The mean aminopyrine % cumulative dose after 120 minutes was significantly lower in cirrhosis group and HCC group compared to control group, and it was significantly lower in HCC group compared to cirrhosis group.

Conclusion: ^{13}C-ABT is non-invasive test and easy to perform in identifying quantitatively different degrees of liver cirrhosis. ^{13}C-ABT correlates well to Child classification and degree of chronic liver diseases. Liver biopsy remains the gold standard technique for the evaluation of patients with cirrhosis, its causes, and presence of hepatocellular carcinoma. ^{13}C-ABT will not replace liver biopsy in diagnosing causes of cirrhosis or diagnosing of HCC. However, in patients in whom biopsy is not safe or in whom an etiologic diagnosis has been established, the aminopyrine breath test may replace serial biopsies.

Introduction: Liver cirrhosis(LC) is a progressing disease commonly caused by alcohol consumption, infections of chronic hepatitis B and C and many other causes. Time period of fibrosis progression to cirrhosis varies in individual patients despite of etiology of liver cirrhosis. The search for genetic factors that could help to select patients at higher risk of developing LC is necessary. Current data indicate role of *PNPLA3* gene product in lipid homeostasis and genome-wide association studies (GWAS) revealed *PNPLA3* (rs738409) single-nucleotide polymorphism (SNP) association with liver diseases and fibrosis risk. A recent GWAS suggest a possible relationship between the clearance of apoptotic cells and liver fibrosis, revealing impact of *MERTK* (rs4374383) and *RNF7* (rs16851720) SNPs. Other GWAS demonstrated that *PSCK7* (rs236918) is a risk factor of cirrhosis in hereditary hemochromatosis (HH) patients. The role of these SNPs for the risk of developing LC needs to be evaluated in independent replication studies.

Aims & Methods: The aim of this study was to determine the association between the presence of *PNPLA3*, *MERTK*, *PCSK7* and *RNF7* SNPs and the risk of developing LC. We included 244 individuals with LC of different etiology and 498 healthy controls. The diagnosis of cirrhosis was confirmed by clinical features, liver biopsy and radiological imaging tests. *PNPLA3*, *MERTK*, *PCSK7* and *RNF7* SNPs in cirrhotic patients and control group were detected using real-time PCR TaqMan® method. Statistical analysis was performed using statistical software PLINK for genetic association studies. Odds ratio was adjusted for age and sex.

Results: *MERTK* and *PCSK7* SNPs were not associated with the risk of developing liver cirrhosis (adjusted odds ratio (OD_a)-1.2, 95% confidence interval (CI_{95}) 0.96-1.52, $p = 0.109$; OD_a-0.79, CI_{95} (0.56-1.11), $p = 0.169$, respectively). *RNF7* SNP showed no significant association in allelic association analysis (OD_a-0.75, CI_{95} (0.56-1.28), $p = 0.074$), but showed lower risk of developing

LC in recessive model when comparing CC *vs.* AA + CA genotype (OD_a-0.18, CI_{95} (0.04-0.79), p = 0.023). *PNPLA3* SNP showed allelic association with higher risk of developing LC (OD_a -1.91, CI_{95} (1.47-2.50), $p = 1.812*10^{-8}$), genotypic association analysis in a recessive model GG *vs.* GC + CC revealed higher risk of developing LC when compared to GG genotype (OR_a-5.01, CI_{95} (2.52-9.94), $p = 4.158*10^{-6}$) and dominant model GG + GC *vs.* CC genotype (OR_a-1.61, CI_{95} 1.13-2.29, p = 0.09).

Conclusion: *PNPLA3* and *RNF7* SNPs were associated with the risk of developing LC and these genetic alterations might contribute to progression to end stage liver disease. *MERTK*, *PCSK7* SNPs were not linked with the risk of LC.

Introduction: Antifibrotic effects on the drugs used in the study were assessed by determining activity of biochemical parameters: aspartate aminotransferase (AST), alanine aminotransferase (ALT), alkaline phosphatase (AP) and concentration of proinflammatory cytokines: interleukin 6(Il-6), interleukin beta 1(Il-beta1), tumour necrosis factor alpha (TNF-alfa), transforming growth factor beta (TGF-beta1) and platetet-derived growth factor (PDGF-AB). Oxidative stress was evaluated by oxidised (GSSG) and reduced glutathione (GSH) levels. Moreover, activity of paraoxonase1 (PON-1), an antioxidative enzyme as well as histological inflammatory changes and fibrosis extent in the liver were evaluated.

