk factors for fecal incontinence (*Gastro* 2009;137(2):512-7), but how the risk varies with frequency of such abnormal stools has not been well characterized.

Aims & Methods: We aimed to elucidate these associations by using data from our nationwide U.S. 2013 Rome Normative Gastrointestinal Symptoms Survey, which was uniquely suited for this as it included the Rome III question on FI ("In the last 3 months, how often have you accidentally leaked liquid or solid stool?") and the Rome III questions on frequency of hard and loose stools with 10% increment response scales from 0 to 100%. A community sample of 1,665 U.S. adults provided by the market research company Cint USA, Inc., completed a secure Qualtrics internet survey including the Rome III Diagnostic Questionnaire with the new validated response formats (Gastroenterology 2013;144 (5), Suppl.1:S-916) planned for Rome IV, as well as demographic and health history questions. Stratified sampling was used to ensure equal gender proportions and adequate race/ethnic minority representation. Responders providing inconsistent survey answers were excluded from analysis, leaving 1,277 response sets.

Results: The analysis sample consisted of 648 females and 629 males, from all 50 U.S. states plus D.C. and Puerto Rico; 701 were white, 218 black, 240 hispanic and 118 other or undeclared race/ethnicity. Mean age was 46.4 years (range 18-94) and 45.7% had a college degree. Of the total sample, 69.8% reported having hard and/or loose/watery stools, and 39.9% experienced both. Overall FI rate in the sample (accidental leakage of liquid or solid stool at least monthly in the past 3 months) was 8.8%, and did not differ between males and females (8.7% vs. 9.0%), age groups or race/ethnic groups. Binary logistic regression analysis confirmed that both hard stools and loose stools were independent risk factors for FI and had similar impact on FI probability (Exp(B): 1.30 and 1.52 respectively, $p < 0.0001$ for both). Collectively, hard and loose stools accounted for 30.3% of the total variance (Nagelkerke R Square) in FI status. Equivalent results were seen for predicting having FI at least once a week (Exp(B): 1.39 and 1.63 respectively, $p < .0001$ for both; 38.9% of the variance explained). As seen in the table, FI risk rose substantially and steadily in the sample as hard stools, loose stools or both became a larger proportion of total bowel movements.

Table: % of individuals in the sample who had FI, by frequency of their abnormal stools

	% of stools with this abnormality in past 3 months								
	0%	10%	20%	30%	40%	50%	60%	70%	80%±
FI incidence (%of people)									
Hard stools:	3.0	6.7	10.0	16.9	33.3	22.4	29.2	30.8	30.6
Loose/watery stools:	1.8	5.9	11.9	20.3	18.6	22.6	40.0	45.5	57.6

Conclusion: Individuals with no stool consistency abnormality have negligible FI risk, but the risk rises dramatically with increasing frequency of hard and/or loose stools. These findings have important FI management implications: Normalizing stool consistency (reducing both hard and loose stools) by means of diet adjustment, fiber supplements and/or medication is likely to offer potent protection against FI incidents, and should be a first-line approach to addressing this health problem [Supported by the Rome Foundation and grants R01DK31369, R21DK096545, and R01HS018695]

Introduction: Recently, the anal-external sphincter continence reflex was shown to be an important factor involved in fecal continence. Nevertheless, still not all of the clinical continence patterns can be explained.

Aims & Methods: To further evaluate the presence of additional mechanisms that control fecal continence.

Anorectal pressure, balloon retention and rectal infusion tests were performed in twenty healthy subjects in order to follow contractions of the pelvic floor muscles that are involved in fecal continence.

Results: During anorectal pressure measurement, voluntary squeeze pressure was observed at the level of the anal sphincter and at the level of the puborectal muscle. Both contractions were held for maximal 90 seconds.
During balloon retention and rectal infusion tests, the anorectal pressure increased for a longer period at the level of the anal sphincter, which was the anal-external sphincter continence reflex. Interestingly, during balloon retention test we observed an additional, gradual increase of pressure at the level of the puborectal muscle, which was significantly longer and stronger (between 3 and 9 minutes continuously) than the contraction observed during voluntary squeeze.
Conclusion: Our results indicate that there is a second continence mechanism, which we call the puborectal continence reflex, that controls fecal continence by gradually increasing contraction of the puborectal muscle. This reflex is activated to maintain the balloon, but not water, therefore controlling only solid fecal continence. This reflex seems to be initiated by traction on the puborectal muscle Presumably, this puborectal continence reflex protects many patients against full fecal incontinence.

Introduction:
Acute hemorrhagic rectal ulcer (AHRU) is frequently encountered, especially in patients with serious comorbidities. This study was conducted to clarify the clinical features of AHRUand to identify risk factors for re-bleeding and the in-hospital mortality on the basis of a 10-year single-center experience in Japan.
Aims & Methods: In this study, we enrolled 45 AHRU patients between April 2005 and April 2015. The background of patients, the bleeding recurrence rate- and the in-hospital mortality were assessed. And potential risk factors for them, such as patient attributes (Age, sex, underlying conditions, and medication) and endoscopic procedures were retrospectively investigated. Multivariate logistic regression analysis adjusted for significant factors was used to evaluate the risk factors.
Results: Among 45 patients, 24 (53%) were male and the median age was 72.8 ± 9.7 years.
All patients had some sorts of atherosclerosis-related comorbidities such as hypertension (69%), diabetes mellitus (33%), cerebro-vascular disease (33%), end-stage renal disease requiring hemodialysis (47%), and cardio-vascular disease (22%). Additionally, 17 patients (38%) suffered from infectious disease.
15 patients were classified as American Society of Anesthesiologists (ASA) Score 4.
Endoscopic study revealed rectal ulcer in all patients and hemostasis procedures were performed to 35 (78%) patients with the result of success in 34 (97%). Surgical treatment was needed in one patient.
20 (44%) patients experienced recurrent bleeding within 14 days. Re-bleeding were found 4.5 ± 3.8 days after the initial endoscopy on average. Fatal outcome occurred in 11 (24%) during the same hospitalization.
In the multivariate logistic regression model, re-bleeding was correlated with hypo-albuminaemia (serum albumin level < 2.8 g/dl)(odds ratio [OR], 7.79 per point; confidence interval [CI], 1.70-42.9; $P = 0.077$). The in-hospital mortality was correlated with ASA score 4([OR], 12.57 per point; [CI], 1.758-140.6; $P = 0.011$) and infectious comorbidity ([OR], 10.02 per point; [CI],1.242-125.2; $P = 0.030$).
Conclusion: In our study, all patients with AHRU had some sort of atherosclerosis-related comorbidities. Re-bleeding tend to occurred in patients with hypo-albuminaemia. ASA score 4 and infectious comorbidity were significant independent predictors for the in-hospital mortality.

Introduction: Subtotal gastrectomy is the standard therapy for early distal gastric cancer. Along with vagotomy and Billroth II reconstruction, gastric environment changed significantly after gastrectomy. However, the alterations in compositions and metabolic potentials of human gastric microbiota after gastrectomy remain unknown.
Aims & Methods: Bacterial DNA extracted from 6 gastric cancer patients' biopsies from tumor and non-tumor (before gastrectomy), gastric stump and high body (after gastrectomy) was sequenced. We analyzed gastric microbiota by utilizing next generation sequencing on the V1-V3 hypervariable regions of bacterial 16S ribosomal RNA (rRNA) genes. The metabolic potentials were predicted from the microbial composition.
Results: Within the same patient, we did not find significant difference in microbial composition between different anatomic sites before and post-gastrectomy. After gastrectomy, the bacterial communities had larger diversities. Before surgery, *Ralstonia* and *Helicobacter* were the two most abundant genera, whereas *Streptococcus* and *Prevotella* represented the top-two genera after surgery. Comparative analysis on metabolic potentials revealed abundant functional genes related to *N*-nitrosation reaction in cancerous stomachs, whereas bile salt hydrolase enriched in the gastric microbiota after gastrectomy.
Conclusion: The gastric microbiota changes in composition after gastrectomy, with differential enrichments in metabolic functions tightly associated with gastric environment.

Introduction: The duodenum represents a unique niche within the digestive tract, characterised by relatively acidic pH, digestive enzymes, and bile. Due to the harsh conditions, the duodenum has long been considered sterile, with bacteria only present as overgrowth resulting from immune deficiencies or motility disorders. Emerging evidence from molecular and culture based studies now supports the presence of bacteria in this region in healthy individuals. However, these studies are constrained by the issue of contamination: either during sampling, particularly from the upper GI tract (oral cavity and stomach); and/or during the technical steps involved with molecular studies.
Aims & Methods: To accurately characterise the duodenal microbiota, we developed the Brisbane Aseptic Biopsy Device (BABD), which is comprised of biopsy forceps protected by a sheath. This device allows targeted, aseptic sampling of the duodenal mucosa. The background microbiome signature in common reagents was also investigated, to further differentiate between resident microbiota and possible contamination. Patients undergoing upper GI endoscopy for iron deficiency, after an overnight fast, were recruited with ethical approval. Matched duodenal biopsies were obtained using the BABD. Total genomic DNA was extracted from samples and amplicon libraries spanning the V6-V8 region of the bacterial 16S rRNA gene were constructed. Reaction mixtures with no added DNA were processed in parallel. All libraries were sequenced using the Illumina MiSeq platform, with taxonomic assignment and bacterial community analysis performed through the QIIME bioinformatics pipeline.
Results: Microbial DNA was recovered from all biopsies obtained using either standard forceps or the BABD. Concurrent sequencing of controls also confirmed the presence of microbial DNA in common laboratory reagents. These sequences showed limited overlap with the duodenal samples, and were excluded during bioinformatics analysis, thereby restricting our comparisons to duodenum derived sequences. Phylogenetic based UniFrac evaluation of beta-diversity revealed samples collected using the BABD clustered together, and showed low levels of inter-individual variability. The duodenal microbiomes from all patients were dominated by *Streptococcus*, representing up to 50% of the total bacterial load, with lower levels of *Prevotella*, *Veillonella*, *Neisseria*, *Porphyromonas* and *Lactobacillus*. Some Streptococcal sequences recovered showed similarity to oral or lower gastrointestinal tract isolates, as well as common food-production organisms such as *Streptococcus thermophilus*. However, two-thirds of the more than 150 different taxonomically assigned sequences identified as *Streptococcus* did not match closely to the 16S reference database, suggesting unexplored diversity within this genus in the duodenum.
Conclusion: The combined use of the BABD and the elimination of contaminating DNA sequences allowed the duodenal mucosa-associated microbiota to be accurately characterised, and confirmed the presence of microbes that are specific to the duodenal niche.

[1]*Division of Hepatogastroenterology, Kaohsiung Chang Gung Memorial Hospital, Kaohsiung,* [2]*Division of Hepatogastroenterology, Chang Gung Memorial Hospital at Linkou, Taoyuan, Taiwan, Taoyuan, Taiwan, Province of China*

Contact E-mail Address: kengliang_wu@yahoo.com.tw
Introduction: *Streptococcus bovis/gallolyticus* (*S. bovis*) bacteria are reported to associate with colorectal cancer and adenoma. 25 to 80% of patients with S. bovis bacteremia have concomitant colorectal tumors. But few studies reported the relation between *Streptococcus bovis* infection with other gastrointestinal disease.
Aims & Methods: To clarify the incidence of gastrointestinal tract disease in patients with *Strep. Bovis*. bactercemia. From Jan. 2004 to Jan. 2014, total 107 patients infected with *Strep. Bovis* bacteremia were retrospectively chart reviewed

from Kaohsiung Chang Gung Memorial Hospital and basic data including age, gender, gastrointestinal diseases (liver disease, gallbladder stones, cholecystitis, pancreatitis, esophageal varices, peptic ulcer disease, colorectal polyp); abdomen echo, panendoscopy and colonoscopy findings were recorded. We analyzed the association between patients with gastrointestinal disease and *Strep. Bovis* bacteremia.
Results: 107 patients (60% male; 66 ± 14 years) were analyzed. Only 49 patients received colonoscopy and 27 (55.1%) patients had colorectal neoplasm (tubular adenoma: 12 (24.5%); tubulovillous adenoma: 5 (10.2%); villous adenoma: 1 (2.0%); adenocarcinoma: 9 (18.4%). 69 (64.5%) patients had liver disease (parenchymal liver disease: 31 (30.0%); 28 (26.2%) with Liver cirrhosis). 10 (9.3%) patients had gallbladder stone. 11 (10.2%) had acute cholecystitis. 2 (1.9%) had acute pancreatitis. 16 (15.0%) had esophageal varices. 24 (22.4%) had peptic ulcer disease.
Conclusion: In current study, 55.1% of patients with *S. bovis* bacteremia had concomitant colorectal tumors and 26.1% patients had liver cirrhosis. Colon study should be done in patients with *S. bovis* bacteremia. High incidence correlation with liver cirrhosis in patients infected with S. bovis could be due to their immunocompromised condition.

P1708 A RETROSPECTIVE STUDY FOR IDENTIFYING RISK FACTORS OF DELAYED HEMORRHAGE AFTER ENDOSCOPIC SUBMUCOSAL DISSECTION FOR GASTRIC TUMOR

K. Abe[1], A. Miki[1], T. Okamura[1], Y. Kawashima[1], H. Aoyagi[1], S. Kimura[1], A. Isono[1], T. Ebato[1], T. Yamamoto[1], H. Kita[1]
[1]*internal medicine, Teikyo University School of Medicine, Tokyo, Japan*

Introduction: Delayed bleeding is one of the serious complications of endoscopic submucosal dissection (ESD). In association with growing aged population, the number of elderly patients with gastric tumors has increased in Japan. Since the elderly have a several risk factors for hemorrhage, such as frequent use of antithrombotic drugs, there is concern about increase in delayed bleeding after ESD.
Aims & Methods: The purpose of this study was to clarify risk factors of delayed bleeding after ESD for gastric tumor. The study subjects were consecutive 103 patients (75 males and 28 females, mean age; 73.0 ± 8.3 years) who underwent ESD for single gastric lesion at Teikyo University Hospital (Tokyo, Japan) between 2010 and 2013. Cases in which two or more lesions were resected at the same procedure were excluded. Delayed bleeding was defined if patients presented hematemesis or hematochezia and blood or coagulants was found in the stomach by endoscopy. The following clinical factors were investigated by the chart review; gender, age, location of the lesion, operation time, tumor size, specimen size, use of oral antithrombotic drugs and heparinization.
Results: Of the study subjects, 19 patients occurred delayed bleeding. As for the clinical factors, specimen size was the significant risk factor for delayed bleeding (Bleed: 46.9 ± 18.7 mm, Nonbleed: 36.5 ± 12.9 mm, p-value: 0.005 by Student's t-test). Additionally, heparinization showed significant risk for bleeding on multivariate analysis (OR 2.278, 95%CI 1.254-11.951, p = 0.019), while oral antithrombotic drugs did not.
Conclusion: The specimen size and heparinization were significant risk factors for delayed hemorrhage after gastric ESD.

Introduction: Aspiration pneumonia is a well-known complication of emergent endoscopy for upper gastro-intestinal bleeding, however, little is known of the characteristics and risk factors for this complication. Endotracheal intubation may be effective for airway protection in this setting. But, in Japan, endoscopic procedure is usually performed without prophylactic endotracheal intubation for aspiration.
Aims & Methods: The aim of this study is to assess aspiration pneumonia after endoscopic hemostasis on the basis of single-center experience in Japan. Consecutive 504 patients who underwent endoscopic hemostasis for upper gastro-intestinal bleeding between January 2004 and January 2015 were enrolled. All procedures were performed under conscious sedation. The incidence rate, clinical course and potential risk factors for aspiration pneumonia, such as patient attributes (Age, sex, underlying conditions, and medication), and endoscopic hemostasis procedures were retrospectively analyzed. Multivariate logistic regression analysis adjusted for significant factors in univariate analysis was used to evaluate the risk factors for aspiration pneumonia.
Results: There were 381 male patients (76%)and the mean age was 65.2 ± 13.3 years. Five-hundred-four patients consisted of 361 non-variceal (72%) and 143 variceal (28%) bleeding. Thirty-one patients (6.2%) were diagnosed with aspiration pneumonia after endoscopic hemostasis. Fatal outcome occurred in 7 patients (1.4%). 8 patients (1.6%) were stepped up to intensive care unit and endotracheal intubations were performed in 3 patients (0.6%). The mean duration of antibiotic treatment was 8.6 ± 5.9 days. Multivariate analysis identified that age over 75 years (OddsRatio [OR] 5.35; 95% confidence interval [CI] 2.19-13.75, P = 0.0003), procedure time over 30 minutes (OR5.63;CI2.2-15.37, P = 0.0004), serum albuminlevel less than3.5mg/dl (OR5.16;CI1.36-34.25, P = 0.0365), and hemodialysis (OR3.43;CI1.16-10.28, P = 0.0258) were the independent risk factors which affected on aspiration pneumonia.
Conclusion: 6.2% patients developed aspiration pneumonia after endoscopic hemostasis. Age, longer procedure time, lower serum albumin level, and hemodialysis are the independent risk factors of aspiration pneumonia. Careful attention should be taken when managing patients with these attributes.

P1710 THE RISK OF PEPTIC ULCER BLEEDING IS HIGHEST IN *H. PYLORI* POSITIVE PATIENTS ON COMBINED ANTIPLATELET THERAPY

M. Venerito[1], R. Costanzo[1], C. Schneider[1], R. Breja[1], F.-W. Röhl[2], P. Malfertheiner[1]
[1]*Dept. of Gastroenterology, Hepatology and Infectious Diseases,* [2]*Institute for Biometrics and Medical Informatics, Otto-Von-Guericke University, Magdeburg, Germany*

Contact E-mail Address: m.venerito@med.ovgu.de
Introduction: The role of *Helicobacter pylori* infection in nonsteroidal anti-inflammatory drug (NSAID) and low-dose aspirin (LDA) induced peptic ulcer bleeding (PUB) is still controversial. Whether *H. pylori* infection increases the risk of PUB in patients on non-LDA antiplatelet agents (APA), anticoagulants, SSRI and steroids is not known.
Aims & Methods: This was a case-control study. Patients with PUD diagnosed by endoscopy from 01/2004 to 12/2014 were identified (N ± 1722, 60% males, mean age 65.7 ± 14.7). 978 (56.7%) had PUB (cases), 744 (43.3%) had uncomplicated PUD (controls). Demographics, intake of NSAIDs, LDA, APA, anticoagulants, SSRI and steroids were documented. *H. pylori* status was determined by ^{13}C urea breath test, histology, rapid urease test or serology.
Results: *H. pylori* infection (OR 1.25, 95% CI 1.01-1.54), aspirin (OR 1.73, 95% CI 1.37-2.18) and NSAID intake (OR 1.79, 95% CI 1.36-2.36) increased the risk for PUB. *H. pylori* infection increased the risk for NSAID- and LDA-induced PUB (OR 3.99, 95% CI 2.36-6.75 and OR, 3.83 95% CI 2.47-5.94, respectively). *H. pylori* increased the risk of PUB in patients on APA (OR 6.09, 95% CI 1.79-20.67) and anticoagulants (OR 1.69, 95% CI 1.06-2.71) but not in patients on SSRI and corticosteroids. Medication with APA dramatically increased the risk of LDA-induced PUB in *H. pylori*-positive PUD patients (OR 16.15, 95% CI 2.11-123.24).
Conclusion: *H. pylori* infection increases the risk for PUB in PUD patients on NSAIDs, LDA, APA and anticoagulants. *H. pylori* positive patients on combined antiplatelet therapy carry the highest risk for PUB.

P1711 ENDOSCOPIC LIGATION OF BLEEDING ESOPHAGEAL VARICES A "GOLD-STANDARD" TO IMPROVE

O. Caputi Iambrenghi[1], E. Lagouvardou[1], R. Francavilla[2], G. Martines[1], I. Ugenti[1], V. Memeo[1]
[1]*Department of Emergency and Liver Transplantation,* [2]*Azienda Ospedaliero Universitaria Policlinico -Bari, Bari, Italy*

Contact E-mail Address: gerrymartines@virgilio.it
Introduction: Endoscopic variceal ligation (EVL) is widely accepted as the optimum endoscopic treatment for oesophageal variceal haemorrhage.
Aims & Methods: The aim of the study was to evaluate the effectiveness and safety of endoscopic variceal ligation in the management of oesophageal variceal bleeding, to define risk factors for early variceal re-bleeding and to identify the best method to reach the variceal eradication.
We retrospectively evaluated all the endoscopic procedures performed in the last 23 years, form 1991 to 2014, in 370 cirrhotic patients with endoscopically proven esophageal hemorrhage treated by endoscopic variceal ligation. 241 patients (65%) with complete clinical-endoscopic data, were included in the study. The early re-bleeding after EVL was confirmed by clinical signs or endoscopy. All clinical features, endoscopic data and technical details of endoscopic treatment were entered in a stepwise multivariate logistic regression analysis to identify time and rate of variceal eradication and risk factors for rate early re-bleeding and mortality.
Results: The mean patient follow-up was 56 months (range: 6-150 months). In the 241 patients the average number of EVL was 2.7 (range: 2-5) performed in a period of 3 months. Primary hemostasis was obtained in 239 patients (99.1%), while early re-bleeding after EVL occurred in 16 patients (4.4%). The stepwise multivariate logistic regression analysis showed that: a) the worst the endoscopic classification of varices the higher the number of rubber bands placed on the first ($p < 0.001$) and following sessions ($p < 0.001$); b) the number of bands placed on the first session influences the necessity of further treatment (< 6 vs. > 6 bands; $p < 0.05$) and c) the chance of varices eradication decreases with the increase of the extension of the varices in the oesophagus (LI: 81% vs. LIM: 72% vs. LIMS 50%; $p < 0.05$).
Conclusion: A more intensive approach in EVL, especially in the first session, is rewarded by a lower incidence of early re-bleeding and a longer free interval before bleeding recurrence. We recommended to place the higher possible number of bands during the first treatment, waiting few minutes before ending the session to fully evaluate variceal recanalization from the upper perforating veins.

Contact E-mail Address: pedroavmcosta@gmail.com
Introduction: A second endoscopic therapy is generally advocated for patients with non-variceal upper gastrointestinal (GI) haemorrhage in the setting of re-bleeding[1]. Risk factors for endoscopic hemostasis failure have been described and involve both patient's and endoscopic features.
Aims & Methods: Study objective was to identify specific risk factors for failure of the second endoscopic therapy in order to improve selection of high-risk patients for rescue surgery. A retrospective cohort study considering all admissions to a tertiary center gastrointestinal intensive care unit from 2003 to 2014 was conducted. Patients with upper GI bleeding who were submitted to two endoscopic therapies were included. Patient's demographics, comorbidities and endoscopic findings were reviewed from medical records. Endpoints were re-bleeding/failure of hemostasis and 28-days mortality.
Results: A total of 64 patients (n = 64) were included. Mean age (72.4 ± 13.5); male:female ratio (2.7:1). Hemostatic failure occurred in 20.3% (n = 13) and 28-day mortality was 3.1% (n = 2). Lesions were mainly located in the stomach (45.3%) and bulb (39.1%) and most were ulcers (82%). Mean lesion size: 14.92 ± 11.8 mm; mean number of blood units transfused (5.88 ± 3.5 units). Univariate analysis unveiled female sex (p = 0.03) RR: 3.21 (CI 95% 1.26-8.24); absence of chronic liver disease/alcoholism (p = 0.027) RR:1.37 (CI:1.15-1.63); posterior duodenal wall lesions (p = 0.023 RR:3.37 (CI95% 1.38-8.22); ulcer size (p = 0.017); units of blood transfused (p = 0.001) and lower baseline hemoglobin (p = 0.03) correlated with endoscopic failure. Ulcer size showed positive correlation with mortality (p = 0.05). In a stepwise multivariate binary logistic regression analysis, ulcer size (p = 0.036) and number of units of blood transfused (p = 0.033) were the only factors positively correlated with therapy failure. Ulcer size (p = 0.036) also correlated with 28-day mortality.
Conclusion: In the setting of upper gastrointestinal non-variceal re-bleeding, patients with higher blood transfusion requirements and large ulcers are at greater risk of hemostasis failure on second endoscopic therapy. Early surgical consultation and ICU admission should probably be considered for these patients.

P1713 EFFICIENCY OF TERAPEUTIC ENDOSCOPY DONE BY FELLOW GASTROENTEROLOGISTS FOR BLEEDING ULCER

R. Oprita[1], G. Constantinescu[1], A. Ragea[1], A. Kostov[1]
[1]*Gastroenterology, Floreasca Clinical Emergency Hospital Bucharest, Bucharest, Romania*

Contact E-mail Address: andreiragea@gmail.com
Introduction: This is a descriptive study conducted in the Departement of Gastroenterology of Clinical Emergency Hospital Bucharest.
Upper gastrointestinal bleeding (UGIB) represents a substantial economic and clinical burden, with an incidence ranging from 48 to 160 cases per 100,000 adults per year. Historically, mortality has ranged from 10% to 14% and only recently has there been a suggestion of a possible decrease.
The training of young gastroenterologist in endoscopic management of the non-variceal bleeding has been a challenge.
Aims & Methods: To determine the outcome of patients with upper gastrointestinal non-variceal bleeding that received endoscopic treatment done by an gastroenterologist fellow on close supervision of an expert.
The study included 260 patients with bleeding ulcers admitted in Clinical Emergency Hospital Bucharest between January 2014 and December 2014. Very early endoscopy (< 6h) was performed on all pacients upon admission.
Results: 260 pacients (68.5% Male) with bleeding ulcer (49.6% duodenal ulcer, 49.2 gastric ulcer and 1.2% esophageal ulcer) were admitted between 0 and 20 days (mean admision duration 5,7 days +/- 7,6). 138 pacients (49.2% by an gastroenterologist fellow unde supervision by an expert) received terapeutic endoscopic treatment with Adrenaline, Alchool, Bipolar probe or hemoclip in different combinations.
Conclusion: Endoscopic treatment of bleeding ulcer done by an gastroenterologist fellow under close supervision by an expert is safe and with the same outcome for the pacient.

P1714 CLINICAL FEATURES OF DELAYED BLEEDING AFTER GASTRIC ENDOSCOPIC SUBMUCOSAL DISSECTION ASSOCIATED WITH HEPARIN BRIDGE THERAPY

T. Inoue[1,2], M. Tsujii[3], Y. Hayashi[1], K. Nagai[1], S. Yoshii[1], T. Fujinaga[1], Y. Tsujii[1], A. Maekawa[1], S. Hiyama[1], S. Shinzaki[1], K. Watabe[1], H. Iijima[1], T. Takehara[1]

Contact E-mail Address: taktaktakkun@gmail.com
Introduction: Heparin is administered to patients undergoing endoscopic treatment at high risk for thromboembolism. Anticoagulants have been known as a cause of delayed bleeding associated with endoscopic treatment, including endoscopic submucosal dissection (ESD). Little is known, however, about how heparin bridge therapy (HB) affects clinical outcome after gastric ESD.
Aims & Methods: The present study aimed to identify the clinical features of HB-associated delayed bleeding after gastric ESD. Data of consecutive inpatients who underwent ESD for gastric neoplasms in Osaka University Hospital between June 2004 and September 2014 were retrospectively investigated. Patients were categorized into a HB group or non-HB group, and the incidence of complication (delayed bleeding, perforation, and thromboembolism) was compared in two groups. The characteristics of HB-associated delayed bleeding were also investigated. The predictor of delayed bleeding after gastric ESD was analyzed using a multivariate analysis by logistic regression.
Results: A total of 605 patients with gastric neoplasm were identified. One hundred twenty-two cases have taken oral antiplatelet agents or anticoagulants, and of them, twenty-six patients were treated by gastric ESD under HB. Characteristics of patients were similar in two groups except for patient age. Four patients experienced delayed bleeding in the HB group (replaced from warfarin 3, novel oral anticoagulants 1), and the incidence of delayed bleeding was significantly higher in the HB group than the non-HB group (15.4% vs. 3.1%, respectively, p = 0.01). Bleeding onset was later in the HB group than the non-HB group [median postoperative day (range): 3.5 (1-5) vs. 1.0 (1-7), respectively], and hemorrhage volume tended to be more in the HB group [Average Hemoglobin reduction (g/dl): 4.6 ± 1.7 vs. 3.1 ± 1.3, p = 0.08]. Although two patients in the HB group required blood transfusion due to massive delayed bleeding, all bleedings were endoscopically controlled. One patient experienced transitional ischemic attack in the HB group. Procedure time, en bloc resection rate, and incidence of perforation were similar in two groups. Hospitalization was significantly longer in the HB group than the non-HB group. The univariate and multivariate analysis showed that HB was the predictor of delayed bleeding after gastric ESD [Odds ratio (95% Confidence Interval): 6.33 (1.67-19.83), p = 0.009].
Conclusion: HB was a predictor of delayed bleeding after gastric ESD, and HB-associated delayed bleeding is characterized by high incidence, late onset, and massive bleeding, resulting in prolonged hospitalization.

Introduction: Despite different scores have been suggested to predict several outcomes in the setting of upper gastrointestinal bleeding (UGIB), few comparative studies have been published. Our aim was to evaluate the accuracy of 5 different scores in predicting different outcomes, namely clinical intervention, rebleeding, and mortality.
Aims & Methods: Between January/2011 and December/2014, 433 UGIB episodes were selected. Pre- (PreRS) and post-endoscopic Rockall scores (PostRS), Glasgow-Blatchford score (GBS) and its simplified version (sGBS) as well as AIMS65 score were calculated for each patient. Areas under the receiver operating characteristics curve (AUROC) were used to evaluate the performance of each score to predict clinical intervention (blood transfusion, endoscopic therapy, surgery, or admission to intermediate care unit), as well as 30-day rebleeding or mortality.
Results: From the analysed patients, 281 (64.9%) were men and the median age was 67.8 years. The most common endoscopic findings were gastric ulcers (16.9%), esophageal varices (15.2%), and duodenal ulcers (14.8%). PreRS, PostRS, GBS and sGBS were calculated for all patients, but AIMS65 calculation was only possible for 315 patients. Any of the 5 scores was good in predicting need for endoscopic therapy or admission to intermediate care unit. GBS and sGBS were good in predicting blood transfusion (AUROC = 0.853, 95% CI, 0.812-0.893; AUROC = 0.854, 95% CI, 0.814-0.894, respectively) and reasonable in predicting surgery (AUROC = 0.734, 95% CI, 0.610-0.859; AUROC = 0.766, 95% CI, 0.640-0.893, respectively). Any of the scores was useful in predicting rebleeding. Only PreRS and PostRS were able to fairly predict 30-day mortality (AUROC = 0.711, 95% CI, 0.618-0.805; AUROC = 0.731, 95% CI, 0.640-0.823, respectively).
Conclusion: Owing the identified limitations, any of the 5 studied scores can be singly used to predict all the clinically relevant outcomes in the setting of UGIB. The simplified version of Glasgow-Blatchford score is as precise as its original version in predicting blood transfusion and surgery. Pre- and post-endoscopic Rockall Scores are the only scores that can predict 30-day mortality. Any of the 5

scores is sufficiently accurate in predicting endoscopic therapy or rebleeding. When globally applied to patients with UGIB, AIMS65 score seems to be useless.

Introduction: Non-variceral gastrointestinal bleeding (NVUGIB) is still a life-threatening disease. It has been known that early endoscopic hemostasis (EH) improves outcomes in patients with NVUGIB. However, it's sometimes difficult to decide whether to perform urgent endoscopy in clinical practice. Some scoring systems are used for determination of need for HE of NVUGIB such as Glasgow-Blatchford score (GBS) and clinical Rockall score. They can securely exclude patients who don't need EH because of its high sensitivity, whereas the specificity remains less than 10%. Therefore, if other predictors for EH are clarified, we would be able to narrow down indication criteria of urgent endoscopy more efficiently.

Aims & Methods: This study was aimed to assess predictors for requirement of EH.

This was a retrospective cross-sectional study from a tertiary hospital. A total of 317 consecutive patients who underwent urgent endoscopy suspected of NVUGIB from April 2010 to March 2014 were included. Requirement of EH was defined as high-risk stigmata for bleeding based on Forrest classification (Ia, Ib, or IIa) by reviewing the recorded endoscopic images. We analyzed the association between high-risk stigmata and clinical factors (age, gender, antiplatelet/anticoagulant therapy, history of gastro-duodenal ulcer (GDU), systolic blood pressure (SBP), heart rate (HR), hemoglobin (Hb), mean corpuscular volume (MCV), PT-INR, blood urea nitrogen-creatinine ratio (BUN-Cr ratio), GBS) using multivariate logistic regression model. Factors were selected by stepwise method.

Results: One hundred thirty three (43.2%) patients underwent EH. History of GDU [OR 3.07, 95% C.I. 1.81-5.27], SBP [OR 1.17 (every 10), 95% C.I. 1.07-1.28], Hb [OR 1.10, 95% C.I. 1.02-1.19], BUN-Cr ratio [OR 1.21 (every 5), 95% C.I. 1.13-1.30], and GBS [OR 1.19, 95% C.I. 1.12-1.28] was significantly associated with high-risk stigmata for EH. In multivariate analysis, Age, HR, history of GDU, BUN-Cr ratio and GBS were selected as factors according to stepwise method. Of these, history of GDU was an independent risk factor for high-risk stigmata [OR 3.21, 95% C.I. 1.82-5.75] as well as HR [OR 1.14 (every 10), 95% C.I. 1.00-1.31], BUN-Cr ratio [OR 1.15 (every 5), 95% C.I. 1.07-1.25] and GBS [OR 1.17, 95% C.I. 1.08-1.27].

Conclusion: Previous history of GDU is an independent predictor for EH for NVUGIB. A careful medical interview in clinical practice would help us to decide whether to perform urgent endoscopy.

Introduction: Recurrence of achalasia cardia after laparoscopic Heller's cardiomyotomy (LHM) or endoscopic balloon dilatation (EBD) is not uncommon. Reported incidence is up to 30%. Per-oral endoscopic myotomy (POEM) is an emerging treatment modality for achalasia cardia. This study reports results of POEM in patients suffering from recurrent achalasia cardia.

Aims & Methods: Consecutive patients with achalasia cardia confirmed on endoscopy (EGD), high-resolution manometry (HRM) and barium swallow and undergoing POEM at three centers were included. Previous treatments for achalasia were recorded. Eckhardt dysphagia score was recorded before and after the procedure. Procedure time, technical success and complications were noted. Follow up was by EGD, HRM at 4 weeks and subsequently monthly by telephone.

Results: Out of 61 patients undergoing POEM over a 22-month period, 20 (32.78%) patients had history of previous treatment for achalasia cardia whereas 41 were naïve patients. Mean age 51.8 years, females – 5. Achalasia Type: I – 8, II – 12, III – nil. Previous therapies included – Heller's myotomy (4), balloon dilatation (14) botulinum injection (1), and POEM (1). Median symptom duration: 66 months. Mean pre-procedure Eckhardt score – 7.14 (range 6 – 9); mean LES pressure 34.94mmHg (17 – 68mmHg). Technical success was 100%. Technical difficulties were encountered during 9 procedures (45%); sub- mucosal fibrosis leading to difficult tunneling in 5, difficult entry due to thickened mucosa in 3 and thickened circular muscle causing difficult myotomy in 1. Mean procedure duration was 107.1 minutes (30 – 270). In comparison, mean procedure duration for the naïve group was 91.7 minutes (45 – 330). ($p > 0.05$, non significant). Clinical success (100%) and no major complications were encountered in both groups. Relief of dysphagia was seen in all 61 patients (100%). At 4-weeks follow up, mean Eckhardt score was 1.41 (range 1 – 2) and mean LES pressure was 10.4 (range 7 – 19). At mean 9-month (range 3 – 22) follow up, mean Eckhardt score remained at 1.48. Occasional heartburn was seen in 5/20 (25%) patients.

Conclusion: POEM is safe and effective treatment for both naïve and recurrent achalasia cardia. Although technical difficulties were encountered in nearly 50% patients in the recurrent group, there was no significant difference in the mean procedure time or complications in both naïve and recurrent groups.

Contact E-mail Address: nick.debortoli@gmail.com

Introduction: The introduction of high resolution manometry (HRM) in clinical practice implied the use of a new classification for motility abnormalities, the Chicago classification (CC). The CC introduced a novel diagnosis to define a manometric picture characterized by impaired relaxation of the lower esophageal sphincter and normal peristalsis: the outflow obstruction (OO). However, limited HRM and clinical data are available on the characteristics of patients presenting this manometric feature.

Aims & Methods: This study aimed to evaluate and compare the characteristics of consecutive patients with a manometric diagnosis of OO with those of a group of patients with GERD. Secondary aim was to evaluate their reserve of esophageal peristalsis by means of multiple rapid swallow (MRS).

Among 112 consecutive HRM, we included 21 patients with an HRM diagnosis of OO, characterized by impaired EGJ relaxation (Integrated Relaxation Pressure; IRP > 15 mmHg) but preserved peristalsis and 21 consecutive patients with GERD, as control patients group (CG). All patients underwent HRM after suspending proton pump inhibitors or prokinetics. We evaluated EGJ basal and maximal pressure, prevalence of compartimentalized waves (pressurization of > 30mmHg extending from front contractile to the EGJ) and intrabolus pressure (IBP) in both groups. All patients underwent a provocative MRS (4ml x 5 times consecutively). IRP and distal contractile integral (DCI) during MRS was evaluated in both groups. Ratio DCI MRS/wet swallow was also calculated and considered normal when higher than 1.

Results: Mean age (58 ± 14.4 vs 56.6 ± 17.4), female (15 vs 12) and BMI (24.2 ± 3.2 vs 22.7 ± 2.7) were similar in both group ($p = ns$). Dysphagia (100%) and regurgitation (59%) were prevalent symptoms in OO. Heartburn (100%) was the prevalent symptom in CG, whereas dysphagia was absent and regurgitation (28.6%) was less frequent. EGJ basal (32.6 ± 11.6 vs 19.5 ± 11.6) and maximal pressure (48.4 ± 13.7 vs 30.4 ± 13.3) were higher in OO ($p < 0.001$). Compartimentalized waves were found in 71.4% of OO patients. As shown in Table 1, IBP was higher in OO ($p < 0.005$). DCI-MRS was two time higher in CG group than in OO. IRP during MRS decreased under 15mmHg in 9/22 (40.9%) of patients with OO. DCI MRS/wet swallow ratio was > 1 in 20/21 patients from CG but only in 3/21 in OO.

Table 1: Main HRM finding between patients with OO and those with CG

	OO	CG	P value
IRP mean (sd)	21.3 (5.3)	9.7 (3.9)	< 0.0001
DCI mean (sd)	1864.4 (1085.7)	1352.1 (911.2)	0.106
DL mean (sd)	6.9 (1.3)	6.7 (1)	0.770
Intra bolus pressure, mean (sd)	20.6 (13.5)	11.2 (5.5)	0.005
MRS mean (sd)	949.9 (620.4)	1884.6 (1493)	0.011
MRS-IRP (sd)	16.7 (9.2)	6 (3.4)	0.001
DCI MRS/wet swallow ratio (sd)	0.6 (0.4)	1.4 (0.8)	< 0.0001

Conclusion: In our cohort, the diagnosis of OO was always associated with the presence of obstructive symptoms (dysphagia ± regurgitation) as major complaint supporting the relevance of this manometric diagnosis which can be achieved by HRM. Moreover, the reserve of esophageal function evaluated with MRS and DCI MRS/wet swallow ratio showed a reduction in OO group. These parameters should be considered in outcome studies evaluating endoscopic treatment in patients with OO.

P1719 CAN PER-ORAL ENDOSCOPIC MYOTOMY BECOME AN ELECTIVE TREATMENT FOR ACHALASIA ALSO IN CHILDREN?

P. Familiari[1], G. Gigante[1], A. Calì[1], L. Dall'Oglio[2], T. Caldaro[2], P. De Angelis[2], I. Boskoski[1], A. Tringali[1], V. Perri[1], G. Costamagna[1]
[1]*Digestive Endoscopy Unit, Gemelli University Hospital,* [2]*Digestive Surgery and Endoscopic Unit, Bambino Gesù Children's Hospital, Rome, Italy*

Contact E-mail Address: pietrofamiliari@tiscali.it

Introduction: Achalasia is very rare in pediatric patients. The usual therapy of achalasia in children is Heller myotomy. Peroral Endoscopic Myotomy (POEM) is a fascinating technique for the treatment of achalasia in adults. Few small series reported on this technique in a pediatric population. We report on a consecutive, prospective, series of children with achalasia who underwent POEM.

Aims & Methods: Between May 2011 and April 2015, 252 patients underwent POEM in a single tertiary referral endoscopy center. Patients who were younger than eighteen were included in this study. Patients were treated with a standard technique. After treatment, patients underwent a close follow-up including physical examination, EGD, high-resolution manometry, barium swallow and pH-monitoring study. The clinical history, procedural data and follow-up information were prospectively collected and analyzed.

Results: Eighteen patients (10 male, mean age 11.9, range 6-17 years) underwent POEM during the study period. In 16 patients achalasia was sporadic; 1 patient had Down's Syndrome, 1 patient was diagnosed with Allgrove's Syndrome. Patients have been presenting symptoms for a mean of 12 months (3-60 months) before the treatment. Growth retardation was a common sign. Preoperative mean Eckardt score was 7.6. Eight patients (50%) especially complained with respiratory symptoms (chronic cough and/or pneumonia). According to the Chicago Classification, 5 patients had type I achalasia, 9 patients type II and 1 type III. Three patients had a diagnosis of classic-type achalasia at standard manometry. One patient (5.6%) underwent one pneumatic dilation before POEM. Length of the myotomy was on average 11cm, but it was usually customized according to the length of the esophagus (range 8-14cm). Mean operative time was 59 minutes (range 37–82 minutes).

No significant adverse events or complications occurred during or after POEM. Median postoperative hospitalization was 3 days. POEM was clinically successful (Eckardt score < 4) in all the patients, during a mean follow-up of 11 months (1-36 months). All the patients gained weight and had a regular growth. Mean Eckardt score after POEM was 0.2. Mean postoperative 4sIRP was 11mmHg. Postoperative EGD revealed reflux esophagitis in 19% (2 out of 11) of the patients who underwent EGD during follow-up. Esophagitis healed completely after therapy with proton pump inhibitors. Only these two patients complained with heartburn. No patients required additional treatments after POEM.

Conclusion: Preliminary results show that POEM is safe and effective for the treatment of achalasia also in pediatric patients. However, because of the lack of long-term evaluations, and the potential risk of the consequences of a iatrogenic GERD, POEM should be still considered an investigational procedure in pediatric patients.

P1720 HETEROGENEITY IN HIGH-RESOLUTION MANOMETRY AROUND THE WORLD

R. Sweis[1], **M. Fox**[2]
[1]*GI Services, University College London Hospital, London, United Kingdom,* [2]*iDigest: Zürich Center for Reflux and Swallowing Disorders Functional GI Diagnostics Laboratory Division of Gastroenterology and Hepatology, University Hospital Zürich, Zurich, Switzerland*

Contact E-mail Address: dr.ramisweis@gmail.com

Introduction: Advances in High-Resolution Manometry (HRM) and the development of the Chicago Classification for esophageal motor disorders have enhanced our understanding of esophageal (dys)function; however much of what is observed remains subjective and open to interpretation. Before considering the developmant of standards in operating procedures, a better understanding of what actually takes place in labs around the world is required.

Aims & Methods: To assess current practice among clinicians and scientists performing manometry around the world.

An on-line survey was distributed through international NGM societies to esophageal laboratories using the internet-based Qualtrics platform. Questions explored infrastructure, staffing, technology, analysis and reporting in HRM. Responses from all labs were then compared.

Results: 90 labs from around the world responded (thus far); 45 were from the Europe (Figure 1). Overall 42 labs receive more than 500 referrals per year (22 in Europe). Of the 14 labs that see more than 1000 referrals per year, 7 are in Europe. High volume (HV; >500/year) and Low volume (LV; <500/year) centers employ a median of 7 and 6 members of staff ($p = 0.03$) and 4 and 3 non-clinicians respectively ($p = 0.09$). Europe employs a median of 8 members of staff overall, 5 of whom are non-clinicians.

74/90 (82%) centers internationally and 33/45 (73%) in Europe use at least a 26 sensor HRM system. Furthermore 52/90 (58%) in total, 20/45 (44%) in Europe and 14/14 (100%) centers in the USA also have HRM-Impedance systems. Water-perfused catheters are less common in the West (15/45 in Europe, 1/8 in South America (SA), 0/14 in USA) as opposed to 8/12 centers in Australia/New Zealand (NZ) and 7/11 centers in Africa/Asia/Fareast. 33% HV and 38% LV centers use water-perfused systems. Some form of anesthetic is used in the nares in 34/42 (81%) HV and 37/48 (77%) LV centers ($p = 0.15$).

Overall HRM studies in the Upright-seated position are included in 38/90 (42%) centers. Some form of adjunctive test is incorporated in 90% of all centers (Figure 1). Although Multiple swallows of water is the most common (70%), 56/90 (62%) centers use more than one adjunctive test (including single solids and/or meals). 64/90 centers use the Chicago Classification routinely, 21 sometimes, 1 rarely and 4 never.

When determining the lower esophageal sphincter margins, there is wide variation in whether to include/exclude a hiatus hernia of less or greater than 3 and 5cm ($p = NS$). There is general uniformity in the content of the final HRM report apart from inclusion of 'therapeutic recommendations' which is more likely in HV (23/42; 54%) than LV (18/48; 38%) centers ($p = 0.05$).

	Adjunctive tests (routinely/ as required)	Single solid/ Viscous swallows	Multiple swallows of water/ Free drinking	Meal	Upright-seated
Europe (n = 45)	40 (89%)	31 (69%)	37 (82%)	10 (22%)	18 (40%)
USA (n = 14)	10 (71%)	6 (43%)	7 (50%)	3 (21%)	6 (43%)
South America (n = 8)	8 (100%)	4 (50%)	7 (88%)	0 (0%)	5 (63%)
Australia/NZ (n = 12)	11 (92%)	3 (25%)	8 (67%)	2 (17%)	6 (50%)
Asia/Africa/ Fareast (n = 11)	11 (100%)	5 (45%)	4 (36%)	1 (9%)	3 (27%)
Total (n = 90)	80 (89%)	49 (54%)	63 (70%)	16 (18%)	38 (42%)

Conclusion: There is marked heterogeneity in the methodology, interpretation and presentation of HRM studies in esophageal laboratories around the world. Mechanisms to improve quality and uniformity in testing and reporting are required. This survey sets the background upon which standards can be developed.

P1721 THE ROLE OF INTEGRATED RELAXATION PRESSURE IN ACHALASIA AND ITS MODIFICATION AFTER HELLER MYOTOMY

R. Salvador[1], E. Savarino[1], E. Pesenti[1], L. Spadotto[1], F. Galeazzi[1], L. Nicoletti[1], S. Merigliano[1], M. Costantini[1]
[1]*University of Padova, Padova, Italy*

Contact E-mail Address: renato.salvador@libero.it

Introduction: A new classification for the diagnosis of primary esophageal motility abnormalities by means of High Resolution Manometry (HRM) has been recently proposed and a new parameter, the Integrated Relaxation Pressure (IRP), has been included for the assessment of esophagogastric junction (EGJ) relaxation. Indeed, the diagnosis of achalasia is established by HRM on the basis of an IRP $>$ 15mmHg and absence of normal peristalsis in the esophageal body.

Aims & Methods: The aims of this study were: a) to investigate the correlation of IRP values with the diagnosis of achalasia, the demographics and clinical findings in a group of consecutive well-defined achalasia patients, b) to assess the effect of Heller myotomy on IRP. We evaluated all consecutive patients who underwent laparoscopic Heller myotomy as first treatment from 2009-14 and had a HRM evaluation before surgery. Patients who had already been treated for achalasia (with Heller myotomy, endoscopic treatment) were excluded. The diagnosis of achalasia was established by manometry on the basis of accepted esophageal motility characteristics. Symptoms were collected and scored using a detailed questionnaire for dysphagia, food-regurgitation, and chest pain; barium swallow, endoscopy, HRM were performed, before and 6 months after surgical treatment.

Results: 139 consecutive achalasia patients (M:F = 72:67) represented the study population. All the patients had 100% simultaneous waves but 11 had a IRP $<$ 15 mmHg. According to the HRM classification, patients were classified as having: 60 (43.2%) type I, 63 (45.3%) type II and 16 (11.5%) type III.

At univariate analysis IRP was correlated with the gender, the basal and residuak lower esophageal sphincter (LES) pressure, and the dysphagia score (Table). All the patients had absence of normal peristalsis, but 11(10.9%) had an IRP $<$ 15 mmHg. All these patients had a barium swallow showing a grade I disease. At a median follow-up of 28 months, the symptom score was significantly lower after surgery (median preoperative score 18 [IQR 11-20] vs median postoperative score 0 [IQR 0-3]; $p < 0.0001$). The resting LES pressure (median preoperatively 27 [IQR 19-36] vs median postoperatively 11 [IQR 8-14]; $p < 0.001$) and IRP (median preoperatively 27.4 [IQR 20.4-35] vs median postoperatively 7.1 [IQR: 4.4-9.8]; $p < 0.001$). The failures of surgical treatment were 7 (5%).

Esophageal diameter *	–0.03	0.79
LES basal pressure *	0.56	**$<$0.001**
LES total length	0.17	0.08
LES abdominal length	0.15	0.14
LES residual pressure *	0.86	**$<$0.001**
Dysphagia score *	0.21	**0.002**
Symptoms score *	0.14	0.17

Conclusion: This is the first study evaluating the role of IRP in achalasia and its modifications after myotomy. An increased preoperative IRP directly correlate with severity of dysphagia in achalasia patients. IRP is reduced to normal values by Heller myotomy. Moreover, the occurrence of an IRP $<$ 15mmHg in more

than 10% of patients despite a clinical/radiological/endoscopic diagnosis of achalasia, requires caution in considering this parameter as a discriminating condition in the manometric diagnosis of the disease.

P1722 IMPAIRED RELAXATION OF THE LOWER ESOPHAGUS SPHINCTER – IS IT ALWAYS PRIMARY ACHALASIA? A CASE SERIES OF 31 PATIENTS WITH ACHALASIA

S. Welsch[1], H. Schulz[2], J. Krapp[2], E. Mayatepek[1], **M. Friedt**[1]
[1]*Department of General Pediatrics, Neonatology and Pediatric Cardiology, Division of Pediatric Gastroenterology, University Hospital, Heinrich-Heine-University Düsseldorf, Germany, Düsseldorf,* [2]*Department of Genereal surgery, Protestant hospital, Castrop-Rauxel, Castrop-Rauxel, Germany*

Contact E-mail Address: simon.welsch@med.uni-duesseldorf.de
Introduction: We report 31 cases of chronic dysphagia with an impaired function of LES treated in two centers between 2005 and 2014. Patients' notes were retrospectively analyzed.
Aims & Methods: Patients' notes were retrospectively analyzed.
Results: Mean age of patients was 14.2 years (7.1-17.6). Half of the patients were female. In 30 cases primary esophageal achalasia was diagnosed. Main symptoms were dysphagia, weight loss, regurgitation, vomiting and heartburn. Half of the patients had respiratory complications.
In one quarter of our patients recurring respiratory complications were misdiagnosed as asthma. Additionally, in 8 patients esophageal candidiasis was detected years before diagnosis of achalasia and could have led to early considering of esophageal motility disorder. In another 7% of patients dysphagia and dystrophy was misdiagnosed as eating disorders.
Bridging therapy with nifedipine showed good results but had to be discontinued in all patients due to side effects. Injection of botulinum toxin into LES had a primary success rate of 83%. Symptom-free interval was only 3 months and repeated interventions were necessary leading to surgery as definite therapy. Repeated pneumatic dilatation (PD) was performed in 63% of the patients and led to a short relief of symptoms for 3 months. Prevention of surgery by PD was not achieved in our cohort. All patients with primary achalasia underwent surgery consisting of Heller's myotomy and an anti-reflux procedure. Minor complications occurred in 10% but did not need extended surgical therapy going beyond intraoperative ligation of small esophageal perforations and did not extend length of hospital stay nor increased postoperative morbidity. At 1-year follow-up 64% were symptom-free. Symptomatic patients complained about heartburn but not dysphagia. After surgery good thriving could be achieved as BMI at follow-up increased by 19 percentiles above BMI at initial presentation.
Interestingly, one patient presented with chronic dysphagia and diagnostics were consistent with achalasia. Additional MRI showed leiomyoma of the esophagus leading to secondary achalasia.
Conclusion: Early and correct detection of achalasia is often impaired by heterogeneous clinical manifestations and low sensitivity of diagnostic tools. Misdiagnoses and inadequate or delayed therapy is common. Oral nifedipine, intraesophageal injection of botulinum toxin and/or pneumatic dilatation can provide a short relief of symptoms. Heller's myotomy combined with a reflux procedure as definite therapy showed good clinical and diagnostic results at follow-up. Additionally, endosonography or MRI of the esophagus might be useful to detect secondary achalasia due to extraesophageal tumors.

P1723 AN INSERTION OF 8 AMINO ACIDS IN THE CYTOPLASMIC TAIL OF HLA-DQB1 IS A STRONG RISK FACTOR FOR ACHALASIA IN SWEDEN

S. Haas[1], J. Becker[2], Z. Ateeb[1], P. Elbe[1], S. Kostic[3], M. Lindblad[1], J. Schumacher[2]

Contact E-mail Address: stephan.haas@ki.se
Introduction: Idiopathic achalasia represents a motility disorder of the esophagus and is characterized by a failure of the lower esophageal sphincter to relax due to a loss of neurons in the myenteric plexus. Most recently, an insertion of 8 amino acids in the cytoplasmic tail of HLA-DQβ1 has been identified as being independently disease-associated.[1]
Aims & Methods: The goal of the present study was to assess whether this variant also confers risk in a Swedish population. Moreover we aimed to compare the frequency found in Sweden with those found in other European conutries. We genotyped the marker rs28688207 in 171 achalasia patients from Sweden. To obtain the information of the insertion in a control cohort, we used a genome-wide genotyped dataset of 732 controls and applied SNP2HLA to imput the insertion. In addition, we analyzed samples from 5 other EU countries (Belgium, Germany, The Netherlands, Spain and Italy; (n = 1480)) that were part of our previous study, but which have not been evaluated separately up to now.[1]
Results: The insertion showed a strong association in the cohort of 171 patients ($P = 7.44 \times 10\text{-}05$; RR = 2.93) with a frequency of 6.1% in patients and only 2.2% in controls. Of note, the frequency of the insertion exhibited a geospatial north-south gradient and was nearly four times more common in southern compared to northern Europeans and showed a stronger attributable risk (AR) in southern Europeans.
Conclusion: The variant rs28688207, which leads to an alternative splicing of the HLA-DQB1 exon 5, is a strong genetic risk factor for achalasia in Swedish patients with achalasia. In addition, the prevalence of achalasia appears to differ geo-epidemiologically.

P1724 OUTCOMES OF PNEUMATIC DILATIONS ACCORDING TO ACHALASIA SUBTYPES

Y. Badat[1], E. Chabrun[1], R. Beyssac[1], H. Lamouliatte[1], F. Zerbib[1]
[1]*Gastroenterology, CHU bordeaux, Bordeaux, France*

Contact E-mail Address: frank.zerbib@chu-bordeaux.fr
Introduction: The treatment of achalasia is not consensual. Some studies have suggested that the response to endoscopic treatment may be influenced by achalasia subtypes as defined by the Chicago classification. The aim of this single-center study was to assess the efficacy of pneumatic dilations according to the different achalasia subtypes.
Aims & Methods: From January 2010 to September 2013, 49 treatment-naive patients were included in our study (20 men, mean age 64.8 +/- 17.3 years). Achalasia subtypes were diagnosed with high resolution manometry (Given Imaging), and classified as type I (no contraction and no esophageal pressurization), type II (esophageal pressurization > 20% of cases) and type III (esophageal premature contractions > 20% of cases). Pneumatic dilations were performed with balloons ranging from 30 to 40 mm until clinical remission (Eckardt score $\leq$3 with each item $<$2) and during follow-up in cases of symptomatic recurrence. Predictive factors of remission were determined by univariate and multivariate analysis using a logistic regression model.
Results: Initially, pneumatic dilation achieved clinical remission in 85% of patients. After a median follow-up of 27 months (5 to 48 months), overall remission rate was 71%, significantly higher for type II (76.6%) and type I (63.6%) than for type III (25%) ($p = 0.024$). In comparison with type II, type III was associated with treatment failure (OR 9.8; 95% CI: 1.6-60.2). Seven patients had surgery, including 25% of type III patients. The overall evolution of the Eckardt score was less favourable for type III compared to type II or I ($p = 0.0006$). In univariate analysis, in addition to achalasia subtypes, female gender ($p = 0.016$) and number of dilations ($p = 0.0002$) were associated with treatment failure. In multivariate analysis, only achalasia subtypes ($p = 0.039$) and female gender ($p = 0.018$) were associated with treatment failure. At the end of follow-up, 35 patients (71%) were in remission after treatment with pneumatic dilations of all types. There was no dilation-related esophageal perforation in this series.
Conclusion: This single-center study further confirms that type III achalasia has less favourable outcome after pneumatic dilation. Whether this subtype should be preferably treated by endoscopic or surgical myotomy needs to be determined by adequate studies.

Introduction: Functional dyspepsia (FD) is gastrointestinal disorder in which the patient suffers from chronic abdominal symptoms despite the absence of organic disease. The cause of functional dyspepsia is unclear and treatment is not efficacious. Benachio Q soln.® is a new prokinetic herbal medicine fomulated with Licorice, Corydalis tuber, Fennel, Citrus unshiu, Ginger, Cinnamon bark, Atractylodes rhizome. Several studies showed that Corydalis tuber, Citrus unshiu, Ginger, Cinnamon bark, Atractylodes rhizome promoted gastric motor function and Licorice, Fennel improved dyspepsia symptoms.
Aims & Methods: The aim of the present study is to determine the efficacy and safety of Benachio Q soln.® in patients with postprandial distress syndrome (PDS), subtype in FD. A single-center, randomized, double-blind, placebo-controlled pilot study was performed in 20 patients with PDS. Patients were assigned to receive either Benachio Q soln.® or placebo t.i.d. After 4 weeks of treatment, the data of response rates, symptoms severity of PDS and gastric emptying time were analyzed for its efficacy. Adverse events, laboratory tests and vital sign were analyzed for its safety.
Results: Nine and 10 patients were assigned to the Benachio group and placebo group. The response rate after 4 weeks were 44.4% and 20.0% in Benachio and placebo group, respectively ($p = 0.350$). The response rates during first week of Benachio group were better compared with placebo group but without statistical significance (33.3% vs 0.0%, $p = 0.087$). Changes of severity score in early satiety on second and third week were -1.8 ± 0.6, -1.9 ± 0.4 and -1.3 ± 0.5, -1.4 ± 0.6 in Benachio and placebo group, respectively ($p = 0.059$ vs $p = 0.033$). No adverse event, significant change of laboratory tests and vital sign were observed.

Conclusion: A new herbal drug, Benachio Q soln.® improved the symptoms of PDS subtype in FD and can be used safely.

Introduction: Patients with hypermobility type Ehlers-Danlos syndrome frequently present with debilitating functional upper gastrointestinal (GI) symptoms including early satiety, bloating, epigastric pain and postprandial distress. EDS-HT is characterized by abnormalities in collagen synthesis potentially resulting in altered mechanical characteristics of the gastric wall serving as a theoretical background for explaining upper GI symptoms. In this study we investigate gastric emptying and motility using Magnetic Resonance Imaging in a group of EDS-HT patients and matched healthy controls.
Aims & Methods: Six patients (mean age 34, range 26 to 50, all female) with a diagnosis of hypermobility-type Ehlers-Danlos (EDS-HT) and referred with upper GI symptoms to a tertiary referral centre were prospectively recruited. An additional six age, sex and body mass index matched healthy subjects were recruited as controls. EDS-HT patients discontinued all motility influencing medication approximately four days before their MRI scan. All subjects' lay prone in a Philips Achieva 3T MRI scan and underwent baseline anatomical (3T BTFE BH) and motility (2D BTFE FB) imaging through the stomach before consuming 300ml of water. The anatomical and motility scans were repeated immediately following the water drink and repeated at 10 minute intervals for a total of 60 minutes. An experienced gastroenterologist manually segmented the total stomach volume for each subject from the anatomical images to provide:
1) Gastric emptying time defined as the time taken for 50% of the water bolus to clear the stomach adjusted for baseline gastric content.
2) Gastric accommodation examined by segmenting the gastric volume above the incisure before and after water challenge presented as a percentage change in volume.
3) Gastric motility was measured by plotting the diameter of the gastric lumen at the incisure and counting the number of contractions that occluded $>10\%$ of the mean gastric diameter at that location, standardised as contractions per minute.
Gastric emptying, accommodation and motility was compared between EDS-HT patients and controls using the paired t test.
Results: 1) The mean gastric emptying time for the EDS-HT patients was 16 minutes (range 8 to 26) and for the healthy controls was 25 minutes (range 8 to 30), $P=0.04$.
2) Gastric accommodation in EDS-HT showed an increase in volume of 244% (range 82 to 468%) and in controls was 317% (range 170 to 567%) with a mean difference of 73%, $P=0.3$.
3) The mean number of contractions for the EDS patients was significantly lower than that of healthy controls (1.1cpm (range 0 to 2.7) vs 2.9cpm (range 2.3 to 3.6), respectively, $p=0.006$.
Conclusion: Gastric empting appears accelerated in EDS-HT patients compared to controls despite a decreased number of contractions. This may reflect disturbances in gastric motor activity and/or altered mechanoelastic properties of the stomach. The protocol was well tolerated by all subjects further supporting MRI's value as a non-invasive, safe and quantitative method to interrogate gastric physiology.

Introduction: Proton pump inhibitors (PPIs) are the most effective antisecretory compounds used in the treatment of acid-related diseases and represent today the most widely prescribed class of drugs. Some studies have shown that generic PPIs are less effective than the corresponding branded formulations. However, available data are scarse and sparse.
Aims & Methods: The purpose of this study was to evaluate the effect of these drugs on serum levels of amidated gastrin-17 (G-17) and pepsinogens (PGI & PGII) in dyspeptic patients and to compare the antisecretory efficacy of branded and generic PPIs.
740 dyspeptic patients ($M=268$, $F=472$, mean age $=45.6\pm14.7$ years, range = 18-86 years) under PPI therapy for at least 1-3 months and without any alarm symptom (i.e. dysphagia, anemia, weight loss and vomiting) were selected from their General Practitioners for fasting blood collection and assay of G-17 and pepsinogens (Biohit Oyj, Finland). To each of them a standard questionnaire (including upper gastrointestinal symptoms, thyroiditis history, family history of stomach cancer and PPI regimen) was administered. Patients with *H. pylori*-related gastritis, chronic atrophic gastritis, half-dose PPI or no compliance were excluded from the study.
Results: 354 patients ($M=138$, $F=216$, mean age $=46.3\pm14.4$, range = 18-83 years) under standard dose PPI were recruited: 154 patients taking a branded PPI and 200 a generic one PPI. The PPIs prescribed were: omeprazole ($n=37$), lansoprazole ($n=72$), pantoprazole ($n=131$), rabeprazole ($n=31$) and esomeprazole ($n=83$). The serum G-17 (15.1 ± 19.4 *versus* 7.7 ± 9.9, $p=0.0001$), pepsinogen I (171.2 ± 92.7 *versus* 144.4 ± 79.4, $p=0.004$) and pepsinogen II (13.7 ± 10.8 *versus* 11.4 ± 9.6, $p=0.031$) concentrations were - in patients taking branded PPIs - significantly higher than those found in patients using generic formulations.
Conclusion: Since, under antisecretory therapy, the G-17 and pepsinogen levels depend on intragastric pH (the higher intragastric pH, the higher the gastric markers), these findings show – *indirectly* – that, in dyspeptic patients, generic formulations of PPIs are less effective than the corresponding branded products.

Contact E-mail Address: a.fikree@qmul.ac.uk
Introduction: Tenascin X (TNX) is an extracellular matrix glycoprotein, deficiency of which causes a recessive form of Ehlers Danlos Syndrome (EDS), a hereditary disorder of connective tissue. It is now known that gastrointestinal (GI) and somatic symptoms, and functional GI disorders are associated with EDS Hypermobility-Type (1,2), however these symptoms have not been systematically characterized in TNX-deficient EDS patients.
Aims & Methods: To determine the GI and somatic symptom profile in a group of TNX-deficient adult EDS patients presenting primarily to neurology clinics, validated questionnaires were completed. Scores on the GI symptom rating scale (GSRS) were compared to those in a Scandinavian control population ($n=2162$, 51% male, age: 19-84) (3) and somatic symptom scores (PHQ15) were compared to those in a primary and secondary care control population ($n=3000$ each) (4). The prevalence of functional dyspepsia and irritable bowel syndrome were determined using ROME III criteria.
Results: 11 patients (3 male, age range: 24-66 years) with TNX mutations and/or absence of TNX serum levels participated. GI scores for indigestion, reflux, abdominal pain and diarrhoea domains were significantly higher than quoted population scores (Table 1). 33% of patients had high somatic sensitivity, which was significantly higher than in a primary care (10%, $p=0.02$) and secondary care control population (9%, $p=0.01$). 3 patients (27%) had irritable bowel syndrome (IBS) (1 IBS-M, 2 IBS-D). 7 (64%) patients had functional dyspepsia (3 postprandial distress syndrome (PDS), 2 epigastric pain syndrome, 2 unspecified). 2 (66%) patients with IBS had overlapping functional dyspepsia (PDS).
Table 1: Mean scores and confidence intervals for each GSRS domain

GSRS Domain	TNX-deficient patients	Swedish control population	p
Reflux	2.68 (1.62-3.75)	1.39 (1.36-1.43)	0.02
Abdominal pain	2.58 (1.69-3.47)	1.56 (1.53-1.59)	0.01
Constipation	2.03 (1.09-2.97)	1.55 (1.51-1.58)	0.2
Indigestion	3.25 (2.53-3.97)	1.78 (1.75-1.82)	0.006
Diarrhoea	2.33 (1.26-3.40)	1.38 (1.35-1.41)	0.02
Total GSRS score	2.61 (1.97-3.26)	1.53 (1.5-1.55)	<0.001

Conclusion: TNX-deficient EDS patients have a high prevalence of functional dyspepsia, an abundance of reflux, indigestion, diarrhoea and abdominal pain symptoms, and high somatic sensitivity, which is similar to EDS-HT patients but greater than in control populations. These findings suggest that abnormalities in extracellular matrix proteins may impact on GI function. Further work is necessary to elucidate possible mechanisms.

Introduction: Proton pump inhibitors (PPIs) represent a widely prescribed class of drugs, often used long-term, especially in the elderly.
The appropriate indications of PPI therapy are the so-called acid-related diseases, including peptic ulcer, GERD and gastro-duodenal protection during NSAID treatment.
Gastric function, however, is not usually assessed before starting PPI therapy. It is therefore not always known whether an antisecretory effect is really needed.
Aims & Methods
Aim: To evaluate gastric function by means of GastroPanel®, i.e. the measurement of serum pepsinogens I and II (PGI and PGII), gastrin-17 (G-17) as well as anti-*Helicobacter pylori* antibodies (IgG against *H.p.*), in a large population of elderly patients.
The use of these gastric biomarkers allows a non-invasive diagnosis of chronic, atrophic gastritis (CAG) as well as of (present and past) *H.p.* infection.
Subjects and Methods: 328 elderly patients (M = 111, F = 217, mean age = 81 ± 9.3, range = 65-103), hospitalized from March to December 2014, were included in the study.
Medical history, existing morbidities and current drug therapies were collected. PGI, PGII and G-17 concentrations as well as anti-*H. pylori* antibodies were all determined *via* a specific ELISA test (Biohit Oyj, Helsinki, Finland) in fasting serum samples.
Results: 192 (M = 60, F = 132) out of 328 patients (58.5%) were on PPI therapy. GastroPanel® analysis showed that 62 patients (18.9%, M = 19, F = 43, mean age = 81.5 ± 9.0) had CAG, later confirmed by gastric biopsy and histology, while 82 patients (25%, M = 32, F = 50, mean age 81.2 ± 9.0) had *H.p.* infection. More than half (i.e. 32 out of 62, i.e. 51.6%) of the patients with CAG, in whom acid secretion is low or absent, were on PPI therapy.
Conclusion: GastroPanel® is able to identify elderly patients, characterized by low rates of acid secretion, in whom PPI administration is not needed and, therefore, inappropriate, exposing them merely to the long-term risks of this kind of therapy.
This non-invasive approach might decrease drug-induced morbidity and reduce healthcare costs.

Contact E-mail Address: hanseung43@naver.com
Introduction: The pathophysiologic mechanisms of overlaps of functional gastrointestinal disorders (FGIDs) are not well understood, but it has been hypothesized that they share a common pathogenesis such as psychosocial factors.
Aims & Methods: The purpose of this study was to determine the effect of job stress and other psychosocial factors on the overlap syndrome. Within a cross-sectional survey, 1140 firefighters completed validated questionnaires regarding FGIDs by at least once a week of typical reflux symptoms and Rome III criteria. Self-reported questionnaires for perceived job stress (KOSS-26), anxiety (GAD-7), depression (PHQ-9), coping styles (WCC), social support and quality of life (WHOQOL-BREF) was also completed.
Results: The overlap syndrome was observed in 134 subjects (11.8%) and each two-way combination of the overlap syndrome was present in overlaps between GERD and IBS were found in 86 subjects (7.6%), GERD and FD in 81 subjects (7.1%), GERD and FC in 49 subjects (4.3%), FD and IBS in 48 subjects (4.2%), FD and FC in 19 subjects (1.7%). The overlap syndrome highly associated with perceived job stress compared to the subjects without overlap syndrome (OR = 10.6, 95% CI: 2.3-49.3, p = .002). Subjects reporting anxiety had a 6.3-fold increased risk of the overlap syndrome (95% CI: 4.2-9.3, $p < 0.001$), and with depression had a 9.3-fold increased risk of the overlap syndrome (95% CI: 5.9-14.6, $p < 0.001$) compared to the subjects without overlap syndrome. We also observed a weak inverse association between informative support and the overlap syndrome (OR = 0.1, 95% CI: 0.0-0.9, p = .043). Impaired quality of life was found in the subjects with overlap syndrome.
Conclusion: Perceived job stress is strongly associated with the overlap syndrome in firefighters. Anxiety and depression was also related to the overlap syndrome and weak inverse association with informative support. Recognition and management of these psychosocial factors may aid in the management of the overlap syndrome.

Contact E-mail Address: jjg79@naver.com
Introduction: Functional dyspepsia (FD) is very common, but its negative influences significantly affect the quality of life. The prevalence of obesity has been increasing worldwide and has been shown to increased risk of various gastrointestinal symptoms. But the relationship between visceral abdominal obesity and incidence of FD is not studied yet.
Aims & Methods: The purpose of this study was to evaluate the association between abdominal adipose tissue area and the risk of FD.
This is a case-control study that compared the abdominal adipose tissue area between subjects with FD and controls without FD, who underwent abdomen computerized tomography (CT) images for routine health checkups in a health promotion center. Retrospectively, telephone survey was conducted to diagnose FD by Rome III criteria. We measured body mass index (BMI), waist circumference, visceral adipose tissue (VAT) area, subcutaneous adipose tissue (SAT) and VAT/SAT ratio to evaluate the association between FD and abdominal obesity.
Results: A total of 363 subjects were included. FD was diagnosed in 90 subjects (24.8%). Among them, postprandial distress syndrome (PDS) was diagnosed in 42 subjects (46.7%), epigastric pain syndrome (EPS) in 33 subjects (36.7%) and mixed type (overlapping PDS and EPS) in 15 subjects (16.7%). In the univariate analysis, waist circumference, VAT area, TAT area, VAT/SAT ratio and erosive esophagitis subjects were significantly higher in the FD group than in the non-FD group. In the multivariate analysis, a higher VAT area (odds ratio (OR), 3.76; 95% confidence interval (CI), 1.24–11.40; highest quartile vs. lowest quartile, $p = 0.019$) and VAT/SAT ratio (OR, 2.35; 95% CI, 1.27–4.32; highest quartile vs. lowest quartile, $p = 0.006$) were independently associated with a risk of FD.
Conclusion: Visceral abdominal obesity measured by VAT area and VAT/SAT ratio is associated with an increased risk of FD.

P1732 FUNCTIONAL DYSPEPSIA IS ASSOCIATED WITH DUODENAL EOSINOPHILIA IN AN AUSTRALIAN PAEDIATRIC COHORT

L. Wauters[1], S. Nightingale[2], B. Sulaiman[3], N. J. Talley[4], M. M. Walker[5]

Introduction: Functional dyspepsia (FD) is a highly prevalent functional gastrointestinal disorder with unknown aetiology. Duodenal eosinophilia has been implicated in the pathophysiology of functional diseases in adults[1] and in a few paediatric studies[2].
Aims & Methods: We aimed to assess the association between dyspeptic symptoms and duodenal eosinophilia in children referred for upper endoscopy. All children who had normal endoscopic and pathologic findings on initial reports were included in this retrospective single centre cohort study (2010-2014). Cases were children with FD, defined as epigastric pain or discomfort for more than 2 months with no response to acid suppressants. Controls were those with non-erosive reflux disease, dysphagia or adolescent rumination syndrome. Duodenal biopsies were reevaluated by pathologists blinded to clinical diagnosis. Intramucosal eosinophils were counted per mm^2 on haematoxylin and eosin stained digital imaged sections using Aperio eSlide Manager. Demographics, clinical variables, family history and histologic findings were compared between cases and controls.
Results: In total, 36 FD cases and 36 controls were identified of which 56% and 53% were female, respectively (p = 0.81). Mean (± SD) age was higher in cases compared to controls (13.6 (± 3.1) vs. 10.5 (± 4.0) years; p = .001). Dyspeptic symptoms (epigastric pain in 81% and upper abdominal discomfort in 33%) were food-related in 69% and nocturnal in 31% of cases. Self-reported nausea (64% vs. 17%; p < .0001), lethargy (19% vs. 0%; p = .005) and family history of functional gastrointestinal disorders (28% vs. 3%; p = .003) were more common in cases than controls. There was a higher rate of atopic history (39% vs. 25%; p = .21) and psychological co-morbidity (53% vs. 39%; p = .24) in cases than controls, but this did not reach statistical significance.

Duodenal intraepithelial lymphocyte counts per 100 enterocytes were similar in cases and controls (median (IQR) 10 (8-13) vs. 12 (8-18); p = 0.12). Duodenal eosinophil counts per mm^2 were significantly increased in cases compared to controls (151 (118-207) vs. 76 (60-106); p < 0.001).
Conclusion: FD is associated with duodenal eosinophilia in children. The high rate of atopic and psychological co-morbidity suggests multifactorial mechanisms in FD, and may explain why current therapeutic options aimed at symptom control (acid suppression and prokinetics) are largely unsatisfactory. This study confirms recent reports of duodenal eosinophilia in adults with FD, and underlines the potential role of eosinophils in symptom generation as well as being a potential therapeutic target.

P1733 HIGH PREVALENCE OF POSTPRANDIAL DISTRESS SYNDROME-LIKE DYSPEPSIA IN PATIENTS WITH AUTOIMMUNE ATROPHIC GASTRITIS

M. Carabotti[1], E. Lahner[1], G. Esposito[1], C. Severi[1], B. Annibale[1]
[1]*Università "Sapienza", Roma, Italy*

Introduction: Autoimmune gastritis (AG) is a chronic disease characterized by loss of oxyntic glands, leading to hypochlorhydria and intrinsic factor deficiency, and, in a later stage, pernicious anemia. AG is considered a silent disease, often occurring with unspecific symptoms and to date, few data on its clinical features are available.
Aims & Methods: Aim of this study was to assess the presence of gastrointestinal (GI) symptoms in AG patients. A cohort of 379 AG patients diagnosed from 1995 to 2013 in a tertiary referral center, was retrospectively analyzed. Gastroscopy was performed in 62.9% of patients for anemia, in 29.8% for GI symptoms and in 7.3% for extra GI or other symptoms. GI symptoms were detected at the time of the first visit and classified following Rome III Criteria. Symptoms were analyzed either separately or altogether to classify patients in dyspepsia, subdivided in epigastric pain (EPS) and post-prandial distress (PDS) syndromes or gastro-esophageal reflux disease (GERD). Since the study dealt with patients affected by AG, PDS and EPS dyspepsia will be indicated as PDS- and EPS-like throughout the abstract. Data were expressed as median (range), and differences between symptomatic and asymptomatic patients were analyzed using Fisher's exact test or Mann-Whitney test; *P* values <0.05 were considered statistically significant.
Results: 56.7% of AG patients had one or more GI symptoms. The table shows the comparison of clinical features between symptomatic and asymptomatic patients.

(*p < 0.05)	All patients n = 379	Symptomatics n = 215	Asymptomatics n = 164
Female gender	266 (70.2%)	162 (75.3%)	104 (63.4%)*
Age median (range)	55 (17-83)	53(22-80)	57 (17-83)*
Smoking	72 (19%)	33 (15.3%)	39 (23.8%)*
Pernicious anemia	203 (53.6%)	101 (47%)	102 (62.2%)*
Parietal cell autoantibodies (PCAs)	255 (67.3%)	144(67%)	111 (67.7%)
Active *H. pylori* (histology)	95 (25.1%)	54 (25.1%)	41 (25%)
Autoimmune disorders	158 (41.7%)	90 (41.9%)	68 (41.4%)

Females were more prevalent in the symptomatic patients. Symptomatic patients were significantly younger and more often no smokers in comparison to asymptomatic. Pernicious anemia was significantly more frequent in the asymptomatic group. No differences were found between symptomatic and asymptomatic patients concerning the presence of PCAs, prevalence of *H. pylori* infection and the concomitant presence of autoimmune disorder. Among symptomatic patients, 69.8% had only upper symptoms, 15.8% lower symptoms and 14.4% upper and lower combined. Analyzing patients with upper GI symptoms, 60.2% reported PDS-like dyspepsia, 3.8% EPS-like dyspepsia, 7.2% overlap PDS and EPS-like dyspepsia, 7.2% GERD, 17.7% GERD and dyspepsia, and 3.8% nausea and/or vomiting.
Conclusion: AG is not a paucisymptomatic condition since more than half of patients have one or more GI symptoms. The most frequently reported symptom is PDS-like dyspepsia. The presence of GERD, even if unfrequently present, does not exclude the diagnosis of AG. This study suggests that in the diagnostic work-up of functional upper GI disorders AG should be considered, especially in PDS-like dyspepsia.

Introduction: Childhood recurrent abdominal pain (RAP) is a common functional gastrointestinal disorder (FGID) with poorly understood pathophysiology.
Aims & Methods: We aimed to investigate histologic features of children with RAP undergoing upper gastrointestinal endoscopy, after exclusion of common organic disease. Children referred for endoscopy were prospectively enrolled at a single tertiary centre between 2008 and 2010, after obtaining informed consent. Cases were defined as children with a clinical diagnosis of RAP, as opposed to controls with proven or suspicious organic disease. Gastric and duodenal biopsies were analysed by pathologists blinded to clinical indication. Demographic and clinical variables, *H. pylori* infection, biochemical, endoscopic and pathologic results were compared between cases and controls.
Results: A total of 101 children were included after exclusion of villous enteropathy (n = 6) and parasitic, rotavirus or salmonella enteritis (n = 14), resulting in 72 cases and 29 controls. There were no significant differences in demographics, clinical symptoms, *H. pylori* infection and endoscopic findings between cases and controls. Duodenal eosinophil counts/5 HPF were significantly increased in cases vs. controls (median (IQR) 86 (62-114) vs. 49 (31-88); p < 0.001) and did not differ regarding age, gender and *H. pylori*. Intraepithelial lymphocytes/100 enterocytes were similar in cases vs. controls (19 (15-25) vs. 18 (14-23); p = 0.89) with ≥ 25 in 25% of cases. Duodenal eosinophilia was equally observed in *H. pylori* negative cases (n = 50) vs. controls (n = 19) (87 (61-119) vs. 53 (36-95); p = 0.01), as well as positive cases (n = 21) vs. controls (n = 10) (85 (55-105) vs. 42 (18-65); p = 0.03). Logistic regression yielded an adjusted odds ratio of 1.23 (95% CI 1.08-1.40) for duodenal eosinophilia in RAP.
Conclusion: Children with RAP have marked duodenal eosinophilia, independent of *H. pylori* infection, suggesting the role of unknown infectious or inflammatory triggers. These findings implicate eosinophils in the pathogenesis of FGIDs in childhood. Further research is needed on the diagnostic and therapeutic benefits of targeting duodenal eosinophilia. Contact E-mail Address: mathieu.pioche@chu-lyon.fr
Introduction: The peroral endoscopic myotomy (POEM) is a promising method for the treatment of the esophageal achalasia. But the precise technique can be refined and the hook knife can be used to precise the myotomy and we evaluated its results in the 54 first patients of our institution.
Aims & Methods: All the consecutive cases refferred for POEM were included and the database was completed prospectively. The patients presented with a complete or incomplete achalasia regarless of the previous treatments were assessed in terms of procedure information and surveillance results.
Results: 54 patients (29 men, average age 59 years) were included. Typical achalasia represented 48 cases (type I: 6, II: 30, III: 12), Jackhammer in 1 case and manometry failure in 6 cases due to the incapacity to pass the probe through the cardia. 36 patients were naives of previous treatments, 10 received previous dilations, 5 Heller's myotomy, 2 botulic toxin and dilation and 1 only botulic toxin. Among the 54 patients, 2 were recused at the beginning of the endoscopy for 1 diverticulum on the tunnel way and 1 largely open cardia. 49 procedures were complete (94.2%), 3 were interrupted (2 sub-mucosal fibrosis preventing the realization of the tunnel and 1 mucosal injury of the tunnel in the cardia). 2 other mucosal injuries occurred but did not prevent to continue the procedure after mucosal closure by clips. Dual Knife ® (n = 41) or the water jet Nestis Enki 2 ® (n = 11) were used for the tunnel. No mucosal injuries were observed with the water-jet system. Hook Knife ® was used for all the myotomies and allowed a precise circular myotomy. The average time of procedure was 96.2 min with a clear learning curve (135-41 min). A pneumoperitoneum was exsufflated with a needle during the procedure in 31 cases (63.2%) without any visible perforation. The 18 first patients were explored by systematic CT scan at day 1 with a pneumomediastinum (n = 14/18), a pneumoperitoneum (n = 14/18) and/or a peumothorax (n = 3/18). 3 patients presented unusual bleedings and one of them presented an hematoma of the tunnel at day 1 without overt bleeding. No sepsis was observed. Feeding was always possible with liquids at day 1. All patients noted a clinical improvement. At 3 months surveillance(available in 42 cases), the mean eckardt score was 1 (0-4) verus 6.5 (3-11) before. The basal

pressure of the SIO was measured in 25 cases and decreased for all patients (8 mmHg (0-15) against 23 mmHg (7-48) initially, $p < 0.01$) as well as the PRI (8 mmHg (0-16) against 23 mmHg (9-28), $p < 0.01$).
Conclusion: Water-jet injection allows rapid and safe tunneling of the submucosa and myotomy with hook knife is very precise. Safety and effectiveness of mytomy is reinforced using these technical refinements.

P1736 EFFICACY OF PSYCHOTROPIC DRUGS IN FUNCTIONAL DYSPEPSIA: SYSTEMATIC REVIEW AND META-ANALYSIS

P. Luthra[1], A. C. Ford[1,2], P. Moayyedi[3], N. J. Talley[4]
[1]*Leeds Gastroenterology Institute, St. James's University Hospital,* [2]*Leeds Institute of Biomedical and Clinical Sciences, University of Leeds, Leeds, United Kingdom,* [3]*Gastroenterology Division, McMaster University, Health Sciences Center, Hamilton, Ontario, Canada,* [4]*Faculty of Health, University of Newcastle, New South Wales, Australia*

Contact E-mail Address: pavit12@gmail.com
Introduction: Functional dyspepsia (FD) is a chronic gastroduodenal disorder. Individuals with FD demonstrate visceral hypersensitivity, abnormal central pain processing, and low mood. However, it is unclear whether psychotropic drugs are an effective treatment for the condition as, surprisingly, there has been no definitive systematic review and meta-analysis undertaken to date.
Aims & Methods: We performed a systematic review and meta-analysis of randomised controlled trials (RCTs). MEDLINE, EMBASE, EMBASE Classic, PsychINFO, and the Cochrane Controlled Trials Register were searched (up to March 2015) to identify RCTs recruiting adults with FD, which compared psychotropic drugs with placebo. We contacted authors directly to obtain extra data in order to maximise trial eligibility and minimise risk of bias of included RCTs. Dichotomous symptom data were pooled to obtain a relative risk (RR) of remaining symptomatic after therapy, with a 95% confidence interval (CI). Adverse events data were also summarized with RRs. The number needed to treat (NNT) and the number needed to harm (NNH), with 95% CIs, were calculated.
Results: The search strategy identified 2572 citations. Nine RCTs were eligible for inclusion, containing 1099 patients. Six trials were at low risk of bias. Overall, 340 (56.5%) of 602 patients assigned to psychotropic drugs reported persistent or unimproved FD symptoms following therapy, compared with 350 (70.4%) of 497 allocated to placebo. The RR of FD symptoms persisting or not improving after treatment with psychotropic drugs versus placebo was 0.77 (95% CI 0.64 to 0.91) (NNT = 6; 95% CI 4 to 16). The efficacy of individual drug classes is provided in the table. The incidence of adverse events was not significantly higher among those taking psychotropic drugs (RR = 1.17; 95% CI 0.85 to 1.62) but, overall, there were more adverse events leading to withdrawal with psychotropic drugs (RR = 1.96; 95% CI 1.17 to 3.27, NNH = 20; 95% CI 8 to 109).

Drug class	Number of trials	Number of patients	RR of persistent symptoms (95% CI)	Number needed to treat (95% CI)
Antipsychotics	4	197	0.48 (0.36-0.63)	3 (2-4)
Tricyclic antidepressants	2	153	0.75 (0.60-0.94)	7 (4-29)
Selective serotonin re-uptake inhibitors	2	388	1.01 (0.89-1.15)	Not estimable
Serotonin norepinephrine re-uptake inhibitors	1	160	1.02 (0.80-1.30)	Not estimable
5-hydroxytryptamine-$_{1A}$ receptor agonists	1	150	0.79 (0.66-0.94)	5 (3-19)

Conclusion: Psychotropic drugs may be an effective treatment for FD, but the effect appears to be limited to antipsychotics, tricyclic antidepressants, and 5-hydroxytryptamine-$_{1A}$ receptor agonists. Intolerable adverse events may be an issue. More data from large, high quality RCTs are required to support the use of psychotropic drugs in the treatment of FD.

P1737 AUTOFLUORESCENCE IMAGING ENDOSCOPY IN DIFFERENTIATING NON-EROSIVE REFLUX DISEASE FROM FUNCTIONAL HEARTBURN: A NEW COMPLEMENTARY METHOD

W. Wang[1], X. Luo[1], Y. Yang[1], N. Uedo[2]
[1]*Department of Gastroenterology and Hepatology, Chinese PLA General Hospital, Beijing, China,* [2] *Osaka Medical Center for Cancer and Cardiovascular Diseases, Osaka, Japan*

Contact E-mail Address: wangwf301@hotmail.com
Introduction: It is difficult to make a distinction between functional heartburn (FH) and non-erosive reflux disease (NERD) endoscopically. Recently, indistinct mucosal lesions invisible on conventional endoscopy could be revealed [1] with the help of tri-modal endoscope which combines white light imaging (WLI) with autofluorescence imaging (AFI) and narrow band imaging. Also, it was found that AFI could reveal indistinct acid reflux-related mucosal changes [2]. NERD is characterized of the etiology of acid reflux, while FH isn't. Whether AFI endoscopy can be used to differentiate NERD from FH hasn't been investigated.
Aims & Methods: This study aimed to explore the diagnostic ability of AFI endoscopy in distinguishing NERD from FH in patients with classic reflux symptoms but no esophageal mucosal breaks at WLI. In our prospective observational trial, 127 consecutive patients with heartburn or acid regurgitation for more than 6 months were screened in a tertiary referral center. All the participants underwent endoscopy during which WLI was followed by AFI with special focus on the esophagus. Finally, 84 patients with negative esophageal findings at WLI were enrolled. Ambulatory 24-h pH/impedance monitoring was performed and a positive finding was defined as a DeMeester score no less than 14.72 or a positive correlation between symptoms and acid reflux. Accordingly, the subjects were divided into two groups including NERD and presumed FH. On AFI endoscopy, the appearance of one or more longitudinal purple lines longer than 1 cm was defined as indicative of NERD [2]. The diagnostic ability of AFI endoscopy to distinguish NERD from FH was assessed by comparison with the pH/impedance test.
Results: The results of the pH/impedance test and AFI endoscopy in 84 endoscopy-negative patients was listed in Table 1. Comparing with the pH/impedance test, the sensitivity and accuracy of AFI in detecting NERD were 71.7% and 64.3%, respectively. Meanwhile, the specificity of AFI was 55.3%. McNemar test showed no significant difference between AFI and the pH/impedance test ($P = 0.584$).
Table 1: Results of the pH/impedance test and AFI endoscopy

the pH/impedance test	AFI endoscopy		Total
positive	negative		
positive(NERD)	33	13	46
negative(presumed FH)	17	21	38
Total	50	34	84

Conclusion: These findings suggest that AFI may serve as a complementary method when evaluating NERD and FH, although the specificity of this method is needed to be improved.

P1738 PERORAL ENDOSCOPIC MYOTOMY FOR ACHALASIA - LONG MYOTOMY VERSUS MODIFIED-LENGTH MYOTOMY-A PILOT STUDY

H. Sato[1], **Y. Kawata**[1], Y. Sato[1], M. Takeuchi[1], K. Takahashi[1], K. Mizuno[1], S. Hashimoto[1], S. Terai[1]
[1]*Division of Gastroenterology and Hepatology, Niigata University Medical and Dental Hospital, Niigata, Japan*

Contact E-mail Address: Yuzo.k@hotmail.co.jp
Introduction: Peroral endoscopic myotomy (POEM) is a minimally invasive endoscopic treatment for achalasia.1 Our objective was to evaluate the relationships between length of myotomy, symptoms, and manometry.
Aims & Methods: Long myotomy (LM) and modified-length myotomy (MM) were defined as ≧ 10cm and ≦5cm length esophageal myotomies, respectively. Nineteen patients with achalasia (n = 19) undergoing POEM underwent LM (n = 8, [Chicago classification type I: 5, type II: 2, type III: 1]) or MM (n = 11, [type I: 8, type II: 3]).2 Written informed consent was obtained from all subjects. All patients had follow up at two months. Procedural success was defined as a post-POEM Eckardt score of less than 2.3
Results: POEM was successfully performed in all patients and no adverse events were observed (0.0%). The overall procedural success rate (Eckardt score less than 2) was 100% in both groups. MM significantly improved achalasia-related symptoms (median Eckardt score; 6 to 1) and reduced lower esophageal sphincter (LES) pressure (37.8 to 7.9 mmHg) with results comparable to LM (Eckardt score; 7.5 to 1, and LES pressure; 30.3 to 7.5 mmHg). Gastroesophageal reflux symptoms were seen in one patient (performed LM for type I achalasia) not receiving a proton-pump inhibitor. There was no recovery of esophageal peristalsis in patients with type I achalasia after POEM in both the LM and MM group. In three patients with type II achalasia who underwent MM (n = 3), two (pre-POEM manometry; single pan-pressurization or week plural pan-pressurization per swallow) had partial recovery of peristalsis, and the other (pre-POEM manometry; strong plural pan-pressurization) had hypercontraction in the esophageal body and developed an esophageal diverticulum. LM for type II&III achalasia (n = 3) completely suppressed esophageal body contractions.
Conclusion: MM and LM are considered equally effective for the treatment of type I achalasia. With type II&III achalasia, preoperative manometry is essential, and LM might be needed in patients with strong plural pan-pressurization (potential for hypercontraction) to prevent the formation of post-POEM esophageal diverticulum.

Contact E-mail Address: arne.kandulski@med.ovgu.de

Introduction: Diagnosis of gastroesophageal reflux disease (GERD) is recommended as a clinical diagnosis based on symptoms. For proper diagnosis of GERD pH metry remains the GOLD standard and is recommended especially for refractory and/or suspected extraesophageal reflux disease (EER).

Aims & Methods: In a multicentric, open label survey in 6 different tertiary centers in Germany, 184 patients (male 111, female mean age 55.9 +/-9.8 years, 2011-2014) were prospectively investigated by wireless capsule pH metry (BRAVO capsule).

Clinical indications for referral were categorized in a) ''typical GERD symptoms'' (n = 60), b) ''suspected EER'' (n = 20) and c) ''exclusion of GERD'' for patients unlikely to have GERD (n = 39).

Furthermore, patients were systematically asked for the exact description of symptoms and for a self-report about the occurrence of heartburn and regurgitation as well as cough and hoarseness. Diagnosis of GERD was confirmed by wireless pH metry (acid exposure time $<$ pH1 (AET) $>$ 4.5% and/or DeMeester $>$ 14.72). The parameters of pH metry were further compared between the three clinical groups.

Results: 139 patients were included in the final analysis. Reasons for exclusion were previous anti-reflux surgery (n = 6), ongoing PPI therapy (n = 38) and drop-off the capsule (n = 1).

Diagnosis of ''typical, symptomatic GERD'' was proven in 61.6%; suspected EER pH metry was confirmed in only 40%. In group (c) (to exclude GERD), 75% of the patients actually had abnormal acid exposure.

Regarding symptom-based diagnosis, heartburn as predominant was described by 63 patients with very poor diagnostic values; regurgitation by 15 patients, only; cough and hoarseness by 28 and 25 patients, respectively. All self-reported symptoms had comparable low diagnostic test values (table 1). Analyzing all patients with abnormal AET, patients with EER showed less intense acid exposure to the distal esophagus than patients with ''typical GERD'' and patients ''to exclude GERD'' (AET %: 9.95 ± 1.85 vs. 5.44 ± 0.89, p = 0.06; DeMeester score: 32.77 ± 5.81 vs. 20.30 ± 3.77, p = 0.07).

	Sensitivity (95% CI)	Specificity (95% CI)	Positive predictive value (PPV, 95% CI)	Negative predictive value (NPV, 95% CI)
Heartburn	48% (0.37-0.59)	59% (0.44-0.72)	67% (0.54-0.78)	40% (0.29-0.52)
Regurgitation	10% (0.05-0.19)	88% (0.77-0.96)	60% (0.33-0.84)	37% (0.28-0.46)
Cough	20% (0.12-0.29)	79% (0.65-0.89)	61% (0.40-0.79)	37% (0.28-0.47)
Hoarsness	17% (0.10- 0.27)	81% (0.67-0.90)	60% (0.39-0.79)	37% (0.28-0.46)

Conclusion: Accuracy of symptom-based diagnosis for GERD was poor in this study cohort, even by GI specialists. Description of symptoms and self-reports are most likely influenced by linguistic differences, therefore early referral to reflux testing should be considered in the clinical management.

Introduction: Gastrin-17 (G-17) could be related to the pathophysiology of GERD through its motor and secretory activities on the upper GI Tract. The peptide indeed decreases lower esophageal sphincter pressure (LESP) and increases the number of transient lower esophageal sphincter relaxations (TLESR), features that are associated with the disease. Gastrin also stimulates gastric acid secretion, thus increasing the aggressive power of the gastric contents that will reflux into the esophagus. Thanks to a feed-back mechanism, plasma G-17 can be considered a mirror of acid secretion: the lower G-17 values, the higher gastric acid secretion. G-17 low levels could therefore be a marker of acid-related conditions, like GERD.

Aims & Methods

Aim: To evaluate the role of G-17 in the diagnosis of GERD in a cohort of GERD or dyspeptic patients.

Material and Methods: 639 patients with typical GERD or dyspeptic symptoms were enrolled in the study. Every patient underwent upper GI endoscopy and had a Gastropanel® by means of immunoassay. 126 out of patients had Los Angeles A esophagitis, 28 patients had Los Angeles B esophagitis, 214 had negative endoscopy (NERD), 114 had chronic atrophic gastritis and 127 were *H.p.* negative dyspeptic subjects.

Statistical analysis was performed by means of logistic regression.

Results: Patients with A esophagitis A and B esophagitis as well as those NERD patients showed a basal G-17 value, which was significantly lower ($p = 0.0001$) than that seen in patients with dyspepsia or CAG (used as control groups).

Conclusion: These results confirm that – by taking a cut-off $<$ 1.9 ng/dL - G17 basal values are useful in the diagnosis of reflux disease. Moreover, being a non-invasive test, able to identify patients with GERD or NERD, G-17 measurement should allow to limit unnecessary endoscopy and histology.

Additional studies are needed to confirm these results.

Contact E-mail Address: drfehmiates@hotmail.com

Introduction: Despite the high prevalence of gastroesophageal reflux disease (GERD) and its impact on quality of life and economic burden, the current GERD diagnostics are suboptimal due to limited sensitivity and specificity, and they are constrained by measurement of esophageal reflux during *a single time point* at *a specified location*. They measure the presence of reflux but do not measure the *long-term mucosal consequences of GERD*, a significant limitation of existing platforms. We developed a minimally invasive device to assess changes in esophageal mucosal impedance (MI), a marker of reflux.

Aims & Methods: The aims of this study were to test the accuracy and reliability of our new devoloped device and identify how measurements react to the used ring sizes and separations.

Methods: Six combinations of single channel Mucosal Impedance (MI) catheters with 360 degree rings were tested by varying ring length to 2 or 3 mm and ring separation to 2, 3 or 4 mm. Each catheter could be easily traversed through the working channel of an upper endoscope. We performed a prospective longitudinal study of patients with erosive esophagitis (n = 40), nonerosive but pH-positive GERD (n = 49), and those without GERD (n = 55). All patients underwent endoscopy and wireless 48-hour pH monitoring 10-days *off* PPI therapy. During index endoscopy, *MI* was measured from the esophagitis site as well as 2, 5 and 10-cm above squamocolumnar junction (SCJ). The optimal MI sensor ring size and separation were determined based on ROC analysis. Predictive value positive of MI measurements were then compared to pH monitoring in diagnosing GERD.

Results: When MI measurements were done on esophagitis site, we observed that MI tracked the grade of esophagitis, $F(3, 57) = 5.34$, $p < .0027$. Next, we evaluated whether MI values can predict esophagitis when the ring size and spacing was 3 and 2 mm, respectively. Our results indicated that MI measured with the 2 mm spacing predicted esophagitis, $\chi^2(1, 109) = 10.38$, $p < .0014$, showing that 3 mm ring size and 2 mm spacing is adequate for prediction of esophagitis. The Spearman's rank correlation between Bravo pH Monitoring values and MI measurements was significant when 2 mm spacing was used from the probes which were placed 2 or 5 cm above SCJ, rs = -.442 and -.430 for 2 cm and 5 cm probes, respectively.

Conclusion: Our results support the conclusion that when the ring size of 3 mm and 2 mm separation are used for MI measurements, we can track the grade of esophagitis. Further, with this configuration, the existence of esophagitis could be predicted. Sensitivity and specificities in this configuration were found to be comparable to Bravo pH Monitoring. Last but not least, we observed significant correlations between our MI values from this configuration and Bravo pH Monitoring. All in all, we conclude that the ability of this configuration to diagnose GERD simply, efficiently and reliability by through the endoscope application during index endoscopy is an innovative step forward in reflux monitoring.

P1742 QUESTIONNAIRES MAY BE INSUFFICIENT TO DIAGNOSE GASTROESOPHAGEAL REFLUX DISEASE (GERD) IN MORBIDLY OBESE PATIENTS WITH TYPE 2 DIABETES

J. Lorentzen[1], J. Hjelmesæth[2,3], A. W. Medhus[4], D. Hofsø[1,2], T.-I. Karlsen[2,5], R. Sandbu[2,6], B. Seip[1]

Contact E-mail Address: jolanta.lorentzen@siv.no
Introduction: GERD is highly prevalent in morbidly obese subjects. Bariatric surgery with gastric sleeve may worsen existing GERD, but few studies have assessed how GERD should be diagnosed in a population referred for bariatric surgery.
Aims & Methods: Our aim was to assess and compare the prevalence of GERD as evaluated by endoscopic examinations and validated questionnaires, respectively, in a population of morbidly obese subjects with type 2 diabetes. Consecutive patients with type 2 diabetes and BMI ≥ 35 kg/m^2 eligible for bariatric surgery, recruited from a tertiary care obesity centre in Southern Norway were included. The validated questionnaires GERD Q and GSRS (Gastrointestinal Symptom Rating Scale) were used for diagnosis of GERD. Upper endoscopy was used for diagnosis and grading of esophagitis, according to the Los Angeles (LA) classification.
Results: A total of 51 patients were included, mean age 47 years (range 32-61) and BMI 43 kg/m^2 (range 35-58). Four out of 51 patients reported dyspepsia according to the GERD Q or GSRS questionnaires. Upper endoscopy showed no erosive reflux in 18 out of 51 patients (35%), reflux LA grade A in 20 out of 51 patients (39%) and reflux LA grade B in 13 out of 51 patients (26%). No patients had reflux LA grade C or D. Twenty-nine out of 33 patients (88%) with reflux A or B were asymptomatic according to the applied questionnaires. No patients used proton pump inhibitors.
Conclusion: Few patients had symptomatic reflux disease as compared with previous studies, although upper endoscopy revealed pathological findings in 65% of the participants. There was no association between symptomatic disease and endoscopic finding. Our findings indicate that the GERD Q and GSRS questionnaires have a too low sensitivity to diagnose reflux disease in this patient group.

Introduction: Previous studies by means of 24h impedance-pH monitoring highlighted the correlation between baseline impedance levels and integrity of the esophageal mucosa and, more important, the possibility to use this parameter to discriminate between different subtypes of GERD. However, no previous studies investigated the possibility to achieve similar results by using impedance-manometry, a test requiring shorter time and providing further data about esophageal motility.
Aims & Methods: Aim of our study was to measure baseline impedance levels during manometric assessment and to correlate them with those obtained at 24h impedance-pH monitoring. Consecutive patients with typical reflux symptoms underwent upper endoscopy and multiple biopsies were taken at Z-line and 2 cm above it, in order to assess the presence and severity of microscopic esophagitis. Within 3 days from endoscopy, patients underwent esophageal impedance-manometry and impedance-pH testing off-therapy. We evaluated BI values for at least 30 seconds during impedance manometry, expressed as mean value over 3 intervals of 10 seconds each. Moreover, BI at 3 and 5cm above the LES, was assessed on MII-pH recording during the overnight rest, for at least 30 minutes. Twenty healthy volunteers (HVs) who underwent the same procedures were also used as controls.
Results: We included 38 patients (M/F 17/11; BMI 27; age 46) with classified according to endoscopy and impedance-pH as: 8 grade A erosive esophagitis (EE), 10 non-erosive reflux disease (NERD), 10 hypersensitive esophagus (HE) and 10 with functional heartburn [(FH) M/F 2/8; BMI 25; age 40]. Moreover, 20 HVs [11F/9M; BMI 24; mean age 44] were included. BI values during impedance-manometry were lower in patients with GERD (2290; 95%CI:1518-3476) than in those without (FH/HVs; 3677, 95%CI: 2648-5074) ($p < 0.05$). Moreover, BI values were lower in patients with ME compared to those without (mean 2178 vs 3328; $p < 0.05$). Although BI levels progressively decreased with the increasing severity of mucosal damage (EE < NERD < HE < FH), a statistical significance was not reached. Finally, BI values assessed during manometry showed a positive correlation with BI levels assessed during impedance-pH monitoring ($r = 0.37$; $p = 0.06$).
Conclusion: Baseline impedance levels measured during esophageal impedance-manometry havebeen associated to the diagnosis of GERD in patients with typical reflux symptoms. In patients with limited compliance this may represent an alternative method in order to investigate GERD. However, due to the complexity of this disorder, the miscellaneous manifestations and inconstant benefit of treatment, MII-pH study remains crucial in the management of patients referred to tertiary centers.

P1744 PEPSIN DETERMINATION IN SALIVA AND OROPHARYNGEAL PH - MONITORING FOR THE DIAGNOSIS OF GASTROESOPHAGEAL REFLUX DISEASE IN PATIENTS WITH PRIMARY EXTRA-ESOPHAGEAL SYMPTOMS

M. Weitzendorfer[1], A. Tschoner[1], C. Schwaiger[1], G. Spaun[1], H. Wundsam[1], K. Emmanuel[1], O. O. Koch[1]
[1]*Department of General and Visceral Surgery, Sisters of Charity Hospital, Linz, Austria*

Contact E-mail Address: michael.weitzendorfer@aon.at
Introduction:
The common standard methods do not enable a sufficient and accurate diagnosis, if extraesophageal symptoms are related to gastroesophageal reflux disease (GERD). The aim of this study was to evaluate the role of pepsin in saliva and oropharyngeal pH - monitoring for the diagnosis of extraesophageal reflux disease.
Aims & Methods: Twenty consecutive patients with primary extra-esophageal GERD symptoms underwent gastroscopy, high-resolution esophageal manometry, 24-hour esophageal impedance pH monitoring (MII-pH) and a barium esophagography. In addition, an ENT examination was performed, including the Belafsky Reflux Finding Score (RFS) as assessment tool. Quality of life was evaluated by means of the Gastrointestinal Quality of Life Index (GIQLI). Evaluation of extra-esophageal symptoms was carried out, using the standardized Belafsky Reflux Symtom Index (RSI) questionnaire. Three times during the 24-h-MII-pH monitoring, a pepsin - determination in saliva (Peptest, RDBiomed ^{TM}) was accomplished, one sample with a pepsin concentration > 210ng/ml was regarded as positive test. Simultaneous to the 24-h-MII-pH monitoring and collection of saliva samples, a detection of laryngopharyngeal reflux events by using the Restech Dx-pH Measurement System ^{TM} (Dx-pH) was performed. Correlation analyses were performed, and statistical significance was defined as a p-value of <0.05.
Results: Of the 20 patients, 12 (60%) patients were male and 8 (40%) were female, the mean age was 49.58 ($\pm$ 11.47) years. There was a significant correlation ($p < 0.038$) between the mean values of RFS score and GIQLI score, as well as between the mean values of RSI score and GIQLI score ($p < 0.029$). A positive Peptest showed a correlation with a pathological DeMeester score ($p < 0.039$), RSI score ($p < 0.002$), pathological results in Dx-pH monitoring ($p < 0.002$) and layringitis gastrica ($p < 0.0001$). Furthermore, elevated Dx-pH results showed a significant correlation with a pathological DeMeester score ($p < 0.002$), RSI score ($p < 0.002$) and laryngitis gastrica ($p < 0.002$).
Conclusion: Pepsin seems to play a major role in the pathophysiology of extra-esophageal symptoms of GERD. Patients refractory to medical treatment, but with positive pepsin testing in saliva and pathological findings in oropharyngeal pH-metry could profit from antireflux surgery. To substantiate this conclusion, further studies will have to be conducted in the future.

P1745 USAGE OF NEW NORMAL DATA FOR PH-IMPEDANCE MONITORING IN THE DIAGNOSIS OF PATIENTS WITH REFRACTORY REFLUX SYMPTOMS SIGNIFICANTLY DECREASES FUNCTIONAL HEARTBURN IN FAVOR OF REFLUX

M. Tahtaci[1], I. Dogan[2], S. Unal[2]
[1]*Gastroenterology, Ataturk Education and Research Hospital,* [2]*Gazi university faculty of medicine, Ankara, Turkey*

Contact E-mail Address: drtahtaci@gmail.com
Introduction: Multichannel intraluminal impedance (MCII) and pH monitorization while receiving drug therapy have an importance place in differential diagnosis of patients presenting with the symptoms of refractory gastro-esophageal reflux disease (GERD) as well as in the evaluation of the efficiency of treatment (1). In the evaluation of the efficacy of therapy with proton pump inhibitors (PPIs), it would be a more appropriate approach to take normal data from healthy volunteers who are already on therapy with PPIs as the reference rather than obtaining reference values from healthy volunteers (2,3).
Aims & Methods: The aim of the present study was to evaluate the impact of the normal ranges on the diagnosis that were obtained from the healthy volunteers on PPI therapy in a recent study by Zerbib et al and which shows efficacy of the anti-reflux therapy with PPIs in healthy volunteers. In the present study, MCII and pH monitorization data of patients with refractory GERD were compared to the reference values obtained from healthy volunteers receiving or those not receiving PPI therapy in the study by Zerbib et al (3).
Results: The present study included 41 patients with refractory reflux who underwent MCII and pH monitorization while receiving therapy with PPIs. Considering normal data from healthy volunteers who were not receiving PPI therapy, 29% were diagnosed with persistent GERD, 54% were diagnosed with functional heartburn, and 17% were diagnosed with hypersensitive esophagus. Of healthy volunteer's normal data who were receiving PPI therapy, 80% were diagnosed with persistent GERD, 13% were diagnosed with functional heartburn, and 7% were diagnosed with hypersensitive esophagus. We found a significant difference between healthy volunteers receiving and those not receiving therapy with PPIs in terms of the diagnosed conditions in each group ($p = 0.0001$).
Conclusion: Our study showed that changes in the reference values also resulted in a change in the diagnosis of refractory reflux. Setting reference values based

on the data of healthy volunteers who are receiving PPI therapy may significantly decrease the rates of functional heartburn and hypersensitive esophagus, while evaluating patients with refractory GERD who are on PPI therapy, using MCII and pH monitorization, and this may substantially affect the diagnosis and the treatment thereafter.

Introduction: Baseline impedance values (BI) has been recently proposed as an up and coming parameter to diagnose gastroesophageal reflux disease (GERD) in patients with typical reflux symptoms. Moreover, it has been described a strong correlation between BI values and the symptom relief during proton pump inhibitor treatment (PPI). However, a partial overlap between BI levels in responders and non-responders has been observed.

Aims & Methods: The aim of the study was to evaluate BI levels in consecutive patients with heartburn responder and non-responder to acid suppressive therapy and to detect the relationship between BI values and number of months of GERD-related symptoms in the same population.

NERD patients with heartburn were enrolled and asked to indicate the level of severity of their symptoms and from how long they experienced heartburn (i.e. disease durantion in months). Thereafter, this patients underwent 24-h impedance-pH testing off-PPI therapy and we selected those with normal acid exposure (AET) and number of reflux events. Thus, 120 patients undertook an 8-week course of PPIs. Sixty of them with $>50\%$ symptom improvement were classified as PPI-responders: 30 patients with pathophysiological characteristics of functional heartburn (negative symptom-reflux correlation; FH + PPI) and 30 with hypersensitive esophagus (positive symptom-reflux correlation; HE). The remaining 30 patients with a $<50\%$ improvement to treatment and with pathophysiological characteristics of functional heartburn were classified as PPI non-responders (negative reflux symptom correlation; FH-PPI). All impedance-pH tracks were manually reviewed and BI value were calculated at the impedance channel placed 5cm above LES for 30 minutes during overnight rest.

Results: The mean duration of symptoms (in months) was not different between FH + PPI (34.1 ± 15.4), HE (35.7 ± 17.8) and FH-PPI (36.5 ± 15.5); p = ns. Patients with FH + PPI showed a higher mean AET (1.9%±1 *vs* 0.6%±0.6, $p < 0.05$), mean reflux number (30.4 ± 9.3 *vs* 23.5 ± 7.9, $p < 0.05$) and acid reflux number (17.1 ± 8 *vs* 10 ± 6.9, $p < 0.05$) compared to FH-PPI. Patients with HE showed mean AET (2.3%±1.8) and total reflux number (34.6 ± 10.4) similar to those recorded in FH + PPI (p = ns). Baseline impedance levels were lower in FH + PPI (1949.6 ± 548.8) and in patients with HE (1839.7 ± 467.6) than in FH-PPI (3812.8 ± 810.2) ($p < 0.001$). The overall correlation between BI and disease duration in months was poor (r = -0.343; p = 0.065) but when we evaluated the patients who responded to PPI (HE and FH + PPI) we found a very strong correlation between baseline value and duration of the disease (r = -0.920; p = 0.0001).

Conclusion: Our results showed a very strong correlation between lower BI and response to PPI treatment. BI could represent a marker for reflux-induced changes of the esophageal mucosa and could help to identify patients affected by HE, especially when reflux-symptom association analysis fails to do it. We also found a strong negative correlation between BI values and disease duration in PPI-responder patients, thus corroborating the relevance of this objective marker in evaluating the esophageal mucosal impairment.

Introduction: Multiple rapid swallowing (MRS) during esophageal high-resolution manometry (HRM) is increasingly utilized as provocative maneuver to assess post deglutitive inhibition and rebound contraction (i.e., esophageal smooth muscle peristaltic reserve).

Aims & Methods: The aim of this study was to evaluate the correlation between amplitude of MRS and ratio DCI MRS/wet swallow with esophageal acid exposure time (AET) and baseline impedance values (BI) in patients with heartburn. We enrolled 48 consecutive patients with heartburn and negative endoscopy who underwent HRM and 24-h impedance and pH study to detect GERD. All patients were divided into two different groups: abnormal AET (NERD); normal AET, normal number of reflux episodes and negative symptom-reflux association (functional heartburn, FH). HRM was performed with 10 wet swallows and one MRS (one swallow every 2–3s, each of 4 ml of water). Patients with major motor disorders were excluded. Mean distal contractile integral (DCI) and MRS-DCI were calculated and then correlated with AET.

Results: We analyzed 40 patients: 22 NERD patients (12 male, 10 female), and 26 FH patients (10 male, 16 female). Mean age was similar between the two groups. Eight patients were excluded (5 for major motor disorders, 3 for positive SI/SAP with normal AET/number of refluxes). As expected, mean AET and number of refluxes were higher in NERD compared to FH ($p < 0.05$). HRM was normal in all selected patients. Mean DCI was similar between NERD and FH (p = n.s.). Mean MRS-DCI was higher in FH than in NERD ($p < 0.005$). The ratio DCI MRS/wet swallow was higher in FH than in NERD (1.8 vs 0.9 respectively). The ratio DCI MRS/wet swallow was inversely correlated with AET (-0.828; $p < 0.001$) and directly correlated with BI (0.854; $p < 0.001$).

TABLE 1: epidemiologic, MII-pH and HRM findings in NERD and FH patients

	NERD (22)	FH (26)	p
Mean age (sd)	51.2 (14.9)	48.2 (14.5)	0.484
Mean BMI (sd)	24.8 (3.8)	23 (2.5)	0.265
Mean AET (%) (sd)	6.7 (3.3)	0.9 (0.8)	0.001
Number of refluxes (sd)	77.7 (31.8)	29 (10.1)	0.001
Patients with negative SI/SAP (%)	5 (22.7%)	26 (100%)	0.05
Mean DCI (mmHg*cm*s) (sd)	1342.4 (801.3)	1404.3 (972.6)	0.813
Mean MRS-DCI (sd)	1268.1 (833.2)	2264.8 (1411.9)	0.005
DCI MRS/wet swallow¶	0.9 (0.2)	1.8 (0.8)	0.0001

¶ = DCI MRS/wet swallow has been provided as suggested by Shaker A et al.

Conclusion: Following MRS, NERD patients showed suboptimal contraction response as compared with FH. Moreover, MRS response was inversely correlated with AET. Overall, this parameter is another potential tool to assess risk for increased acid exposure time.

Introduction: The basal impedance level evaluated by 24-hour intraesophageal pH-multichannel intraluminal impedance (24pHMII) has been reported to be the index of inflammation of the esophageal mucosa caused by acid exposure. However, there has been no unified opinion regarding the 24pHMII procedure or evaluation system. Moreover, no report exists regarding the relationship between the condition of proton pump inhibitor (PPI)-refractory non-erosive gastro-esophageal reflux disease (NERD) patients and the basal impedance level.

Aims & Methods: We evaluated the usefulness of the measurement of impedance in PPI-refractory NERD patents, and the relationship between the impedance and reflux symptoms. Sixty-seven NERD patients without esophageal motility disorder underwent 24-pHMII while taking the PPI. The impedance was measured at three time points; 0:30 am, 10:00 am and 04:00 pm.

Results: The mean value of the impedance did not differ among the three time points in 67 PPI-refractory NERD patients (0:30 am, 3162.0 ± 2035.0 Ω; 10:00 am, 3140.6 ± 1986.5 Ω; 04:00 pm 3124.8 ± 1816.1 Ω). Therefore, we defined the mean value of the impedance at 10:00 am as the basal impedance value. Acid exposure time (AET) negatively correlated the acid present time (APT) among the three time points ($p < 0.01$). Sixty-seven NERD patients were divided into two groups; 49 patients with esophageal acid reflux events [endoscopy-negative reflux disease (ENRD) group] and 18 patients without esophageal acid reflux events [functional heartburn (FH) group]. ENRD group were subdivided into 20 patients with prolonged acid exposure time (pH-POS group) and 29 patients with normal acid exposure time [Hypersensitive esophagus (HE) group]. There

were no significant differences related with the patients' background, their quality of life and symptoms between ENRD group and FH group. There were also no significant differences related with the patients' background, their quality of life, gastroesophageal reflux (GER) episodes among pH-POS group and HE group. The average of basal impedance in the ENRD group was significantly lower than FH group (ENRD group, 2793 ± 2125.5 vs. FH group, 4085.9 ± 265.7, $p < 0.01$). AET and APT were significantly related with the basal impedance in the ENRD group (AET, r = -0.34, $p < 0.05$; APT, r = -0.43, $p < 0.05$). Median Bolus Clearance Time (MBCT) and the Longest Episode (LE) were significantly related with the basal impedance in the ENRD group (MBCT, r = -0.45, $p < 0.01$; LE, r = -0.48, $p < 0.01$). However, there was no significant difference between the basal impedance and the reflux in the FH group.

Conclusion: The measurement of basal impedance is simple method for evaluating the condition of PPI-resistant NERD patients. The measurement of basal impedance value was useful for distinguishing ENRD patients from FH patients in the PPI-resistant NERD patient.

Introduction: Radiofrequency ablation (RFA) leads to replacement of Barrett's esophagus (BE) mucosa with a neosquamous epithelium, but sometimes the metaplastic mucosal regression is unsatisfactory after initial procedure. Thus the additional biomarkers that are associated with an increased risk of progression to adenocarcinoma are needed.

Recently, it has been shown that several microRNAs (miR-192, miR-194, miR-196a, and miR-196b) high expression is associated with the progression of BE to esophageal adenocarcinoma (EAC).

Aims & Methods: This study aim was to identify microRNAs levels before and after RFA procedure and to assess their prognostic role in RFA outcome.

We included 13 patients who underwent RFA for BE with low grade dysplasia. Esophageal mucosa of 4 patients with BE without dysplasia represented controls.

The expression of 4 miRNAs (hsa-miR-192, hsa-miR-194, hsa-miR-196a, hsa-miR-196b) in esophageal mucosa and blood samples before RFA procedure and in 6 months after first RFA procedure was determined using quantitative real-time RT-PCR technique (iQ5 Biorad, USA). MiRNA was extracted using MirVana miRNA Isolation Kit (Thermo Fisher Scientific, USA). cDNA expression levels was measured by using TaqMan MicroRNA RT kit and TaqMan MicroRNA Assay (Thermo Fisher Scientific, USA).

6 patients required only one RFA procedure to complete IM eradication, which was confirmed both in endoscopy and pathology. Another 6 patients needed more than 1 RFA procedure (2-4).

Results: Expression levels (mean Ct - threshold cycle) of miR-192, -194, -196a, -196b assessed before RFA were: 20, 23; 21,6; 24,47; 27,14, respectively. All 4 microRNAs expression levels were significantly lower compared to their expression levels after RFA (23,14; 25,71; 31,06; 32,63, respectively; $p < 0.01$; $p < 0.05$). Expression levels of miR-192, -194, -196b before RFA were also significantly lower compared to controls (20.23 vs 24.15; 21.6 vs 21.47; 27.14 vs 30.76, respectively). Expression levels of all miRNAs assessed after RFA were not different from controls (NS).

There were no differences in expression levels of miR-192, -194, -196a, -196b between those with satisfactory first RFA attempt compared to the remaining group (22.45 vs 23.62; 26.06 vs 24.66; 29.68 vs 31.3; 30.83 vs 33.69).

Differences in expression of microRNAs in blood samples did not reach statistical importance.

Conclusion: Regaining miRNA expression after RFA the normal levels which are seen in controls could be considered a sign of the recovery. Increased expression levels of miRNA after ablation could represent their temporary apoptotic affect, however the continuation of surveillance is essential. miRNA levels did not predict initial response to RFA, however studies on larger groups are needed.

P1751 MULTI LAYERED EPITHELIUM INDUCED BY BILE AT THE SQUAMO-COLUMNAR JUNCTION IN MICE ORIGINATES FROM SQUAMOUS AND COLUMNAR CELLS

D. Straub[1], C. M. Chen[2], P. fockens[1], **K. Krishnadath**[1]

Introduction: Barrett's esophagus (BE), a premalignant condition of esophageal adenocarcinoma (EAC) is defined as the replacement of normal stratified squamous epithelium of the lower esophagus by metaplastic columnar epithelium [1]. The observation of multi-layered columnar epithelium (MLE) regularly observed at the squamo-columnar junction (SCJ) in BE patients suggests a transitional stage between these two types of epithelia. Studies, in both human and rats, have shown that especially the combination of acid and biles can induce MLE and metaplasia at the SCJ [2,3]. In this study we investigated if the diverse layers as observed in MLE is a transitional stage between epithelia originating from one progenitor cell, or is a mix of different types of epithelia with diverse progenitors.

Aims & Methods: 0.5% deoxycholic acid (DCA) was given to mice in drinking water for a maximum of 30 weeks. Animals were sacrificed and studied by immunohistochemistry (IHC) at different time points. Bile treatment induced gland formation at the SCJ starting from week 15. The MLE glands were positive in the outer layer for squamous markers K14, p63 and K5 and in the inner layer for columnar markers K19, TFF2 and Alcian Blue. In one of our previous studies we also observed Lgr5 positive cells (*RNA in situ*) in these multi-layered glands [4].

To investigate if MLE originates from a squamous or columnar stem cell, we performed lineage tracing experiments. A Cytokeratin 5 (K5)-cre (n = 20) mouse specific for tracing squamous progenitor lineages, and a Leucine-G-coupled receptor (Lgr5)-cre mouse (n = 20) were crossed with Rosa-lacZ mice. Lineage tracing was induced by tamoxifen injection prior to bile treatment at the age of 8 weeks. Mice were sacrificed 20 weeks after induction.

Results: K5-lacZ-positive cells were present in the outer layer of the gland demonstrating that the origin of these cells is from squamous progenitors, which is in concordance with the IHC results. Negative K5 lineage tracing in columnar cells within the MLE in mice excludes the transdifferentiation hypothesis in which squamous cells change into columnar cells, which has been a prevailing theory for many years. The negative lineage experiments for LGR5 suggests a columnar cell of origin, other than Lgr5 for the inner layer.

Conclusion: Continuous acid and bile reflux changes the environment at the SCJ in mice and disrupts the natural homeostatic environment of squamous and columnar cells. It appears that MLE is the result of competitive interactions between cell lineages driven by environmental changes.

P1752 BARRETT'S ESOPHAGUS CELL OF ORIGIN DOES NOT DERIVE FROM CYTOKERATIN 5 EXPRESSING SQUAMOUS CELLS IN MICE

D. straub[1], N. Buttar[2], P. Fockens[1], **K. Krishnadath**[1]
[1]*AMC, Amsterdam, Netherlands,* [2]*Mayo Clinic, Rochester, United States*

Contact E-mail Address: d.straub@amc.nl
Introduction: Barrett's esophagus (BE) is defined as replacement of the stratified squamous epithelium in the distal esophagus with a metaplastic, intestinal like columnar epithelium [1]. A major unanswered question is whether the BE cell of origin derives from transdifferentiation of the esophageal squamous epithelium [2], or originates rather from a progenitor cell in the esophagus [3], the esophageal submucosal glands [4], residual embryonic cells located at the squamocolumnar junction [5] or from the gastric cardia [6].
Since Lgr5 expressing cells have been observed in human BE, it has been suggested that the stem cells that give rise to BE may originate from the neighboring columnar epithelia harboring Lgr5+ stem cells [7]. Recently we showed by performing lineage tracing experiments that Lgr5+ progenitors are not at the basis of the columnar metaplasia that develops in the tubular esophagus in a surgical esophagitis-metaplasia mouse model [8].
Aims & Methods: To investigate if the metaplasia observed in the esophagus in a surgical mouse model originates from cytokeratin 5 (CK5) expressing esophageal cells, we performed lineage tracing by creating the esophago-jejunostomy in CK5-EGFP-ires-CreERT2/Tomato-GFP mice ($n=13$). The anastomosis was performed one week after administering Tamoxifen, and metaplasia was allowed to develop over six ($n=3$), twelve ($n=5$) and sixteen weeks ($n=5$).
Results: Development of metaplastic glands at the junction was observed in 2 of the animals. None of the glands in all the animals studied showed positive GFP staining although the normal esophagus lying adjacent to the site of the metaplasia showed entire green squamous tissue indicating successful lineage tracing in the esophagus. Our data suggests that CK5+ esophageal cells are not at the basis of the columnar metaplasia that develops in the tubular esophagus and at the neo-SCJ in our surgical model.
Conclusion: In conclusion, progenitors other than Lgr5 and CK5 positive stem cells might be candidates for the cell of origin in the metaplastic lesions as observed in a surgical Barrett mouse model.

Introduction: Barrett esophagus (BE) is one of the most common premalignant conditions and it is considered to be a primary risk factor for esophageal adenocarcinoma (EAC). BE-associated EAC develops through a multi-step process (intestinal metaplasia-dysplasia-adenocarcinoma) that involves different triggers of neoplastic progression such as chromosomal abnormalities, genetic and epigenetic events and environmental factors. Many biomarkers have been tested in BE but none of them have shown clinical significance in disease progression besides dysplasia.
Aims & Methods: The aim of this study was to evalute the role of mismatch repair system (MMR) in metaplasia-dysplasia-adenocarcinoma sequence of Barrett's esophagus (BE). Data from 70 patients with patohistological diagnosis of BE or esophageal adenocarcinoma (EAC) was retrospectively analysed. Patients were divided into three groups: BE with intestinal metaplasia without dysplasia (22 patients), BE with dysplasia (37 patients) and adenocarcinoma (11 patients). Immunohistochemical expression of MLH1, MSH2, PMS2 and MSH6 of DNA mismatch repairs (MMR) system in different groups was measured, statistically analysed and compared with p53 expression.
Results: MLH1 and PMS2 expression in different phases of BE was statistically significant. Loss of MLH1 and PMS2 expression was present in 81.8% patients with adenocarcinoma, 67.6% and 64.9% respectively in dysplasia group, 50% and 54.5% respectively in patients without dysplasia. Neither patients with adenocarcinoma or dysplasia had MSH2 or MSH6 loss of expression, and in group without dysplasia loss of expression was observed in 18.2% patients, which was all statistically significant. There is a strong positive correlation between MLH1 and PMS2 expression and also MSH2 and MSH6 in the whole sample and in different BE groups. Patients who had positive p53 expression did not have MLH1 or PMS2 expression but statisticaly significant correlation was only shown in dysplasia group.
Conclusion: MLH1 and PMS2 can be a promising biomarkers in surveillance and therapy making decisions of BE patient.

P1754 EFFECT OF DIET-INDUCED OBESITY ON PROGRESSION OF CHRONIC ESOPHAGITIS IN EXPERIMENTAL MODEL OF BARRETT'S OESOPHAGUS. BENEFICIAL EFFECT OF MELATONIN AND L-TRYPTOPHAN, A PRECURSOR OF MELATONIN

M. Wierdak[1], I. Brzozowska[1], K. Magierowska[1], M. Strzalka[1], A. Targosz[1], M. Magierowski[1], R. Pajdo[1], **T. Brzozowski**[1]

Introduction: Gastro-oesophageal reflux disease (GERD) is a major health problem in Western countries and obesity is also a major risk factor for reflux-associated oesophageal lesions, such as erosive oesophagitis, Barrett's oesophagus, and oesophageal adenocarcinoma. The effects of diet-induced obesity (DIO) in development of chronic esophagitis and the therapeutic efficacy of melatonin precursor, L-tryptophan and melationin in mediating of the effects of body and abdominal obesity in experimental rodent model of Barrett's esophagus has not been extensively studied.
Aims & Methods: Using eighty rats surgically prepared with esophagogastroduodenal anastomosis (EGDA) resulting with esophageal mucosal damage we studied the hypothesis that 1) diet-induced obesity (DIO) augments the severity of chronic esophagitis, and 2) exogenous melatonin or that originated in the gut from its precursor, L-tryptophan, could attenuate the experimental Barrett's esophagus in DIO rats. Rats fed with high- or low-fat-diet were randomly divided into five groups and received for 12 weeks: 1) standard laboratory rodent diet (control, fat equivalent 30 kcal%); 2) high-fat diet (fat equivalent of 70 kcal%) and 3) low-fat diet (10 kcal %) with or without vehicle (saline), melatonin (40 mg/kg i.g.) or L-tryptophan (200 mg/kg i.g.). The effect of removal of major source of melatonin, the pineal gland (pinealectomy) without or with melatonin treatment, was studied in separate group of animals fed with DIO and low-fat diet. At 8 and 12 weeks esophageal damage was evaluated by macroscopic and histological lesion index (LI), esophageal blood flow (EBF) was determined by H_2-gas clearance technique, and malonyldialdehyde (MDA) contents were assessed in the esophageal mucosa. The mucosal expression of mRNA and protein for caudal-related homebox gene family Cdx1 and Cdx2, COX-2, and proinflammatory cytokines IL-1β and TNF-α were analyzed by RT-PCR and Western Blot.
Results: Chronic esophagitis developed in all EGDA animals fed with DIO as manifested by a significant decrease in EBF, an increase in body weight, MPO activity, oesophageal MDA content and an increase in Cdx2- and COX-2 mRNAs. In EGDA rats, extensive esophageal ulcerations, development of columnar epithelium, formation of mucus glands in squamous epithelium and intestinal metaplasia were observed. These effects were further significantly more pronounced in pinealectomized rats fed with DIO. Melatonin and its precursor L-tryptophan which raised significantly the plasma melatonin levels and EBF, significantly reduced the LI and attenuated expression of Cdx2 and COX-2 in both non-pinealectomized and pinealectomized animals fed with DIO compared with those fed normal or low fat diet. The expression of IL-1β and TNF-α was downregulated and plasma levels of these cytokines were significantly reduced in melatonin and L-tryptophan rats fed with DIO.
Conclusion: Melatonin and that derived endogenously from L-tryptophan may represent a novel therapeutic option against reflux esophagitis progressing to Barrett's esophagus due to an improvement of esophageal circulation, antiinflammatory activity resulting in attenuation of proinflammatory markers COX-2-, Cdx2, IL-1β- and TNF-α and inhibition of lipid peroxidation.

P1755 IMPACT OF ENDOSCOPIC SURVEILLANCE IN BARRETT 'S ESOPHAGUS WITHOUT DYSPLASIA - A RETROSPECTIVE STUDY

V. Anapaz[1], R. Carvalho[1], J. Reis[1], J. Branco[1], L. Lourenço[1], L. Santos[1], M. Cardoso[1], A. Oliveira[1]
[1]*Gastroenterology, Hospital Professor Dr. Fernando Fonseca, Lisbon, Portugal*

Contact E-mail Address: vera_anapaz@hotmail.com

Introduction: Barrett's esophagus (BE) is a potentially malignant entity, with an annual incidence of esophageal cancer of 0.5% per year and a risk of progression to adenocarcinoma varying from 0% to 2.9%. According to guidelines, endoscopic surveillance should be performed in patients with BE with predefined intervals related to the grade of dysplasia[1,2,3].
Aims & Methods: The aim of this study is to evaluate the impact of endoscopic evaluation of patients with BE without dysplasia and to assess incidence of low-grade dysplasia, high-grade dysplasia and adenocarcinoma. This is a retrospective analysis of a cohort of patients with Barrett's esophagus in surveillance program between 2008-2014. We evaluated the number of endoscopies per patient and the progression to dysplasia and ADC.
Results: We included 52 patients, of whom 69% were male, with an average age at diagnosis of 67 ± 12.81 years old. 73% of patients had symptoms of gastroesophageal reflux medically controlled. At diagnosis, 48 patients (92.3%) had no dysplasia and 4 (7.7%) had low-grade dysplasia. The average number of endoscopies was 4.8 ± 1.37 per patient. During the study period, 3 patients without dysplasia at diagnosis (6.2%) progressed to low-grade dysplasia and 2 patients (4.2%) progressed to adenocarcinoma. Both patients with adenocarcinoma were submitted to surgery.
Conclusion: The data obtained demonstrate the importance of endoscopic surveillance in patients with BE without dysplasia. The results of our study are different from the literature, in the incidence of adenocarcinoma. This can be related with the small sample size and to the fact that this was a retrospective study.

P1756 STATIC IMAGES VERSUS DYNAMIC VIDEOS FOR ENDOSCOPIST TRAINING: THE ELEPHANT IS IN THE ROOM!

K. Kandiah[1], **F. Chedgy**[1], R. Bhattacharyya[1], G. Longcroft-Wheaton[1], P. Bhandari[1]
[1]*Gastroenterology, Queen Alexandra Hospital, Portsmouth, United Kingdom*

Contact E-mail Address: kesavankandiah@gmail.com

Introduction: Training modules on lesion recognition and in-vivo diagnosis have traditionally utilised static images. In real-life, assessments are made on dynamic and moving organs. Therefore, assessment and training of endoscopists in lesion recognition and characterisation using video-clips would reflect real-world practice. There have been no studies thus far comparing assessments using still images versus videos in lesion recognition and characterisation.
Aims & Methods: We aimed to assess the difference in accuracy and confidence in Barrett's neoplasia recognition and characterisation when using still images versus videos. We also want to assess the impact of a training intervention using the same library of static and video files. 14 endoscopists, with varying degrees of experience in the use of acetic acid chromoendoscopy (AAC), were asked to identify neoplasia versus metaplasia in Barrett's oesophagus (40 static images and 20 videos each approximately 3 minutes long) using a web-based platform. Accuracy and confidence in diagnosis were measured. No feedback was given. Following this intial test, participants completed a structured online training programme on the concepts of in-vivo diagnosis of Barrett's neoplasia using AAC including both stills and videos. Upon completion of the training module, participants repeated the test.
Results
Three Experts when tested with this library showed an accuracy of 93% with static images and 93% with video based assessment. 14 endoscopists (6 regular users of AAC) participated in the training study. Diagnostic accuracy improved from 78% (pre-training) to 85% (post-training) when images were used as the assessment tool ($p < 0.05$). Additionally, confidence in diagnosis improved by(?% to? %) 7% ($p < 0.05$). In contrast, the training intervention showed an improvement in diagnostic accuracy (77% to 81%) and confidence (75% to 80%) on video-based assessments ($p = 0.19$).

	Pre-Online Module Test		Post-Online Module Test	
	Mean accuracy (%)	Confidence (%)	Mean score (%)	Confidence (%)
Images(n = 40)	31 (78)	31 (78)	34 (85)	34 (85)
Videos(n = 20)	15 (77)	15(75)	16 (81)	16 (80)

Conclusion: This is the first study comparing image and video-based assesments in Barrett's neoplasia recognition. Experts did not show any difference in accuracy between images and videos. Endoscopists with no or little experience with AAC in Barrett's oesophagus had a significantly lower accuracy rates then experts but it was equally low on images and videos. Training led to significant improvements in accuracy and confidence in image-based assessment but not on video-based assessment. This questions the validity of static image-based training and assessment as a surrogate marker of real life.

Introduction: Esophageal atresia (EA) is a rare congenital anomaly and requires surgical correction shortly after birth. In EA patients gastroesophageal reflux (GER) is frequently reported (25-58%). Due to the high prevalence of GER and increased survival in EA patients (>90%), concerns arise about an increased risk of developing Barrett's esophagus (BE) and esophageal carcinoma in this population.
Aims & Methods: Esophageal atresia (EA) is a rare congenital anomaly and requires surgical correction shortly after birth. In EA patients gastroesophageal reflux (GER) is frequently reported (25-58%). Due to the high prevalence of GER and increased survival in EA patients (>90%), concerns arise about an increased risk of developing Barrett's esophagus (BE) and esophageal carcinoma in this population.
Results: To date, 74 patients (60.8% male; median age (range) 21.9 years (16.8-55.9)) underwent a gastroscopy. History of GER before adulthood was present in 47 (63.5%) patients, 21 (28.4%) of whom underwent fundoplication surgery. At baseline, 19 (25.7%) patients had GER complaints and 7 (9.5%) patients used anti-reflux medication. Endoscopic findings were: extension of gastric epithelium above the GEJ in 20 (27%) patients, esophagitis in 4 (5.4%) patients and normal mucosa in 50 (67.6%) patients. In one patient biopsies were not taken. Histology revealed BE without dysplasia in 7 (9.6%) patients with a median age of 31.0 years (range 17.9-45.3 years; 86.7% male) and gastric metaplasia in 1 patient. Esophagitis was present in 21 (28.8%) patients. In 44 (60.3%) patients inflammatory changes were within normal limits. One male had developed squamous cell carcinoma of the distal esophagus at the age of 44 years. This was before endoscopic screening and surveillance of EA patients had started in our hospital.
Conclusion: EA patients have a six-fold increase in developing BE compared to the general population (9.6 vs 1.6%) and at a much younger age (31 vs 55 years). One third of the adult EA patients have histological esophagitis at the GEJ. These findings may signify important and relevant clinical implications including use of proton pump inhibitors and lifelong endoscopic follow-up by experts to facilitate early diagnosis of clinically relevant lesions.

Introduction: Barrett's esophagus (BE) is a premalignant condition which may lead to oesophageal cancer. For this reason, a careful endoscopic surveillance is of paramount importance. So far, only few data on the preferred location of BE and high-risk lesions associated with BE are available.
Aims & Methods: The aim of this study is to identify the preferred circumferential location of BE and associated high-risk lesions. We retrospectively reviewed a prospectively maintained database of patients with noncircumferential, short-segment, histologically proven BE who underwent upper endoscopy between January 2008 and February 2015 at our Endoscopy Center. In the case of multiple BE lesions, each tongue was counted individually. The circumferential location of each lesion was identified as on a clock face. The position of dysplastic lesions was compared with that of simple BE tongues without dysplasia (S-BE). Chi-square test was used to compare the expected and observed distribution of lesions both in the left and right hemicircumferences and in the 4 quadrants.
Results: Over the study period, a total of 209 subjects were newly diagnosed of BE or had an endoscopic follow-up of BE. 24 patients with long-segment BE and/or circumferential lesions were excluded. Among the 185 remaining patients, multiple lesions were diagnosed in 110 of them, for a total amount of 341 areas of BE. 28 of them were associated with low-grade dysplasia (LGD-BE), and 1 with adenocarcinoma. No lesions with high-grade dysplasia were found. LGD-BE lesions were significantly more common in the posterior wall (5 to 7 o'clock) than within other areas of the esophageal circumference, accounting for 42% versus, respectively, 38% in the anterior wall (11 to 1 o'clock), 23% in the right wall (2 to 4 o'clock), 4% in the left wall (8 to 10 o'clock) ($P = 0.03$). S-BE lesions were more frequently observed in the posterior wall (38%), compared with right wall (29%), anterior wall (22%), left wall

(11%), in a significant manner ($P < 0.0001$). Both S-BE lesions and LGD-BE lesions were more commonly found in the right (1 to 6 o'clock) than in the left (7 to 12 o'clock) arc, respectively, with a significant (S-BE: 63% versus 37% – $P < 0.0001$) and non-significant difference (LGD-BE: 64% versus 36% – $P = 0.13$) between the two hemispheres.
Conclusion: Our results show a non-homogenous location of BE lesions with and without dysplasia in the circumference of the distal oesophagus, LGD-BE was more commonly observed in the posterior quadrant. Accurate evaluation of these areas is therefore advisable during the endoscopic follow-up of BE. Should our findings be confirmed by further, larger experiences, they should be taken into account for the development of future surveillance protocols of BE.

P1759 USEFULNESS OF INSULIN-LIKE GROWTH FACTOR BINDING PROTEIN-3 IN BARRETT'S ESOPHAGUS AS A POTENTIAL BIOMARKER OF NEOPLASTIC PROGRESSION. PRELIMINARY RESULTS

H. I. Uchima[1], M. Cuatrecasas[2], C. Sánchez-Montes[1], H. Córdova[1], À. Ginès[1], I. Elizalde[1], I. Araujo[1], N. Rakislova[2], B. González[1], J. Llach[1], A. Bombi[2], G. Fernández-Esparrach[1]

Introduction: Barrett's esophagus (BE) is an entity with a well known histological progression to malignancy.
Malignant transformation in patients with BE may arise from alterations of apoptotic regulatory proteins and the insulin-like growth factor (IGF) system is involved in the regulation of cell proliferation, diferentiation and apoptosis. Dys-regulation of IGF1 increases the risk of a number of malignancies. IGF binding protein-3 (IGFBP3) is over-expressed in BE, dysplastic and tumour tissue of patients with adenocarcinoma. The possibility of having a plasmatic biomarker of BE progression is very appealing. However, the role of IGFBP3 in cancer progression is not clear with controversial results regarding circulating levels of this protein.
Aims & Methods: The objective of this study is to evaluate circulating levels of IGFBP-3 in patients with BE at different histological stages.
We performed a prospective longitudinal study and determined baseline concentrations of IGFBP3 in all patients with BE who underwent an upper endoscopy from May 2012 to May 2015. Endoscopy was performed under conscious sedation and biopsies were obtained following the Seattle protocol. Ten mL of blood were taken and determination of IGFBP-3 was performed using the ELISA technique. We included patients without BE as a control group. The protocol was approved by the Ethics Committee and patients gave informed consent.
Results: A total of 61 patients with blood samples were included at the time of this preliminary analysis: 42 with BE (15 non-dysplastic, 13 with low-grade dysplasia and 14 with adenocarcinoma) and 19 controls. BE patients had a mean age of 60.4 ± 13.7 years and 39 (92.9%) were male with a mean BMI of 26.2 ± 3.3.
Mean levels of IGFBP3 were equal in BE and control group (2.1 ± 1 and 2.1 ± 1.1 ug/ml, respectively, $p = NS$), with 20 cases (including 5 controls) over the upper limit of reference (>2.3 ug/mL). No patient showed levels of IGFBP3 below the inferior limit of reference (<0.7 ug/mL).
There were no differences in IGFBP-3 serum levels between non-dysplastic BE (2.1 ± 0.7 ug/ml), low-grade dysplasia (2.2 ± 0.8 ug/mL), and adenocarcinoma (1.9 ± 0.6 ug/mL), $p = NS$.
Conclusion: In this preliminary analysis, IGFBP-3 circulating levels are similar in patients with BE (including BE associated neoplasia) and patients without BE. Serum levels of IGFBP-3 are not different in non-dysplastic BE compared to dysplastic and adenocarcinoma, bringing into question its potential role as a biomarker of neoplastic progession in BE.

Contact E-mail Address: k.belghazi@amc.nl
Introduction: Radiofrequency ablation (RFA) is an established endoscopic therapy for treatment of Barrett's esophagus (BE) with different grades of dysplasia. Generally, patients are initially treated with circumferential RFA using the balloon-based Barrx360 system. A standard procedure consists of sizing the esophageal inner diameter at multiple levels using a sizing catheter. Then an ablation balloon with the appropriate diameter is selected and introduced to ablate the BE using 2 applications of 12 J/cm^2 with cleaning of the ablation zone and catheter in between. A recent study comparing different regimens for circumferential RFA demonstrated that this standard circumferential RFA procedure using the Barrx360 balloon results in a BE surface regression of 83% at 3-month follow-up, with a median total procedure time of 39 minutes. By incorporating the sizing and ablation balloon into a single device, procedure time may be shortened and patient discomfort decreased, since less introductions of the endoscope and catheters are needed.
Aims & Methods: Aim of this pilot study was to assess efficacy and safety of the recently developed Barrx™ 360 Express RFA Balloon Catheter (360 Express). Patients with BE 2-10cm with low-grade dysplasia (LGD), high-grade dysplasia (HGD) or early cancer (EC), confirmed by an expert pathologist, were included. In case of visible lesions, endoscopic resection (ER) was performed prior to RFA. Circumferential RFA was performed using the 360 Express catheter, applying 2 applications of 12J/cm^2 with cleaning of the ablation zone and catheter in between. The first follow up endoscopy was performed 3 months after treatment. Primary outcome: percentage of endoscopically visual surface regression of BE at 3 months graded by two independent endoscopists. Secondary outcomes: procedure time and complications.
Results: Thirty patients (24 men, median age 66 yrs (IQR 62-73), median BE C4 (IQR 2-6) M6 (IQR 4-8)) were included. Four patients underwent ER prior to RFA (worst pathology: EC (n = 2), HGD (n = 1), LGD (n = 1)). Worst histological grade prior to RFA: HGD (n = 6), LGD (n = 22), no dysplasia (n = 2). Median BE surface regression at 3 months was 90% (IQR 77-95). Median procedure time was 31 min (IQR 28-38); median ablation time was 20 min (IQR 17-25). Complications occurred in 4 patients (13%): 1 superficial mucosal laceration that did not require intervention; 1 patient showed atrial fibrillation after the RFA procedure; 1 patient presented with vomiting and dysphagia, however, endoscopy did not show any signs of esophageal narrowing; 1 patient was admitted with dysregulated diabetes mellitus. In seven patients esophageal scarring was observed during the 3 months endoscopy, however, all patients were asymptomatic and no interventions were needed.
Conclusion: This pilot study shows that circumferential RFA using the Barrx™ 360 Express RFA Balloon Catheter may shorten procedure time, but maintains efficacy when compared to standard circumferential RFA using the Barrx360 balloon. No severe adverse events related to use of the device were observed.

Introduction: Diagnosis and surveillance of Barrett's esophagus (BE) is commonly performed by means of upper endoscopy with biopsies, which is also important to assess the extension of Barrett's metaplasia. Several studies demonstrated the risk of dysplasia and adenocarcinoma development in BE is associated to its extension. However, endoscopic evaluation of esophago-gastric junction (EGJ) may be inaccurate, especially in patients with hiatal hernia, reflux esophagitis and abnomal z-line. Recent studies carried out with 24-h impedance-pH testing showed that Barrett mucosa is characterized by very low basal impedance values compared to the normal esophageal epithelium. High resolution impedance manometry (HRiM) is able to localize with more accuracy than upper endoscopy the EGJ and, also, has been recently applied for baseline impedance levels in patients with reflux disease.
Aims & Methods: We aimed to assess Barrett extension by means of baseline impedance levels (BIL) assessed by HRiM using upper endoscopy as reference standard. In contrast, HRiM was considered reference for EGJ evaluation. Consecutive patients with proven Barrett's esophagus and a group of healthy volunteers (HVs) were enrolled. Patients underwent endoscopy and HRiM before imp-pHmetry off-PPI therapy was performed.BE extention was endoscopically assessed according to Prague classification. During HRiM, EGJ has been identified by assessing the position of lower esophageal sphincter (i.e. proximal and distal borders) and crural diaphragm. BIL was recorded every cm above the EGJ. After measuring BIL at Barrett mucosa level and normal esophageal epithelium in each patient we decided that a stable increase $\geq 100\Omega$ was a good cut-off to discriminate BE length. Maximal length (M) at endoscopy was used for comparison.
Results: Ten HVs (4M/6F; mean age 35, BMI 23) and 20 consecutive BE patients (11M/9F; mean age 46, BMI 25.9) were enrolled. Among BE, hiatal hernia (HH) was found in 15 pts (75%) during endoscopy and 12 (60%) with HRiM. Endoscopy overestimated HH of at least $\geq$1cm in 9 cases. Mean HH was 1.7 vs0.9cm, respectively (mean error 0.75 cm, median SD:0.25; r:0.78). HVs had no HH. During HRiM BE mucosa showed lower BIL compared to the normal epithelium in each BE patients ($p < 0.01$; median BIL 430Ω vs 650Ω 1 to 3 cm above BE, vs 1077Ω 4 to 7cm) and Hvs (shown in Table). Median BE length was 1.7cm (1.5-2.3) at endoscopy, whereas was 2cm (1.0-3.5) at HRiM (median SD error:1cm; r:0.32).

	Barrett (Ω) median (IC95%)	HVs (Ω) median (IC95%)
Z-line	412 (295-562)	1690 (1286-2181)
1 cm	473 (378-584)	1678 (1516-2308)
2 cm	544 (425-683)	1859 (1644-2344)
3 cm	573 (441-732)	2176 (1775-2416)
4 cm	738 (478-856)	2267 (1943-2303)
5 cm	899 (550-1121)	2278 (2159-2523)
7 cm	1191 (953-1248)	2495 (2380-2604)
9 cm	1241 (1029-1633)	2718 (2612-3134)
13 cm	1334 (1128-1691)	2835 (2623-3476)

Conclusion: Our data showed that HRiM was able to discriminate Barrett mucosa from normal esophageal epithelium. Considering that HRiM is the reference standard to assess EGJ position and borders, this technique might become a useful tool combined with endoscopic examination to assess more precisely BE length.

P1762 INVESTIGATION OF THE INFLUENTIAL FACTORS PROVIDING TECHNICAL DIFFICULTY OF ENDOSCOPIC SUBMUCOSAL DISSECTION FOR EARLY CANCER LOCATED IN ESOPHAGO-GASTRIC JUNCTION

M. Imajoh[1], T. Yano[1], T. Kadota[1], S. Osera[1], H. Morimoto[1], Y. Oono[1], H. Ikematsu[1], K. Kaneko[1]
[1]*Department of Gastroenterology, Endoscopy Division, National Cancer Center Hospital East, Kashiwa city, Japan*

Contact E-mail Address: maomiimajo@gmail.com
Introduction: Endoscopic submucosal dissection (ESD) is accepted as a curative treatment for early gastrointestinal cancer, although only skillful endoscopists can perform ESD. Especially, esophago-gastric junction (EGJ) is known as difficult area to work with endoscope due to narrow space, and reflux. However, the influential factors providing technical difficulty of ESD in EGJ region are uncertain.
Aims & Methods: The aim of this study is to reveal the short-term outcomes after ESD and the influential factors for technical difficulty of ESD in EGJ.
We enrolled consecutive patients who were treated with ESD for EGJ cancer in our institution from January 2006 to December 2014 and met the following criteria: 1) histologically confirmed adenocarcinoma (Adeno) or squamous cell carcinoma (SCC), 2) the depth of tumor invasion limited within T1 (submucosal layer). We adopted the Japanese criteria of EGJ (area within 2cm above and below the EGJ). For ESD procedure, a electric device (Dual Knife, IT knife, Olympus) was used through a single-channel endoscope (GIF-Q260J or -H260Z, Olympus). We defined the case requiring more than 120 minutes for the procedure as difficult case. Curative resection was defined if the pathological assessment of the resected specimen fulfilled following criteria: 1) The depth of invasion was limited within muscularis mucosa in SCC, and within 500μm of submucosa in Adeno, 2) No lymphovascular invasion, 3) No cancer cells at horizontal and vertical margin in the resected specimen. Comparative investigations were conducted regarding: short-term outcomes, complete en bloc resection rate, procedure time of ESD, complication, curative resection rate and assessed the influential factors for long procedure time.
Results: A total of 70 lesions in 70 patients with a median age of 70 years (range, 42-86) and a male/female ratio of 57:13 were enrolled in this study. The median tumor size was 21.5mm in diameter (range, 6-49 mm), and there were 14 lesions (20%) spreading more than half of circumference of the lumen. Histologically, 44 lesions (including 21 lesions deriving from short-segment Barrett's esophagus) were Adeno, besides the remaining 26 lesions were SCC. The en bloc resection rate by ESD was 94% (66 of 70 lesions), and the remaining 4 cases forced to be piecemeal resection were SCC. Severe complications were seen in 2 cases; one case with bleeding required blood transfusion; another with perforation during ESD. 32 lesions (46%) were assessed as non-curative resection due to following reasons: submucosal invasion in 18, presence of cancer cells at horizontal margin in 5 and vertical margin in 2, and lymphovascular invasion in 7 lesions. Median procedure time was 90 minutes (range 20-260). Furthermore, 21 cases (30%) were assessed as difficult cases. In multivariate logistic regression analysis, ''more than half of circumference of the lumen'' was the most influential factor for technical difficulty in ESD ($p = 0.035$, 95%CI: 1.198-129.379, Odds ratio: 12.451). Second influential factor was SCC in histology ($p = 0.043$, 95%CI = 1.055-23.962, Odds ratio: 5.027).
Conclusion: We should pay attention for the difficulty of ESD for early EGJ cancer, in case of the lesion spreading more than half of circumference of the lumen, or if the lesion is revealed as SCC histologically.

P1763 THE ROLE OF SURVEILLANCE ENDOSCOPIC ULTRASOUND AFTER ENDOSCOPIC TREATMENT OF INTRAMUCOSAL CANCER IN THE SETTING OF BARRETT'S ESOPHAGUS

M. Gonzalez-Haba[1], V. Konda[1], A. Koons[1], U. Siddiqui[1], A. Gelrud[1], I. Waxman[1]
[1]*Center For Endoscopic Research and Therapeutics, University of Chicago Medical Center, CHICAGO, United States*

Contact E-mail Address: mghrubio@hotmail.com
Introduction: Endoscopic treatment, including endoscopic mucosal resection (EMR) of visible lesions and radiofrequency ablation (RFA) of the remainder of Barrett's Esophagus (BE) epithelium, has become standard of care in the management of Intramucosal cancer (IMC) in patients with BE (1). The risk of lymph node metastases (LNM) among patients with IMC is estimated to be less than 2% (2) and Endoscopic Ultrasound (EUS) may be performed at evaluation to exclude LNM. After endoscopic therapy, regular endoscopic follow up is required to detect potential recurrence. There is a lack of consensus of whether follow up of patients with IMC should include EUS for detection of LNM.
Aims & Methods: The aim of this study is to evaluate the value of EUS added to endoscopy in the setting of follow up after endoscopic treatment for IMC in patients with BE. For that purpose a retrospective chart review was conducted on a prospectively collected database to select cases. Cases were identified as patients referred for BE associated neoplasia and were diagnosed with IMC, either by endoscopic biopsy or EMR from August 2003, through May 2013. All patients underwent endoscopic therapy either with complete endoscopic resection of the BE or with hybrid therapy (EMR for visible lesions and RFA/Cryoablation of the remainder epithelium). Patients lost to follow up were excluded. Patients in which an EUS was performed in follow up at least one year after initial diagnosis were selected for analysis.
Results: Out of 59 patients with IMC who completed endoscopic therapy, 50 patients fulfilled inclusion criteria. (39 Male, median age 70) with BE (mean length, 4.7cm) Ten were diagnosed with IMC by initial biopsy and 40 were diagnosed by EMR specimen. Median follow up time from diagnosis was 46.5 months (range 12-124). During this follow up period, a total of 165 EUS (mean 3.3) were performed. Confirmed lymph node metastasis (LNM) was found in two patients on EUS during follow up. One patient (2%) presented a positive lymph node for metastatic esophageal adenocarcinoma at 1 year after endoscopic treatment associated with buried neoplasia. Another patient had LNM found by EUS from a non-gastrointestinal malignancy without any evidence of recurrence of BE associated neoplasia. In 5/50 patients (10%) enlarged lymph nodes were found on EUS during follow up without evidence for malignancy after FNA sampling and/or by subsequent exams. One patient had an incidental newly diagnosed malignancy (dendritic cell tumor) and 5/50 patients had other benign findings, including choledocolithiasis and gallbladder stones.
Conclusion: The rate of LNM from esophageal neoplasia in patients who were endoscopically treated for IMC is very low. Although EUS has the potential to demonstrate significant incidental pathology, its role in serial examinations during follow up after treatment of IMC is limited.

Introduction: Malta is a southern European island-state with a relatively homogenous and stable population of 400,000 served by a centralised national health service. Oesophageal adenocarcinoma (OAC) is not considered to be a common pathology but accurate data are lacking. This study is a preliminary assessment of the prevalence of columnar-lined oesophagus (CLO) and associated neoplasia.
Aims & Methods: Since the inception of a specialist oesophago-gastric endosurgical practice all patients with endoscopically identified CLO equal to or longer than 1cm, were enrolled into a prospective longitudinal cohort study. Endoscopic assessment of the oesophageal mucosa was carried out using i-scan (Pentax), narrow band imaging (NBI, Olympus) and acetic acid spray as necessary. Subjects were assigned a Prague CM classification noting Kudo pit patterns. Biopsies were taken following the Seattle protocol with additional biopsies taken from visible lesions. Nodular lesions, especially if confirmed histologically as dysplastic or in keeping with T1a lesions were excised by EMR, employing argon plasma coagulation (APC) to complete ablation. The data collected were analysed with SPSS v. 23 (IBM SPSS Statistics).
Results: In the period January 2012 to April 2015, a total of 98 subjects were enrolled, 60 males and 36 females, with a mean age 58 years (range 19-94, SD 16.4). The mean circumferential CLO segment length (C) was 2.2cm with the mean mucosal (M) length being 3.4cm. Sixty eight subjects (70%) had short segments. Nine subjects were of Northern European extraction and longer segments were significantly higher in this subgroup ($p = 001$). Prevalent low

grade dysplasia was identified in 2 subjects, high grade dysplasia in 2, T1a OAC in 5 and invasive OAC in 17. Specialised intestinal metaplasia (SIM) was identified in 73 subjects and its presence was positively associated with longer segment lengths ($p = 0.014$), benign stricturing ($p = 0.010$) and neoplasia ($p = 0.004$).
Conclusion: This is the first study addressing CLO and OAC in this country. SIM was identified in 75% of subjects with CLO. Short segments appear to constitute the predominant indigenous phenotype, whereas immigrant Northern Europeans are more likely to have long segments. At present prevalent invasive cancer is commoner than early cancer three-fold. A comprehensive surveillance programme has been implemented to follow these CLO patients up in order to identify disease at an early and curable stage.

Introduction: Combined RFA and EMR are now established as first-line intervention for patients with mucosal HGD and IMC arising in BE. Patients with LGD have previously been managed with vigilant surveillance but more recently guidelines have changed to allow treatment to be offered to these patients. Accurate histological diagnosis of LGD remains problematic with inter-observer variability even amongst expert pathologists. However with confirmed LGD, rates of progression to cancer can be as high as 20% justifying early endoscopic treatment.
Aims & Methods: A multi-center patient registry of patients in the UK to assess the efficacy of RFA in the treatment of patients with LGD arising in BE. Patients for this study were included from 12 of the sites within the registry.
All patients required at least two successive procedures where LGD was identified. All LGD pathology was confirmed by two expert pathologists prior to treatment. Before RFA, any superficial lesions were removed by EMR. Patients then underwent RFA every 3 months until all visible BE was ablated there was disease progression (endpoints). Biopsies were taken at 12 months or when endpoints reached.
Primary outcomes for clearance of all dysplasia (CR-D) & BE (CR-BE) at 12 months were assessed.
Results: Forty patients, mean age 62 years (range 42-68), mean BE length 5.7cm (range 1-14) have undergone treatment. Six patients (15%) had EMR for visible lesions prior to RFA therapy. Once RFA was started no patients needed rescue EMR for new lesions. Patients needed a median of 2 RFA treatments (range 1-5) before reaching the end of protocol. Reversal of dysplasia (CR-D) was seen in all patients (100%) at 12 months. CR-IM was observed in 88% of patients after treatment. Three patients (8%) had symptomatic strictures that required endoscopic dilatation. With a median follow up of 6 months after completion of therapy, there has so far been no progression to HGD or cancer observed although long-term follow-up data are yet to surface.
Conclusion: In patients with confirmed LGD by expert pathologists, RFA is highly effective in the short term at eradicating neoplasia and BE following sequential treatments.

Introduction: Argon-plasma coagulation (APC) is a widely used, contact-free, operator-dependent endoscopic ablation technique for the eradication of BE with the relevant risk of stricture formation and buried metaplastic glands under a layer of neosquamous epithelium. Novel hybrid ablation method based on combination of APC and submucosal saline injection (Hybrid APC) has been recently developed to overcome these disadvantages [1].
Aims & Methods: The aim of the present trial was to evaluate efficacy and safety of Hybrid APC in ablation of BE. From July 2014 to March 2015 12 patients (mean age 54, range 40-68) with BE (median length C 1 M2) and low-grade dysplasia confirmed by two expert pathologists were selected for Hybrid APC. After raising the Barrett's mucosa with 0.9% saline solution injected by the high-pressure water jet system (ERBEJET 2, Erbe Elektromedizin, Tuebingen, Germany), the mucosa was ablated with the aid of the Hybrid APC probe (PULSED APC, Effect 2, 60 Watt). The ablation zone was mechanically cleaned with a transparent cap on the tip of the endoscope for further detailed inspection. Detected remnant areas of Barrett's mucosa were re-treated with a second APC application with the lower power (PULSED APC, Effect 2, 40–50 Watt). High dose PPI regimen (esomeprazole 80 mg/day) was used after procedures for strong acid suppression that provided an environment for development squamous mucosa on the site of ablation [2]. 1 and 3 months after completion of Barrett's ablation, upper GI endoscopy was carried out for evaluation of treatment-related strictures and for taking 4-quadrant biopsies from the whole area of the former BE segment including the Neo-Z-line.
Results: In a total of 12 patients complete macroscopic BE ablation was achieved after a mean of 3.4 (range 1-4) treatment sessions and the rate of histologically complete Barrett's ablation was 100%. A mean duration of one treatment session was 14.1 ± 3.2 min. No perforations or uncontrollable bleeding occurred during and after the procedures. In none of the patients stricture formation was observed after Hybrid APC. Mean follow-up after APC was 4.5 months. Buried metaplasia was not found in biopsy specimens contained sufficient subepithelial lamina propria.
Conclusion: Hybrid APC is a new operator dependent treatment modality for BE with LGD that has been shown to be effective and safe, especially in cases of short-segment BE. Short-term follow up didn't reveal any recurrence of BE mucosa or any major complications. Future evaluation of Hybrid APC in a multicenter study an interesting next step in this field.

Contact E-mail Address: simon.dunn@doctors.org.uk
Introduction: Barrett's Oesophagus is a common condition that is widely encountered in clinical practice. This European Society of Gastrointestinal Endoscopy (ESGE) survey asked clinicians attending United European Gastroenterology Week (UEGW) 2014 in Vienna to answer questions about their practice in the diagnosis and management of Barrett's Oesophagus.
Aims & Methods: A ten-question survey was programmed on to two iPads and delegates attending the ESGE learning area were asked to complete it. The information gathered was demographics, practice settings and management strategies for Barrett's Oesophagus. This survey was based on a similar survey done in the USA in 2013[1], and was carried out as an ESGE initiative on behalf of the ESGE research committee. Permission was obtained from the original author of the American survey to reproduce it in a European setting.
Results: 163 responses were obtained. Over half of respondents (61%) were based in university hospitals, the majority (78%) were aged 30-50 and half had more than ten years' experience in gastroenterology. 66% routinely attended courses on Barrett's Oesophagus and more than half (60%) used the Prague C&M classification. Advanced imaging was used by 73% of clinicians and 72% of respondents stated that their group practiced ablation therapy. Most (76%) practiced surveillance for non-dysplastic Barrett's, 6% offered ablation therapy in some situations and 18% offered no intervention. For low grade dysplasia 56% practiced surveillance, 19% ablated some cases and 15% ablated all cases. 32% of clinicians referred high grade dysplasia to expert centres, 20% referred directly for surgery and 46% used ablation therapy in certain cases. Endoscopic mucosal resection was the most commonly used ablation technique (44%).
Conclusion: There has been good uptake of the Prague C&M classification for describing Barrett's Oesophagus and ablation is widely practiced. However practice patterns in the endoscopic diagnosis and management of Barrett's Oesophagus vary widely between clinicians. Clear guidance and quality standards are therefore required.

Introduction: Barrett esophagus with low-grade dysplasia is associated with an increased risk of developing esophageal adenocarcinoma
Aims & Methods: Prospective multicenter trial that enrolled 86 patients with a confirmed diagnosis of Barrett esophagus containing low-grade dysplasia at four Czech endoscopic sites since January 2012. Patient follow-up will end in December 2015. Eligible patients were assigned to either endoscopic treatment or endoscopic surveillance. Radiofrequency ablation was performed with the balloon device for circumferential ablation of the esophagus (Barrx^{TM}360 RFA Balloon Catheter), or the focal device for targeted ablation (Barrx^{TM} 90 and 60 RFA Focal Catheter). In case of visible lesion, endoscopic resection was performed with suck-and-cut technique. The primary outcome was comple teeradication of dysplasia during an 12 months follow-up with surveillance endoscopy in 6th and 12th month. Secondary outcomes were neoplastic progression to high-grade dysplasia or adenocarcinoma, complete eradication of intestinal metaplasia and adverse events.
Results: Since January 2012 until March 2015, 49 individuals (43 men, mean age 54 years) received endoscopic therapy and 37 persons (22 men, mean age 61 years) received control. All patients used proton pump inhibitor (esomperazol 40mg daily) during the follow-up. The results at 6th month of follow-up are being presented. Among 25 patients in the therapy group who underwent surveillance endoscopy, complete eradication occurred in 100% for dysplasia and 60% for intestinal metaplasia. Among 27 patients in the control group, complete eradication occurred in 19% for dysplasia and 0% for intestinal metaplasia. One progression to high-grade dysplasia was recorded in the control group. Treatment-related adverse events occurred in 5 patients (10%) receiving endoscopic therapy (esophageal stricture, chest pain after procedure, overwedging of the ablation catheter and one perforation after dilatation of esophageal stricture)
Conclusion: In this multicenter trial, endoscopic therapy of Barrett esophagus with low-grade dysplasia has appeared to have a high effectivity in eradication of dysplasia. Low incidence of neoplastic progression in control group can be explained by the short period of follow-up.

P1769 A COMPARISON OF HIGH DEFINITION WHITE LIGHT ENDOSCOPY (HD-WLE) VERSUS HIGH DEFINITION MICROSCOPY IN PATIENTS DIAGNOSED WITH BARRETT'S ESOPHAGUS: A RETROSPECTIVE REVIEW

V. Joshi[1], S. Brewer[2], A. Egger[3]
[1]*Ochsner Clinic Foundation,* [2]*Tulane School of Public Health,* [3]*Ochnser Clinic Foundation, New Orleans, LA, United States*

Introduction: Probe-based confocal laser endomicroscopy (pCLE) is a new technique allowing in vivo detection of neoplastic tissue using a standard endoscope.
Our aim was to compare the dysplasia detection rate of biopsies obtained by high-definition white light endoscopy (HD-WLE) or by pCLE in a cohort of patients with Barrett's esophagus (BE) referred for definitive therapy with ablation at a tertiary referral center between 2012-2014. Data was analyzed with SAS Software (version 9.4, SAS Institute, Cary, NC). Categorical variables were analyzed using the Pearson's chi-square test. Continuous variables were assessed for normality via the Shapiro Wilk statistic, and then the T-test or Wilcoxon rank sum test was applied where appropriate. Multivariate logistic regression was used to determine the impact of group assignment when considering other factors related to dysplasia. P values < 0.05 are considered statistically significant.
Aims & Methods: Data for 218 BE patients was reviewed. 105 of these patients underwent pCLE in addition to HD-WLE. Seattle protocol biopsies were obtained in WLE only group while targeted biopsies were taken in pCLE group. Diagnosis of dysplasia/neoplasia was made by a blinded gastrointestinal pathologist. pCLE images were reviewed by 2 experienced reviewers.
Results: There were more males ($p = 0.016$) and Caucasians ($p = 0.004$) in the non-pCLE group, and this group was slightly older ($p = 0.0081$). Histological diagnosis of dysplasia was significantly higher in the pCLE group ($p = 0.0052$), where 22.86% of patients were diagnosed with dysplasia in the group with pCLE and 9.09% of patients diagnosed in the group without pCLE. Logistic regression analysis indicates that age ($p = 0.006$) and use of pCLE ($p = 0.0019$) are significantly related to positive histological dysplasia diagnosis. There was a significantly higher quantity of biopsies in the pCLE group ($p = 0.0041$), specifically high-grade dysplasia biopsies ($p = 0.0019$). This difference was not seen in low-grade dysplasia biopsies ($p = 0.2433$).
Conclusion: 1. Incident dysplasia can be more frequently detected by pCLE than by HD-WLE in BE. The higher dysplasia detection rate provided by pCLE could improve the efficacy of BE surveillance programs and lead to early detection and ablative therapy.
2. pCLE targeted biopsies have higher yield of dysplasia detection than standard Seattle protocol biopsies.

Introduction: Barrett Esophagus (BE) is a complication of chronic gastroesophageal reflux disease and is a major risk factor for esophageal adenocarcinoma. BE registries are regarded useful tools in expanding the knowledge and natural progression of this disease.
Aims & Methods: Polish Barrett Esophagus Registry (POBER) was established in 1999 after a dedicated training of endoscopists and histopathologists. The aim of the POBER was to characterize patients with BE and estimate the risk of BE malignant progression. Physicians registered newly diagnosed BE patients (with confirmed intestinal metaplasia) using a dedicated registry form. After excluding patients known to have endoscopic ablative therapies, follow-up < 1 year and adenocarcinoma found at index endoscopy we have linked patients personal identification numbers with the National Cancer Registry to identify those with a diagnosis of esophageal or gastric cardia adenocarcinoma.
Results: In total 843 patients were registered [609 men (72.2%), male to female ratio 2.6:1] with median age at diagnosis of 56 years (IQR:47-67). Long segment BE was found at index endoscopy in 294 patients (39.4%) whereas low grade dysplasia in 147 (17.4%). 112 (13.3%) patients fulfilled the exclusion criteria and the remaining 731 were followed for a median of 9.8 years (IQR: 9.3 – 10.0). After 6,779 patient–years 6 adenocarcinomas were diagnosed yielding an incidence rate of 0.89 per 1000 patients–years (95% confidence interval [CI 0.40-1.97]). Patients with low-grade dysplasia had malignancy incidence rate of 3.70 per 1000 patient–years (95% CI 1.39-9.85).
Conclusion: In BE patients the risk of malignant progression was lower than previously reported, however it was notably higher in those with low-grade dysplasia at index endoscopy.

Contact E-mail Address: esmecuol@intramed.net
Introduction: Non-steroidal anti-inflammatory drugs (NSAIDs) are a long established first-line treatment for the management of pain associated with rheumatic diseases but carry a risk of gastrointestinal (GI) disturbance. Evidence-based guidelines recommend concomitant use of gastroprotective agents (GPAs) in NSAID users with one or more risk factors. Current data from developed countries (USA and Europe) suggests that a significant proportion of these patients are at risk for GI events; however they do not receive properly a GPAs strategy. The prevalence of GI risk factors (RF) and recommendations for an appropriate therapeutic strategy in Latin America countries remain unknown.
Aims & Methods
Objectives: To describe the prevalence of GI risk factors and the adherence to the use of GPAs in patients with rheumatic diseases in Latin America.
Methods: An observational, multicenter and cross-sectional study (RATIONAL) was conducted in patients with rheumatoid arthritis (RA), osteoarthritis (OA) and ankylosing spondylitis (AS) receiving at least one dose of NSAIDs in the 15 days before enrolment. The single study visit was part of standard practice and was conducted by rheumatologists in four countries from Latin America. Information collected included the presence of well-established GI risk factors, NSAID treatment over the year preceding the study visit and GPA use.
Results: The distribution of rheumatic disorders in the 2469 consecutive patients from Latin America (Argentina, Colombia, Mexico and Venezuela) was OA 1200 (48.6%), RA 1050 (42.5%), AS 145 (5.9%), and a combination of them 74 (3.0%). The prevalence of individual RF and treatment with GPAs is shown in the Table. A great proportion (85.6%) of the study population had one or more GI risk factors and 32.0% of patients had two or more RF. The most commonly occurring RF was age ≥ 60 years' (48.0%). Treatment with GPAs was received by 55.9%of the study patients. Of the well established RF, only patients with histories of GI complications or GI ulcer had appropriate and high prescription rates of GPA agents (90.0% and 95.0%,

respectively), whereas patients with other RFs such age, or concomitantly using antiplatelets or anticoagulants had much lower rates of GP.

Risk factor	Risk factor present		Receiving a GPA	
	n	%	n	%
Any risk factor	4711	87.70	3112	57.9
Age ≥60 years	2627	48.89	1534	58.4
Concomitant ASA	564	10.64	360	63.8
Concomitant corticosteroids	1202	22.37	850	70.7
Concomitant anticoagulants	87	1.64	53	60.9
History of complicated ulcer	45	2.08	42	93.3
History of GI complications	405	7.50	28	96.6
History of dyspepsia	569	26.34	501	88.0
High dose NSAID	1206	22.45	773	64.1
More than one NSAID	21	0.39	15	71.4

Conclusion: Most patients with rheumatic diseases requiring NSAIDs from Latin America showed a high prevalence of GI risk factors. However, only less than 60% received any form of GPA. While age was not perceived as a significant RF, history of ulcer was clearly considered for GPAs. A poor physician adherence with published safe NSAID prescribing guidelines are common in these Latin American countries.

Contact E-mail Address: yshimada@juntendo.ac.jp

Introduction: Since non-vitamin K antagonist oral anticoagulants (NOAC) was released in 2011, the therapeutic strategy for the prevention and treatment of thrombosis has been changed greatly in Japan. NOAC have similar efficacy as vitamin K antagonists (VKA), however, recent studies have reported some kinds of NOAC increase risk for gastrointestinal bleeding compared with VKA (1, 2). Previous reports were investigated the relationship between NOAC and gastrointestinal bleeding or bleeding risk, however there is no reports which were investigated the relationship between NOAC and gastrointestinal mucosal injury. As it is known individual NOAC have different bioavailability (2), each NOAC might have a different effect in upper gastrointestinal tract.

Aims & Methods: To reveal the clinical features of NOAC-associated upper gastrointestinal mucosal injury, we evaluate mucosal injury endoscopically in patients taking VKA or NOAC. Data were extracted from the records of subjects who underwent upper gastrointestinal endoscopy in our department between March 2011 and March 2015. Of the 41,040 subjects analyzed, 564 subjects who took VKA (Warfarin) or NOAC (Rivaroxaban, Apixaban, Edoxaban, Dabigatran). Esophageal mucosal injury are based on the definition of Los Angeles classification and gastroduodenal mucosal injury are based on the definition of ulcer classification which was defined by Murakami et al (3). Statistical analyses were performed by Fisher's exact test.

Results: The results are shown in the figure below. There was no significant difference in prevalence of upper gastrointestinal mucosal injury in individual organs between Warfarin users and each NOAC users. However, NOAC users tend to have less mucosal injury than Warfarin users except for the case of esophageal mucosal injury in Dabigatran users.

	Number of subjects	Concomitant use of PPI	Esophageal mucosal injury	Gastric mucosal injury	Duodenal mucosal injury
Warfarin	487	276(56.7%)	23(4.7%)	159(32.7%)	23(4.7%)
Rivaroxaban	22	13(59.1%)	0(0%)	6(27.3%)	1(4.6%)
Apixaban	8	5(62.5%)	0(0%)	2(25.0%)	0(0%)
Edoxaban	1	1(100%)	0(0%)	0(0%)	0(0%)
Dabigatran	46	30(65.2%)	4(8.7%)	11(24.4%)	2(4.4%)

Conclusion: These results suggested that taking NOAC is not a risk factor for upper gastrointestinal mucosal injury. Although further consideration will be needed to confirm these results, it's going to be possible that NOAC is more mucosal-friendly agent than Warfarin.

Contact E-mail Address: carlos.hernandez-saez@uv.es

Introduction: Gastrointestinal damage is the major limitation to the use of NSAIDs. These drugs cause gastric damage by hampering the epithelial defence through cyclooxygenase inhibition. However, the pathogenesis of NSAID enteropathy is still not fully understood. Autophagy is a catabolic process that degrades superfluous and damaged organelles, cytosolic proteins and invasive microbes. In the gut, autophagy plays a role as part of the defensive mechanisms that protect the intestinal mucosa. It is important for the clearance of bacteria by immune cells and it controls the function of Paneth and goblet cells. Furthermore, defective autophagy has been related with inflammatory bowel disease.

Aims & Methods: Our aim is to study the effects of indomethacin on intestinal autophagy in a well-known in vivo model of intestinal damage by NSAIDs. BALB/C mice were treated with 10 mg/kg indomethacin (s.c.) for 24 hours. The presence of ulcers along the small intestine was assessed histologically in Swiss roll preparations. The effects of indomethacin on intestinal autophagy were studied in samples of stomach, duodenum, jejunum and ileum. The autophagic flux was analyzed by measuring the levels of an autophagosome component (LC3-II protein) and the accumulation of an autophagic substrate (p62 protein).

Results: The histological analysis revealed that intestinal ileal, but not duodenal and jejunal, mucosa of mice treated with indomethacin presented several ulcers with complete loss of the epithelium. Western blot analysis of gastric and intestinal samples showed that indomethacin treatment increased LC3-II protein levels and decreased p62 protein levels in stomach, duodenum and jejunum, indicating an activation of autophagy in these territories. In contrast, both LC3-II and p62 protein levels remained unaltered in ileal samples.

Conclusion: Our data show that indomethacin activates autophagy in the stomach, duodenum and jejunum, but not in the ileum, where it causes ulcerations, and suggest that this increased autophagy constitutes a defensive mechanism that preserves mucosal integrity in the proximal gut while its absence makes the ileum more susceptible to indomethacin-induced damage.

P1774 ASPIRIN-INDUCED GASTRIC DAMAGE IS ASSOCIATED WITH AN INHIBITION OF EPITHELIAL CELL AUTOPHAGY

C. Hernández[1,2], J. Vallecillo-Hernández[1], M. D. Barrachina[1], L. Gisbert[1], Á. Álvarez[1], D. Ortiz-Masiá[1], **J. Cosín-Roger**[1], J. V. Esplugues[1,2], S. Calatayud[1]
[1]*Departamento de Farmacología, Universidad de Valencia,* [2]*Hospital Dr. Peset, Fisabio, Valencia, Spain*

Contact E-mail Address: carlos.hernandez-saez@uv.es

Introduction: Treatment with NSAIDs constitutes a challenge to gastric epithelium because, by suppressing gastric prostaglandin synthesis, it debilitates the gastric mucosal barrier. Autophagy is an intracellular process for elimination of

long-lived proteins and organelles in which a portion of the cytoplasm is sequestered by a double-membrane structure called autophagosome, which fuses with lysosomes in order to degrade its content. It is assumed that autophagy contributes to basal cellular homeostasis and acts as a survival mechanism under conditions of stress, maintaining cellular integrity by regenerating metabolic precursors and clearing subcellular debris.

Aims & Methods: We aim to analyze whether aspirin (ASA) affects the autophagic flux in gastric epithelial cells and, if so, the consequences of those effects on ASA-induced gastrotoxicity. The effects of aspirin on gastric epithelial cell autophagy were studied in a rat model of ASA-induced gastric damage and in human gastric epithelial AGS cells. The autophagic flux was analyzed by measuring LC3 protein levels and the accumulation of the autophagic substrates p62 and ubiquitinated proteins. We also analyzed the phosphorylation of mTOR and ULK1, which regulate the autophagy process. In parallel, macroscopic gastric damage and cell viability was evaluated after treatment with ASA in the presence of the autophagy inhibitor 3-methyladenine (3-MA).

Results: The gastric mucosa of rats treated with ASA (150 mg/kg, p.o., 3h) presented multiple haemorragic wounds, an increased presence of ubiquitinated proteins, a significant increase in LC3-I and LC3-II (total LC3) protein levels as well as a reduction in the LC3-II/LC3-I ratio (suggestive of a reduced autophagosome formation). The mucosa of ASA-treated rats also presented an increased level of mTOR-mediated ULK1 phosphorylation, which negatively regulates autophagy. Administration of the autophagy inhibitor 3-MA enhanced the macroscopic damage induced by ASA. In AGS cells, treatment with ASA (1-10 mM, 24h) significantly and dose-dependently reduced the autophagic flux, as demonstrated by a reduced LC3-II accumulation in the presence of lysosomal inhibitors and increased levels of p62. Treatment of cells with the autophagy inhibitor 3-MA (2 mM), reduced the concentration of ASA necessary to induce cell apoptosis and necrosis.

Conclusion: Our results demonstrate that aspirin inhibits autophagy in the gastric mucosa and that a further inhibition of the residual autophagy exacerbates the damage caused by this drug, which suggests that the gastrotoxic effect of aspirin is partly due to an impairment of this homeostatic process in epithelial cells.

Introduction: The use of oral bisphosphonates such as alendronate which is inhibitor of osteoclast mediated bone resorption, has increased dramatically despite its association with adverse gastrointestinal effects, including an increased risk of gastrointestinal bleeding erosions and ulcers. Hydrogen sulfide (H_2S) protects gastric mucosa against gastric injury induced by various ulcerogenes but the role of these gaseous transmitters in pathogenesis of bisphosphonates-induced gastric lesions has not been extensively elucidated.

Aims & Methods: We determined the role of H_2S released from its donor NaHS in gastroprotection against lesions caused by alendronate in the gastric mucosa compromised by mild cold stress. Male Wistar rats were pretreated with NaHS (0.1-20 mg/kg i.g) 30 minutes before alendronate (150 - 700 mg/kg i.g.) (series A). In series B, rats were additionally exposed to 1 h of mild cold stress before NaHS application in rats subsequently treated with alendronate. At day 3 upon alendronate administration, the area of gastric lesions was assessed by planimetry, the gastric blood flow (GBF) was determined by H_2-gas clearance technique, H_2S production as measured by analyzing the key H_2S synthesizing enzymes CSE/CBS/3-MST pathway, and the concentration of myeloperoxidase (MPO) and proinflammatory cytokines IL-1β and TNF-α was determined by ELISA. The expression of proinflammatory markers hypoxia inducible factor 1a (HIF1α), IL-1β and TNF-α, in gastric mucosa were determined by RT-PCR and Western Blot.

Results: Alendronate dose-dependently increased the gastric mucosal damage mainly in antral part of the stomach, and this effect was accompanied by significant fall in the GBF and these effects were exacerbated by cold stress. NaHS (5 mg/kg i.g.) significantly reduced the alendronate-induced gastric lesions in no-stressed and stressed animals and significantly raised GBF and H_2S production assessed by CSE/CBS/3-MST assay while significantly inhibiting the plasma levels of MPO, IL-1β and TNF-α and mRNA and protein expression of HIF-1αa, IL-1β and TNF-α in the gastric mucosa.

Conclusion: H_2S protects gastric mucosa against alendronate-induced gastric damage compromised by stress *via* an increase in gastric microcirculation and a potent anti-inflammatory and anti-oxidative activities as reflected by inhibition of HIF1α, and proinflammatory cytokines IL-1β and TNF-α by this gaseous mediator.

Introduction: Single-nucleotide polymorphisms (SNPs) in the *CYP2C* gene cluster have been extensively investigated as predisposing factors for nonsteroidal anti-inflammatory drug (NSAID)-induced gastropathy or upper gastrointestinal bleeding (UGIB). However, results have been inconclusive owing to different study designs, limited genotyping strategies, and small sample sizes.

Aims & Methods: Our aim was to evaluate whether three functional SNPs in the *CYP2C* family of genes—*CYP2C8*3, CYP2C9*3* and *CYP2C19*17*—are associated with *Helicobacter pylori* (*Hp*)-positive or *Hp*-negative NSAID-induced peptic ulcer disease (PUD). This SNPs were selected on the basis of their known functionality from the literature and their common occurrence in Caucasian populations. We investigated 124 patients (76 male, mean age – 64 years) who were categorized into two groups: 1) patients with endoscopically confirmed PUD (64 pts) within 2 weeks of using NSAIDs (including aspirin); 2) patients without endoscopic evidence of PUD (60 pts), whose use (38 pts) or nonuse (22 pts) of NSAIDs prior to endoscopy was determined. Patients were defined as NSAID users if they had taken a drug, as part of a continuous period of treatment lasting for 1 week or more, during the 2 weeks prior to endoscopy. Genomic deoxyribonucleic acid was extracted from ethylenediaminetetraacetic acid whole blood using the Chemagen 5 ml whole-blood deoxyribonucleic acid extraction kit on the Chemagic Magnetic Separation Module I according to the manufacturer's protocol (PerkinElmer chemagen Technologie, Baesweiler, Germany). Genotyping was performed using its proprietary fluorescence-based competitive allele-specific polymerase chain reaction assay.

Results: We found that only one SNP, *CYP2C19*17*, was significantly associated with the presence of PUD (odds ratio 1.45 (95% confidence interval (CI) 1.14 to 1.90); $P = 0.005$). This association with PUD did not differ depending on NSAID use (P value for interaction term = 0.156), NSAID type and *H. pylori* status (positive or negative). A greater proportion of patients with PUD was seen among *CYP2C19*17* variant allele carriers (*1*/17* - 71.9%; *17*/17** - 73.6%) as compared with wild-type homozygotes (*1*/1** - 63.9%, $P = 0.024$ using $\chi 2$ test). No significant association was found between any of the SNPs and UGIB status. Sensitivity analysis including only the *Hp*-negative cases (42 pts, 33.9%) showed no significant association with *CYP2C19*17* when comparing those with or without PUD ($P = 0.072$) or those with or without UGIB ($P = 0.60$).

Conclusion: *CYP2C19*17* polymorphism is associated with NSAID-induced peptic ulcer disease and can be considered as risk-factor for NSAID-gastropathy.

P1777 CLINICAL AND DIAGNOSTIC SIGNIFICANCE OF ASCITES FOUND ON PREOPERATIVE COMPUTED TOMOGRAPHY IN GASTRIC CANCER PATIENTS

S. Lee[1], J. W. Kim[1], S.-J. Koh[1], on behalf of Department of Internal Medicine, Seoul Metropolitan Government Seoul National University Boramae Medical Center, Seoul, Korea
[1]*Internal Medicine, Metropolitan Government Seoul National University Boramae Medical Center, Seoul, Korea, Republic Of*

Contact E-mail Address: tjgmldl16@naver.com

Introduction: In gastric cancer, malignant peritoneal carcinomatosis is regarded incurable but routinely performed computed tomography (CT) has questionable accuracy in evaluating the nature of ascites. We tried to evaluate the clinical significance of ascites which was defined by CT in association with the peritoneal seeding.

Aims & Methods: This single-center, retrospective study includes patients with newly diagnosed gastric cancer and ascites on CT and excluded patients with distant metastasis or definite peritoneal carcinomatosis on CT, or no surgical data. Factors associated with malignant seeding were analyzed.

Results: During 10 years, 2207 patients visited our institution on the diagnosis of gastric cancer. Ninety-three patients were eligible and 12 (12.9%) patients were confirmed peritoneal carcinomatosis based on the pathologic examination. Factors indicating peritoneal metastasis identified by univariate analysis include feature of advanced gastric cancer on preoperative endoscopy (odds ratio [OR], 1.14; $p = 0.031$), regional lymph node metastasis (OR, 5.37; $p = 0.013$), and undifferentiated pathology on endoscopic biopsy (OR, 5.60; $p = 0.038$). Regional lymph node metastasis was significant as predictors of carcinomatosis (OR, 0.592; $p = 0.038$) on multivariate analysis.

Conclusion: Regional lymph node metastasis was associated with peritoneal metastasis. Ascites alone defined on CT is rarely relevant to peritoneal carcinomatosis, and so overestimation should be avoided.

P1779 IS THERE STILL A REASON TO SCREEN FOR GASTRIC PREMALIGNANT LESIONS?

S. M. Batagа[1], I. Torok[1], M. Tilinca[1], A. Negovan[1], H. Farkas[1], O. Varodi[1], A.-M. Botianu[1], M. Macarie[1]

Introduction: Gastric cancer (GC) was the second most common cancer until recently. Worldwide the incidence of the gastric cancer has dramatically decreased in the last years, while the incidence of the esophageal cancer (adenocarcinoma) has increased. GC is now the fifth most common cancer in the world, after lung, breast, colorectal and prostate cancer and the third leading cause of cancer death. About 1 million (952 000) persons are diagnosed with GC every year and about 723 000 die every year(1). Still, GC is the third worldwide cause of mortality from malignant diseases. In Romania GC had an incidence of 19/100000 inhabitants before 1990, but it dramatically decreased.

Aims & Methods: This is a retrospective study to follow-up if the incidence of GC continued to decrease in our region in the last 10 years. The trends in the incidence of the esophageal cancer were also followed-up. The study included 12384 patients (53% females, mean age 62.3years) who underwent upper digestive endoscopy in the Clinical Emergency Hospital, between 2005 and 2014. Multiple biopsies were made.

Results: In the last 10 years from 12384 patient who underwent endoscopy, 678 patients were diagnosed with gastric and esophageal cancer. From these 528 had GC (non-cardia gastric cancer) and 150 had esophageal cancer.

In all the 10 years the incidence of GC/year remain stable, between 45 patients/year and 52 patients/year, more frequent in males (67%). Most of the tumors were located in the corpus (54%). The incidence of the GC on this period was 5.47% in our group of patients.

Regarding the incidence of the esophageal adenocarcinoma this increased, but the epidermoid carcinoma remains the prevalent histology in our area with 98(65.33%) cases and 52(34.66%) cases of adenocarcinoma. Epidermoid carcinoma/adenocarcinoma ratio decreased from 3.33/1 in 2005 to 1.2/1 in 2014. Regarding gender distribution, there was a high predominance of males (131 males and 19 females).

Conclusion: Despite the fact that in the last 30 years GC decreased, dramatically, in the last 10 years, its incidence remained stable, 5.47% in our database. The incidence of esophageal adenocarcinoma has doubled in the last 10 years, but is still lower than the epidermoid type in our region. The upper digestive cancer rate is still high, so the screening should be cost-effective (2). The population screening for the premalignant gastric lesions with serological biomarkers should be a priority in the future (3,4).

P1780 DIAGNOSTIC YIELD OF MUCOSAL INCISION WITH DEEP BIOPSY FOR SMALL GASTRIC SUBEPITHELIAL TUMOR: A COMPARISON WITH ENDOSCOPIC ULTRASOUND-GUIDED FINE NEEDLE ASPIRATION

S.-E. Park[1], J. Y. Ahn[2], H.-Y. Jung[2], K. W. Jung[2], K.-S. Choi[2], J. H. Lee[2], D. H. Kim[2], K. D. Choi[2], H. J. Song[2], G. H. Lee[2], J.-H. Kim[2]
[1]*Gastroenterology, Hansol Hospital,* [2]*Gastroenterology, Asan Medical Center, Seoul, Korea, Republic Of*

Contact E-mail Address: silverbirchs@naver.com

Introduction: Adequate tissue acquisition is important for the definite diagnosis of subepithelial tumor (SET). Endoscopic ultrasound-guided fine needle aspiration (EUS-guided FNA) has better diagnostic yield than routine endoscopic biopsy for these lesions. However, the amount of acquired specimen is sometimes not sufficient to diagnose.

Aims & Methods: The purpose of this study was to determine the safety and diagnostic yield of mucosal incision with deep biopsy compared to EUS-guided FNA for small gastric SETs. A retrospective review of patients who underwent both EUS-guided FNA and incision by needle-knife with deep biopsy for the SET, which size was from 20 to 30mm under endoscopic examination, from January 2013 to September 2014 was performed. A total of 15 patients (M: F = 6: 9) were enrolled. We analyzed the diagnostic yield of EUS-guided FNA and mucosal incision with deep biopsy.

Results: The median age of patients was 49 years (interquartile range [IQR], 37.6-55.5 years) and the median size of the SETs was 20.7 mm (IQR 18.2-26.1 mm). The locations of tumors were 7 upper third, 2 middle third, and 6 lower third of stomach. The diagnostic yield of mucosal incision with deep biopsy was 86.7% (13/15), whereas that of EUS-guided FNA was 73.3% (11/15) ($P = 0.625$, McNemar test). The histological diagnoses were 8 leiomyomas, 3 gastrointestinal stromal tumors, 2 heterotopic pancreases, 1 schwannoma, and 1 nondiagnostic lesion. There was one delayed bleeding in patient with mucosal incision with deep biopsy site. Other bleedings, which were occurred during procedures, were minor and easily controlled by using hemoclip, coagrasper, and/or fibrin glue injection.

Conclusion: Mucosal incision by needle-knife with deep biopsy could be alternative diagnostic tool to diagnose gastric SETs with size from 20 to 30mm under endoscopic examination by getting sufficient tissue sample with relatively higher diagnostic yield. It could be useful to make therapeutic decision for small size of gastric SETs.

P1781 IS PROBE-BASED CONFOCAL ENDOMICROSCOPY BETTER THAN WHITE LIGHT ENDOSCOPY FOR THE GENETIC AND HISTOLOGIC STUDY OF GASTRIC CANCER: A PILOT STUDY

S. Y. Kim[1], C. H. Park[2], S. K. Lee[1]
[1]*Institute of Gastroenterology, Department of Internal Medicine, Severance Hospital, Yonsei University, Seoul, Korea, Seoul,* [2]*Institute of Gastroenterology, Department of Internal Medicine, Kyoungchun-ro, Guri-si, Gyeonggi-do, Korea, Guri-si, Korea, Republic Of*

Contact E-mail Address: SKLEE@yuhs.ac

Introduction: Although high yield of biopsy for gastric cancer is mandatory to perform genetic and histologic study using gastric cancer tissues obtained from endoscopic biopsy, proportion of cancer cells in biopsy samples is very low. We aimed to evaluate whether probe-based confocal laser endomicroscopy (pCLE) can increase the yield of endoscopic biopsy for gastric cancer compared to white light endoscopy (WLE).

Aims & Methods: Between April 2014 and March 2015, thirty patients diagnosed with gastric cancer were enrolled in the study. Patients were randomly allocated to either pCLE or WLE group. In the pCLE group, lesions were examined by both WLE and pCLE. Then, five pieces of tissue was acquired by biopsy forcep at the lesion where showing the most distinct feature of gastric cancer on pCLE. In cases of the WLE group, lesions were examined by WLE, and then biopsy samples were obtained at the five lesion just as usual endoscopic procedure. The primary outcome was proportion of cancer cells in biopsy samples according to the differentiation of gastric cancer. The secondary outcome was number of biopsy samples which contain cancer cell and concordance of histology between biopsy and resected tissue.

Results: Of 30 patients enrolled in the study, 12 had early gastric cancer. The remaining 18 patients showed advanced gastric cancer. Number of patients with undifferentiated cancer was 8 (53.3%) and 9 (60.0%) in the pCLE and the WLE group, respectively. The proportion of cancer cells in biopsy samples did not differ between the pCLE and the WLE group (median proportion [interquartile range (IQR)]; pCLE vs. WLE, 60% (40–70%) vs. 40% (20–60%), $P = 0.136$). However, the proportion of cancer cells in biopsy samples of cancers with undifferentiated histology was higher in the pCLE group than the WLE group (median proportion [IQR]; pCLE vs. WLE, 65% (45–77.5%) vs. 30% (15–40%), $P = 0.010$). The median number of biopsy samples which contain cancer cell did not differ between the two groups ($P = 0.288$). In addition, concordance rate of histology between biopsy and resected tissue did not differ between the groups ($P = 0.667$).

Conclusion: Biopsy technique for gastric adenocarcinoma with undifferentiated histology using pCLE provided superior result in terms of proportion of cancer cells in biopsy samples compared to that under WLE. When genetic or histologic analyses are planning to investigate, pCLE should be under active consideration for tissue acquisition of gastric adenocarcinoma with undifferentiated histology.

P1782 PREDICTIVE FACTORS OF PYLORIC STENOSIS AFTER ENDOSCOPIC MUCOSAL DISSECTION AND ITS PROPER MANAGEMENT

S. G. Lim[1], M. J. Yang[1], S. J. Shin[1], M. W. Jeong[1], K. M. Lee[1]
[1]*Gastroenterology, Ajou University School of Medicine, Suwon, Korea, Republic Of*

Contact E-mail Address: mdlsk75@gmail.com
Introduction: Endoscopic submucosal dissection (ESD) is a curable method for resection of gastric neoplasia. But, it can cause early complications such as bleeding and perforation, and late complication such as pyloric stenosis which would be treated by endoscopic balloon dilation. In this study, we evaluated the predictive factors of pyloric stenosis after ESD and its proper treatment method.
Aims & Methods: A total of 1621 cases of gastric neoplasia was resected by ESD at our institution from June 2005 to December 2012 and 125 cases were located in the pylorus. We reviewed retrospectively the cases of pyloric stenosis and analyzed clinical factors such as size, surface area, circumferential extent, and number of ESD. Also, we reviewed treatments of stricture site.
Results: Pyloric stenosis was occurred in six cases. In analysis, post-ESD stenosis was related to longitudinal diameter of resected specimen (>5cm, $P=0.035$) and circumferential mucosal defect over 75% ($P=0.019$). Also, stricture was higher in more than 2 times of ESD procedure than single ESD ($P=0.024$). Six patients of post ESD pyloric stenosis were managed with endoscopic balloon dilation and 4 patients improved the symptom.
Conclusion: Longitudinal diameter of specimen (>5cm) and circumferential mucosal defect (>75%) are associated with pyloric stenosis after ESD.

P1783 LONG-TERM FOLLOW-UP RESULT OF ENDOSCOPIC RESECTION OF GASTRIC GASTROINTESTINAL STROMAL TUMOR

S. G. Lim[1], M. J. Yang[1], M. W. Jung[1], S. J. Shin[1], K. M. Lee[1]
[1]*Gastroenterology, Ajou University School of Medicine, Suwon, Korea, Republic Of*

Contact E-mail Address: mdlsk75@gmail.com
Introduction: Although endoscopic resection (ER) for various gastric tumors has been widely promoted, the suitability for gastrointestinal stromal tumor (GIST) is not clear. The aim of this study was to evaluate the feasibility, efficacy, safety, and long-term follow-up results of ER for gastric GIST.
Aims & Methods: The medical records of 49 patients who underwent ER for gastric GIST were collected between January 2000 and July 2014. After procedure, the recurrence of tumor was checked by endoscopy and abdominal CT during follow-up. Demographics, clinical data, therapeutic outcomes, complications, pathological characteristics, and follow-up outcomes were analyzed.
Results: ER including endoscopic enucleation, endoscopic snare resection (SR), and endoscopic submucosal dissection (ESD) technique was performed in 49 patients. Procedure-related complications developed in 16 patients: perforation (22.4%, 11/49), intra-procedure bleeding (8.2%, 4/49) and post-procedure bleeding within 7 days which required additional endoscopic hemostasis (6.1%, 3/49). Median follow-up period was 52.0 months (range: 12-116). En-bloc resection was achieved in 91.8% of patients (45/49); 91.9% (34/37) in enucleation, 80.0% (4/5) in EMR, 100.0% (7/7) in ESD. Complete resection rate was 71.4% (35/49); 70.3% (26/37) in enucleation, 80% (4/5) in EMR, 71.4% (5/7) in ESD. Recurrence occurred in 20% of patients (5/25); 15.8% (3/16) in enucleation, 33.3% (1/3) in EMR, 33.3% (1/3) in ESD. The rate of recurrence showed increasing tendency in lesions larger than 3cm, comparing lesion less than 3.0cm [66.7%(2 of 3) vs 13.6%(3 of 22); $p=0.091$], and in the group of incomplete resection than the group of complete resection [50.0%(3 of 6) vs 10.5%(2 of 19); $p=0.070$]. The median recurrence period was 73.0 months (range: 19-102).
Conclusion: Endoscopic resection (especially, enucleation, ESD technique-used endoscopic muscular dissection) could be alternative option for gastric GIST treatment. Long-term follow-up over 5 years should be considered in cases of incomplete resection and with lesion size larger than 3cm.

P1784 COMPARISON OF CLINICAL AND ENDOSCOPIC CHARACTERISTICS AMONG UPGRADE, CONCORDANCE AND DOWNGRADE PATHOLOGY AFTER ESD

S. G. Lim[1], M. J. Yang[1], S. J. Shin[1], K. M. Lee[1], M. W. Jeong[1]
[1]*Gastroenterology, Ajou University School of Medicine, Suwon, Korea, Republic Of*

Contact E-mail Address: mdlsk75@gmail.com
Introduction: Histologic discrepancies between endoscopic forceps biopsy (EFB) and endoscopic resection (ER) specimens, including ESD and endoscopic mucosal resection, have been reported at rates ranging from 2.7–49%. Our aims were to analyze the prevalence of upgraded, concordant, and downgraded pathology results after ESD and to compare their clinical and endoscopic characteristics.
Aims & Methods: We retrospectively reviewed the 1186 consecutive ESD performed at our center from February 2005 and December 2011, and included 837 cases diagnosed as low or high-grade dysplasia on the pre-ESD endoscopic forceps biopsy. The following endoscopic variables were analyzed; tumor size, surface area, sampling ratio (tumor size/number of forceps biopsy, surface area/number of forceps biopsy), predominant gross morphology, and surface configuration such as depression or ulceration.
Results: There was upgrade group in 203 cases (24.3%), concordance group in 552 cases (65.9%), and downgrade group in 82 (9.8%). Our database presented the mean length as follows: upgraded group 20.3 ± 9.7mm, concordant group 18.4 ± 8.6mm, and downgraded group 13.2 ± 7.8mm. The mean surface were represented as these: upgraded group 316.0 ± 302.1mm^2, concordant group 249.6 ± 232.1mm2, and downgraded group 141.2 ± 209.8mm2. Mean sampling ratio in tumor size were calculated as follows: upgraded group (6.9 ± 3.8mm/fragment and 99.2 ± 88.5 mm2/fragment), concordant group (6.6 ± 4.0mm/fragment and 94.8 ± 84.6 mm2/fragment), and downgraded group (4.8 ± 3.5mm/fragment and 51.1 ± 74.8mm2/fragment). Compared with upgraded and concordant group, the downgraded group showed smaller tumor size and lower sampling ratios (all, $P<0.001$). And then the upgraded group had higher incidence of ulceration (13.5% vs 4.1%) and depression (46.5% vs 32.9%) more than concordant group (all, $P<0.001$).
Conclusion: The tumor size and sampling ratio were predictable factor for downgraded final pathology after of ESD. And the ulceration and depression were forecasted for upgraded final pathology after ESD.
Disclosure of Interest: None declared

P1785 THE CLINICAL CHARACTERISTICS AND OUTCOMES OF AGENT ORANGE EXPOSED EARLY GASTRIC CANCER PATIENTS AFTER ESD

S. H. Kim[1], S. H. Yang[1], J. S. Bang[1], J. S. Jang[1], T. K. Kim[1], W. H. Park[1], M. K. Lee[1], H. J. Lim[1], S. H. Ko[1], Y. J. Kim[2], E. J. Kim[2], M. J. Lee[2]
[1]*Internal Medicine,* [2]*Pathology, VHS Medical Center, Seoul, Korea, Republic Of*

Contact E-mail Address: tkdance@medicus.co.kr
Introduction: Currently, endoscopic submucosal dissection (ESD) is accepted as one of the treatment modalities for early gastric cancer and shows excellent treatments outcomes. Agent Orange (AO) is an herbicide used in the Vietnam War to defoliate forest areas. Many Korean veterans who participated in the Vietnam War were exposed to this chemical. But, the influence of the material remained uncertain to the stomach cancer disease course. So, we investigated the clinical characteristic and outcomes of AO exposed early gastric cancer (EGC) patients after ESD.
Aims & Methods: From January 2008 to December 2013, 121 EGC patients, including 61 AO exposure veterans, treated by ESD and followed up more than 12 months were enrolled, retrospectively. All patients were checked by gastrofiberscope and CT scan regularly for recurrence. Synchronous and metachronous lesion were defined as a new lesion found out within 1 year and as a new lesion found out more than 1 year after 1st ESD treatment. We analyzed the clinical characteristics and outcomes such as survival rate, the synchronous and metachronous lesion occurrence between the two groups whether or not exposed to AO.
Results: The median age was lower in AO exposed patients than in those not exposed (66 (57-78) vs. 77.5 (52-85), $p < 0.05$). Otherwise, there was no difference between the two groups in clinical characteristics such as tumor location, type, size, and histology, statistically. On the clinical outcomes, there was no relationship between AO exposure and the occurrence of the synchronous and metachronous lesion, statistically (8.3% vs. 3.3%, $p=0.272$, 13.3% vs. 8.2%, $p=0.305$). There was no meaningful difference of the two groups about the cumulative survival rate and disease free survival rate, too.
Conclusion: Although the AO exposed EGC patients were younger, the clinical characteristics and the clinical outcomes were not different in compare with those who were not exposed to AO.
Disclosure of Interest: None declared

P1786 GASTRIC POLYPS: WHAT IS THE CLINICAL SIGNIFICANCE?

T. Araújo[1], R. Marcos-Pinto[1], I. Vilas-Boas[2], I. Pedroto[1]
[1]*Gastroenterology, Centro Hospitalar do Porto, Porto,* [2]*Universidade do Minho, Braga, Portugal*

Contact E-mail Address: araujo.tarcisio@gmail.com
Introduction: Gastric polyps are a frequent endoscopic diagnosis, but the evidence supporting approach of this pathologic finding is scarce, which is reflected in the absence of clear recommendations.
Aims & Methods: Characterize a cohort of patients undergoing endoscopy and gastric polypectomy.
240 patients were included in which were made 447 polypectomies. We performed a retrospective review of demographics, phenotype of polyps (number, size and histology), presence of *Helicobacter pylori* and clinical outcome in the period from 01/01/2012 to 31/12/2014.
Results: Mean age 62.3 years; 67.9% were female; Mean age in patients with polyps dysplasia was 66.8 years and in patients with polyps without dysplasia was 61.9 years. Histological type: 64.2% (n = 287) hyperplastic, 17% (n = 76) nonspecific/foveolar polypoid hyperplasia, 10.7% (n = 48) fundic glands, 3.8% (n = 17) inflammatory fibroid, 2.2% (n = 10) adenomas, 0.9% (n = 4) hamartoma, 0.9% (n = 4) neuroendocrine tumor and 0.2% (n = 1) adenocarcinoma. 2.2% of polyps had dysplasia (all adenomas) - low-grade 70%, high grade 30%. Polyps < 5 mm were observed in 42.5% and ≥ 5 mm in 57.5%. 19.6% had previous polypectomy. Size of polyps ≥ 5 mm was significantly associated with risk of dysplasia ($p < 0.05$). *H. pylori* infection present in 50.4%.

Location of polyps in gastric body was associated with female sex ($p < 0.05$). It was also found that location in gastric body associated to polyps < 5mm ($p = 0.01$).
There was no statistically significant difference between dysplasia and presence of *Hp*, histological type or association with familial syndromes.
Conclusion: All polyps with more than 5 mm must be excised by the potential risk of malignancy. In this population the most frequent polyps were hyperplastic. The dysplasia/carcinoma is an uncommon phenomenon in gastric polyps.

Contact E-mail Address: ueo14@athena.ocn.ne.jp
Introduction: White opaque substance (WOS) on magnifying endoscopy with narrow band imaging (M-NBI) was first reported by Yao *et al.* as a substance in the superficial area of gastric neoplasias that obscured the subepithelial microvascular architecture. Yao *et al.* reported that WOS is caused by lipid droplets and used oil-red-O staining to detect the accumulation of lipid droplets in the cells of WOS-positive gastric neoplasms [1]. In a previous study from our group, the accumulation of lipid droplets was confirmed as a cause of WOS in gastric neoplasias by immunohistochemical and immunoelectron microscopic studies of adipophilin, which was recently identified and validated as a marker of lipid droplets [2]. However, the precise clinicopathological significance of WOS-positive gastric neoplasias remains unclear.
Aims & Methods: The aim of the present study was to investigate the characteristics of the histological differentiation and mucin phenotype in WOS-positive gastric epithelial neoplasias.
A total of 130 gastric epithelial neoplasias (46 adenomas and 84 early adenocarcinomas) from 120 consecutive patients were retrospectively evaluated. The presence or absence of WOS was evaluated by M-NBI. Lipids were examined by immunohistochemical staining for adipophilin. Tissue phenotypes were immunohistochemically classified as intestinal (I), gastrointestinal (GI), and gastric (G) using antibodies against CD10, MUC2, MUC5AC and MUC6. The histological differentiation and mucin phenotype of WOS-positive neoplasias were characterized and examined according to adipophilin expression.
Results: The presence of WOS by M-NBI was correlated with histological differences between adenoma or differentiated type adenocarcinoma and mixed type or undifferentiated type adenocarcinoma ($P = 0.0153$, Fisher's exact test). Adipophilin was only expressed in primary adenoma and well to moderately differentiated adenocarcinoma components but not in undifferentiated components. WOS and adipophilin expression were only observed in neoplasias with I or GI phenotypes, but not in those with the G phenotype ($P < 0.0001$, Fisher's exact test).
Conclusion: WOS in gastric epithelial neoplasias indicates differentiation into a mature histological subtype with GI or I mucin phenotype.

P1788 THE USEFULNESS OF ENDOSCOPIC SUBMUCOSAL DISSECTION FOR EARLY GASTRIC NEOPLASMS IN THE REMNANT STOMACH

T. Yamaguchi[1], T. Kuwai[1], H. Imagawa[1], T. Nishimura[1], S. Iio[1], A. Tsuboi[1], T. Mori[1], A. Yamaguchi[1], H. Kouno[1], H. Kohno[1]
[1]*Gastroenterology, National Hospital Organization Kure Medical Center/Chugoku Cancer Center, Kure, Japan*

Contact E-mail Address: toshiki4662@yahoo.co.jp
Introduction: Endoscopic submucosal dissection (ESD) appears to be desirable for early gastric neoplasms (EGNs) in the remnant stomach because it is less invasive than surgical resection. However, ESD after gastrectomy is a technically difficult procedure because of the limited working space in the remnant stomach as well as the presence of severe fibrosis and staples left under a suture line.
Aims & Methods: The aim of this study was to evaluate the usefulness of ESD for early gastric neoplasms in the remnant stomach. Between June 2007 and December 2014, ESD was performed for 680 EGNs in 447 consecutive patients at the National Hospital Organization Kure Medical Center/Chugoku Cancer Center. These lesions were divided into two groups: 22 lesions in the remnant stomach of 17 patients (Remnant Group) and 658 lesions in the entire stomach of 430 patients (Entire Group). We compared the treatment results, adverse events and clinical outcomes of ESD between two groups.
Results: Among the 17 patients in Remnant Group, 11 had previously undergone a distal gastrectomy, three a gastric conduit, two a proximal gastrectomy and one a partial gastrectomy. The en block resection rate was 95.5% (21/22) for Remnant Group and 97.1% (639/658) for Entire Group. The en bloc resection rate with tumor-free margins was 91.0% (20/22) for Remnant Group and 94.4% (621/658) for Entire Group (a non-significant difference [n.s.]). In terms of adverse events, the rate of perforation was 0% (0/22) for Remnant Group and 0.5% (3/658) for Entire Group. The rate of delayed bleeding was 0% (0/22) for Remnant Group and 3.2% (21/658) for Entire Group (n.s.). Histopathologically, three lesions in Remnant Group were diagnosed as non-curative resection. One of these patients had undergone piecemeal EMR due to severe fibrosis. In another patient, the lesion invaded the submucosa to a depth into 800μm. These two patients declined additional surgical treatment. Only one patient underwent additional surgery because the lesion invaded the muscularis propria. The curative resection rate was 86.4% (19/22) for Remnant Group and 88.6% (583/658) for Entire Group (n.s.). The local recurrence rate was 0% (0/21) during the median follow-up duration of 25 months for Remnant Group and 0.6% (4/630) during the median follow-up duration of 36 months for Entire Group.
Conclusion: In terms of treatment results, adverse events and clinical outcomes, there were no significant differences between the remnant-stomach and entire-stomach groups. Therefore, ESD for EGNs in the remnant stomach can be a feasible and safe therapeutic method.

P1789 ENDOSCOPIC RESECTION OF NON-AMPULLARY DUODENAL EPITHELIAL TUMORS: A SINGLE-CENTER EXPERIENCE

T. Yamaguchi[1], T. Kuwai[1], H. Imagawa[1], T. Nishimura[1], S. Iio[1], **A. Tsuboi**[1], T. Mori[1], A. Yamaguchi[1], H. Kouno[1], H. Kohno[1]
[1]*Gastroenterology, National Hospital Organization Kure Medical Center/Chugoku Cancer Center, Kure, Japan*

Contact E-mail Address: toshiki4662@yahoo.co.jp
Introduction: Because non-ampullary duodenal epithelial tumors (NADETs) are rare, the standardized clinical management of NADETs has not been established. Endoscopic resection (ER) is a standard treatment for superficial tumors in the digestive tract, and ER was recently applied to NADETs.
Aims & Methods: The aim of our study was to investigate the clinical outcomes and adverse events of ER of NADETs at the National Hospital Organization Kure Medical Center/Chugoku Cancer Center, Kure, Japan. Twenty-five consecutive patients with 26 NADETs underwent ER by endoscopic mucosal resection (EMR) or endoscopic submucosal dissection (ESD) between May 2008 and January 2015. We analyzed clinicopathological features of NADETs, clinical outcome and adverse events for ER of NADETs.
Results: The median tumor size was 12mm (range 3–40mm). The lesions were 11 adenomas, 12 mucosal carcinomas and 3 carcinoid tumors. The ERs included 21 EMRs and 5 ESDs. Six lesions underwent additional argon plasma coagulation after ER. Immediate closure following ER was performed in all but one of the 26 lesions by means of prophylactic clipping. The en block resection rate was 88.5% (23/26) and the en bloc resection rate with tumor-free margins was 73.1% (19/26). Regarding adverse events, only one delayed bleeding and one delayed perforation were observed, in the same patient, who required emergency surgery. This was the only case in which prophylactic clipping was not applied. Additional surgery was done in two other cases. One mucosal carcinoma underwent piecemeal EMR, and as that patient had an advanced colon cancer, additional duodenal resection and surgery for the colon cancer was performed at the same time. An other patient underwent ESD for a carcinoid tumor, and since the histopathologically vertical margin was positive, additional surgery was conducted. Among the other 23 patients, no recurrence was observed during the 22-month median follow-up period.
Conclusion: Duodenal ER was feasible as a therapeutic procedure. Prophylactic clipping can probably reduce the risk of adverse events.

Contact E-mail Address: huangxiaojunlzu@163.com
Introduction: Gastric cancer (GC) is still highly prevalent in the world and remains the second most common leading cause of cancer death. In recent years, the usefulness of the serum pepsinogens (PG), gastrin-17 (G-17) and *Helicobacter pylori* IgG Antibodies (Hp-IgG) has been used for screening of early diagnose chronic gastric atrophy and gastric cancers.
Aims & Methods: To estimate if serum levels of PG, G-17 and Hp-IgG are valuable as non-invasive methods to diagnose patients with Atrophic gastritis (AG) and those with Gastric cancer (GC) in Gansu province in China. A total of 190 patients who underwent endoscopic examination and biopsy were enrolled in this study. Based on the pathological results of endoscopic biopsies, these studied subjects were classified into the following four groups: normal group (n = 40); AG group (n = 45), including antrum-predominant AG (AAG, n = 30) and corpus-predominant AG (CAG, n = 15); early GC group (EGC, n = 45) and advanced GC group (AGC, n = 60). In AGC and GGC groups there were gastric antral cancer(n = 45), gastric body cancer(n = 42) and cardiac cancer(n = 18) in all. Serum levels of PgI, PgII and G17 were tested by enzyme-linked immunosorbent assay (ELISA) and Hp-IgG was measured with Gastro Panel kit.
Results: Serum PGI and PGR values were decreased significantly in AG, EGC and AGC groups compared with normall group ($P < 0.05$). PGR was decreased

in EGC and AGC compared with AG group (P = 0.02). G17 was significantly increased in EGC and AGC groups compared with normal group (P < 0.05). In AG group G17 was significantly decreased in AAG compared with CAG (P = 0.03). The positive rate of Hp-IgG was most high in advanced GC group (72.58%). The PGI combined with PGR test showed the predicted percentage of correct were 64.6%, 74.8%, 76.0%, 78%, respectively for diagnose patients with AAG, CAG, gastric antral cancer and gastric body cancer. While the percentage increased to 72.3%, 83.5%, 78.7%, 86.0% when combined PGI, PGR with G17 and Hp-IgG. And it showed an estimate sensitivity and specificity of 31.1%, 94.1%; 66.7%, 91.8%; 77.1%, 80%; 50.0%, 95.0% for diagnosing patients with gastric antral cancer, gastric body cancer, AAG and CAG when combined these serum markers.
Conclusion: Our findings suggested the low levels of serum PGI and PGR and high levels of G17 are predictive for patients with GC. Serum Pgs combined with G17 and Hp-IgG could reflect function of gastric mucosa and increase the screening rate for patients with GC and AG in this high risk area in China.

Introduction: Gastric cancer remains one of the most important malignant tumors. Japanese scholars began to recommend the use of serum Hp-IgG antibodies and PG - ''ABC method'' for large-scale screening for early gastric cancer in 2007. While this method has not yet been widely used in China.
Aims & Methods: To evaluate if the ''ABC method'' is useful to screen patients with gastric cancer in China. A total of 1008 participants were diagnosed(by endoscopy examination combined with endoscopic biopsies)as normal group (n = 323), atrophic gastritis (AG) patients (n = 648), early gastric cancer (EGC) patients (n = 8), advanced gastric cancer (AGC) patients (n = 4), gastric and duodenal ulcer patients (n = 25). PGI, PGR levels and Hp-IgG were analyzed by latex immunoassay and colloidal gold method, respectively. The ''ABC method'' was cited to group the studied patients, such as group A[Hp(-)PG(-)], B[Hp(+)PG(-)], C[Hp(+)PG(+)] and D[Hp(-)PG(+)]for analysis.
Results: PGI and PGR values decreased significantly in patients with AG(P = 0.04) and PGR decreased the most in patients with AGC group (P = 0.01). It showed that the incidence of AG in A, B, C and D group was 61.83%, 59.74%, 74.52% and 88.33%, respectively. While the incidence of GC in A, B, C and D group was 1.14%, 0.57%, 2.55% and 3.33%, respectively. The incidence of AG were significantly higher in group C and D than those in group A and group B (P < 0.05, respectively). No significant difference in the incidence of GC was found in four groups (P > 0.05).
Conclusion: The ''ABC'' method is valuable to assess the degree of atrophic gastritis but not the incidence of gastric cancer. Some cohort studies is needed in China.

Introduction: Endoscopic submucosal dissection(ESD) is the effective therapy for early gastric cancer (EGC). Japan has the longest life expectancy in the world, the number of eldely patients in whom ESD performed has also increased. However, there were few reports about outcomes of ESD for EGC.
Aims & Methods: The aim of this study is to evaluate clinical outcomes of ESD for EGC in elderly patients.
131 elderly patients (≧75 years) with early gasric cancer received first ESD at our hospital between February 2002 and July 2012. Clinical outcomes were analyzed. The patients were classified into a curative group and a noncurative group. We compared the characteristics of patients and lesions, and the overall survival rates between the two groups. We also analyzed the predictors for survival using the cox regression modeling.
Results: The subjects comprised 85 males and 46 females with a mean age (SD) of 79.9 (±3.8) years. En bloc, R0 and curative resection were achieved in 90.1%, 92.4% and 85.5%, respectively. 31 patients were died, none of them died due to gastric cancer. As additional treatment in the noncurative group, 5 patients underwent operation, 2 underwent ESD and 1 patient underwent APC. 11 patients was monitored without additional treatment in the noncurative group. There were no significant differences in age, gender, location and depth of the lesions, and lymphovascular invasion between the two groups. The size of tumor in the noncurative group was larger than that in the curative group. The overall 3- and 5-year survival rates in the curative group were 81.6% and 71.1%, respectively, and the rates in the noncurative group were 80.5% and 71.6%, respectively. These differences are no statistically significant. On univariate analysis, cardiovascular disease tended to contribute to survival(p = 0.0549). The cumulative survival rate was significantly lower in patients with cardiovascular disease than in those without cardiovascular disease(p = 0.0483, Log-rank test).
Conclusion: ESD was useful for EGC in elderly patients. However we should carefully consider the indication of ESD for patients with cardiovascular disease.

Introduction: En bloc resection of larger lesions and lesions with ulcer scars is now possible by endoscopic submucosal dissection (ESD), allowing for detailed pathological evaluation. We often experience cases with a preoperative diagnosis of differentiated adenocarcinoma and a postoperative diagnosis of mixed differentiated and undifferentiated adenocarcinoma (mixed-type early gastric cancer: MGC). Although MGC has a higher incidence of metastases to lymph nodes than pure differentiated early gastric cancer (PGC), adequate evidence for its clinical management has not been well investigated.
Aims & Methods: This study aimed to evaluate the clinicopathological features of MGC by comparisons between MGC and PGC. Among 330 cases of early gastric cancer who underwent ESD in our hospital between April 2009 and February 2015, we examined age, sex, main histological type, histological type of preoperative biopsy, tumor location, morphological type, tumor size, depth of invasion, depth of submucosal (SM) invasion, resection margins (lateral and vertical margin), lymphatic and venous invasion, and pathological ulcer scars in 284 PGC cases (197 males, 87 females; mean age 71.8 y; 315 lesions), and 31 MGC cases (24 males, 7 females; mean age 71.5 y; 31 lesions). The following cases were excluded: undifferentiated early gastric cancer (6), Barrett's esophagus adenocarcinoma (4), remnant gastric cancer (2), and recurrent cancer after endoscopic resection (3). Histological types were classified according to the Japanese Classification of Gastric Carcinoma: papillary (pap), well-differentiated (tub1), and moderately-differentiated (tub2) as ''differentiated'' and poorly-differentiated (por) and signet-ring cell carcinoma (sig) as ''undifferentiated''.
Results: There were no significant differences in tumor locations (U/M/L = 41/142/132 and 7/10/14 in PGC and MGC, respectively), morphological types (elevated/flat/depressed = 137/7/171 and 8/2/21 in PGC and MGC, respectively), lateral margins (positive/negative = 20/295 and 1/30 in PGC and MGC, respectively), and pathological ulcer scars (positive/negative = 22/293 and 5/26 in PGC and MGC, respectively). Regarding main histological type and histological type in preoperative biopsy, tub2 was observed significantly higher in MGC than PGC (51.6% vs. 3.8%, $P<0.01$ and 45.2% vs. 4.4%, $P<0.01$). Twenty-eight of 31 (90.3%) cases in MGC were diagnosed as ''differentiated'' on preoperative biopsy specimens. Compared to PGC, tumor size in MGC was significantly larger (23.2 ± 11.4 mm vs. 14.9 ± 10.9 mm, $P<0.01$) and there were more SM cancers (51.6% vs. 11.4%, $P<0.01$), deeper SM invasion (683.8 ± 793.0 μm vs. 1468.8 ± 1259.9 μm, $P<0.01$), more positive for vertical margins (12.9% vs. 2.5%, $P<0.05$), more lymphatic invasions (22.6% vs. 1.6%, $P<0.01$), and venous invasions (6.5% vs. 1.3%, $P<0.01$).
Conclusion: In cases in which histological type in preoperative biopsy shows tub2, we should pay particular attention to the possibility of mixed-type early gastric cancer. This study elucidated that the clinicopathological features of mixed-type early gastric cancer possessed higher malignant potential than pure differentiated early gastric cancer.

Introduction: Tumor burden is important to predict clinical behaviors of cancer such as lymph node metastasis (LNM), recurrence after treatment, or survival rate. Tumor size has been used as an indicator of tumor burden such as indication of endoscopic resection in early gastric cancer (EGC) to predict LNM. Several studies reported the clinical significance of tumor area or volume measured by endoscopic ultrasound in EGC or esophageal cancer.

Aims & Methods: The aim of study was to investigate whether tumor area can be more helpful to predict clinical behaviors than tumor size in gastric cancer. Between January 2000 and December 2005, data for 4,719 patients (2208 EGC; 2511 advanced gastric cancer) who underwent gastrectomy for gastric cancer were reviewed retrospectively. Tumor area was calculated by multiplying long and short diameter of the tumor in surgical specimen. Tumor size means long diameter of the tumor in specimen. Clinical behaviors included LNM, recurrence rate, and survival rate. Clinical behaviors were compared between tumor area and tumor size using area under receiver operating characteristic (AUROC) curves. For survival rate, integrated AUC (iAUC) was used.

Results: The mean tumor size and tumor area was 39.82 mm (1-280) and 1.787 mm^2 (1-56000). Tumor size and tumor area showed a strong correlation (correlation coefficient 0.880, $P<0.01$). The cutoff value for prediction of LNM was 33 mm of tumor size and 858 mm^2 of tumor area. There was no significant difference between tumor size and tumor area for prediction of LNM (AUC 0.874 vs. 0.873, respectively). For prediction of recurrence rate, the cutoff value was 38 mm of tumor size and 1.480 mm^2 of tumor area. However, there was no significant difference between tumor size and tumor area for prediction of recurrence rate (AUC 0.857 vs. 0.857, respectively). For survival rate, the cutoff value was 12 mm of tumor size and 100 mm^2 of tumor area. However, tumor size and area didn't show the significant differences to predict survival rate (iAUC, 0.557 vs. 0.554, respectively). When analyzed among EGC or advanced gastric cancer, prediction power about clinical behaviors between tumor size and tumor area was not significantly different.

Conclusion: Tumor area was not more helpful to predict clinical behaviors than tumor size in gastric cancer. Therefore, tumor size may be sufficient as an indicator of tumor burden.

P1795 CLINICAL OUTCOME OF CLUTCH CUTTER ENDOSCOPIC SUBMUCOSAL DISSECTION (CCESD) FOR EARLY GASTRIC CANCER IN ELDERLY PATIENTS

Y. Otsuka[1], K. Akahoshi[1], K. Yasunaga[1], Y. Motomura[1], M. Kubokawa[1], J. Gibo[1], N. Kinoshita[1], S. Osada[1], K. Tokumaru[1], K. Miyamoto[1], T. Hosokawa[1], R. Utsunomiya[1]
[1]*Aso Iizuka Hospital, Fukuoka, Japan*

Introduction: Endoscopic submucosal dissection (ESD) has the advantage of permitting en bloc and histologically complete resection for early gastric cancer. There is currently little information on the clinical outcomes of ESD for gastric cancer in elderly patients.

Aims & Methods: The aim of the present study is to evaluate the clinical outcome of CCESD in elderly patients. We reviewed 232 consecutive patients with early gastric cancer of absolute and expanded indication according to the Japanese Gastric Cancer Association who underwent CCESD between June 2010 and February 2014 at Aso Iizuka hospital. We divided them into two groups according to age: elderly patients(>80 years; $n=64$) and non-elderly patients($\leqq 80$ years; $n=168$). We retrospectively compared the prevalence rates of pre-existing comorbidities, anticoagulant therapy, en-bloc resection rate, mean duration of hospitalization, incidence of CCESD-related complications, change of performance status (PS) before and after ESD, and the financial cost of admission.

Results: The elderly group was comprised of 64 patients and the non-elderly group was comprised 168 patients with mean ages of 84.1 and 69.5, respectively. Elderly patients had significantly more pre-existing comorbidities than nonelderly patients, specifically heart diseases. En-bloc resection rates in the nonelderly group were significantly higher than those in the elderly group (100% v.s. 95.3%, $p=0.02$). There were no significantly differences in anticoagulant therapy, mean duration of hospitalization, incidence of CCESD related complications, change of performance status (PS) before
and after ESD, and financial cost of admission.

Conclusion: CCESD has a good clinical outcome in the treatment of early gastric cancer in elderly patients.

Contact E-mail Address: ytsuji-tky@umin.ac.jp

Introduction: Endoscopic resection (ER) for non-ampullary duodenal neoplasms is still challenging because of the difficulty in scope maneuverability in the duodenum and the high incidence of complications: intraoperative perforation, delayed perforation, and delayed bleeding. Even in Japan, where endoscopic submucosal dissection (ESD) is prevalent nationwide, the feasibility of ER for non-ampullary duodenal neoplasms remains unclear.

Aims & Methods: We aimed to investigate the clinical outcomes of ER for non-ampullary duodenal neoplasms. This is a single-center retrospective analysis. We extracted all duodenal ER cases from our prospectively-pooled database and medical records. The following factors were assessed: patient characteristics, ER methods, pathological findings, complications, and tumor recurrence.

Results: From January 2009 to February 2015, 50 sessions of endoscopic treatment for non-ampullary duodenal neoplasms were performed. After excluding one session of additional coagulation following the previous ER, a total of 49 sessions of ER in 46 patients were included in the present analysis (29 males, 17 females; mean age 62.3 ± 10.7 years). Therapeutic techniques were as follows: 2 polypectomies, 19 ESDs including 7 cases of snaring after circumferential incision and 4 cases of snaring after partially submucosal dissection, and 28 cases of endoscopic mucosal resection (EMR). 1 EMR case was aborted because of massive intraoperative bleeding, and emergency surgery was performed for this case. En block resection was achieved in 32 cases (65.3%; EMR 19/ESD 11/polypectomy 2). The pathological findings were as follows: 23 adenocarcinomas (4 submucosal adenocarcinomas), 9 high-grade adenomas, 11 low-grade adenomas and 6 other histological types. R0 en block resection was achieved in 17 cases (34.7%; EMR 7/ESD 8/polypectomy 2). As for complications, the results were as follows: 6 cases of delayed bleeding (12.2%; EMR 3/ESD 3); 1 case of intraoperative perforation (2.0%; EMR 0/ESD 1); 2 cases of delayed perforation (4.1%; EMR 1/ESD 1). Both of the delayed perforation cases were treated conservatively. Among the 29 patients who could be followed >1 year, 2 patients had tumor recurrence during follow-up, but both the cases were treated endoscopically. There have been no metastasis cases to date.

Conclusion: ER for non-ampullary duodenal neoplasms seems feasible, but a relatively high complication rate implies that en block resection may not always be imperative.

P1797 ALCOHOLIC LIVER DISEASE IS ASSOCIATED WITH AN INCREASED RISK OF GASTRIC NEOPLASM

Y. S. Park[1], H. Y. Kim[1], Y. J. Jung[1], J. W. Kim[1], B. G. Kim[1], K. L. Lee[1], S.-J. Koh[1]
[1]*Internal Medicine, Seoul National University Boramae Hospital, Seoul National University College of Medicine, Seoul, Korea, Republic Of*

Contact E-mail Address: p5018@naver.com

Introduction: The risk factors strongly associated with gastric cancer are *Helicobacter pylori* and smoking. However, an association between alcohol drinking and gastric cancer is still controversial. We performed a retrospective study to evaluate whether alcohol induced liver disease (ALD) is associated with the increased risk of gastric cancer development.

Aims & Methods: We reviewed the medical records of 514 patients who were diagnosed with ALD (alcoholic fatty liver disease, alcoholic hepatitis, or alcoholic liver cirrhosis) at Seoul Metropolitan Government Boramae Hospital between January 2000 and December 2011. For each patient, an age- and gender-matched control was identified from a population of asymptomatic individuals. And the clinical characteristics and risk factors associated with the development of gastric cancer of ALD patients group were compared with those of healthy group. A case-control study was performed to determine whether ALD patients had an increased risk of developing gastric neoplasm. Time to detect gastric adenoma was calculated using Kaplan-Meier cumulative curves and estimated using the log-rank test.

Results: The prevalence of gastric neoplasm were 16 (3.1%) in ALD patients and 8 (1.6%) in healthy control ($P = 0.098$). There was significant difference in the prevalence of gastric cancer (2.7% vs 0.6%, $P = 0.007$) between ALD and healthy group. Odds for detecting a gastric cancer in ALD patients were approximately 4.77 times greater than in healthy control (OR = 4.77 (95% CI:1.36-16.69)). Alcohol liver disease (Hazard ratio (HR) = 5.32; 95% CI: 1.51-18.68; $P = 0.009$) and age (HR = 12.49; 95% CI: 1.65-94.84; $P = 0.015$) was significant risk factors in a multivariate Cox-regression analysis. In addition, a significant difference was found in the cumulative incidence of gastric cancer between ALD and healthy subjects (Log rank test, $P = 0.005$).
Conclusion: The yield of gastric neoplasm was significantly higher in patients with alcoholic liver disease than in healthy subjects. Careful endoscopy surveillance is warranted in patients with ALD who expected long-term survival.

Contact E-mail Address: 11996@ncc.re.kr
Introduction: Early gastric cancer (EGC) lesions estimated to be within endoscopic submucosal dissection (ESD) indications before treatment often turns out to be out-of-expanded criteria on the pathological evaluation of resected specimen. We investigated the curative resection rates according to the pre-treatment clinical indications for ESD in EGC patients.
Aims & Methods: We retrospectively reviewed data of EGCs meeting the absolute or expanded indications before ESD between 2004 and 2011 at the National Cancer Center, Korea. The pre-ESD clinical indications were compared with the post-ESD criteria for curative resection. Pre-ESD factors, which are associated with out-of-expanded criteria cases at the final ESD pathologic evaluation, were also analyzed.
Results: Of 756 patients, pre-ESD estimated indications were absolute in 660 patients and expanded in 96 patients. En-bloc resection rates were not different between both pre-ESD indication groups (98.6% in pre-ESD absolute indication and 96.9% in pre-ESD expanded indication, $P = 0.197$). However, curative resection rate was significantly lower in patients with pre-ESD expanded indication than in those with pre-ESD absolute indication (64.6% vs. 81.7%, respectively; $P < 0.001$). In patients with pre-ESD absolute indication, post-ESD pathological criteria were absolute in 407 patients (61.7%), expanded in 162 (24.6%), and out-of-expanded in 91 (13.8%). In patients with pre-ESD expanded indication, post-ESD curative resection critera turned out to be absolute in 26 patients (27.1%), expanded in 41 (40.2%), and out-of-expanded in 29 (30.2%). Rate of non-curative resection due to out-of-expanded criteria were significantly higher in pre-ESD expanded group than in absolute group ($P < 0.001$). Of pre-ESD expanded indications, rates of post-ESD out-of-expanded criteria were 27.4% (17/62 patients) in mucosal EGCs with differentiated histological type of size > 2 cm without ulcer, 21.1% (4/19 patients) in those with differentiated histological type of size ≤ 3 cm with ulcer, and 53.3% (8/15 patients) in those with undifferentiated histological type of ≤ 2 cm without ulcer. A multivariate analysis showed that age > 65 years, tumor size > 2 cm, upper third of tumor location, and undifferentiated histologic type on pre-ESD evaluations were significant risk factors for out-of-expanded criteria after ESD.
Conclusion: Non-curative resection because of out-of-expanded criteria was found in as much as one third for EGC lesions clinically meeting expanded indication before ESD. Possibility of additional surgery should be emphasized to patients before undergoing ESD for EGC lesions meeting expanded indications, especially for tumors with undifferentiated histological type.

P1799 THE LONG-TERM OUTCOMES OF ESD FOR UNDIFFERENTIATED-TYPE EARLY GASTRIC CANCER AND INCIDENCE OF MULTIPLE GASTRIC CANCERS (SYNCHRONOUS OR METACHRONOUS)

Y. Miyamoto[1], T. Yoshio[1], Y. Muramatsu[1], T. Shimizu[1], Y. Horiuchi[1], M. Omae[1], T. Hirasawa[1], A. Ishiyama[1], Y. Yamamoto[1], T. Tsuchida[1], J. Fujisaki[1], M. Igarashi[1]
[1]*The Cancer Institute Hospital Of JFCR, Tokyo, Japan*

Contact E-mail Address: miyajimail0413@yahoo.co.jp
Introduction: Endoscopic submucosal dissection (ESD) for early gastric cancer (EGC) in histology of undifferentiated-type (UD-type) adenocarcinoma is gradually prevailing from its minimally-invasive approach, though it is defined as clinical research in expanded indication of ESD according to Japanese Gastric Cancer Association (JGCA). There are still few reports of long-term outcomes and no report of multiple gastric cancers (synchronous or metachronous).
Aims & Methods: The aim is to clarify long term outcomes of ESD for UD type EGC and frequency and histological type of synchronous and metachronous cancer. We treated 248 UD-type EGC in 237 patients by ESD which is preoperatively diagnosed as expanded indication (within 20 mm, intramucosal, without ulceration, UD-type adenocarcinoma) from May 2004 to October 2014, in Cancer Institute Hospital, Tokyo, Japan. Median observation period was 46.5 months.
Results: Noteworthy, 237 patients (Male/Female 132/105, 60.6 years old on average) include 82 of *H.pylori* (Hp) uninfected patients (Male/Female 49/33, 56.9 years old in average). Regarding the mean age and tumor diameter, HP+ patients were significantly older and larger than HP- patients (62.6 vs 57.0 ($p < 0.001$), 13.4mm vs 8.2mm ($p < 0.001$)). Histological type of signet ring cell carcinoma (sig) and poorly differentiated adenocarcinoma (por) were 78.1%/21.9% for Hp + and 90.4%/9.6% for Hp - patients ($p < 0.001$). About macroscopic type, 79% of lesions were depressed type and 21% were flat type. Depressed type was significantly more dominant in HP+ patients than HP- patients ($p < 0.001$). Curative resection rate was 81% (192/237) and in 45 non-curative resection cases, 43 cases were performed additional surgery and 2 cases were followed without surgery. The reasons of non-curative resection were as follows: sm invasion/lymohovascular involvement/ulceration in tumor 24/5/9. About long-term outcomes, 222 cases are alive, 13 cases died of other causes and 2 cases died of gastric cancer, both of which were performed additional surgery, because one case had mp invasion and lymphovascular involvement, and the other case had sm massive invasion. They had recurrence and died of gastric cancer a year and 4 years later. Overall survival rate was 94.0% in 3 years and 90.1% in 5 years. Synchronous and metachronous cancers were detected in 7 cases (8 lesions) and 2 cases (3 lesions), respectively. Histological type was tub1/pap/sig/por 2/1/4/1 for synchronous cancer and tub1/tub2 2/1 for metachronous cancer. In total, 54.5% of the multiple cancers were UD-type. Synchronous cancers were detected in 1.32% (5/155 in Hp +, 2/82 in Hp -). The cumulative incidence rate of metachronous cancer was 0% in 3 years and 2.6% in 6 years. The incidence of synchronous and metachronous cancer were not different between Hp + and Hp - in this study.
Conclusion: Long-term outcomes of ESD for the UD type EGC in expanded criteria is satisfactory. Multiple gastric cancers were not frequent, however, the ratio of UD type was very high after resecting UD type gastric cancers by ESD.

P1800 DEVELOPMENT OF THE STRUCTURED ASSESSMENT OF GASTROINTESTINAL SYMPTOMS (SAGIS) INSTRUMENT AS A NOVEL INSTRUMENT TO MEASURE THE SEVERITY OF GASTROINTESTINAL SYMPTOMS IN THE CLINICAL SETTING

N. A. Koloski[1,2], D. Jhaveri[2], M. Jones[3], M. Walker[4], N. Talley[4], **G. Holtmann**[2,5], on behalf of Australian Gastrointestinal Research Alliance (AGIRA)
[1]*School of Medicine, University of Queensland, St Lucia,* [2]*Department of Gastroenterology & Hepatology, Princess Alexandra Hospital, Woolloongabba,* [3]*Department of Psychology, Macquarie University, Ryde,* [4]*Faculty of Health & Medicine, University of Newcastle, Callaghan,* [5]*Faculty of Medicine & Biomedical Sciences, Faculty of Health & Behavioural Sciences, University of Queensland, St Lucia, Australia*

Contact E-mail Address: g.holtmann@uq.edu.au
Introduction: The assessment of gastrointestinal symptoms is key for targeted management of patients with a variety of gastrointestinal disorders. On the other hand, symptom assessment in the clinical setting is constrained by the available time and potentially biased by the special areas of interest of the clinician. Thus there is a need for a clinical instrument that supports the standardised assessment of patients.
Aims & Methods: Development of the SAGIS consisted of initial interviews with 8 patients referred for the diagnostic work up of digestive symptoms and relevant complaints identified. The instrument was refined with initially 22 and later 21 items developed and included. In addition, patients were asked to document what was their first and second most important problem. The questionnaire was given to 1384 consecutive patients. The sample was randomly split into derivation (n = 716) and validation datasets (n = 668). In addition, completed forms were handed with the case- notes to the treating physician at the time of the consultation, and after the consultation the clinician provided a working clinical diagnosis.
Results: Exploratory factor analysis conducted on the derivation sample supported a five factor model. This accounted for 68% of the total variance. The five GI symptom clusters were labelled as abdominal pain/discomfort (seven items), diarrhea/incontinence (five items), gastroesophageal reflux disease/regurgitation symptoms (four items), nausea/vomiting (three items) and difficult defecation and constipation (2 items). Confirmatory factor analysis conducted on the validation sample supported the initially developed five-factor measurement model ($c2/df = 4.76$; CFI = 0.92; RMSEA = .075). Further, 19 of 21 items demonstrated consistent factor loadings across gastrointestinal disease groups (e.g. functional gastrointestinal disorders (FGID), inflammatory bowel disease, liver disease, $p < 0.01$). Evidence of discriminant validity comes from observing that epigastric symptoms (F1) was higher in the FGID group than all other ($p < 0.0001$) and all symptom groups demonstrated some differentiation between disease groups.
Conclusion: The SAGIS questionnaire has good psychometric properties to assess type and severity of gastrointestinal symptoms in a standardised manner. The SAGIS shows differentiation across gastrointestinal disease groups and appears to support the clinical assessment of and symptom-based categorisation of patients.

P1801 UNITED EUROPEAN GASTROENTEORLOGY (UEG) WEEK – PROVIDING A PLATFORM FOR RESEARCHERS TO ACHIEVE FULL PUBLICATION FOLLOWING ABSTRACT PRESENTATION

M. Kurien[1], R. Akram[1], R. E. Glover[1], A. I. Al-Rifaie[1], E. M. Peever[1], J. W. Purves[1], E. J. Scanu[1], D. S. Sanders[1]
[1]*Academic Unit of Gastroenterology, Royal Hallamshire Hospital, Sheffield, United Kingdom*

Contact E-mail Address: matthew.kurien@sth.nhs.uk
Introduction: The UEG week is the largest and most prestigious meeting about digestive diseases in Europe. Like other scientific meetings it encourages abstract submissions, permitting researchers the opportunity to convey novel research findings rapidly and also acquire informal peer review prior to full publication. The percentage of abstracts that actually achieve full publication is however highly variable, ranging between 11-78% from other medical specialty meetings.
Aims & Methods: Given the paucity of data evaluating gastroenterology meetings, this study aimed to evaluate UEG week abstracts and assesses their conversion rate to full publications in indexed journals. All abstracts presented at UEG week meetings between 2009 and 2011 were assessed in October 2014. PUBMED and EMBASE databases were reviewed using cross-referencing of first author, senior author and at least one key word from the abstract title. Abstracts and possible full publications were then examined in tandem to ensure they represented the same study. Abstracts that were withdrawn were excluded from the study. In addition to publication rates, data was collected on lag time to publication, journal impact factors and factors that may influence subsequent publication. Statistical analyses were performed using contingency tables and c2 statistics for categorical data using SPSS version 20.0.
Results: 6595 abstracts (1212 oral, 5348 poster presentations) were presented at UEG weeks between 2009-2011. Of these, 30.8% (2033/6595) went on to full publication in indexed journals, with a mean impact factor for journals of 3.93. The mean lagtime between abstract and full publication was 16 months. Abstracts selected for oral presentation had a conversion rate of 37.9% (459/1212), which was significantly higher than poster presentations at 29% ($p < 0.0001$). Poster sections with the highest conversion rates to full publications were Therapeutic Endoscopy/Interventional Radiology (39.3%), Oncology (38.3%) and Inflammatory Bowel Disease (34.3%), which were all significantly higher than Pancreas and Surgery sections at 25.9% and 22.9% respectively ($p < 0.001$)
Conclusion: This study demonstrates that almost one in three abstracts presented at UEG week progress to full publication, providing credibility to the process of abstract submission and enhancing the reputation of UEG week as being a premier platform for researchers to present their work. Given recent initiatives to enhance the quality of abstract submission at UEG week including abstract prizes, travel grants and poster champ award, the likelihood is that this conversion rate is only likely to increase.

Contact E-mail Address: takanaka@ota-hosp.or.jp
Introduction: The combination of serum anti-*Helicobacter pylori* IgG antibody (*Hp*Ab) and serum pepsinogen (PG), is known as the ABC method, classifies subjects into four different risk groups (A, B, C, or D) of developing gastric cancer (GC). Individuals in group A (*Hp*Ab(-)PG(-)) have the lowest GC risk but are not cancer free and the esophagogastroduodenoscopy (EGD) identifies chronic atrophic gastritis (CAG) in a certain number of them. The individual with CAG has a high probability of previous exposure to *Helicobacter pylori* (*Hp*) and a material risk of developing GC. Periodic GC screening via EGD is required for such a case. If any noninvasive and simple test could identify the individual with CAG, it would make GC screening more efficient for the selection of candidates who definitely require the periodic EGD.
Aims & Methods: The data of EGD screening program at Ota Memorial Hospital (OMH) between June 2012 and January 2015 was reviewed. *Hp*-er Hx and the false negative result in PG and *Hp*Ab were analyzed as the presumed predictive factor for CAG. The false negative in PG (PG(±)) and *Hp*Ab (*Hp*Ab(±)) were defined as follows: *Hp*Ab(±) is $3U/ml \leq HpAb < 10U/ml$ and PG(±) is $PG1 \leq 40ng/ml$ or $PG1/2 \leq 2.5$. Clinicopathological characteristics of GC cases detected in group A were also analyzed.
Results: The 11346 subjects were enrolled in an EGD screening program of OMH. The ABC method was undertaken by 10404 individuals. Of these, 142 cases were excluded from the analysis due to a past history of gastrectomy, which influences PG. Proportions of group A, B (PG(-)*Hp*Ab(+)), C (PG(+)*Hp*Ab(+)) and D (PG(+)*Hp*Ab(-)) were 72.5% (7442 individuals), 18.3% (1878), 8.2% (841), and 1% (101) respectively. In group A, EGD identified CAG in 1846 individuals (24.8%). 24.2% (1798 individuals) had *Hp*-er Hx. PG(±), *Hp*Ab(±), and "PG(±) or *Hp*Ab(±)" were recognized in 11.4%, 17.4%, and 20.7% of group A, respectively. Sensitivity, specificity, and predictive accuracy of *Hp*-er Hx, PG(±), *Hp*Ab(±), and "PG(±) or *Hp*Ab(±)" to CAG were 76.1, 46.0, 70.3, 83.4% in sensitivity, 92.9, 72.4, 88.6, 64.1% in specificity, and 88.7, 65.9, 84.1, 68.9% in predictive accuracy, respectively. Malignant neoplasms were found in 38 individuals during the term considered. 24 cases were diagnoses as GC (detection rate was 0.21%). 12 cases belonged to group A and EGD found CAG at 10 of these. These 10 cases were identified by the test results as "PG(±) or *Hp*Ab(±)", although they were not always detected via *Hp*-er Hx, PG(±), or *Hp*Ab(±) alone. Other two cases of GC in group A did not have CAG and were negative to *Hp*-er Hx, PG, and *Hp*Ab.
Conclusion: "PG(±) or *Hp*Ab(±)" revealed the highest sensitivity to CAG in group A, while specificity and predictive accuracy were high in *Hp*-er Hx and *Hp*Ab(±) alone. Half of GC cases detected in our screening program were classed as group A. Of these, all 10 cases with CAG could be identified via serum test as the result of "PG(±) or *Hp*Ab(±)". It should be also mentioned that CAG negative GC might increase its prevalence in Japan because the national financial support for *Hp*-er started on February in 2013.

P1803 ANALYSIS OF ESOPHAGEAL AND GASTRIC CANCER SCREENING AT MINQIN COUNTY OF WUWEI CITY, CHINA

W. Wang[1], L. Wei[1], Y. Feng[1], T. Liu[1], **X. Huang**[1]
[1]*Digestive Department, The Second Hospital of Lanzhou University, Lanzhou, China*

Contact E-mail Address: huangxiaojunlzu@163.com
Introduction: Gastric cancer remains one of the most important malignant tumors and is considered as the second most common leading cause of cancer deaths worldwide. Gansu Province is the high incidence place in China, especially the Hexi area. gastric cancer is still the first cause of death in Gansu Province. Therefore, the prevention and early diagnosis of gastric cancer has great significance.
Aims & Methods: To explore the effects of gastroscopy combined with pathological biopsy pathologic in screening and follow-up at high-incidence regions of gastric cancer, and the prevalence of *Helicobacter pylori* infection, and the implication of endoscopic treatment for early cancer and precancerous lesions. In this study, 1343 natural populations were enrolled, with aged from 35 to 69 years old, from 5 villages randomly selected from Minqin county, Wuwei city, Gansu province of China. Between July 29th and Aug 24th in 2013, C13-urea breath test was used to diagnose *Helicobacter pylori* infection, endoscopic examination and pathological biopsy were performed for suspicious lesions. lugol chromoendoscopy was performed for screening early esophageal cancer. Follow-up by endoscopic examination and biopsy were accomplished for important cases. The clinically evaluated cases of gastric and esophageal cancer had been assigned to surgical operation or endoscopic treatment accordingly, and then follow-up.
Results: The positive rate *Helicobacter pylori* infection was 61.1% (820/1341), which accounted for 49% in men, 51% in women. A total of 1244 (92.8%) people were successfully accepted endoscopic screening, meanwhile, 41 (3.3%), 87 (7.0%) and 692 (55.6%) cases were diagnosed as gastric polyps, gastric ulcer and different degrees of chronic atrophic gastritis respectively. The overall cancer detection rate was 1.1% (14/1244), including 0.72% (9/1244) and 0.4% (5/1244) of gastric cancer and esophageal cancer respectively. Of 14 screened cancer cases, early stage cancer accounted 66.7% (6/9) and 80% (4/5) for gastric and esophageal cancer respectively. Surgical procedures were performed in all advanced cancers cases and 1 early gastric cancer. The rest of the early stage cancer were underwent endoscopic submucosal dissection successfully. With subsequent follow-up about 1 years, 1 case of early gastric cancer was underwent ESD again for ectopic early gastric cancer after 3 months of ESD, the rest cases without discomfort and recurrence.
Conclusion: Endoscopic and histological biopsies screening and treatment for precancerous and early stage cancer is a positive effect mode on prevention and treatment for gastric neoplasms. It is favorable for detecting early esophageal cancer to use esophageal iodine staining in gastric cancer screening. *Helicobacter pylori* infection rate is higher in Minqin County of Wuwei city.

Introduction: Multiple myeloma is a haematological cancer of unknown origin, characterized by abnormal accumulation of plasmocytes secreting a pathological monoclonal immunoglobulin (mc Ig), and always preceded by a stage of monoclonal gammopathy of undetermined significance (MGUS). The pathogenic mechanisms leading to the development of MGUS are not understood. Our aim was to test the hypothesis that chronic antigenic stimulation by infectious

pathogens, in particular by *Helicobacter pylori*, may be one of the mechanisms involved in the development of MGUS stage.
Aims & Methods: Patients with MGUS or myeloma presenting a mc Ig at concentration >8 g/L were included. *H. pylori* serology was performed and the mc Ig of these patients was purified. The analysis of the specificity of purified mc Ig was done using a new assay developed by our team, based on "protein chips", the Multiplexed Infectious Antigen Array (MIAA) assay. This assay includes the main antigenic epitopes of *H. pylori* and of 7 other pathogens (HCV, EBV, CMV, HSV-1, HSV-2, VZV, *T. gondii*). Whenever purified mc Ig specifically recognized *H. pylori*, confirmation of *H. pylori* recognition using western blotting was performed.
Results: Out of 242 patients examined at the Nantes University Hospital, 42 (17.4%) presented with *H. pylori*-positive serology. The mc Ig was successfully purified for 31 of these patients. For 5/31 patients (2 with MGUS, 3 with myeloma), the mc Ig was specifically directed against a *H. pylori* antigen: urease B in 3 cases, CagA in 1 case, and HSPB in 1 case.
Conclusion: The data suggest a causal relationship between *H. pylori* infection and the presence of mc Ig for a subset of patients with MGUS and myeloma. Prospective therapeutic studies are necessary to establish whether eradication of the bacterial infection will lead to the decrease or disappearance of mc Ig, particularly for MGUS patients.

P1805 *HELICOBACTER PYLORI* INFECTION IN PERIMENOPAUSAL WOMEN

E. Walecka-Kapica[1], J. Chojnacki[1], K. Tomaszewska-Warda[2], C. Chojnacki[1]
[1]*Dept. of Clinical Nutrition and Gastroenterological Diagnostics,* [2]*Dept. of Gastroenterology, Medical University, Lodz, Poland*

Contact E-mail Address: ewawk@op.pl
Introduction: *H. pylori* infection causes symptoms or its course is asymptomatic. The external gastrotoxic factors or deficiency of enteroprotective factors may adversely affect the natural history of chronic gastritis in Hp-infected patients. Protective factors include among others female hormones and melatonin, which secretion decreases with age, especially affecting postmenopausal women. At this period women often complain of gastrointestinal symptoms. It is not clear whether this is due to hormonal disorders or coexisting Hp infection.
Aims & Methods: The study was conducted in a group of 65 women before and after menopause. Group I –women without Hp infection and gastrointestinal tract pathology, Group II–with asymptomatic Hp infection. Diagnostic procedures-endoscopic and histologic appearance of the gastric mucosa, UBT-13C, the levels of 17-β-estradiol, FSH and melatonin. In the second stage the study included only women from group II. In 2006–2014 the overall assessment of their health state was performed every 12 months and examinations included all procedures as at the start of the program 2 years after the last menstruation. Two groups of women were determined in the postmenopausal period: IIa–without gastrointestinal complaints, IIb–with dyspeptic symptoms. In group IIb a 10-day antibacterial treatment was introduced (pantoprazole + amoxicillin + metronidazole or levofloxacin). The follow-up UBT-13C test was performed 8 weeks after the end of the treatment.
Results: No significant differences in the levels of estradiol, FSH and melatonin in both groups of women before menopause draws attention. In postmenopausal period the major changes occurred in the secretion of hormones. Compared to baseline estradiol levels decreased from 54.90 ± 4.91 to 20.00 ± 7.14pg/ml in the group with asymptomatic infection ($p < 0.001$) and to 17.40 ± 6.58pg/ml in the group with dyspeptic symptoms ($p < 0.001$);level of FSH increased to 62.60 ± 15.33mIU/L in group IIa ($p < 0.001$) and to 85.47 ± 17.71mIU/L in group IIb ($p < 0.001$). No significant differences were observed in the levels of 17β-estradiol and FSH between groups IIa and IIb. The level of melatonin decreased in both groups-respectively 9.93 ± 2.96pg/ml ($p < 0.05$) and 6.83 ± 2.32pg/ml ($p < 0.01$). However the level of melatonin was lower in the group with symptomatic infection– 6.83 ± 2.32 pg/ml ($p < 0.05$)-compared to the group with asymptomatic infection – 9.93 ± 2.96 pg/ml ($p < 0.05$). No significant differences found between both groups with regard to endoscopy pictures and UBT-13C test result. After the treatment, eradication of Hp was obtained in 25 women (92.6%). Dyspeptic symptoms resolved in 14 patients (51.8%) and decreased in 9(33.3%). Four patients (14.8%) still complained of mild epigastric pain.
Conclusion: Asymptomatic *H. pylori* infection can progress to symptomatic phase in postmenopausal women due to decreased secretion of female hormones and melatonin which have gastroprotective properties.

Introduction: The aim of this study was to evaluate the efficacy of a bismuth-based quadruple regimen as first-line therapy for *Helicobacter pylori* (HP) eradication in patients with unexplained iron deficiency anemia (IDA). We evaluated serum hepcidin-25, iron, ferritin, total iron binding capacity levels before and after eradication of *H. pylori* in IDA patients to assess whether it plays a role in IDA related to *H. pylori* infection.
Aims & Methods: Eighty consecutive patients with unexplained iron deficiency anemia and *H. pylori* infection were enrolled in this study. All patients received Pantoprazole (40 mg b.i.d.), bismuth citrate (120 mg q.i.d.), tetracycline (500 mg q.i.d.), and metronidazole (500 mg t.i.d.) for 14 days as the eradication regimen. Blood was sampled before treatment to eradicate *H. pylori* and again 1 month later. We used commercial enzyme-linked immunosorbent assay kit to determine serum hepcidin-25 levels in both groups.
Results: Hemoglobin, Fe, TIBC and ferritin levels improved in all the subjects after *H. pylori* eradication. Serum hepcidin-25 levels decreased significantly after with *H. pylori* eradication ($p < 0.001$).
Conclusion: Gastric *H. pylori* infection is a common cause of iron deficiency anemia of previously unknown origin in adult patients. Our result provides evidence that hepcidin level decreases after successful *H. pylori* eradication with the improvement of iron deficiency anemia.

Introduction: *Helicobacter pylori* could play a role in appetite regulation by affecting gastric secretion of ghrelin and leptin.
Aims & Methods: We aimed to evaluate the association of *H. pylori* infection and the type of gastric pathology with serum ghrelin and leptin concentrations and anthropometric nutritional status of dyspeptic patients. Fasted adults referred for an upper gastrointestinal endoscopy were enrolled in this study. A sociodemografic survey was administered to the patients and the ^{13}C-Urea Breath Test was performed. Height and weight were assessed for BMI calculation, and waist circumference to determine central adiposity. Serum total ghrelin and leptin levels were analyzed by ELISA. Four biopsies, two from the antrum and two from the corpus, were obtained during endoscopy for histopathology evaluation and Polimerase Chain Reaction DNA amplification. Statistical analysis was performed using a χ^2 test, Mann–Whitney U test, Kruskal-Wallis test and linear regression.
Results: 163 patients (40.8 ± 14.0y), 98/65 females/males, were included. Prevalence of *H. pylori* infection was 53.4% (CI95%;45.7-65.8%). Presence of *H. pylori* was associated with the type of gastric pathology both in the antrum ($P < 0.0001$) and the corpus ($P < 0.0001$), with a higher prevalence of active chronic gastritis among *H. pylori* positive patients. Overweight/obesity and central adiposity did not differ significantly between *H. pylori* infected and uninfected patients ($P = 0.09$ and $P = 0.87$, respectively). Median ghrelin concentrations were 306.5 pg/mL (IQR; 230.0–385.5) for the *H. pylori* positives and 358.3 pg/mL (IQR; 253.8-547.8) for the *H. pylori* negatives. Statistical analysis demonstrated that the infection was associated with lower serum ghrelin concentrations ($P = 0.016$), remaining associated after adjusting for BMI and gender in a linear regression analysis ($P = 0.019$). Moreover, the type and severity of gastric pathology in the corpus was also associated with lower ghrelin serum levels ($P = 0.03$), independently of the infection. Median leptin values were 1.75 ng/mL (IQR; 0.71–4.70) in the infected group and 1.84 ng/mL (IQR; 0.50-5.09) in the uninfected group, which were not significantly different ($P = 0.76$).
Conclusion: *H. pylori* infection and the type of gastric pathology in the corpus were associated to lower ghrelin serum concentrations in adult dyspeptic patients, supporting the role of *H. pylori* in the regulation of appetite.

Introduction: Consistent infection by *Helicobacter pylori* and chronic gastritis have been shown to be correlated with the development of gastric cancer. Triple antibiotic therapy is standard treatment for eradication of the bacteria, but the emergence of antibiotic resistance is an increasing concern. Several alternative treatments have been studied, but none have yielded efficacy comparable to that of antibiotic therapy. Egualen sodium hydrate, an azulene derivative, has protective effects on the stomach, ameliorating damage of stomach mucosa, and has been used as an antiulcer medication. In the present study, we investigated the anti-inflammatory activity of egualen sodium hydrate in a mouse model of *H. pylori* infection, including histopathological analysis and investigation of the host immune response.

Aims & Methods: C57BL/6 mice were divided into four groups of 10 animals each, as follows: Group 1, negative control; Group 2, infection control (0.5 mL sham vehicle: carboxymethyl cellulose solution only); Group 3, treatment with low-dose (20 mg/kg) egualen sodium hydrate; and Group 4, treatment with high-dose (60 mg/kg) egualen sodium hydrate. Starting eight weeks after challenge infection with *H. pylori* (5×10^7 CFU/mouse), animals in Groups 2-4 were treated by once-daily oral gavage for 4 weeks with sham vehicle or egualen sodium hydrate. At 4 days after the final dose administration, mice were sacrificed and tissues were harvested for evaluation of drug efficacy. CFU of colonizing bacteria in mouse stomach was calculated, the severity of gastritis was evaluated histologically, and cell proliferation was analyzed by histochemical staining for BrdU. Localized expression (in gastric mucosa) of the genes coding for Cox-2 and selected cytokines (interleukin [IL]-10, TNF-α, Interferon [IFN]-γ) also were measured using real time-PCR. Data were analyzed and compared using Kruskal–Wallis test and Student T-test.

Results: The severity of gastritis was significantly reduced in the egualen sodium hydrate-treated mice. The gastritis score in high-dose egualen-treated mice (1.7 ± 1.45) was significantly lower than that in the infection control mice (3.8 ± 1.45) ($p = 0.014$). The number of BrdU-labelled cells in the stomach of the high-dose egualen sodium hydrate-treated mice (39.2 ± 18.3 cells/20 glands) was significantly reduced compared to that observed in the infection control mice (63.0 ± 22.8 cells/20 glands) ($p = 0.004$). Neither the number of colonizing bacteria nor cytokine expression levels differed significantly among the groups.

Conclusion: Treatment with egualen sodium hydrate brought significant improvement of *H. pylori*-induced gastritis in mouse. This effect did not depend on reduction of bacterial number, suggesting that egualen sodium hydrate might serve as a therapy for preventing the progression of gastritis in patients not amenable to antibiotic therapy.

Introduction: Despite the proven ability of immunization to reduce *Helicobacter* infection in mouse models, the precise mechanism of protection has remained elusive.

Aims & Methods: In this study, we evaluated the role of inflammatory monocytes in the vaccine-induced reduction of *Helicobacter* infection.

Results: We first showed by using flow cytometry analysis that $CD11b^+CCR2^+Ly6C^{low}$ inflammatory monocytes accumulated in the stomach mucosa during the vaccine-induced reduction of *Helicobacter* infection. To determine whether inflammatory monocytes play a role in the vaccine-induced reduction of *Helicobacter* infection, these cells were depleted with anti-CCR2 depleting antibodies. Remarkably, depletion of inflammatory monocytes is associated with an impaired vaccine-induced reduction of *Helicobacte*r infection on day 5 post infection. Finally to determine whether inflammatory monocytes have a direct or indirect role, we studied their antimicrobial activities. We observed that inflammatory monocytes produced TNF-a and iNOS, two major antimicrobial factors. Lastly, by using a *Helicobacter in vitro* killing assay, we showed that inflammatory monocytes kill *H. pylori.*

Conclusion: Collectively, these data show that inflammatory monocytes play a direct role in the immunization-induced reduction of *Helicobacter* infection from the gastric mucosa.

Introduction: *Helicobacter pylori* (*H. pylori)* is a well-recognized gastroduodenal pathogen and class I carcinogen. Dual oxidase-2 (DUOX2) and NOX2, members of NADPH oxidase family, have several critical physiological functions including hormone biosynthesis and host mucosal defense.

Aims & Methods

Aim: To investigate DUOX2 and NOX2 expression in human stomach in the presence and absence of *H. pylori* infection.

Methods: The biopsies were obtained from patients underwent endoscopic diagnosis. The serum of patients was assayed for two virulent factors of *H. pylori,* CagA and VacA. The inflammation in gastric mucosa was analyzed with histology. Quantitative real-time PCR was used to detect the expression of three members of NADPH oxidase, NOX1, NOX2 and DUOX2, as well as lactoperoxidase (LPO) in the gastric mucosa. DUOX2 protein levels were also quantified by Western blots and immunohistochemistry. NOX2 protein level was only observed by immunohistochemistry.

Results: The expression of DUOX2 mRNA and protein was lower in gastric mucosa of patients with *H. pylori* infection compared to those without infection. Among the *H. pylori*-infected patients, those infected with CagA and VacA strains had the lowest DUOX2 expression levels than those infected with at least one virulent factor or both CagA and VacA negative strain. The levels of NOX2 mRNA and protein were higher in patients infected with *H. pylori* than those without infection. NOX1 and LPO mRNA was undetectable in the gastric mucosa.

Conclusion: DUOX2 is expressed in the inflamed human gastric epithelium, with lower expression levels in patients with *H. pylori* infection than those without *H. pylori* colonization. This finding suggests that *H. pylori* infection may suppress DUOX2 expression to promote its own survival.

Introduction: The CagA protein is a well-known virulent factor of *Helicobacter pylori (H. pylori*), and is related to an increased risk of peptic ulcers or gastric cancer (GC). Meta-analysis has shown a positive association between CagA seropositivity and GC. On the other hand, almost all *H. pylori* strains possess the *cagA* gene in Japan, but patients infected with *cagA*-positive *H. pylori* do not always induce serum CagA antibodies. Therefore, it is difficult to use CagA seropositivity as a marker for GC. A low level of serum pepsinogen (PG) has been used in Japan as a serum biomarker for early GC detection, the combined use of serum *H. pylori* antibody and PG measurement is useful for evaluating the risk of GC. However, few studies have considered serum CagA antibody and PG status when investigating GC classified by histopathological differentiation.

Aims & Methods: We aimed to estimate the seropositivity rates of *H. pylori* antibodies, CagA antibodies, and the abnormal PG status in patients with differentiated-type (i.e. intestinal type by Lauren) or undifferentiated-type (i.e. diffuse type) GC or gastric ulcers (GUs) or duodenal ulcers (DUs). A total of 234 patients, including 138 with differentiated-type GC (diff-GC), 21 with undifferentiated-type GC (undiff-GC), 44 with GUs, and 31 with DUs, were enrolled. The seropositivity of *H. pylori* antibodies and CagA antibodies were judged by the manufacturer's recommendations. The levels of serum gastrin PG I and II were measured and serum PG status was defined as abnormal when the criteria of PG I < 70ng/mL and PGI/II ratio < 3.0 were fulfilled.

Results: There was no significant difference in seropositivity rates of *H. pylori* antibodies between groups (diff-GC, 87.7%; undiff-GC, 85.7%; GU, 97.1%; DU, 96.0%). However, the seropositivity rates of CagA antibodies were significantly lower in the diff-GC group than in the other groups (diff-GC, 75.4%; undiff-GC, 90.5%; GU, 100.0%; DU, 96.8%); furthermore, CagA antibody titer levels were significantly lower in the diff-GC group than in the GU or DU groups (mean levels: diff-GC, 51.7 U/mL; undiff-GC, 68.1 U/mL; GU, 86.7 U/mL; DU, 89.6 U/mL). The rate of abnormal PG status was significantly higher in the diff-GC and undiff-GC groups than in the GU or DU groups. On the other hand, in the diff-GC group, the rate of the *H. pylori* seropositivity and abnormal PG status (Hp(+)/PG(+)) patients, and the CagA seropositivity and abnormal PG status ((CagA(+)/PG(+)) patients was 68.2%, 55.8%, respectively; the rates of Hp(+)/PG(+) patients were significantly higher than those of CagA(+)/PG(+) patients. The rate of the Hp(+)/PG(+) patients, and the CagA(+)/PG(+) patients in the undiff-GC group was 81.0%, 71.2%, respectively.

Conclusion: There is a difference in seropositivity rates and titer levels of CagA antibodies among the *H. pylori* related gastroduodenal diseases. In particular, these values were lower in patients with diff-GC than in those with undiff-GC or peptic ulcers. Therefore, this result suggests that the immune response against CagA is lower in patients with diff-GC. Moreover, the rate of CagA(+)/PG(+) patients did not surpass the rate of Hp(+)/PG(+) patients in the diff-GC and undiff-GC groups; therefore, the combined use of CagA antibodies and PG status would not be useful for detecting GC.

Contact E-mail Address: vyshyvanyuk@rambler.ru
Introduction: Peptic ulcer disease belongs to classic acid-related disorders. The important factor contributing to duodenal ulcer occurrence is duodenal acidification which is an alkaline in normal case. Dysmotility of gastroduodenal area such as so-called arterio mesenteric duodenal compression and duodenogastric reflux also promotes ulceration. The main acidity regulator in duodenum outside of a digestion phase is gastrointestinal hormone secretin which is secreted by S-cells of duodenal mucosa and stimulates the production of liquid part of pancreatic juice by pancreas.
Long-term *Helicobacter pylori* persistency supports inflammation and ulceration which possibly can change production of APUD (Amine Precursor Uptake and Decarboxylation) system hormones.
Aims & Methods: The aim of our investigation was to study the secretin level in blood serum of patients with *Helicobacter pylori*-associated peptic ulcer disease.
Materials and methods: The study involved 148 patients with duodenal ulcer. The diagnosis of peptic ulcer was confirmed by endoscopy. ^{13}C-urea breath test detected *Helicobacter pylori* infection in all patients. The secretin content was determined by ELISA using of a set "Secretin", Peninsula, USA.
Results: During examining of patients with ulcer a reduction of secretin level in serum to 23.91 ± 0.83 ng/L was detected vs. 41.27 ± 2.66 ng/L ($p < 0.001$) in healthy persons. Thus, significant decrease of this index to 1.73 times was found in all patients with ulcer indicating to secretin insufficiency.
Considering that secretin inhibits gastrin secretion, i.e. naturally decreases gastric secretion, its insufficiency is one of the mechanisms of hypersecretion. Patients with low levels of secretin in the blood turned out to have the lowest pH. Direct strong correlation was detected between these indicators ($r = 0.71$; $p < 0.001$). Credible feedback was also found between the levels of secretin and the labeled $^{13}CO_2$ concentration in exhaled air during the ^{13}C-urea breath test ($r = -0.49$; $p < 0.001$). Furthermore, the higher $^{13}CO_2$ concentration was observed (indicating more intensive affection of mucosa membrane by *Helicobacter pylori*), the lower level of secretin was detected.
Conclusion: Secretin insufficiency was found in patients with duodenal ulcer. It could be considered as a result of continuous inflammation caused by *Helicobacter pylori*.
Disclosure of Interest: None declared

P1813 MIR-155 IS A MUCOSAL BIOMARKER FOR SEVERITY OF GASTRIC INFLAMMATION AND CORRELATES WITH HELICOBACTER PYLORI VIRULENCE FACTORS

W. Schirrmeister[1], A. Kandulski[1], C. Langner[1], T. Wex[1], P. Malfertheiner[1], **A. Link**[1]
[1]*Department of Gastroenterology, Hepatology and Infectious Diseases, Otto-von-Guericke University Magdeburg, Magdeburg, Germany*

Contact E-mail Address: alinkmail@gmail.com
Introduction: *Helicobacter pylori (H.pylori)* infection is the main cause of gastric mucosal inflammation and the recognized trigger of gastric carcinogenesis. Pathogenicity of *H.pylori* is partly dependent on main bacterial virulence factors, such as *cagA* and *vacA*, but also on host genetic, environmental and other factors. We have recently identified a link between microRNA (miRNA) miR-155 and *H. pylori* infection and development of preneoplastic conditions (1).
Aims & Methods: Here we perform in depth analyses on miR-155 expression in large cohort of gastric mucosa samples and correlate the results with *H.pylori* infection specifically histological phenotype of gastritis, *H.pylori* virulence factors/genotype. In the prospective study (HELDIVPAT, ERA-NET), 192 patients (with normal mucosa (N), chronic gastritis (CNAG), atrophic gastritis ± intestinal (AG) underwent upper GI endoscopy. Gastric biopsies were histologically characterized according to Sydney classification. *H.pylori* genotyping (*cagA*, *vacA*) was performed following bacterial cultivation. Quantitative TaqMan assay has been used to evaluate the miR-155 expression.
Results: MiRNA-155 expression was higher in antrum mucosa of CNAG and AG compared to N ($p < 0.001$). Already presence of CNAG/AG without *H. pylori* was associated with increased miR-155 expression in antrum mucosa, while the highest expression was observed in *H. pylori*-related CNAG/AG in antrum ($p < 0.001$). Active *H. pylori*-infection (defined by direct microbiological cultivation and/or histological visibility), was associated with greater miR-155 expression compared to patients without detectable *H. pylori* despite *H. pylori*-positive serology ($p = 0.015$). In subgroup analyses regarding the bacterial virulence factors, expression of miR-155 was dependent on *H. pylori cagA* and *vacA* with highest expression in *cagA*+and *vacA s1i1m1* genotype strains ($p < 0.001$). Histological analyses showed the strong correlation of miR-155 expression with chronic lymphatic inflammation score in a *H. pylori*-dependent manner; however, the correlation to PNMs infiltration, atrophy or intestinal metaplasia was rather modest or missing.
Conclusion: Here, we suggest the link between *H. pylori* infection and mucosal miR-155 expression. According to our results miR-155 is a biomarker of chronic *H. pylori*-triggered inflammation in gastric mucosa. The extent of miR-155 expression is dependent on *H. pylori* genotype and may be predictive for progression of gastric mucosa inflammation. Further studies are needed to evaluate the biomarker potential in clinical settings.

Introduction: *Helicobacter pylori* (*H. pylori*) infection is a cause of unexplained iron-deficiency anemia (IDA). The mechanism through which *H. pylori* contributes to IDA is unclear, but may involve hepcidin, an antimicrobial peptide and a key hormone in iron homeostasis. We have found that serum levels of prohepcidin, the precursor of hepcidin, in patients with *H. pylori*-related disease (nodular gastritis (NG), duodenal ulcer (DU), gastric ulcer (GU), or gastric hyperplastic polyp (GHP)) are higher than those in uninfected adults, and are higher in *H. pylori*-infected patients with NG compared to those with DU, GU or GHP (*Helicobacter* 20(1):11-8. 2015). These data suggest that iron depletion in patients with H. pylori infection is due to hepcidin overproduction induced by *H. pylori*, and that the iron-deficient state in NG patients is strongly related to hepcidin. However, it is unclear why overproduction of hepcidin occurs in patients with NG in comparison with other *H. pylori*-infected patients. We have also shown that hepcidin is located in gastric parietal cells and lymphocytes in the deep layer of the lamina propria in the gastric mucosa (UEGW 2014). In the current study, we compared mucosal hepcidin expression and distribution immunohistologically between *H. pylori*-infected patients with NG and those with chronic gastritis.
Aims & Methods: The subjects were 15 patients with NG (M:F = 1:14) and 20 patients with chronic gastritis (M:F = 8:12). All patients were *H. pylori*-positive and all underwent esophagogastroduodenoscopy (EGD). During EGD, biopsy specimens were obtained from the greater curvature of the gastric antrum and corpus. These specimens were fixed in 10% formalin and embedded in paraffin. Immunohistochemical staining of sections from the specimens was performed using a monoclonal antibody against hepcidin (Abnova, Taiwan). The study was approved by the ethics committee of our institution. Written informed consent was obtained from all patients.
Results: Hepcidin was expressed in the cytoplasm and intracellular canaliculi of gastric parietal cells in both groups, with no differences in expression levels and patterns of distribution in the gastric mucosa. However, hepcidin was strongly expressed in the germinal center of lymph follicles in patients with NG. Lymph follicles were observed in the gastric antrum and corpus, and there was no difference in hepcidin expression between these lymph follicles.
Conclusion: Our results show that hepcidin is produced in lymph follicles in the gastric mucosa of patients with *H. pylori*-related NG. Histological findings of lymph follicles in the gastric mucosa are characteristics of NG. This suggests that overproduction of hepcidin in lymph follicles is a cause of the difference in iron-deficiency between patients with NG and other *H. pylori*-infected patients.

Contact E-mail Address: prof.miehlke@mdz-hamburg.de
Introduction: Recommendations for diagnosis and treatment of *H. pylori* infection have been prosposed by national and European guidelines, with special attention to antimicrobial resistance. The aim of this study was to explore the current management strategies among gastroenterologists in Germany.
Aims & Methods: Between 12/2014 and 02/2015, a standardized questionaire including 19 multiple choice questions was sent to 1507 gastroenterologists in private practice. Data were captured and analyzed using the SurveyMonkey software.
Results: 540 questionaires (36%) were completely returned and analyzed. The following regimens were used for 1-line therapy in patients without penicillin intolerance: PPI + CLA + AMX 84%, PPI + CLA + MET 12%, bismuth quadruple therapy (BQT) 3%; in patients with penicillin intolerance: PPI + CLA + MET 81%, BQT 19%. The prevalence of CLA resistance in Germany was correctly estimated by 58% of responders. Country of origin and previous macrolide exposure were always assessed prior to 1-line therapy by 22% and 17% of responders (sometimes assessed by 40% and 34%). In 2-line therapy, BQT (42%) and levofloxacin triple therapy (24%) were the preferred regimens, however 29% of responders have used another clarithromycin-contaning triple therapy. After failure of 2-line therapy, 70% of responders

always performed antibiotic susceptibility testing, and 26% did so depending of the planned 3-line regimen.
Conclusion: Awareness of clarithromycin resistance as important risk factor for treatment failure appears to increase among gastroenterologists in Germany. Bismuth quadruple therapy is already the most commonly used 2-line regimen, and is increasingly being used in 1-line therapy of *H.pylori* infection. However, 30% of responders still do not adhere to current recommendations for 2-line therapy

Introduction: Trends in eradication rates of *Helicobacter pylori* by second-line bismuth-based quadruple therapy, comprised of a proton pump inhibitor, metronidazole, bismuth and tetracycline, have been understudied.
Aims & Methods: The aims of this study were to identify *H. pylori* eradication rates using second-line eradication therapy during the last ten years and identify risk factors related to eradication failure. This study included 362 patients who were failed to first-line triple therapy and received 7 days of bismuth-based quadruple therapy between January 2005 and December 2014. We retrospectively demonstrated *H. pylori* eradication rates with respect to the year of therapy as well as demographic and clinical factors. *H. pylori* eradication was confirmed by a ^{13}C-urea breath test or a rapid urease test at least 4 weeks after the completion of bismuth-based quadruple therapy.
Results: The overall *H. pylori* eradication rate was 95.3%. Annual eradication rates from 2005 to 2014 were 100.0%, 92.9%, 100.0%, 100.0%, 100.0%, 97.4%, 100.0%, 93.8%, 84.4%, and 98.9% respectively, by per-protocol analysis. The eradication rate in second-line bismuth-based quadruple therapy decreased during the last ten years ($P = 0.003$). Multivariate analysis showed that diabetes mellitus (OR 5.84; 95% CI 1.78-19.20) was associated with the failure of *H. pylori* eradication therapy.
Conclusion: The efficacy of second-line bismuth-based quadruple therapy for *H. pylori* infection has decreased during the last ten years, however, the overall *H. pylori* eradication rate was still high. Therefore, bismuth-based quadruple therapy is worth considering as second-line therapies for *H. pylori* eradication in Korea.

Contact E-mail Address: dr.wu.taiwan@gmail.com
Introduction: With the declined *Helicobacter pylori* (*H. pylori*) eradication rate, many new regimens have been developed. However, there is no systematic comparison to evaluate their efficacy.
Aims & Methods: We conducted a network meta-analysis in Bayesian framework to investigate the efficacy of different *H. pylori* eradication regimens. We searched Pubmed and Cochrane Central Register of Controlled Trials for randomized controlled trials that evaluated *H. pylori* eradication rate in treatment-naïve adults. Using a random effect model, we performed traditional pairwise meta-analyses and network meta-analysis by R software and WINBUGS, respectively.
Results: We identified totally 66 trials with 18,923 treatment naive patients. Network meta-analysis suggested that, when compared with clarithromycin-based triple therapy for 7 days, sequential therapy for 14 days (OR 4.18, 95% CI: 2.54-6.95) and concomitant therapy for more than 10 days (OR = 3.44, 95CI: 2.18-5.50) presented highest efficacy. Increasing age was inversely correlated with eradication rate.
Conclusion: From network analysis, we found the 14 days sequential therapy, and more than 10 days concomitant therapy had significantly higher eradication rate compared with the standard *H. pylori* eradication therapy.

Introduction: For the patients who had failed in eradication of *H. pylori* by the first and second-line regimens, the triple therapy with sitafloxacin, amoxicillin and PPI has been performed as the rescue therapy, which has yielded with relatively high eradication rates. However, some patients cannot clear their infection with this regimen. Strategy for patients allergic to penicillin has not been well established. In our institution, personalized therapy has been performed. Here, we report results of our strategies for patients who had failed in eradication more than three times and those who are allergic to penicillin.
Aims & Methods: DNA samples were extracted from gastric juice or tissue samples collected during endoscopy. CYP2C19 genotypes of patients and 23S rRNA mutations of *H. pylori* were measured by automated SNP analyzer. Culture test was performed to check the susceptibility of H. pylori to variety of antimicrobial agents. Based on CYP2C19 genotypes and susceptibility test results, we designed the personalized regimen.
Results: Incidences of clarithromycin and levofloxacin resistant strains were 80.0% and 60.0%, respectively, while that of sitafloxacin was 9.5%. The incidence of extensive metabolizer of CYP2C19 was 88/9%. The eradication rate with the triple PPI (high dose)/metronidazole/sitafloxacin was 83.9% (73/87), that with the triple PPI (high dose)/amoxicillin/ecabet sodium was 83.8% (31/37), that with the triple PPI (high dose)/amoxicillin/metronidazole was 100.0% (18/18). In patients allergic to penicillin, the eradication rate with the triple PPI/sitafloxacin/metronidazole therapy was 97.7% (43/44).
Conclusion: Personalized strategy based on CYP2C19 genotypes and susceptibility test results could yield with sufficient eradication rates in patients with frequent failures with the previous regimens.

Introduction: Since proton pump inhibitors are metabolized by CYP2C19, it is difficult for the subjects with rapid metabolizer genotype of CYP2C19 (RMs) to attain sufficient acid inhibition with a PPI at the standard dose within a short term. Therefore, the eradication rates of *H. pylori* with the standard triple therapy in RMs are lower in comparison with those in intermediate (IM) or poor metabolizers (PM) of CYP2C19. Recent studies have indicated that rabeprazole (RPZ) 10 mg 4 times a day (qds) attains sufficient acid inhibition even in RMs. However, to dose rabeprazole 10 mg 4 times daily is costly and difficult to keep the good adherence, while it would be possible to keep the good adherence if the dosing period of 4 times daily is one day.
Aims & Methods: Then, we investigated the effect of one-day pretreatment with RPZ 10 mg qds on the following treatment with RPZ 10 mg twice daily (bd). The results were compared with the acid inhibitions attained with RPZ 10 mg qds in RMs and RPZ 10 mg bd in IMs and PMs.
Fourteen *H. pylori*-negative healthy volunteers, consisting of CYP2C19 RMs (n = 5), intermediate metabolizers (IMs) (n = 5), and poor metabolizers (PMs) (n = 4), were enrolled in the study. RMs received three different 1-week regimens in a crossover manner, as follows: (1) RPZ 10 mg bd from day 1 to 7, (2) RPZ 10 mg qds for 1 day (day 0) followed by RPZ 10 mg bd from day 1 to 7, and (3) RPZ 10 mg qds from day 1 to 7. IMs and PMs received RPZ 10 mg bd from day 1 to 7. For each regimen, 24-hour intragastric pH-monitoring tests were performed three times on days 1, 4 and 7.
Results: The median pH values with RPZ 10 mg bd, the pretreatment regimen and the RPZ qds in RMs were 3.18, 5.09, 4.42, respectively. Those on day 4 were 5.0, 4.87, 5.44, respectively. Those on day 7 were 4.72, 5.14, 5.59, respectively. The median pH values of IMs and PMs on day 1, 4, and 7 were 4.05 and 5.02 on day 1, 5.7 and 6.15 on day 4, and 5.96 and 6.29 on day 7, respectively. The pretreatment regimen in RMs attained the intragastric pH profile that was almost the same as those of RPZ qds and RPZ 10 mg bd in PMs and higher than that of RPZ bd in RMs on day 1. The similar results were observed on days 4 and 7.
Conclusion: We could demonstrate that the one-day pretreatment with RPZ 10 mg qds made it possible for RPZ 10 mg bd to attain sufficient acid inhibition in RMs of CYP2C19. Level of acid inhibition with this strategy was almost the same as those in IMs and PMs of CYP2C19. We are sure that this new strategy overcomes the insufficient eradication rates of *H. pylori* in RMs with low cost and is applicable for the treatments of other acid related disorders.

P1821 THE EFFICACY OF 10-DAY HIGH-DOSE METRONIDAZOLE CONTAINING SEQUENTIAL THERAPY FOR SECOND LINE *HELICOBACTER PYLORI* ERADICATION AFTER FAILURE OF STANDARD TRIPLE THERAPY

S.-K. Chuah[1], **W.-C. Tai**[1], C.-M. Liang[1], K.-L. Wu[1]
[1]*Division of Hepatogastroenterology, Kaohsiung Chang Gung Memorial Hospital and Chang Gung University, College of Medicine, Taiwan, Kaohsiung, Taiwan, Province of China*

Contact E-mail Address: chuahsk@seed.net.tw

Introduction: The global eradication rate of the standard first line triple therapy has fallen below 80% in many countries(1). It has been reported that the combination of levofloxacin and metronidazole shows a synergistic effect against anaerobic bacteria and high-dose metronidaozole can overcome metronidazole resistancy(2, 3). We hypothesized that the addition of high-dose metronidazole might also lead to a higher eradication rate for levofloxacin-based therapy in the treatment of *H. pylori* infection.
Aims & Methods: This pilot study aimed to assess the efficacy of 10-day high dose metronidazole containing sequential therapy treating patients after failure of standard triple therapy and to determine what clinical factors influenced the efficacy of salvage regimens.
Ninety-eight patients who failed *H pylori* eradication using the standard triple therapy (proton pump inhibitor bid, clarithromycin 500 mg bid., amoxicillin 1g bid.x 7 days) are randomly assigned to either 10-day levofloxacin containing triple therapy(esomeprazole 40 mg bid., amoxicillin 1 g bid., and levofloxacin 500 mg qd) or 10-day high-dose metronidazole containing sequential therapy (EALM-10, esomeprazole 40 mg bid., amoxicillin 1 g bid. for 5 days and followed by levofloxacin 500 mg qd and metronidazole 500 mg tid for 5 days). Repeated endoscopy with rapid urease test, histological examination and culture is performed at four weeks after the end of anti-*H pylori* therapy. If patients refused follow-up endoscopy, urea breath tests are conducted to assess *H. pylori* status. The rates of eradication, adverse events and compliance will be compared between groups by chi-square test, and the clinical and bacterial factors influencing the efficacy of salvage regimens are assessed by multivariate analysis.
Results: Eradication rates attained by EAL-10 and EALM-10 were 79.1%; 95% CI = 68.1-90.1% and 86.0%; 95% CI = 73.8-98.2%, $p = 0.372$ in the intention-to-treat analysis; 88.4%; 95% CI = 76.7-100% and 95.6%; 95% CI = 82.7-108.5%, $p = 0.213$ in the per protocol analysis. The adverse events were 18.6% vs. 22.2%, $p = 0.674$; The compliance was 100% in both groups. Univariate analysis showed that the clinical factors influencing the efficacy of *H. pylori* eradication therapy were antibiotics resistances to levofloxacin alone ($p = 0.011$) and dual resistances to both levofloxacin and metronidazole.($p < 0.001$).
Conclusion: This study suggests that 10-day high-dose metronidazole containing sequential could be a good treatment option as second line *H. pylori* eradication after failure of standard triple therapy as it achieved a grade "A" success rate.

P1822 FIVE-YEAR SEQUENTIAL CHANGES IN ANTIBIOTIC RESISTANCES OF *HELICOBACTER PYLORI* AMONG PATIENTS WHO FAILED FIRST-LINE THERAPY

W.-C. Tai[1], C.-M. Liang[1], S.-K. Chuah[1], I.-T. Wu[1], K.-L. Wu[1]
[1]*Division of Hepatogastroenterology, Department of Internal Medicine, Chang Gung Memorial Hospital, Kaohsiung, Taiwan, Kaohsiung, Taiwan, Province of China*

Contact E-mail Address: luketai1019@gmail.com

Introduction: Antibiotics resistance of *Helicobacter pylori (H. pylori)* is the major cause of eradication therapy failure. Levofloxacin-based treatment, has been recommended after failure of first line standard triple therapy. Since the rapid development of quinolone resistance worldwide, especially in Asia, empiric second line quinolone-based therapy should be carefully monitored.
Aims & Methods
Aim: This study was designed to access the 5-year sequential changes in antibiotic resistances of *H. pylori* in Southern Taiwan after failure of first line standard triple therapy.
Methods: We analyzed 137 *H. pylori*-infected isolates from patients who failed eradication after standard first line triple therapies from January 2010 to December 2014. The *H. pylori* strains were tested for amoxicillin, clarithromycin, levofloxacin, metronidazole and tetracycline susceptibility using the E-test. The minimal inhibitory concentration (MIC) was determined by the agar dilution test. *H. pylori* strains with MIC values ≥ 0.5, ≥ 1, ≥ 1, ≥ 4 and ≥ 8 mg/L were considered to be the resistant breakpoints for amoxicillin, clarithromycin, levofloxacin, tetracycline and metronidazole respectively.
Results: High resistance rate was found in Clarithromycin (65-75%) and metronidazole (30-40%) among patients who failed first line standard therapy. The resistances of amoxicillin and tetracycline remained very low, but levofloxacin resistance was as high from 25% to 37.5%.

Table: Trend of antibiotics resistance rate annually in treatment of *H. pylori*

		Proportion (95% C.I.) (%)	P value Chi-square test for linear trend
Amoxicillin	2010	0 (-)	-
	2011	0 (-)	
	2012	0 (-)	
	2013	0 (-)	
	2014	0 (-)	
Clarithromycin	2010	70.8 (51.2-90.4)	P = 0.736
	2011	65.6 (48.2-83.0)	
	2012	65.0 (42.1-87.9)	
	2013	75.0 (54.2-95.8)	
	2014	70.7 (57.9-83.5)	
Levofloxacin	2010	37.5 (16.6-58.4)	P = 0.391
	2011	34.4 (17.0-51.8)	
	2012	30.0 (8.0-52.0)	
	2013	35.0 (12.1-57.9)	
	2014	26.8 (7.9-41.0)	
Metronidazole	2010	37.5 (16.6-58.4)	P = 0.312
	2011	25.0 (9.1-40.9)	
	2012	30.0 (8.0-52.0)	
	2013	30.0 (8.0-52.0)	
	2014	43.9 (23.3-59.8)	
Tetracycline	2010	0 (-)	P = 0.556
	2011	0 (-)	
	2012	10.0 (0-24.4)	
	2013	0 (-)	
	2014	2.4 (0-7.4)	

Conclusion: Increase in antibiotics resistance of *H. pylori* in southern Taiwan is becoming a problem for effective eradication in Taiwan. Clarythromycin should not be prescribed in second line *H.pylori* eradication. Levofloxacin-based second-line therapy should be used cautiously under careful monitoring the status of resistances in the area.

P1823 THE EFFECT OF *HELICOBACTER PYLORI* ERADICATION ON THE GASTROINTESTINAL FLORA IN PEPTIC ULCER

X. Zhou[1]
[1]*Gastroenterology, the First Affiliated Hospital of Nanjing Medical University, Nanjing, China*

Contact E-mail Address: zhouxiaoying0926@sina.cn

Introduction: Recent reports indicated that *Helicobacter pylori* (*H. pylori*) might have an effect on the gastrointestinal flora, moreover, gastric commensal bacteria are observed in the development of peptic ulcer (PU), including gastric ulcer (GU) and duodenal ulcer (DU).
Aims & Methods: In our study, we aimed to observe the effect of *H. pylori* eradication on gastrointestinal flora in PU with completely cure. A case-control study in China was performed at Jiangsu Shengze Hospital between December, 2013 and April, 2014. Gastric mucus and feces specimens were used to extract bacteria DNA to quantify by real-time polymerase chain reaction.
Results: Following institutional ethical approval, 40 DU cases, 9 GU cases and 30 chronic gastritis cases served as controls were enrolled. Twenty-three DU patients and 3 GU patients completed the study. In *H. pylori*-related DU cases, after the eradication of *H. pylori*, an increase of Lactobacillus group, Clostridium leptum subgroup, Enterobacteria and a decrease of Clostridium coccoides subgroup were seen in the antrum. In the corpus, the number of Lactobacillus group was increased and the expression of Clostridium coccoides subgroup was significantly down-regulated. In feces samples, only the number of Lactobacillus group was increased. Moreover, the distribution was different between the female and the male patients with DU.
Conclusion: The existence of *H. pylori* in stomach suppressed the colonization of Lactobacillus group, Clostridium leptum subgroup and Enterobacteria. And Lactobacillus group could promote the healing of duodenal ulcer. Gender is a confounding factor in distribution and/or recolonization in DU patients.

P1824 EFFICACY OF FIRST-LINE BISMUTH-CONTAINING QUADRUPLE THERAPIES WITH LEVOFLOXACIN OR CLARITHROMYCIN FOR THE ERADICATION OF *HELICOBACTER PYLORI* INFECTION: A ONE-WEEK, OPEN-LABEL, RANDOMIZED TRIAL

X. Zhou[1]
[1]*Gastroenterology, the First Affiliated Hospital of Nanjing Medical University, Nanjing, China*

Contact E-mail Address: zhouxiaoying0926@sina.cn

Introduction: The aim of the present open-label, randomized control trial was to determine the clinical efficacy and safety of two one-week bismuth-containing quadruple regimens and one levofloxacin-based triple regimen for the eradication of *H. pylori* infection in treatment- naïve patients. The influence of susceptibility and host CYP2C19 polymorphisms on the efficacy was also evaluated.
Aims & Methods: Eligible patients were randomly to receive esomeprazole and colloidal bismuth pectin along with clarithromycin and amoxicillin (EBCA), esomeprazole and colloidal bismuth pectin along with levofloxacin and amoxicillin (EBLA), or esomeprazole along levofloxacin and amoxicillin (ELA) for one week. The primary outcome was the eradication rate in the intention-to-treat (ITT) and per-protocol (PP) analyses. This trial was registered with Chinese Clinical Trial Registry, Number: TRC13003256.
Results: Overall, 270 patients were randomized. The eradication rates in the above three groups were 80.25%, 89.66% and 81.93% in PP analysis and 72.22%, 86.66% and 75.56% in ITT analysis, respectively. The eradication rate of EBLA was significantly higher than that of EBCA ($P = 0.016$) in ITT analysis. No significant differences were found among these groups in terms of adverse effects and compliance. The efficacy was significantly affected by levofloxacin resistance for EBLA ($P = 0.01$) and ELA ($P = 0.04$), but not by polymorphisms of CYP2C19 gene for any of the three groups.
Conclusion: One-week bismuth-containing quadruple therapies and levofloxacin-based triple therapy can all obtain an acceptable eradication rate and levofloxacin-based quadruple regimen exhibits the highest eradication rate. The antibiotic resistant rate of levofloxacin was associated with the eradication rate.

P1825 BROCCOLI SPROUT EXTRACT CONTAINING SULFORAPHANE (BSES) CAN PREVENT LIPID PEROXIDATION IN THE GASTRIC MUCOSA WITH *HELICOBACTER PYLORI* INFECTION

Y. W. Chang[1], J. Byun[1], J. Y. Jang[1]
[1]*Gastroenterology, Kyung Hee University Hospital, Seoul, Korea, Republic Of*

Contact E-mail Address: cywgi@chollian.net

Introduction: The standard triple therapy for *Helicobacter pylori* (*H. pylori*) eradication has become less effective, requiring the development of new treatment strategies that increase the eradication rate and reduce adverse effects. A broccoli sprout extract containing sulforaphane (BSES) exhibits anti-oxidative and bactericidal activity against *H. pylori*.
Aims & Methods: The aims of this study were to investigate whether BSES inhibits *H. pylori* infection density, and exerts an anti-oxidative effect on gastric mucosal damage. The enrolled subjects were randomized double blindly into three groups. Finally, 33 *H. pylori* (+) BSES treatment subjects (group A), 28 *H. pylori* (+) placebo subjects (group B), and 28 *H. pylori* (-) BSES treatment subjects (group C) were studied. *H. pylori* infection density was quantified indirectly by a C^{13}-urea breath test (UBT) and measurement of the ammonia concentration in gastric juice aspirate through the gastroscopic examination. Malondialdehyde (MDA), as an oxidative damage biomarker, and reduced glutathione (GSH), as an anti-oxidant biomarker, were measured in gastric mucosa by ELISA.
Results: BSES treatment did not significantly affect UBT values or ammonia concentration in Group A ($p = 0.634$, $p = 0.505$, respectively). BSES treatment did significantly reduce mucosal MDA concentrations in Group A ($p < 0.05$) and Group C ($p < 0.001$), while gastric mucosal GSH concentrations were not different before and after treatment in all three groups.
Conclusion: BSES did not inhibit *H. pylori* infection density. However, BSES prevented lipid peroxidation in the gastric mucosa and may play a cytoprotective role in *H. pylori*-induced gastritis.

P1826 MAGNIVIEW ZOOM ENDOSCOPY FOR THE DETECTION OF MARKERS OF COELIAC DISEASE: A FEASIBILITY STUDY

P. D. Mooney[1], M. Kurien[1], M. Burden[1], D. Sanders[1]
[1]*Academic Department of Gastroenterology, Royal Hallamshire Hospital, Sheffield, United Kingdom*

Contact E-mail Address: p_d_mooney@hotmail.com

Introduction: Coeliac disease (CD) remains underdiagnosed. Previous studies have shown that 5-13% of patients with CD have undergone a previous gastroscopy where the opportunity to take duodenal biopsies and make a diagnosis had been missed. Clinicians may rely on the presence of endoscopic markers of CD to guide biopsy however these have been shown to lack the required sensitivity. A routine duodenal biopsy approach may solve this problem but this is time consuming and expensive. Methods to improve the macroscopic detection of CD at endoscopy to guide biopsy would seem advantageous. Magniview endoscopes are capable of 136x optical zoom without loss of definition. At this level of magnification it should be possible to identify blunting and absence of villi. We aimed to assess the feasibility of magniview in patients with suspected CD.
Aims & Methods: Patients with attending for a duodenal biopsy to diagnose CD were invited to take part. Appearances were graded on a 3-point scale: normal, partial villous atrophy or marked villous atrophy. All patients received 4 biopsies from the second part of the duodenum and at least 1 biopsy from the bulb. Concurrently serum for endomysial (EMA) and tissue transglutaminase (tTG) antibodies were taken at the time of endoscopy. Macroscopic markers of CD are compared VA on histology as the gold standard. Sensitivity of endoscopic markers was compared to a control group CD who had standard endoscopy using the Fisher exact test.
Results: 27 patients (52% female, mean age 49.6) have been recruited to date. 14 (51.9%) patients tested had positive serology. In total 13 (48%) patients were diagnosed with CD. All 13 patients diagnosed with CD were correctly identified on Magniview giving a sensitivity, specificity, PPV and NPV of 100% (72 - 100), 71% (42 - 90), 76% (50 - 92) and 100% (66 - 100) respectively. 4 patients had a false positive Magniview assessment. Of these 3 (75%) were felt to have partial villous atrophy. A single patient with false positive Magniview had a positive EMA and tTG and was felt to have marked villous atrophy in the bulb but normal D2. However biopsies were normal from both sites. Sensitivity of standard endoscopy for detecting VA in 89 patients with coeliac disease was inferior to Magniview (41.6% vs. 100%, $p < 0.0001$).
Conclusion: The addition of Magniview to standard endoscopy to aid the diagnosis of CD is feasible and currently has 100% sensitivity and negative predictive value. However a larger study in a lower prevalence population is required to fully elucidate the utility of Magniview in clinical practice.

Contact E-mail Address: p_d_mooney@hotmail.com

Introduction: Current British iron deficiency anaemia guidelines recommend pre-endoscopy serological testing for coeliac disease (CD) and duodenal biopsy only for patients with a positive test. However many patients who attend endoscopy for investigation of anaemia do not have serology available. Thus the clinician is then committed to perform a duodenal biopsy. This gap in clinical practice could

be bridged by a rapid point of care test (POCT). We aimed, to assess the role of a novel POCT (Simtomax which detects IgA and IgG de-amidated gliadin peptide antibodies) in anaemic patients in a pre-endoscopy setting.
Aims & Methods: Group 1, a multicentre retrospective analysis of patients attending endoscopy for duodenal biopsy was undertaken in 4 UK hospitals (Whipps Cross, Hull, Bradford, Addenbrookes). The presenting characteristics and availability of serology prior to endoscopy was recorded. Group 2, patients presenting to endoscopy for investigation of anaemia were prospectively recruited. All patients received the POCT prior to their OGD and duodenal biopsy. Results were compared to the gold standard of villous atrophy.
Results: Group 1, 2339 patients (58% female, mean age 75.3) underwent duodenal biopsy. Serology was available prior to endoscopy in 912 patients (39%). Anaemia was the most common indication (934 patients, 39.9%). In anaemia, serology was available prior to OGD in 32%. On multivariate analysis of presenting characteristics patients with anaemia were less likely to have serology available than other groups (AOR 0.55 (0.44 - 0.70) $p < 0.0001$). CD was more likely if patients had serology done prior to their OGD (8.1% vs. 1.1%, $p < 0.0001$).
Group 2, 129 patients (64% female; mean age 56.6) being investigated for anaemia underwent POCT and duodenal biopsy. 23 patients (17.8%) were diagnosed with CD. Sensitivity, specificity, positive and negative predictive values of the POCT were 100% (82 - 100), 76% (67 - 84), 48% (34 - 63) and 100% (94 -100). In this cohort 81 (63%) duodenal biopsies could have been avoided. Based on a cost of £86 for duodenal biopsy this could result in a saving of £5,399 per 100 endoscopies. In a recent 3 month audit in Sheffield 479/2719 (18%) OGDs were performed for anaemia. Using the POCT in Sheffield could save £103,445 per year.
Conclusion: Availability of coeliac serology prior to endoscopy is poor. Diagnostic yield of duodenal biopsy is significantly higher in patients who have had serology prior to their endoscopy ($p < 0.0001$). An accurate POCT prior to endoscopy could significantly reduce the numbers of unnecessary duodenal biopsies resulting in significant cost savings. In this pilot cohort, Simtomax had 100% sensitivity. Further large studies are required.

P1828 COMPARISON OF THREE COMMERCIALLY AVAILABLE POINT OF CARE TESTS FOR COELIAC DISEASE

P. D. Mooney[1], M. Burden[1], M. kurien[1], A. Johnston[1], S. Wong[1], D. Sanders[1]
[1]*Academic Department of Gastroenterology, Royal Hallamshire Hospital, Sheffield, United Kingdom*

Contact E-mail Address: p_d_mooney@hotmail.com
Introduction: Coeliac disease (CD) remains an underdiagnosed condition. A rapid finger prick based point of care test (POCT) may increase uptake of serological testing in appropriate patient groups. There are 3 commercially available POCTs on the UK market and in continental European pharmacy outlets: Biocard an IgA tissue tranglutaminase (tTG) test (BHR pharmaceuticals); Celiac Quick Test (Biohit Healthcare) detecting IgA, IgG and IgM tTG and Simtomax (Tillotts Pharma) which detects IgA and IgG antibodies against deamidated gliadin peptides (DGP). A fourth POCT has also been developed but not marketed (Xeliac Test Pro, Personal Diagnostics), with availability being solely from the manufacturer and no published data existing supporting its validity. Of the 3 commercially available POCTs, there is a limited evidence base with significant ascertainment bias. For this reason we decided to compare 3 commercially available tests in an endoscopic setting.
Aims & Methods: Patients referred with a positive endomysial antibody (EMA) for duodenal biopsy to confirm CD were invited to take part. All patients had whole blood taken for repeat serum EMA, tTG and immunoglobulins. All patients were tested simultaneously with the 3 POCTs as per the manufacturers' instructions. All patients had quadrantic duodenal biopsies from the sec ond part of the duodenum as well as a duodenal bulb biopsy. Demonstration of villous atrophy (VA) on duodenal biopsy was required to diagnose CD.
Results: 82 patients (51.2% female, mean age 41.0) have been recruited. In 10 patients the EMA had normalised on repeat testing. None of these patients had VA on duodenal biopsy. 9 of these patients were referred with a weak EMA and had a negative tTG. One patient had a tTG of 10 times the upper limit of normal, and subsequent gluten challenge revealed a positive EMA and VA. Of the remaining 72 patients 59 new cases of CD were confirmed with the presence of villous atrophy, of the 13 EMA positive patients without VA 8 had Marsh 1 or 2 changes present with the remaining 5 patients having normal histology. Full sensitivity, specificity PPV and NPV for all of the tests compared to VA on duodenal biopsy are shown in table 1.

Test	Sensitivity (%)	Specificity (%)	PPV (%)	NPV (%)
Serum tTG	98.3 (89.7- 99.9)	34.8 (17.2 – 57.2)	79.5 (68.1 – 87.7)	88.9 (50.7 – 99.4)
Biocard	72.9 (59.5 – 83.3)	65.2 (42.8 – 82.8)	84.3 (70.9 – 92.5)	48.4 (30.6 – 66.6)
Celiac Quick Test	71.2 (57.7 – 81.9)	52.2 (31.1 – 72.6)	79.2 (65.5 – 88.7)	41.4 (24.1 – 60.9)
Simtomax	96.6 (87.3 – 99.4)	30.4 (14.1 – 53.0)	78.1 (66.6 – 86.6)	77.8 (40.2 – 96.1)

Conclusion: In this pilot data set Simtomax appears to be the most sensitive of the POCTs when compared to histology with similar results to serum tTG as screening test. Further work is required in larger cohorts and lower prevalence populations to confirm the utility of these tests in adult CD.

P1829 FRAX SCORE CAN BE USED TO AVOID SUPERFLUOUS DXA SCANS FOR DETECTING OSTEOPOROSIS IN COELIAC DISEASE

R. Tortora[1], P. Capone[1], N. Imperatore[1], N. Gerbino[1], N. Caporaso[1], A. Rispo[1]
[1]*Gastroenterology - Clinical Medicine and Surgery, Federico II University of Naples, Naples, Italy*

Contact E-mail Address: raffaellatortora@live.com
Introduction: The W.H.O. developed the FRAX tool to estimate the patient's 10-years probability of fracture, and this tool is widely used to decide which patients should undergo Dual energy X-ray Absorptiometry (DXA) scan and appropriate therapy; on the other hand, most guidelines recommend DXA for all patients at higher risk of osteoporosis (OP).
Aims & Methods
Aim: To evaluate if the FRAX tool can replace and/or optimize the DXA scan in coeliac disease (CD), a well known cause of secondary OP.
Methods: We prospectively enrolled all CD patients aged over 40 years diagnosed at our third level University Centre. At time of diagnosis all CD patients underwent FRAX score calculation for risk of major osteoporotic fracture and DXA scan (used as gold standard) in order to assess the accuracy of FRAX score in diagnosing/predicting OP. FRAX score was constituted by 10 variables (Table 1). The FRAX score was dichotomized as normal or pathological in accordance with the National Osteoporosis Guideline Group (NOGG). About DXA scan the diagnosis of osteoporosis was made in presence of a T-score $\leq$ -2.5 SD. Statistical analysis included use of X^2 and Mann-Whitney U test when indicated. To test the concordance between FRAX score and DXA scan the Cohen's k measure was applied. Diagnostic accuracy (sensitivity, specificity, positive and negative predictive values) of FRAX score versus DXA scan was evaluated by MedCalcSoftware. All differences were considered significant with a $p < 0.05$. The remain statistical analysis was performed using SPSS software.
Results: Finally, 60 CD patients were enrolled (M/F = 7/53; mean age 44.8 years). A pathological FRAX score was evident in 5 out of 60 patients (8.3%) while final diagnosis of OP based on DXA scan was made in 3 patients (5%) ($k = 0.6$); only 1 patient with OP (1.6%) showed a 10-year risk of major fracture > 10% according to NOGG criteria. About diagnostic accuracy, FRAX score showed: 0 true positive, 52 true negative, 5 false positive and 3 false negative cases (sensitivity of 0%, specificity 91%, positive predictive value 0%, negative predictive value 94%).
Table 1

1	Age		Between 40 and 90 years
2	Sex		Male/female
3	BMI	Weight	Kg
Height	cm		
4	Previous fractures		Yes/not
5	Parent Fractured Hip		Yes/not
6	Current Smoking		Yes/not
7	Glucocorticoids		Yes/not
8	Rheumatoid arthritis		Yes/not
9	Secondary osteoporosis		Yes/not
10	Alcohol 3 or more units/day		Yes/not

Conclusion: The prevalence of OP in CD patients at diagnosis appears to be quite low and only a small proportion of patients would require a DXA. The FRAX score could be an effective tool to avoid useless DXA scans in CD patients in view of its high negative predictive value. These results could contribute to improving the diagnosis of CD comorbidities by allowing for a significant reduction in diagnosis-related time and costs.

P1830 INVESTIGATION OF IRON DEFICIENCY ANAEMIA. DUODENAL BIOPSIES – ARE THEY WORTH IT?

S. Paremal[1], S. Nair[1], A. Boyd[1], J. Robertson[1], M. Gunn[1], C. Mountford[1]
[1]*Gastroenterology, Freeman Hospital, Newcastle upon Tyne, Newcastle Upon Tyne, United Kingdom*

Contact E-mail Address: drsparemal@nuth.nhs.uk
Introduction: The prevalence of iron deficiency anaemia (IDA) in adult men and postmenopausal women in the developed world is 2-5%[1]. British Society of Gastroenterology (BSG) IDA Guidelines recommend tissue transglutaminase (tTG) antibody as a screening test for coeliac disease. Indications for duodenal biopsies include patients with diarrhoea, weight loss and positive tTG serology. Where coeliac serology is positive, duodenal bulb and D2 biopsies should be taken[2]. BSG IDA Guidelines do not recommend duodenal biopsy for tTG negative, asymptomatic patients[3]. However a separate BSG guideline for

diagnosis of coeliac disease recommends duodenal biopsies in IDA patients irrespective of Coeliac serology due to the finding of seronegative coeliac disease[2].
Aims & Methods: This audit was carried out to assess adherence to BSG IDA Guidelines for duodenal biopsies in patients referred for IDA investigation with negative tTG antibodies. The study also set out to establish the positive diagnostic yield where biopsies were taken in the same cohort. Patients referred to Newcastle upon Tyne NHSFT adult IDA service between 2011 and 2014 identified as ttG negative and who underwent endoscopy were included.
Results: Two hundred patients were identified, median age 66 (range 19-91); 126 (63%) female and 74 (37%) Male. 114 (57%) patients had duodenal biopsies taken despite tTG being negative and asymptomatic. 28 (19.7%) patients were symptomatic and duodenal biopsies taken, though only 8 (28%) of these patients had 4 biopsy samples and none were from duodenal bulb. Where biopsies were taken, none confirmed coeliac disease. 5/142 (3.5%) patients biopsied had lymphocytic duodenitis but none of them were subsequently diagnosed or treated as coeliac disease.
Conclusion: Duodenal sampling in tTG negative patients did not yield any additional positive diagnosis of coeliac disease. This confirms the recommendations of BSG IDA guidelines. The results of this audit do not appear to support the recommendations made within the BSG coeliac disease guideline for duodenal biopsy being performed regardless of coeliac serology. However, the fact that only 4.9% of patients who had duodenal biopsies taken had duodenal bulb sampled, may limit this conclusion. More efficient use of local endsoscopy and pathology resources can occur by appropriate selection of patients on whom to perform duodenal biopsies.

Introduction: Low faecal Elastase 1 (FE-1) is found in some coeliac disease (CD) patients before starting treatment with a gluten-free diet. This indicates that exocrine pancreatic insufficiency (EPI) is a contributing factor of malabsorption in this group.
Aims & Methods: We aimed to evaluate if EPI is a common finding in untreated CD patients. In patients with suspicion of coeliac disease, endoscopic secretin stimulation test (EST) was performed. During the same upper endoscopy procedure diagnostic duodenal biopsies were collected.
Duodenal bicarbonate and enzyme activity and FE-1 in patients was compared with results from healthy controls. The cut-off for EPI was FE-1 $<200\mu g/g$ or duodenal bicarbonate <80mmol/L.
Results: 16 CD patients were included and compared with 25 controls. 15 patients were classified as MARSH 3 (a-c) and one as MARSH 1. Our results are displayed in Table 1 (median (IQ range)). In all patients FE-1 was within normal range. Two patients had a bicarbonate concentration below cut-off. Duodenal chymotrypsin ($p = 0.003$) and elastase activity ($p = 0.039$) in patients were lower than in controls.
Conclusion: We did not find reduced faecal elastase or reduced secretin stimulated duodenal bicarbonate in this **small** group of untreated CD patients. However, we did find evidence of lower enzyme activity for duodenal chymotrypsin and elastase. This can be indicative of reduced enzyme output in untreated coeliac disease.

Contact E-mail Address: th_greuter@bluewin.ch

Introduction: This study investigates patient-reported symptoms, diagnostics and diet adherence in celiac disease (CD) patients in a real-life setting in Switzerland from a patient's perspective.
Aims & Methods: We performed a large systematic, nation-wide patient survey study among unselected CD patients in Switzerland. Results were analyzed in total and among selected subgroups by means of descriptive statistics.
Results: A total of 1689 patients (76.0% female; mean age 41.3y, range 0-92y, mean age at diagnosis 31.1y, range 0-83y) were analyzed. Only 15.3% initially presented with isolated gastrointestinal (GI) symptoms. The majority complained of both GI and non-specific symptoms (71.5%). 1.8% reported asymptomatic disease. Most of the patients presented to a non-gastroenterologist first (75.1%). However, physician's diagnostic delay was shorter – although not significantly – if patients presented to a gastroenterologist first (31.6 vs. 41.3 months, $p = 0.093$). Irritable bowel syndrome was considered significantly more often in those patients evaluated by a gastroenterologist (21.3% vs. 15.2%, $p = 0.01$). In summary, 35.8% of all CD diagnoses were done by a non-gastroenterologist. 16.4% were diagnosed based on serology and/or genetics, while in the majority diagnosis was established by a combination of serology and duodenal biopsy (46.9%) or biopsy alone (31.9%). Under the diagnostic lead of non-gastroenterologists ordered diagnostic tests differed significantly compared to gastroenterologists, with the latter using more often duodenal biopsy alone or in combination with serology (95.0% vs. 61.1%), while diagnosis without endoscopy was more frequently established by non-gastroenterologists (35.6% vs. 5.2%) ($p < 0.001$). 97.7% of all patients reported to adhere always (77.0%) or only with minor mistakes (20.7%) to a gluten-free diet. More than three out of four patients (79.8%) received expert nutrition counseling. This counseling was more often prescribed, if CD diagnosis was established by a gastroenterologist (83.5% vs. 76.0%, $p = 0.001$). Follow-up serology after 6 months was done in half of all patients (49.4%), while 69.9% had at least one follow-up serology within the first year after diet initiation. 39.7% had a follow-up endoscopy (median duration after diet initiation 12 months, range 1-600 months). 43.7% showed complete clinical remission (CR) 6 months after diet initiation. After 24 months proportion of CR was 61.7%.
Conclusion: According to patient's respective, more than 1 out of 3 CD patients are diagnosed by a non-gastroenterologist. Under the diagnostic lead of the latter, more than a third of patients receive their diagnosis by positive serology and/or genetics only, in evident violation of current diagnostic guidelines. Accordingly, there is a substantial risk of over-diagnoses and therefore unnecessary, potentially life long dietary restrictions as well as follow-up evaluations in these "sham-CD" patients. On the other hand, our data reveals a relevant discrepancy between treatment adherence and rate of CR, which suggests frequent misinterpretation of diet adherence despite a relatively high proportion of patients receiving specialized nutrition counseling.

P1833 PREVALENCE OF TREHALOSE MALABSORPTION AND INTOLERANCE IN PATIENTS WITH BLOATING AND ABDOMINAL PAIN

F. Durchschein[1], J. Reif-Breitwieser[1], H. F. Hammer[1]
[1]*Division of Gastroenterology and Hepatology, Department of Internal Medicine, Medical University Graz, Graz, Austria*

Contact E-mail Address: franziska.durchschein@medunigraz.at

Introduction: Symptoms suggestive of carbohydrate malabsorption (bloating, abdominal cramps, diarrhea) are a common clinical problem. The disaccharide trehalose (1-α-Glucopyranosyl-1-α-Glucopyranosid), which is present in mushrooms and invertebrates like crab or lobster, requires digestion by intestinal trehalase before its monosaccharide components can be absorbed. In 2001, regulatory approval as a novel food was granted in Europe. Due to its physical features, trehalose is increasingly used as a food-ingredient. In patients with a reduced activity of trehalase, trehalose passes into the colon, possibly resulting in symptoms of carbohydrate malabsorption. There are no data on the prevalence of trehalose malabsorption in symptomatic patients and only few data on the incidence of isolated trehalase deficiency, the highest prevalence of 8% having been found in Greenland.
Aims & Methods: 36 patients (10 male; median age: 35 yrs; range: 20-72yrs) who were referred for a lactose or fructose hydrogen breath test for the evaluation of symptoms suggestive of carbohydrate malabsorption were offered to be additionally tested for the presence of trehalose malabsorption and intolerance on a separate day. Following an established clinical protocol, simultaneous breath hydrogen (H_2) measurements and symptom assessments (bloating and pain on a scale from 0 to 5) were performed for up to 4 hours after ingestion of 50 g trehalose. Malabsorption (TM) was defined as an increase over baseline of breath H_2 concentration of ≥ 20 ppm ($\Delta H_2 \geq 20$ppm); intolerance (TIT) was defined as an increase over baseline in symptom score of ≥ 2 ($\Delta S \geq 2$). Occurrence of TM was compared with lactose (LM) and fructose malabsorption (FM), and of TIT was compared with intolerance of lactose (LIT) and fructose (FIT). Prevalence of hydrogen nonexcretors in our patient population is 17%.
Results: The table shows the number of patients with TM and TIT, and the relations between TM and LM or FM respectively, and between TIT or LIT and FIT, respectively.

		TIT		LM		FM	
		yes	no	yes	no	yes	no
TM	yes	*5*	*5*	*6*	*5*	*1*	*9*
	no	*4*	*22*	*13*	*12*	*2*	*24*
LIT	yes	*6*	*11*	–	–	–	–
	no	*4*	*15*	–	–	–	–
FIT	yes	*2*	*3*	–	–	–	–
	no	*7*	*24*	–	–	–	–

Conclusion: In patients with bloating, abdominal pain and diarrhoea, in whom carbohydrate malabsorption is considered, the prevalence of trehalose malabsorption is ***27.8%*** and of trehalose intolerance is ***25%***. There is a poor concordance between TM and TIT, and there is no relation between malabsorption or intolerance of trehalose with fructose or lactose malabsorption and/or intolerance. The use of trehalose in the food industry has to be declared more thoroughly.

P1834 H2 BREATH TEST WITHOUT SIMULTANEOUS SYMPTOM ASSESSMENT HAS NO CLINICAL RELEVANCE

F. Durchschein[1], C. Papula[1], H. F. Hammer[1]
[1]*Division of Gastroenterology and Hepatology, Department of Internal Medicine, Medical University Graz, Graz, Austria*

Contact E-mail Address: franziska.durchschein@medunigraz.at

Introduction: Bloating, abdominal pain and diarrhoea are commonly evaluated by lactose or fructose hydrogen breath test (HBT) and a positive result is usually followed by dietary advice. New guidelines suggest that, in order to improve clinical relevance, HBT should be accompanied by symptom assessment.

Aims & Methods: Retrospective analysis of consecutive patients who were referred between 4/2009 and 8/2014 for lactose or fructose HBT with simultaneous symptom assessment. Following an established clinical protocol, simultaneous breath hydrogen (H2) measurements and symptom assessments (bloating and pain on a scale from 0 to 5) were performed for up to 4 hours after ingestion of 30 g fructose or 50 g lactose. Malabsorption (lactose: LM, fructose: FM) was defined as an increase over baseline of breath H2 concentration of ≥ 20 ppm ($\Delta H_2 \geq 20$ppm); intolerance (lactose: LIT, fructose: FIT) was defined as an increase over baseline in symptom score of ≥ 2 ($\Delta S \geq 2$). Prevalence of hydrogen nonexcretors in our patient population is 17% and prevalence of lactose malabsorption in the general population is 20%.

Results: Lactose HBT was performed in 497 patients (age 37 ± 15 yrs., 358 female, 139 male), and fructose HBT in 344 patients (age: 39 ± 14 yrs, 257 female, 87 male). The table shows the results of HBT($\Delta H_2 \geq 20$ppm) and symptom measurement ($\Delta S \geq 2$) after lactose and fructose, respectively. 28% of patients with LM had no LIT, and 43% with LIT had no LM; 47% of patients with FM had no FIT and 62% of patients with FIT had no FM.

Conclusion: In symptomatic patients referred for HBT, about the same proportion of patients have intolerance of fructose or lactose, or malabsorption of fructose or lactose. However, intolerance is more frequent than malabsorption of the respective carbohydrate and there is a poor concordance between malabsorption and intolerance, which cannot be accounted for by the prevalence of hydrogen nonexcretion. Our data suggest that in order to reliably detect those patients, who will most likely have an improvement on lactose or fructose reduced diet more emphasis has to be put on symptom assessment than on hydrogen breath test.

P1835 THE EFFICACY OF CHOLESTYRAMINE TREATMENT IN PATIENTS INVESTIGATED FOR BILE ACID DIARRHOEA

N. Mottacki[1], M. Simrén[1], K.-A. Ung[1], A. Bajor[1]
[1]*Internal Medicine and Clinical Nutrition, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden*

Contact E-mail Address: nima.mottacki@vgregion.se

Introduction: The enterohepatic circulation of bile acids is usually very efficient, with only 1-5% leaking into the large bowel with each cycle. When this homeostasis is affected, excess loss of bile acids into the large intestine can cause bile acid diarrhoea (BAD), which can be associated with ileal disease (type 1) or other predisposing GI conditions (type 3), or can be idiopathic (type 2), and diagnosed with the ^{75}SeHCAT test. The first-line treatment is cholestyramine, a luminal bile acid sequestrant.

Aims & Methods: We aimed to study the efficacy of cholestyramine treatment in a large cohort of patients referred for a ^{75}SeHCAT test as part of the investigation of chronic diarrhoea, and its relationship to gender and BAD subtype/presence or absence of predisposing conditions.

We reviewed 2112 consecutive ^{75}SeHCAT tests performed at the Sahlgrenska University Hospital between 1985 and 2005. Medical records from the referring clinic were also investigated. Patients were included if referred for the investigation of chronic diarrhoea and excluded if no information regarding the effect of cholestyramine treatment was available. Two definitions of an abnormal ^{75}SeHCAT test were used: ^{75}SeHCAT retention on day 7 of either $< 10\%$ or 15%.

Results: 409 cases (276 female, 133 male) were included, of whom 301 (74%, F:M gender = 200:101) had ^{75}SeHCAT retention $< 10\%$. Of these, 224 (74%) experienced symptomatic improvement on cholestyramine, without difference in efficacy between males and females ($p = 0.53$). Of the 107 patients with retention $> 10\%$ (range 10-67%), 68 (64%) also noted symptomatic improvement on cholestyramine ($p < 0.05$ compared to those with retention $< 10\%$), again with no gender difference. As seen in the table, median ^{75}SeHCAT retention was lower in patients with ileal disease, and cholestyramine showed less efficacy in patients with other predisposing GI conditions than ileal disease/resection. The results were similar when a cut-off of ^{75}SeHCAT retention on day 7 of 15% instead of 10% was used.

Conclusion: This retrospective study shows a high degree of efficacy in treating patients with chronic diarrhoea and a positive ^{75}SeHCAT test with cholestyramine. However, also patients with chronic diarrhoea and a normal ^{75}SeHCAT test seem to respond favourably to cholestyramine treatment. Future prospective studies are needed to elucidate underlying mechanisms behind these findings.

P1836 LONG-TERM SAFETY OF TEDUGLUTIDE TREATMENT FOR PATIENTS WITH INTESTINAL FAILURE ASSOCIATED WITH SHORT BOWEL SYNDROME: POOLED DATA FROM 4 CLINICAL TRIALS

U.-F. Pape[1], E. Delmaestro[2], B. Li[2], N. N. Youssef[2], D. Seidner[3]
[1]*Charité University Medicine, Berlin, Germany,* [2]*NPS Pharmaceuticals, Inc., Bedminster, NJ,* [3]*Vanderbilt University Medical Center, Nashville, TN, United States*

Contact E-mail Address: ulrich-frank.pape@charite.de

Introduction: Teduglutide (TED) is indicated for the treatment of adult patients (pts) with intestinal failure associated with short bowel syndrome (SBS-IF) who are dependent on parenteral support (PS). In phase III randomised placebo-controlled trials, TED significantly reduced PS volume requirements and number of PS infusion days per week in pts with SBS-IF. Here, we present combined safety data from TED-treated pts in these trials and their respective open-label extension studies.

Aims & Methods: Safety data were pooled from 4 TED clinical studies conducted in adult pts with SBS–IF: two 24-week, double-blind, placebo-controlled trials with 2 respective open-label extensions of 28 weeks' and 2 years' duration.

Results: A total of 173 pts received subcutaneous TED (134 treated with 0.05 mg/kg/d and 39 treated with 0.10 mg/kg/d) across the 4 studies. Of these, 140 (81%) were treated with TED for ≥ 6 months and 111 (64%) were treated for ≥ 12 months; mean duration of TED exposure in all pts was 67 weeks. Most pts (97%) experienced ≥ 1 treatment-emergent adverse event (TEAE); the majority were mild (53%) or moderate (38%) in severity. TEAEs reported by $\geq 10\%$ of pts were 42% abdominal pain; 29% upper respiratory tract infection; 27% catheter sepsis or nausea; 20% headaches or asthenic conditions; 19% injection-site reactions; 18.5% abdominal distension or urinary tract infections; 18% gastrointestinal (GI) stoma complications; 17% catheter site–related reactions or febrile disorders; and $\leq 15\%$ vomiting, musculoskeletal pain, diarrhoea, fluid overload, hypersensitivity, or flatulence. The incidence rates of the most commonly reported GI adverse events (AEs) and fluid overload decreased over time during the treatment period **(Table)**. TEAEs that led to premature discontinuation occurred in 20% of pts (n = 34); the most common was abdominal pain (5%; n = 8). Serious AEs (SAEs) were reported by 58% of pts (n = 101). The only SAE that occurred in $\geq 5\%$ of TED-treated pts was catheter

Abstract number: P1831 Table 1

	FE-1(μg/g)	D-bicarbonate (meq/L)	D-chymotrypsin (U/mL)	D-elastase (U/mL)	D-amylase (U/mL)	D-lipase (10^3 U/mL)
CD patients (n = 16)median (interquartile range)	573 (464-670)	109.5 (96.3-116.0)	0.76 (0.63-1.77)*	0.044 (0.018-0.162)*	277 (209-498)	43.6 (25.9-90.5)
Controls (n = 25)median (interquartile range)	553 (425-587)	114 (101-122)	2,85 (1.88-3.83)	0.137 (0.087-0.192)	296 (196-517)	33.7 (28.7-43.1)

sepsis (25%; n = 43). As previously reported, 3 cases of malignant neoplasms occurred (metastatic adenocarcinoma, non–small-cell lung cancer, and squamous cell carcinoma). Only the metastatic adenocarcinoma was considered treatment related; this pt also had a history of Hodgkin disease treated with chemotherapy and radiation.
Conclusion: TED was generally well tolerated in pts with SBS-IF. No new safety signals were identified in the pooled analysis. The most frequently reported AEs were consistent with the underlying disease condition and the known mechanism of action of TED and tended to occur early in the treatment period. Data from phase III trials demonstrate the safety of long-term TED treatment.

P1837 TREATMENT OF INTESTINAL FOLLICULAR LYMPHOMA: PROSPECTIVE STUDY OF COMPARISON BETWEEN "WATCH AND WAIT" AND "RITUXIMAB-CONTAINING CHEMOTHERAPY"

A. Tari[1], Y. Kitadai[2], H. Asaoku[3], K. Shinagawa[4], S. Fujimori[5], S. Tanaka[4], T. Koga[6], T. Yoshino[7], K. Chayama[2]

Introduction: The treatment modality of intestinal follicular lymphoma (FL) without mass formation causing bowel obstruction remains unstandardized.
Aims & Methods: In this study we compared "watch and wait" and "rituximab-containing chemotherapy (R-Chemo)" in the treatment of intestinal FL in a prospective way. Fifty eight patients met the GELF criteria for low-tumour-burden (LTB) and had no mass formation that could cause bowel obstruction. Informed consent of the treatment were obtained from these patients. Thirty-five cases [M/F = 17/18, age 62.5+/-9.6 (mean +/- S.D.), clinical stage (CS) (Lugano classification) I: 17, II1: 0, II2: 8, IV: 10, WHO grade 1: 34, 2: 1, 3: 0, follicular lymphoma international prognostic index (FLIPI) Low: 23, Intermediate: 11, High: 1] were followed by "watch and wait", median time period of 52 months (14-117 months). Twenty-three cases [M/F = 12/11, age 59.1+/-7.1 (mean +/- S.D.), CS I: 15, II1: 0, II2: 1, IV: 7, WHO grade 1: 23, 2: 0, FLIPI Low: 16, Int.: 6, High: 1] were treated by R-Chemo and followed for the median time period of 63.5 months (20-149 months). The CS was confirmed at diagnosis [1]. In "watch and wait" group, esophagogastroduodenoscopy (EGD) and blood test were performed every four months and positron emission tomography (PET) or CT scan [contrast-enhanced (CE+), from neck to pelvis], colonoscopy and capsule endoscopy (CE) were performed every year. In "R-Chemo" group, blood test, EGD and CE were performed every year and colonoscopy and CT scan were performed every two years after confirming CR of the lesions by BM aspiration, PET-CT or CT scan and double-balloon enteroscopy (DBE) at the end of treatment.
Results: There was no difference in age, sex, CS, WHO grade, FLIPI and BM involvement and clinical data between "watch and wait" and "R-Chemo". In "R-Chemo", both overall survival (OS) and event-free survival (EFS) of this group were 100%. In 2 patients under "watch and wait" the lesions enlarged and the macroscopic findings worsened. Another patient had CS progression and enlargement of the area of the lesions. Three patients had CS progression but they met the indication for "watch and wait" because they remained within the criteria for LTB and had no passage disturbance. In two patients, the gastrointestinal lesions transformed into diffuse large B-cell lymphoma and they received rituximab chemotherapy at 37 months and 49 months, which led to CR with no recurrence. OS of this group was 100%.
Conclusion: Comparing "watch and wait" and "R-Chemo", "watch and wait" is appropriate for the treatment of LTB intestinal FL even in the era of rituximab. However, transformation of intestinal FL to an aggressive lymphoma can occur. During "watch and wait" treatment, periodic observation of the clinical course is necessary.

P1838 HIGHER OCCURRENCE OF DUODENAL LESION IN LYNCH SYNDROME RELATED TO MSH2

M. Dhooge[1,2], F. Maksimovic[1,2], R. Coriat[1], S. Leblanc[1], M. Camus[1], J. Dréanic[1], C. Brezault[1], V. Abitbol[1], F. Beuvon[3], F. Prat[1], S. Grandjouan[1,2], S. Chaussade[1]

Contact E-mail Address: marion.dhooge@cch.aphp.fr
Introduction: Lynch syndrom (LS) is the most common cause of inherited Colorectal Cancer (CRC) with autosomal dominant inheritance. LS patients have an increased risk for small bowel adenocarcinoma but routine screening of the small intestine is not recommended in both US and European recommandations (1,2). Esophagogastroduodenoscopy (EGD) is recommended at age 30–35 years for gastric cancer screening but there is no recommendation for systematic subsequent surveillance (1,2). The aim of the present study is to determine the prevalence of duodenal lesion (adenoma or adenocarcinoma) in a cohort of LS patients.
Aims & Methods: Patients identified with LS and registered in a tertiary center were identified. Patients with an upper endoscopy were included in the present study.
Results: 135 LS patients were identified. Six out of 135 (4.4%) had a duodenal lesion. Ratio male/female was 5/1. No patients had a known familial history of duodenal adenoma. The mean age at diagnosis was 59.7 years (range 51-71). Lesions were located in the descending duodenum (n = 2), the genu inferius (n = 2), the duodenal bulb (n = 1) or in the ampulla (n = 1). At the time of diagnosis lesions were adenomas with low-grade dysplasia (n = 1), high-grade dysplasia (n = 2), intra-muquous adenocarcinoma (n = 1) and invasive adenocarcinoma (n = 2). The incidence rate of LS patients with a MSH2 or MLH1 mutation was 6.8% (5 out of 74) and 2.9% (1 out of 35), respectively. No patients with MSH6 or EPCAM mutation experienced a duodenal lesion.
Conclusion: The prevalence of duodenal neoplasm was 4.4% in LS patients and was higher in MSH2 mutations carriers (6.8%) than in MLH1 patients (2.9%). Those data stressed the usefulness of an upper endoscopy survey in LS' patients, in particular in MSH2 mutations carriers.

P1839 THE STRATEGY FOR THE EVALUATION OF JEJUNOILEAL INVOLVEMENT OF MALIGNANT LYMPHOMA PERFORMED BY COMBINATION OF DOUBLE BALLOON ENDOSCOPE (DBE), CAPSULE ENDOSCOPE (CE), AND FDG-PET

T. Ibuka[1], H. Araki[1], C. Watanabe[1], T. Mizutani[1], T. Sugiyama[1], J. Takada[1], M. Kubota[1], M. Shiraki[1], T. Kato[1], M. Shimizu[1]

Introduction: The examination of the jejunoileum is important to determine the most appropriate treatment. Here, we investigated the strategy for the evaluation by using double-balloon endoscope (DBE), capsule endoscope (CE), and FDG-PET to detect small intestinal (jejunoileum) involvement of malignant lymphoma.
Aims & Methods: A total of 89 cases of malignant lymphoma examined by DBE (84 cases), CE (5 cases), or both examination (1 case) between March 2004 and June 2014 were analyzed. Among them, FDG-PET was performed in 67 cases. As histopathological classification, 41 cases were with diffuse large B-cell lymphoma (DLBCL), 26 with follicular lymphoma (FL), 8 with MALT, 4 with mantle cell lymphoma (MCL), 3 with peripheral T-cell lymphoma (PTCL), 2 with enteropathy associated T-cell lymphoma (ETL), and 1 with T-lymphoblastic lymphoma (T-LBL), T-cell prolymphocytic leukemia (T-PLL), small lymphocystic lymphoma (SLL), anaplastic large cell lymphoma (ALCL), and Hodgkin disease (HD).
Results: Jejunoileal involvement of malignant lymphoma was observed in 51 cases (57.3%) by DBE or CE. As endoscopic findings by DBE, 19 cases had ulcerative type (17 DLBCL cases, 1 T-LBL case, 1 MALT case), 13 had elevated type (11 FL cases, 1 MALT case, 1 PTCL case), 11 had multiple lymphomatous polyposis (MLP) type (9 FL cases, 2 MCL cases), 2 had stenosis type (FL cases), 1 had diffuse-infiltrating type (1 TPL case), 4 had diffuse-infiltrating plus

No predisposing conditions (n = 185)	50% (F = 93)	4.5% (0.7, 15.8)	90% (n = 167)	83% (n = 154)	79% (n = 147)	81% (n = 124)

*$p < 0.001$ when comparing the three groups. 7 day ^{75}SeHCAT retention not available in one case, pre-investigation diagnosis not available in 9 cases.

ulcerative type (2 ETL cases, 1 PTCL case, 1 MALT case), 2 had ulcerative plus elevated MLP type (1 FL case, 1 MCL case), 1 had elevated MLP type (MCL), and 1 had diffuse-infiltrating plus elevated type (DLBCL). As endoscopic findings by CE, 2 had elevated type (FL), 1 had ulcerative type (DLBCL), and 1 had MLP type (FL). Among 14 cases of FL having other gastrointestinal (GI) lesions, 13 cases (92.9%) showed jejunoileal involvement. However, compared to this rate, frequency of jejunoileal involvement in FL cases (58.3%, 7/12 cases) that did not have lesions in other GI tract was significantly low ($P = 0.014$). In the cases except FL, no relationship was seen between jejunoileal involvement and other GI lesions. The sensitivity, specificity, positive predictive value, and negative predictive value of FDG-PET in 23 FL cases were 27.8%, 80.0%, 83.3%, and 23.5%. In the 44 cases except FL, the values were 80.0%, 87.5%, 84.2%, and 83.1%, respectively. Three cases were perforated during chemotherapy. All cases complicated with perforation were ulcerative type of DLBCL.

Conclusion: FDG-PET is insufficient to detect jejunoileal involvement in FL cases. Therefore, DBE or CE should be performed when other gastrointestinal lesions are observed. In the cases except FL, FDG-PET is feasible for detection of jejunoileal involvement. Since DLBCL ulcerative type has a high risk of intestinal perforation during chemotherapy, the evaluation for jejunoileal involvement should be done by DBE for FDG-PET positive cases.

Contact E-mail Address: thomas.aparicio@avc.aphp.fr

Introduction: Small bowel adenocarcinoma (SBA) is a rare tumour poorly studied. Data are coming from register study or monocentric retrospective studies. The purpose of the NADEGE cohort (*Cohorte Nationale d' ADEnocarcinomes du GrêlE*) is to describe characteristics, prognosis and chemotherapy regimens of SBA in unselected patients (pts) at a nationwide level.

Aims & Methods: All the pts with a SBA diagnosed from January 2009 to December 2012 were enrolled in the NADEGE cohort. The study involved 72 centres in France that enrolled 330 eligible pts. This work presents the final demographic data.

Results: Pts were predominantly male (59%) and median age was 63 years [23-90]. WHO performance status was 0-1 in 52%, 2 in 30%, 3-4 in 17% and not determined (ND) in 21% of the pts. Primary locations were duodenum (60.9%), jejunum (21.2%), ileum (17%) and ND (0.9%). The tumour was poorly differentiated (18.8%), moderately (34.8%), well differentiated (38.2%) and ND (8.2%). A predisposing disease was reported in 72 (21.8%) cases: Crohn disease 28 (8.5%), Lynch syndrome 20 (6.1%), familial adenomatous polyposis (FAP) 7 (2.1%), celiac disease 6 (1.85%) and Peutz-Jeghers syndrome 2 (0.6%). The tumour was metastatic at diagnostic in 99 (30%) pts. Among 194 resected localized tumours the stage was 0 (3%), I (7.7%), II (31.4%), III (47.4%), and ND (10.8%). Adjuvant chemotherapy was performed in 10/61 (16%) stage II and 36/92 (39%) stage III. FOLFOX regimen was used in 36/46 (78%) pts. A palliative chemotherapy was performed in 73/99 (74%) of pts with metastatic disease. Oxaliplatin regimen was decided for 59% of the metastatic patient. According to the location of primary tumours duodenum/jejunum/ileum the tumours were: metastatic in 62/201 (31%), 20/70 (28%) and 17/56 (31%); poorly differentiated in 33/201 (16%), 11/70 (16%) and 18/56 (32%) of cases. Among the resected tumours, according to primary tumours duodenum/jejunum/ileum there were: T4 in 27/107 (25%), 21/50 (42%) and 10/34 (29%), stage III in 54/107 (50%), 19/50 (38%) and 19/34 (56%). Primary tumours were duodenum/jejunum/ileum: 7%/14%/78% ($p = 0.0001$%) in case of Crohn disease and 60%/35%/5% ($p = 0.01$%) in case of Lynch syndrome. Multivariate analysis revealed that Crohn disease was significantly associated with ileum primary ($p < 0.0001$) and Lynch syndrome with early tumour stage ($p = 0.02$).

Conclusion: NADEGE cohort is a large prospective SBA study. Predisposing disease is more frequent than in colorectal cancer. Several tumours characteristics differs according to predisposing disease. FOLFOX chemotherapy is the main regimen used in adjuvant and metastatic setting. Follow-up is ongoing until 2017 to determine predictive factor for survival.

P1841 CLINICAL USEFULNESS OF VIRTUAL ENTEROSCOPY FOR SMALL INTESTINAL NEOPLASMS

T. Yoshikawa[1], M. Kikuyama[1], K. Ohno[1], N. Shirane[1], T. Kurokami[1], A. Morishita[1]
[1]*Gastroenterology, Shizuoka General Hospital, Shizuoka, Japan*

Contact E-mail Address: t-yoshi@med.nagoya-u.ac.jp

Introduction: We established a new imaging technique, virtual enteroscopy (VE) (or 3D-CT enteroclysis), to explore the small bowel (1). The examination is performed routinely to detect gross lesions in the small intestine in our hospital. The clinical performance of VE was analyzed to evaluate its safety, feasibility, and usefulness for small intestinal neoplasms.

Aims & Methods: Data on VE performed in our hospital from May 2011 to March 2015 were reviewed. In VE, the small bowel was inflated with air using a nasojejunal tube or nasoduodenal tube, CT images were taken, and then 3D overviews, virtual endoscopy views, and virtual dissection views were generated using a virtual colonoscopy system. Total volume of injected air, intra-intestinal pressure, and length of the depicted small bowel were recorded. Patients' data were analyzed and images of small intestinal neoplasms were collected.

Results: Seventy-three VEs were performed for 47 males and 26 females. Mean age was 45.9 +/- 18.2 y at the examination. Examinations were indicated for definite/suspected Crohn's disease in 33, intestinal obstruction in 28, suspected small intestinal neoplasms in 5, definite small intestinal neoplasms in 3, suspected Meckel's diverticulum in 1, NSAID enteropathy in 1, obscure gastrointestinal bleeding in 1, and enterovesicular fistula in 1. Vomiting/belching and abdominal pain (requiring pain medication) were noted in 9 and 2 patients, respectively, but no additional treatments were necessary. The volume of air and intraintestinal pressure were recorded in 59 examinations for patients without previous resection of the small bowel. Mean total volume of injected air was 1774 +/- 662 ml, mean maximum intraintestinal pressure was 2.66 +/- 0.88 kPa, mean length of the depicted small bowel was 496 +/- 103 cm, and whole small bowel tracing was achieved in 73% of these 59 examinations. Eight small intestinal neoplasms were depicted in 3 cases of intestinal obstruction, in 3 cases of suspected small intestinal neoplasms, and in 2 out of 3 cases of definite small intestinal neoplasms. There was no abnormal finding in one case of Peutz-Jeghers syndrome, in which all major lesions already had been removed by surgery. Surgery was performed for 6 cases, and diagnoses of gastrointestinal stromal tumor (GIST) in 3 cases and in 1 case respectively, of lipoma, Peutz-Jeghers type polyp, and adenocarcinoma. Clinical diagnosis of malignant lymphoma was made and chemotherapy was performed in 1 case. A submucosal tumor was confirmed by video capsule enteroscopy in 1 case, which has been followed up.

Abstract number: P1836 Table: Most Common GI AEs and Fluid Overload by Time to Onset From Start of Teduglutide Treatment

AE, %	Time Period, week						
	<4(n = 173)	4 to <12(n = 163)	12 to <24(n = 156)	24 to <36(n = 148)	36 to <48(n = 123)	48 to <72(n = 117)	≥72(n = 69)
Abdominal pain	23	12	9	10	2	0	10
Nausea	15	6	2	1	2	3	1
Abdominal distension	8	7	1	2	0	2	0
GI stoma complication	12	2	1	1	0	2	3
Fluid overload	5	4	3	3	1	3	0

Conclusion: VE can be performed safely and examination of the whole small bowel was possible in the majority of cases. VE can depict elevated lesions more than 1 cm, detect stenosis of small intestinal neoplasms, locate the position of the lesions, and present objective information for surgery and follow up. VE is a powerful new tool for diagnosis, pre-surgical evaluation, and follow-up for small intestinal neoplasms.

P1842 ETIOLOGY OF SMALL BOWEL STRICTURES WITHOUT MASS LESION OR ASSOCIATED LYMPHADENOPATHY

U. Sonika[1], S. saha[2], P. das[3], V. ahuja[1], P. sahni[2]
[1]*Gastroenterology,* [2]*G I Surgery,* [3]*pathology, AIIMS, New Delhi, India, New Delhi, India*

Contact E-mail Address: peush_sahni@hotmail.com

Introduction: The etiology of small bowel strictures without any mass lesion or associated lymphadenopathy has not been described. In tuberculosis endemic countries, these patients are routinely treated with empirical anti tubercular drugs whereas in western countries these patients are treated as Crohn's disease. However, no data is available which has provided the common etiologies of small bowel strictures and thus can justify such an approach.

Aims & Methods: This is a retrospective study which analyzed surgical case records from Jan 2000 to October 2014 at a tertiary referral centre in North India. The study included all adult patients with small bowel strictures without mass lesions or lymphadenopathy who remained undiagnosed after imaging and endoscopic studies and required surgical resection. Demographic parameters, symptoms, biochemical tests, imaging and endoscopic findings and histologic diagnosis were noted. Statistical analyses were performed using STRATA software version 12.1.

Results: 89 patients fulfilled the inclusion criteria and were included. The most common symptoms were colicky abdominal pain (90%), weight loss (67.4%), acute obstruction (43.8%), fever (33.7%), diarrhea (18%) and gastrointestinal bleeding (7.8%). Most common site of strictures was proximal small intestine (41.5%) and the etiologies were: tuberculosis (27%), Crohn's disease (23.5%), non-specific (20%), ischemic (10%), adenocarcinoma (9%), lymphoma (4.4%) and others (5.5%). Of 38 patients who had been started on presumptive anti tubercular therapy, only 11(28.9%) were confirmed as having intestinal TB.

Conclusion: Tuberculosis and Crohn's disease account for only 50% of the etiologies of small bowel strictures without mass lesion or lymphadenopathy. 13% may have a mitotic etiology We suggest the option of early surgical resection in this group of patients as it will provide both a definitive diagnosis and cure.

P1843 FOLLOW-UP IN PATIENTS WITH OGIB AND A NORMAL CAPSULE ENDOSCOPY: NO REASSURANCE IN THE LONG TERM

C. Van de Bruaene[1], P. Hindryckx[1], C. Snauwaert[2], B. Vanduyfhuys[3], D. Dooremont[4], M. De Vos[1], D. De Looze[1]
[1]*Gastroenterology, Ghent University Hospital, Ghent,* [2]*Gastroenterology, UCL St Luc, Woluwe-Saint-Lambert,* [3]*Gastroenterology, AZ Alma, Sijsele,* [4]*Gastroenterology, AZ Sint-Elisabeth, Zottegem, Belgium*

Contact E-mail Address: Pieter.Hindryckx@UGent.be

Introduction: Obscure Gastrointestinal Bleeding (OGIB) accounts for approximately 5% of all digestive bleeding causes. Capsule Endoscopy (CE) is a useful tool to identify an underlying etiology located in the small bowel (SB). However, data on further long-term follow-up after a negative CE are scarce.

Aims & Methods: The aim of this study was to investigate the outcome of patients who presented with OGIB and had a normal CE of the SB. Standardized application forms of all patients that underwent CE for OGIB between 2002 and 2013 were reviewed and the subgroup of patients with a negative CE result was identified. Follow-up information of these patients was retrieved by contacting the referring physician and/or general practitioner.

Results: Between 2002 and 2013, 458 patients underwent CE for the indication of OGIB, from which 263 (57.4%) had a normal CE. Follow-up (FU) was available for 222 patients (Male, n = 114; Female, n = 108) of whom 81 presented with overt and 141 with occult bleeding. Median FU time was 52.8 months (range 1.4-139.6 months). Ninety-six patients underwent further diagnostics showing a cause for OGIB in 57 (diagnostic yield 59.4%). Further endoscopy was associated with a higher overall diagnosis rate, while further imaging and surgical exploration led to more SB diagnoses ($p < 0.05$). In 45 patients a previous origin for OGIB was suspected and CE was used to exclude a SB etiology. The final cause of anemia was identified in 102 patients: 33 in the upper GI tract, 26 in the lower GI tract, 24 outside the GI tract (i.e. gynaecological, renal, urological or hematological etiology) and 19 in the SB. Final outcome for the complete cohort of negative CEs was: 145 (65.3%) true negative (i.e. non SB cause of bleeding/resolved anemia), 19 (8.6%) false negative (i.e. SB cause of OGIB) and 58 (26.1%) ongoing bleeding without cause. Missed SB lesions were: angiodysplasia (n = 11), Meckel's diverticulum (n = 3), SB malignancy (n = 3), jejunal erosions (n = 1) and NSAID-induced SB ulcerations (n = 1). False negative CEs could not be predicted by age, gender, overt/occult bleeding, hemoglobin value or relevant comorbidities at the moment of CE. Bleeding resolved in 142/220 patients (64.5%) of which 83 underwent non-specific and 59 specific therapy for a GI cause of bleeding, leading to therapy success rates of 68.6% and 67.8% respectively. Worse prognosis was observed in patients with a higher age, comorbidities, using anticoagulants or needing transfusions before CE, following multivariate analysis ($p < 0.05$).

Conclusion: Further diagnostics can initially be deferred after negative CE. However, if anemia persists, diagnostics are warranted: repeat upper and lower GI endoscopy, followed by re-examining the SB. In 59.4% of these patients a cause for anemia was identified during FU, mostly outside the SB. Relevant SB lesions on the other hand account for 8.6% of all negative CEs. OGIB did not resolve in 35.5% of cases and, therefore, negative CEs do not reassure.

Introduction: We previously presented our data identifying an association between serum abnormalities in the angiopoietin (Ang) pathway in patients with small bowel angiodysplasia (SBA) compared to healthy controls. Other studies have reported varied serum Ang levels in association with other conditions including Chronic Kidney Disease (CKD) and Inflammatory Bowel Disease (IBD). It is not yet known whether there is a differential expression profile of serum Ang1 and Ang2 levels in patients with SBA versus other small bowel conditions.

Aims & Methods: To measure serum levels of Ang1 and Ang2 in a cohort of patients undergoing Small Bowel Capsule Endoscopy (SBCE) for a variety of conditions.

After obtaining ethical approval we prospectively recruited patients undergoing SBCE for any indication in Tallaght Hospital over a 12 month time period. Phlebotomy was performed on participants the day of their SBCE and Haemoglobin and renal function was measured. Serum was collected, centrifuged and stored for batch analysis at -80^{0}C. Commercially available ELISA kits (R&D sytems) were used to measure Ang1 and Ang2 levels according to the manufacturer's guidelines. Patient demographics, indication for and result of SBCE were collected. Results of Ang1 and Ang2 were expressed as a mean and the mean ratio of Ang1/Ang2 in each group was calculated. Results were compared between groups depending on SBCE result using a student's t test with a p value of <0.05 considered statistically significant.

Results: To date, serum from 80 patients has been analysed. Patient's mean age was 52.6 years (16-80), and 48% (n = 38) were Male. The indications for SBCE were: iron deficiency anaemia 50% (n = 40), Suspected Crohn's disease 26% (n = 21), obscure gastrointestinal bleeding 20% (n = 16), and other 4% (n = 3). Of these, 56% (n = 45) had normal findings on SBCE, with positive findings in 44% including; SBA 16% (n = 13), small bowel inflammation 16% (n = 13, including Crohn's = 1)), other bleeding source (GAVE, Dieulafoy's lesion) 5% (n = 4), and other (malabsorption, lymphangiectasias) 7% (n = 5). There were significantly higher mean Ang2 levels in patients with SBA (5112pg/ml, range 2481-18184) compared to both normal findings [3320pg/ml (range 1188-9688), $p = 0.026$ 95% CI -3353.5649 to -231.7855] and inflammation [2629pg/ml (1465-3570), $p = 0.049$ 95% CI 0.7358 to 4966.6489]. There was no difference in Ang2 levels between patients with normal findings and small bowel inflammation, and Ang1 levels were similar in all 3 groups (49295pg/ml vs 49723pg/ml vs 43227pg/ml). There was a trend towards a lower median ratio of Ang1/Ang2 in the SBA patients (11) compared to both the normal (18) and inflammation (18) groups however this did not reach statistical significance. In the group overall there were 7 participants with CKD and 19 patients with anaemia, however, neither factor was associated with a higher mean Ang2 level with means of 4105pg/ml vs 3423pg/ml ($p = 0.36$) and 4106pg/ml vs 3128pg/ml ($p = 0.079$) respectively.

Conclusion: In keeping with our previous findings, elevated Ang2 levels appear selective for SBA in both a cohort referred for SBCE with a variety of conditions and in healthy controls. Ongoing assessment with larger numbers in each group, particularly in small bowel Crohn's disease are necessary to determine whether Ang expression could be a useful clinical selection tool for SBCE.

Introduction: Baloon-enteroscopy, capsule enteroscopy (VCE), CT-scan and MRI are useful procedures for the diagnosis of small bowel lesions.

Aims & Methods: The aim was to evaluate the agreement and find predictors of non-agreement between baloon-enteroscopy and other diagnostic methods. Retrospective analysis of patients undergoing single-baloon enteroscopy between 2010 and 2014 and comparative analysis with VCE, CT-scan and MRI.

Results: From 165 procedures (101 anterograde and 64 retrograde), 56% were performed in men; mean age was 53 ± 18 years. Gastrointestinal bleeding of obscure origin was the main indication for performing baloon-enteroscopy (n = 54, 33%), followed by Crohn's disease (n = 39, 23%) and polyp/polyposis syndromes (n = 27, 16%). The procedure was normal in 52 (32%), and the main findings were angiodysplasia (n = 23, 14%), ileitis (n = 18, 11%), polyps (n = 14, 9%), stenosis (n = 14, 9%), inflammatory anastomotic changes (n = 12, 7%) and

jejunitis (n = 8, 5%). More than half (n = 102, 62%) had prior VCE and 51 (30%) had CT or MRI within the previous 3 months. The agreement between single-baloon enteroscopy and VCE was good (kappa = 0.60, $p < 0.001$) and was moderate/poor (kappa = 0.39, $p < 0.001$) relative to imaging procedures. No differences were found between the procedures regarding enteroscopy indications nor between anterograde and retrograde enteroscopy.
The agreement between enteroscopy and VCE was good in patients without previous small bowel surgery (kappa = 0.617, $p < 0.001$) and only moderate (kappa = 0.538, $p = 0.021$) in patients with surgical history. The agreement was also higher in jejunal lesions (good: kappa = 0.546, $p < 0.001$) than in ileal lesions (moderate: kappa = 0487, $p < 0.001$).
Conclusion: The agreement between single-baloon enteroscopy and VCE was good, being moderate/poor between enteroscopy and imaging. The absence of previous small bowel surgery and lesions with jejunal location were predictors of greater agreement. The agreement was similar in concerning the different indications for ballon-enteroscopy.

P1846 ASSESSMENT OF OBESITY AND HEART FIBROSIS DEGREE IN PATIENTS WITH METABOLIC SYNDROME

T. Deeva[1], **O. Drapkina**[1], V. Ivashkin[1]
[1]*I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation*

Introduction: Assessment of obesity and heart fibrosis degree in patients with metabolic syndrome.
Aims & Methods: To investigate level of obesity and heart fibrosis in patients with metabolic syndrome (MetS).
The research has included 76 patients, from them 43 patients were with MetS (basic group), 33 patients without MetS (control group). Epicardial fat thickness was evaluated by transthoracic echocardiogram. Besides the above we conducted noninvasive evaluation of the fraction of fibrosis of the myocardium we used echocardiography, then we obtained the resulting images in "jpeg" format and analyzed them using software "Image J v.1.4(NIH,2009)". The level of leptin and galectin-3 was investigated.
Results: Patients in the basic group had significantly higher epicardial fat thickness than control (4.67 ± 1.7 vs 2.66 ± 1.15 mm, $p < 0.001$). An average volume fraction of fibrosis in the interventricular septum had significant difference in the groups studied ($22.6 \pm 4.45\%$ in basic and $16.5 \pm 3.95\%$ in control groups, $p < 0.001$). An average level of leptin in the group with MetS was significantly higher in comparison with control - 41.89 ± 33.28 and 17.64 ± 16.87 ng/ml, $p < 0.001$. Correlation was revealed between the level of leptin and weight (r = 0.55), the body mass index (r = 0.70), the degree of obesity (r = 0.33), abdominal obesity (r = 0.47), waist circumference (r = 0.62), level of glucose (r = 0.33) and the high-density lipoprotein (r = -0.30), epicardial fat thickness (r = 0.60), degree left ventricular hypertrophy (r = 0.26), systolic (r = 0.39) and diastolic (r = 0.35) blood pressure, hepatic (r = 0.42) and pancreatic (r = 0.37) steatosis, $p < 0.05$.
An average level of galectin-3 in the group with MetS was reliably higher (1.89 ± 1.71 ng/ml), compared with the control group (1.03 ± 0.22 ng/ml), $p = 0.006$. Positive correlation was revealed between the level of galectin-3 and left ventricular hypertrophy (LVH) (r = 0.29), coronary heart disease (r = 0.35), chronic heart failure (r = 0.34), fraction of fibrosis of the myocardium (r = 0.24), hepatic (r = 0.43) and pancreatic (r = 0.24) steatosis, NAFLD fibrosis score (r = 0.23), $p < 0.05$.
Conclusion: 1) Patients with MetS have epicardial fat thickness significantly more often than control group, leptin level has been correlated with obesity as for the whole body so for the heart, which can be a powerful predictor of cardiovascular disease.
2) All patients with MetS had significantly higher rates of galectin-3. More strongly pronounced septal fibrosis was found in patients with MetS.
3) Relationship has been found between the level of leptin, galectin-3 and diseases related to MetS. The basis of the progress of these diseases is depending on inflammation and fibrosis, and thus it could indicate that these molecules are playing role in development of these pathological processes. That can serve as a prognostic marker of development of cardiovascular and hepatobiliary diseases.

P1847 THE CLINICAL SIGNIFICANCE OF MARKERS OF FIBROSIS AND APOPTOSIS IN PATIENTS WITH METABOLIC SYNDROME

T. Deeva[1], **O. Drapkina**[1], V. Ivashkin[1]
[1]*I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation*

Introduction: The clinical significance of markers of fibrosis and apoptosis in patients with metabolic syndrome.
Aims & Methods: To investigate the level of serum markers of obesity (leptin), apoptosis (caspase-8) and fibrosis (galectin-3) in patients with metabolic syndrome (MetS).
The research has included 76 patients, from them 43 patients were with MetS (basic group), 33 patients without MetS (control group). The average age of 61 ± 12 years. There was held comprehensive survey, including the determination of the level of leptin, caspase-8, galectin-3.
Results: An average level of leptin in the group with MetS was significantly higher in comparison with control - 41.89 ± 33.28 and 17.64 ± 16.87 ng/ml, $p < 0.001$. Correlation was revealed between the level of leptin and weight (r = 0.55), the body mass index (r = 0.70), the degree of obesity (r = 0.33), abdominal obesity (r = 0.47), waist circumference (r = 0.62), level of glucose (r = 0.33) and the high-density lipoprotein (r = -0.30), epicardial fat thickness (r = 0.60), degree left ventricular hypertrophy (r = 0.26), systolic (r = 0.39) and diastolic (r = 0.35) blood pressure, hepatic (r = 0.42) and pancreatic (r = 0.37) steatosis, $p < 0.05$.
An average level of galectin-3 in the group with MetS was reliably higher (1.89 ± 1.71 ng/ml), compared with the control group (1.03 ± 0.22 ng/ml), $p = 0.006$. Positive correlation was revealed between the level of galectin-3 and left ventricular hypertrophy (LVH) (r = 0.29), coronary heart disease (r = 0.35), chronic heart failure (r = 0.34), fraction of fibrosis of the myocardium (r = 0.24), hepatic (r = 0.43) and pancreatic (r = 0.24) steatosis, NAFLD fibrosis score (r = 0.23), $p < 0.05$.
An average level of caspase-8 in a group with MetS was significantly higher than in control (0.28 ± 0.19ng/ml and 0.2 ± 0ng/ml, $p < 0.05$). Positive correlation was revealed between the level of caspase-8 and obesity (r = 0.23), BMI (r = 0.47), atherosclerosis of aorta (r = 0.31), hepatic (r = 0.46) and pancreatic (r = 0.35) steatosis, non-alcoholic steatohepatitis (r = 0.31), gastroesophageal reflux disease (r = 0.25), $p < 0.05$.
Conclusion: In the patients' group with MetS, compared with the control group, were identified the following higher levels of: 1) Leptin, at the level correlated with parameters of obesity, as for the whole organism, as well as for the heart' obesity, which can be a powerful predictor of cardiovascular disease; 2) Caspase-8, as one of the markers of apoptosis 3) Galectin-3, as one of the promising markers of the heart' and liver' fibrosis. Relationship has been found between the level of leptin, caspase-8, galectin-3 and diseases related to MetS, that can serve as a prognostic marker of adverse development of cardiovascular and hepatobiliary diseases.

Contact E-mail Address: scoban72@yahoo.com
Introduction: The prevalence of morbid obesity is gradually increasing throughout the world. Morbid obesity is associated with hypoadiponectinemia and endothelial dysfunction. Intragastric balloon treatment (IBT) is an effective therapeutic modality for obesity.
Aims & Methods: The aim of this study was to evaluate short-term outcome of IBT on endothelin-1, adiponectin levels along with metabolic profile and body fat. This single-center study was conducted on 34 consecutive morbid obese patients, 6 man and 28 women, aged 37.1 ± 9.2 years who inserted intragastric balloon (IB) with body mass index (BMI) of 47.6 ± 8.2 kg/m^2. Patients were evaluated by taking a detailed account of their medical, social, psychological, dietary, family and medical history. All subjects' BMI and homeostasis model assessment of insulin resistance (HOMA-IR) were determined. Metabolic variables were obtained after an overnight fasting. The main determined variables included waist circumference, weight loss, insulin sensitivity, lipid profile, alanin transaminase (ALT), aspartat transaminase (AST), and gamma glutamil transferase (GGT), and body fat percentage. All variables including endothelin-1 and adiponectin were studied before inserting and just after removing of IB. Body fat percentage was measured using a body composition analyzer (TANITA TBF300). All endoscopic examinations were performed under conscious sedation with midazolam in the Endoscopy Unit of Diskapi Yildirim Beyazit Education and Research Hospital, Gastroenterology Clinic. Intragastric balloon were removed after 6 months of inserting in all patients. All metabolic variables including adiponectin and endothelin-1 levels were compared with 20 healthy volunteers as a control group.
Results: Anthropometric variables, ALT, triglyceride, waist circumference, fasting glucose, HOMA-IR, adiponectin, and endothelin-1 levels were significantly different between groups ($p < 0.05$). Anthropometric variables, Endothelin-1, ALT, GGT, and body fat percentage decreased significantly in all patients with IBT ($p < 0.05$) but Adiponectin levels increased significantly after this treatment. However, no significant changes were found in AST, fasting glucose, insulin, and HOMA-IR levels. When the lipid profile was assessed, a significant decrease was found only in triglyceride levels. We found a significant positive correlation between endothelin-1 levels and BMI, and GGT (r = 0.366, p = 0.01 and r = 0.453, p = 0.01, respectively).
Conclusion: In morbid obese patients, weight loss achieved by IBT is associated with a decrease in serum endothelin-1 levels and anthropometric variables, and an increase in adiponectin levels.

Contact E-mail Address: scoban72@yahoo.com

Introduction: Nonalcoholic fatty liver disease is a common morbidity of obesity, and it may be complicated with non-alcoholic steato-hepatitis (NASH) which proceeds to end stage liver disease. In the recent years, M30, an apoptotic cell death serum marker, has promising results leading to determine underlying NASH in obese patients. However, it is still confused whether M30 values in serum declines with improving in body mass index (BMI) values.

Aims & Methods: We aimed to investigate the rate of abnormal NASH biomarkers in morbid obese patients undergoing intra-gastric balloon placement and the effect of intra-gastric balloon placement on the same biomarkers after a six months of therapy.

We analyzed 30 morbid obese (BMI > 40 kg/m^2) patients. In all patients, we placed an intra-gastric balloon, Bioenterics Intragastric Balloon, after a detailed evaluation. None of our patients had a history of heavy alcohol drinks (greater than 20gr/day for man, 10gr/day for woman). Laboratory tests for investigation of other hepatic diseases including viral hepatitis, Wilson disease, hemochromatosis and auto-immune hepatitis were performed and all of them were excluded. In addition to routine laboratory investigations, serum M30 levels (M30 Apoptosese Elisa, Peviva, Sweden) were measured for this intervention. Serum samples obtained before insertion of intra-gastric balloon and after removing of intra-gastric balloon via peripheral venous blood, and stored at -80© were used for M30 level determination. Routine labaoratory parameters, BMI, HOMA-IR index, and mean platelet volume (MPV) values were measured at the baseline and at the end of the treatment.

Results: A total of 30 morbidly obese patients undergoing intra-gastric balloon placement and 40 lean controls, were included into the study. As expected, BMI level, HOMA-IR index and triglyceride levels were higher in patient group than controls. AST and GGT levels were similar in each group, but ALT was higher in patients. Both MPV, a possible indicator to predict underlying hepatic inflammatory process, and APRI index, a score able to predict underlying significant hepatic fibrosis, did not differ in controls from the patient group. The serum apoptotic index, M30 level, was found to be significantly higher in obese patients compared with lean controls. After the six months period of intra-gastric balloon placement therapy, mean BMI values decreased from 47.6 to 41.7 kg/m^2, accompanied with ALT and GGT levels. However, surprisingly, serum M30 levels, APRI index, MPV values and triglyceride levels did not decrease during the treatment period in patient group.

Conclusion: The current study revealed that intra-gastric balloon placement did not improve underlying NASH biomarkers, even though the therapy achieved in success with decreasing the BMI values significantly. Not only M30, but also some other indexes, predicting underlying NASH, did not revealed improving by the intra-gastric balloon placement therapy.

P1850 VISCERAL OBESITY AND SERUM GAMMA-GLUTAMYL TRANSFERASE LEVELS: IS THERE A RELATIONSHIP?

S. M. D. Giestas[1], A. Oliveira[1], S. Campos[1], R. Alves[1], A. Giestas[2], C. Agostinho[1], C. Sofia[1]
[1]*Gastroenterology, Centro Hospitalar e Universitário de Coimbra, Coimbra,* [2]*Centro Hospitalar Entre Douro e Vouga, Santa Maria Feira, Portugal*

Contact E-mail Address: silviagiestas@gmail.com

Introduction: Visceral obesity has been associated with increased oxidative stress. Serum gamma-glutamyl transferase (GGT) activity changes in response to oxidative stress and some studies have shown that an increase in serum GGT levels is associated with an increased risk of cardiovascular events.

Aims & Methods: The aim of this study was to assess serum GGT levels in patients with visceral obesity and its relationship with metabolic abnormalities found in visceral obesity. Methods: We evaluated waist circumference (WC), blood pressure (BP) and serum levels of GGT, highty sensitive C-reactive protetin (hsCRP), fasting glucose, total cholesterol, LDL, HDL, triglycerides, ApoA1, ApoB, ApoCIII, Lp(a) and oxLDL in 100 asymptomatic non-smoking patients (56 men/44 women) aged 50–60 years, without cardiovascular disease. Subjects were grouped as it follows: i) WC < 102 cm in men and WC < 88 cm in women; ii) WC ≥ 102 cm in men and WC ≥ 88 cm in women (Adult Treatment Panel III).

Results: The group with visceral obesity had higher levels of GGT (women: 31.8+/−14.7 vs 47.8+/−14.8 U/L, $P<0.05$; men: 37.3+/−21.1 vs 49.0+/−19.5 U/L, $P<0.05$), hsCRP (women: 3.44+/−2.23 vs 2.04+/−1.9mg/L, $P<0.05$; men: 3.51+/−2.90 vs 2.13+/−1.87 mg/L, $P<0.05$), systolic BP (women: 135+/−24 vs 146+/−27 mmHg, $P<0.05$; men: 134+/−22 vs 145+/−25 mmHg, $P<0.05$), triglycerides (women: 129.5+/−54.0 vs 172.9+/−13.0 mg/dl, $P<0.05$; men: 132.2+/−18.0 vs 183.6+/−76.0 mg/dl, $P<0.01$), oxLDL (women: 59.8+/−14.7 vs 67.8+/−14.8 mg/dl, $P<0.05$; men: 61.3+/−21.1 vs 69.0+/−19.5 mg/dl, $P<0.05$) and ApoCIII (women: 8.8+/−4.3 vs 12.3+/−9.9 mmHg, $P<0.01$; men: 9.4+/−5.3 vs 14.4+/−7.4 mmHg, $P<0.01$), and lower levels of HDL (women: 56.8+/−11.8 vs 47.3+/−13.4 mg/dl, $P<0.05$; men: 44.5+/−11.1 vs 36.8+/−10.4 mg/dl, $P<0.05$) and ApoA1 (women: 170.0+/−22.6 vs 152.6+/−27.6 mg/dl, $P<0.05$; men: 144.6+/−22.3 vs 133.2+/−24.2 mg/dl, $P<0.05$). There was no significant difference ($P>0.05$) between the groups in fasting glucose, LDL, ApoB and Lp(a) levels. Serum GGT levels was positively correlated with WC ($r=0.86$, $P<0.01$), systolic BP ($r=0.27$, $P<0.05$), plasma triglyceride ($r=0.29$, $P<0.05$), ApoCIII ($r=0.38$, $P<0.05$), LDL ($r=0.51$, $P<0.01$) and ApoB ($r=0.54$, $P<0.01$); and negatively correlated with HDL ($r=-0.26$, $P<0.01$) and ApoA1 ($r=-0.20$, $P<0.01$).

Conclusion: The study showed that high WC was strongly associated with high levels of GGT and other serum markers of oxidative stress. These results suggested that weight loss or other approaches aimed to reducing visceral obesity may have a significant impact on the prevention of subclinical inflammation and thus reducing cardiovascular risk.

Introduction: Today the prevalence of obesity continues to increase that provides challenge to scientists. Obesity is strongly associated with systemic inflammation and with oxidative stress. A recent study showed the presence of melanin in visceral adipose tissue (VAT). This pigment as known has antioxidant and anti-inflammatory properties. In this connection we were interested in study of antiobesity properties of exogenous polyphenolic complex melanin obtained from the antarctic black yeast *Nadsoniella nigra*.

Aims & Methods: So, the aim of our work was to study the influence of melanin on the development of obesity in rats induced by monosodium glutamate (MSG). The study was carried out on 60 white rats, that were divided into 3 groups: intact, MSG- and MSG + melanin groups (10 male and 10 female rats in each group). Newborn rats of MSG- and MSG + melanin groups were administered with MSG (4 mg/g, 8 µl/g, subcutaneously) at 2nd -10th days of life. Since the age of 1 month, rats of MSG-group were treated with water (0.25 ml/100 g), rats of MSG + melanin groups – with melanin (1 mg/kg) dissolved in water (0.25 ml/100 g). Polyphenolic complex melanin was extracted from the antarctic black yeast *Nadsoniella nigra* harvested from Galindez Island and cultivated. Introduction had been performed intermittently (two-week courses alternated with two-week breaks) for 3 months. In 4-month rats anthropometrical parameters and VAT mass were estimated, and adiponectin in serum and leptin in VAT were measured by ELISA.

Results: In 4-month rats we diagnosed the changes of the anthropometrical parameters and significant increase of VAT mass that suggest development of visceral obesity. In male rats, there were more pronounced changes. It was also established the decrease of serum adiponectin by 60% ($p < 0.01$) in males and by 42% ($p < 0.05$) in females and increase of VAT leptin level adiponectin by 61% ($p < 0.01$) in males and by 46% ($p < 0.05$) in females compared with intact rats. The introduction of melanin prevented the visceral obesity that was confirmed by reduction of index Lee and body mass index. Melanin decreased the VAT by 44.5% ($p < 0.01$) in males and by 41.2% ($p < 0.01$) in females compared with MSG-group. Melanin also restored the adipose tissue endocrine function under the conditions of obesity: in MSG + melanin group the level of adiponectin and leptin didn't differ from the intact group.

Conclusion: Thus, the introduction of melanin prevents MSG-induced obesity in rats and recovers the endocrine function of adipose tissue. The antarctic black yeast *Nadsoniella nigra* can be proposed as a producer of the antiobesity drug.

Introduction: Recently much attention has been paid to a potential biochemical "cross-talk" between metabolisms of the adipose tissue (AT) and bone (marrow), termed "bone-fat axis". We hypothesized that selected substances participating in this molecular "dialog" are associated with body mass and peripheral trafficking of bone marrow-derived stem cells (BMSCs) in both - generally healthy individuals and patients with obesity-associated malignancy, such as pancreatic adenocarcinoma.

Aims & Methods: We performed an analysis of systemic levels of selected substances involved in the regulation of bone (marrow) homeostasis (parathormone, calcitonine, osteopontin, osteonectin, stem cell factor [SCF] and fibroblast growth factor-23) in 35 generally healthy volunteers and 35 patients with pancreatic cancer. Results were correlated with i) absolute numbers of circulating BMSCs enumerated using flow cytometry and ii) body mass values. Additionally, subcutaneous and visceral/omental AT levels of the aforementioned molecules were analyzed in lean and overweight/obese individuals.

Results: Intensified steady-state trafficking of only Lin-CD45 + CD133 + hematopoietic stem/progenitor cells was observed in overweight/obese individuals, and this was associated with BMI values. Also elevated levels of both osteonectin and SCF were detected in overweight/obese patients, and these concentrations were also correlating with BMI values. In comparison to healthy individuals, cancer patients had significantly higher osteopontin levels, and lower values of both osteonectin and osteonectin/osteopontin ratio. While in cancer patients no significant correlation was observed between BMI values

Abstract number: P1856

Carbohydrates/protein, g/g	3.32 ± 0.93	3.13 ± 1.26*	2.73 ± 1.54*	3.0 ± 1.1
MDS/carbohydrates, g/g	0.43 ± 0.18	0.44 ± 0.17	0.47 ± 0.15	0.45 ± 0.15

and numbers of circulating BMSCs, peripheral trafficking of CD34 + KDR + CD31 + CD45-endothelial progenitor cells and CD105 + STRO-1 + CD45-mesenchymal stem cells was associated with values of osteonectin/osteopontin ratio, which were also correlating with BMI ($r = 0.52$; $p < 0.05$). AT levels of examined substances were similar to those measured in plasma, with an exception to osteonectin values, which were around 10-times lower.

Conclusion: Our study highlights that osteonectin, osteopontin and SCF may serve as probable communicating signals between bone (marrow) and AT in both generally healthy individuals and patients with pancreatic cancer. We postulate that these molecules may be overlooked biochemical players linking body mass and BMSCs with obesity-associated cancer development and/or progression in humans.

Introduction: In ulcerative colitis (UC), dietary supplements and nutritional strategies may have anti-inflammatory properties and improve the disease course. We investigated the effects of casein glycomacropeptide (CGMP), a fraction of bovine whey protein, in active UC.

Aims & Methods

Aim: To compare clinical, endoscopic, and mucosal disease activity markers before and after 4 weeks treatment with either CGMP plus usual oral mesalazine dose or increase to maximum oral mesalazine dose in patients with active distal UC.

Methods: In a randomised open label intervention study, 24 adult patients with active UC involving 10-40 cm of the distal colon, were randomised in a 2:1 ratio to their usual treatment plus a daily nutritional supplement of CGMP 30 grams or dose escalation to 4.800 mg oral mesalazine daily (standard treatment) for 4 weeks. Acceptance and adherence to CGMP up to 8 weeks were documented.

Results: After 4 weeks treatment, 10/16 (63%) who received CGMP had unchanged or decreased Simple Clinical Colitis Activity Index (SCCAI) which was similar to those on standard treatment, 4 of 8 (50%) ($p = 0.67$). The number of patients where SCCAI fell 3 or more did not differ between the two groups, 9/16 (56%) versus 4/8 (50%) ($p = 0.77$). Changes in disease extend and severity were similar between the two groups. CGMP was well tolerated and accepted by the patients.

Conclusion: The addition of CGMP as nutritional therapy to standard treatment was safe and well accepted by patients with active distal UC. The disease-modifying effect of CGMP was similar to that of mesalazine dose escalation.

Introduction: Fatty acids (FAs) are involved in the development of inflammatory processess. Their role in the ethiopathogenesis od inflammatory bowel diseases (IBD) is not fully understood. It is known that w-3 FAs and their derivates have an anti-inflammatory effects. In contrast, w-6 FAs are mainly pro-inflammatory compounds. There are some indications that patients with inflammatory bowel diseases are at risk of essentials fatty acid insufficiency (EFAI) and, in severe cases, of essentials fatty acid deficiency (EFAD).

The aim of the study was to assess the relationship between the FAs content in mucosa phospholipids of non-involved/involved colon tissue and clinical activity of the disease in patients with inflammatory bowel diseases.

Aims & Methods: The aim of the study was to assess the relationship between the FAs content in mucosa phospholipids of non-involved/involved colon tissue and clinical activity of the disease in patients with inflammatory bowel diseases. The study included 18 patients with IBD (16 pts with ulcerative colitis, 2 pts with Crohn's disease), M/F 9/9, mean age 60.2 ± 15.5 years. Ten patients without abnormality under colonoscopic examination (M/F 4/6, mean age 47.2 ± 18.7 years) served as controls. Non-involved and involved colon tissues as well as one blood sample were taken from each patient. The clinical activity of the disease was assessed using the Mayo and the Geboes activity index. Total lipids were extracted from tissues homogenate with chloroform-methanol. Next, lipid fractions were isolated from the mixture using aminopropyl columns. After solid phase extraction, serum and tissue FAs of phospholipids fraction were measured by GC-FID. The results of individual FAs were expressed as percentage of total FAs.

Results: Significantly higher the mean percentage of C16 and C18 as well as the sum of saturated FAs in colon tissue of IBD patients as compared to control has been found ($p < 0.03$-0.0005). In contrast the mean percentage of C18:1cis, C18:2(w-6), C18:3(w-3), C20:5(w-3) as well as monounsaturated FAs were significantly lower in IBD patients as compared to control ($p < 0.02$-0.001). Significant negative correlation between clinical activity of the disease and w-3 FAs, w-6 FAs and the PUFA/noPUFA ratio were observed ($r = -0.364$, $p < 0.04$; $r = -0.413$, $p < 0.02$; $r = -0.434$, $p < 0.01$, respectively). In contrast, significant positive correlation between clinical activity of the disease and the ratio of C16:1/C18:2 and the sum of saturated FAs were found ($r = 0.624$, $p < 0.0001$; $r = 0.3689$, $p < 0.01$). The significantly higher the mean percentage of C20:5(w-3) and the sum of polyunsaturated FAs (PUFA) ($p < 0.05$ in both cases) in IBD patients as compared to control were the only differences found in serum.

Conclusion: The fatty acids profile in mucosa of colon tissue phospholipids in patients with inflammatory bowel diseases is characteristic for Essential Fatty Acids Insufficiency.

Contact E-mail Address: pilipenkowork@rambler.ru

Introduction: Bacterial overgrowth is highly prevalent among IBS-patients. Overproducing H_2 or CH_4 was found to correlate with the spectrum of IBS symptoms. However, the influence of diet in IBS patients to H_2/CH_4 production was still not assessed.

Aims & Methods: 271 patients were classified according to Rome III criteria (124 IBS-D and 147 IBS-C) were evaluated by lactulose breath test (LBT, Gastrocheck, Bedfont Scientific Ltd, UK). LBT was performed using 10 g of lactulose mixed in 150 mL of water in fasting condition, and breath samples collected every 15 min for a 180-min period. "H_2-producers" and "CH_4-producers" were defined as the patients produced $H_2 > 20$ ppm more than the basal sample and patients with mean CH_4 excretion of 12 ppm or more, respectively. Dietary pattern of patients was assessed using 24/48/72h recall or validated food diary.

Results: Among patients tested by LBT, 24 patients demonstrated normal production of H_2/CH_4; 33 were CH_4-producers, 154 were H_2-producers and 60 demonstrated excess production of both gases. No differences were found in consumption of energy or protein, fat and carbohydrates between groups of patients with different production of H_2/CH_4 (Table 1). Differences in nutrient delivery and nutritional groups were unreliable because of marked variability in variables due to differences in food intake (men and women, skinny and fat, etc.). However, after recalculation of energy quota of nutrients (kcal from nutrient/total kcal) CH_4-producers demonstrated significantly higher quota of protein in the diet in compare to H_2-producers and to CH_4/H_2-producers ($p = 0.01$ both). Protein quota in patients with normal production of H_2/CH_4 was also significantly lower than in CH_4-producers ($p = 0.03$). In the diet of H_2-producers and H_2+CH_4 producers fat/protein ratio was significantly higher than in the diet of CH_4-producers ($p < 0.001$ and $p = 0.001$, respectively). Analysis of the ratio carbohydrate/protein also showed a significantly lower content of carbohydrates in the diet CH4-producers than in the other groups

(CH_4/H_2-producers, $p = 0.006$, H_2-producers $p = 0.018$, normal production of H_2/CH_4 $p = 0.035$).
Conclusion: Excessive CH4 production is associated with high protein and low carbohydrate quota in the diet. The diet of H2-producers or H2 + CH4 producers, is characterized by increased fat quota. Therefore, treatment options of the bacterial overgrowth should include specific dietary modifications.

Introduction: Irritable bowel syndrome (IBS) is the world's most common gastrointestinal functional disorder and is associated with several social and economic costs. Health-related quality of life is often impaired in patients with IBS. The therapeutic approach to patients with IBS is based on symptoms, and fibers may play an important role in treatment.
Aims & Methods: Functional food product (jelly) containing 2g inulin, 5mg curcumin and 2mg of pyridoxine was developed and evaluated. Fifty patients (5 males and 45 females, mean age 47.3 ± 16.3 yrs) fulfilling the Rome III criteria for IBS-C were randomly assigned into two groups: one received standard diet plus two jellies a day for 2 weeks and control group received standard diet. Response to therapy was recorded on a daily basis using Likert scale of abdominal pain, bloating and feeling of incomplete bowel emptying. Stool was evaluated by frequency of bowel movement and Bristol stool scale. Quality of life assessed by IBSQoL questionnaire before and after the treatment.
Results: Using functional food jelly was associated with positive effect on the stool parameters (0.6 ± 0.25 vs 1.15 ± 0.65 t/d in stool frequency, $p = 0.001$, 2.62 ± 1.22 vs 3.99 ± 1.27, index Bristol scale, $p = 0.001$), reduces the severity of abdominal pain (1.69 ± 0.44 vs 1.36 ± 0.44 Likert scale points, $p = 0.001$), bloating (2.03 ± 0.90 vs 1.55 ± 0.83 points of Likert scale, $p = 0.02$) and a sense of incomplete bowel emptying (2.25 ± 0.98 vs 1.68 ± 0.92 points of Likert scale, $p = 0.001$), as well as an increase in quality of life (64.5 ± 13.5% vs 81.2 ± 9.1%, $p = 0.05$). Patients in control group have improvement in abdominal pain (2.16 ± 0.98 vs 1.8 ± 0.55 Likert scale points, $p = 0.05$) and bloating (2.42 ± 0.94 vs 2.16 ± 0.81 Likert scale points, $p = 0.05$) only. No adverse events were observed in both groups.
Conclusion: In conclusion, functional food jelly jelly containing inulin, curcumin and pyridoxine is well tolerated and associated with improve in stool parameters, abdominal pain, Bristol stool scale index and increase in quality of life in patients with IBS-C.

Contact E-mail Address: xllop@novintethical.com
Introduction: Gelatin or xyloglucan are currently used for gastroenteric disorders, although data from randomized studies are needed to completely assess the efficacy of these products in acute diarrhea or acute gastroenteritis in different types of patients.
Aims & Methods: To assess the efficacy, safety and time of onset of the antidiarrheal effect of xyloglucan and gelatin (Tasectan Plus®, containing xyloglucan and gelatin of animal origin) in children with acute gastroenteritis receiving oral rehydration solution (ORS).
This randomized, controlled, open-label, parallel group, multicentre, clinical trial included children (from 3 months to 12 years old) with acute gastroenteritis of infectious origin.
Children were randomized to receive a 5-day treatment. Both control and active groups received ORS and active group also received Tasectan Plus® (one sachets/8 hours in children younger than 3 years and 2 sachets/8 hours in children between 3 and 12 years). Diarrheal symptoms and safety were assessed in 3 visits (baseline, at 2 and 5 days) and by phone call at 10 days, and by fulfillment of a diary card by the parents or legal representatives.
The number and characteristics of stools (type 6 and 7 on Bristol Scale) and the evoluation of other diarrheal symptoms (nausea, vomiting, abdominal pain, flatulence, fever and dehydration) were assessed during the 72 hours previous to baseline and, after inclusion, at 24-hour intervals (during the first day of treatment assessments were performed at 1, 3, 6, 12 and 24 hours). Occurrence of adverse events was recorded during the whole study period.
Results: A total of 36 patients (58.3% girls; age: 13.9% ≤ 1 year, 47.2% 1-5 years, 25.0% 5-10 years, 13.9% > 10 years) were included (n = 18 in each group). The group treated with xyloglucan/gelatin and ORS had a better evolution in almost all parameters than the group receiving ORS alone. A faster onset of action was observed in the xyloglucan/gelatine group compared with the control group, since at 6 hours, xyloglucan/gelatin produced a statistically significant higher decrease in the number of type 7 stools (0.11 vs 0.44; $p = 0.027$). At days 3 and 5, xyloglucan/gelatin was also able to produce a statistically significant higher reduction of type 6 and 7 stools in comparison with ORS alone ($p = 0.026$ and 0.034, respectively). A better evolution for nausea, vomiting and abdominal pain was also recorded for the xyloglucan/gelatin group, although the differences vs the control group were not statistically significant. Xyloglucan/gelatin plus ORS was safe and well tolerated, without the occurrence of adverse events throughout the study.
Conclusion: Xyloglucan/gelatin is a fast, efficacious and safe option for the treatment of acute gastroenteritis in children, with a rapid onset of action in reducing diarrheal symptoms.