Aims & Methods: The aim of the present study was to determine the effects of the selected AT_1 receptor antagonists (losartan, telmisartan) on liver fibrosis induced by chronic administration of thioacetamide (TAA) in rats.

Results: The experiments were performed on Wistar rats. Animals were divided into 6 groups, 8 individuals each: Control (received water, ad libitum'' for 12 weeks), TAA (thioacetamide-treated rats in a dose of 300 mg/L, ad libitum'' for 12 weeks), losartan (30 mg/kg bw) or telmisartan (10 mg/kg bw, intraperitoneally (ip.) once a day for 4 weeks), TAA + L (thioacetamide- treated rats, 300 mg/L, ad libitum ' for 12 weeks followed losartan in a dose 30 mg/kg/bw ip. for 4 weeks), TAA + T (thioacetamide-treated rats, 300 mg/L, ad libitum'' for 12 weeks followed telmisartan in a dose 10 mg/kg bw ip. for 4 weeks).

The immunoenzymatic findings revealed a significant decrease in concentrations of the following cytokines: TNF-alpha in groups: TAA + L ($P < 0.01$), TAA+ T ($P < 0.01$), TGF-beta1 in the groups: TAA+ T ($P < 0.01$), TAA + L ($P < 0.05$) and Il-6 in group: TAA+ T ($P < 0.05$), as compared to the TAA group. Analysis of oxidative stress indices (GSH and GSSG) in the liver homogenates revealed statistically significant improvement: concentration of GSH in groups: TAA+ L and TAA+ T increases ($P < 0.001$) and concentration of GSSG in groups: TAA+ L ($P < 0.05$) and TAA + T ($P < 0.001$) decreases compared to the TAA group.

Conclusion: The present study suggest that both used drugs: losartan and telmisartan significantly inhibited the progression of hepatic fibrosis induced by TAA. Inhibitory effect of losartan and telmisartan might be associated with ability to inhibit the production of profibrotic cytokines such as TNF-alfa, TGF-beta1, IL-6 and improvement concentration parameters of oxidative stress.

Introduction: Bacterial translocation from the gut and inflammation play an important role in the pathogenesis and complications of liver cirrhosis, including hepatic encephalopathy (HE). Calprotectin is a protein derived from neutrophilic granulocytes and it is used as an indirect marker of intestinal inflammation.

Aims & Methods: We aimed to study the correlations between fecal calprotectin (FC) concentration, the severity of liver cirrhosis and hepatic encephalopathy. We performed a prospective study which included 92 patients with liver cirrhosis between April 2014 – September 2014. Cantitative FC (by fluorescent-enzyme imuno-assay) was measured in all subjects. Patients with gastrointestinal bleeding or diarrhea, who were given proton pump inhibitors, antiplatelet therapy or antibiotics, were excluded. HE grading was measured by West Heaven criteria and the degree of liver insufficiency was assessed according to the Child-Pugh classification and Model for End Stage Liver Disease (MELD).

Results: 64.5% of patients were female and the mean age was 54.34 ± 8.72 years. The major cause for liver cirrhosis was virus C infection (65%) and the most common precipitating factors for HE were infections (51%) and constipation (42%). There were no significant differences in values of FC between the patients with different stages of liver cirrhosis according to Child-Pugh classification and MELD score ($p < 0.05$). The mean concentrations of FC significantly increased with aggravating hepatic encephalopathy as it follows: 84 ± 32μg/g (without HE), 144 ± 43μg/g (Grade I HE), 196 ± 56μg/g (Grade II HE), 238 ± 48μg/g (Grade III HE) and 291 ± 45μg/g (Grade IV HE), $p < 0.05$.

Conclusion: FC was not associated with the severity of liver disease. FC concentrations increased with aggravating HE grade. FC could be used as a simple, non-invasive and rapid test for the diagnosis and evaluation of HE severity in patients with liver cirrhosis.

Introduction: Non-alcoholic steatohepatitis (NASH) can progress to advanced liver fibrosis and ultimately make hepatocellular carcinoma. L-carnitine is synthesized in the body from the amino acids and was proposed as the antioxidant for kidney disease and many body conditions.

Aims & Methods: The aim of this study is to investigate whether L-carnitine has any effects on the enlargement of liver fibrosis as well as preneoplastic lesions.

Methods: The effects of L-carnitine were examined using the choline-deficient L-amino acid-defined (CDAA) diet-induced NASH model. Diethylnitrosamine (DEN) 10 mg/kg was injected intraperitoneally once a week. The total study periods were 16 and 20 weeks. One group received a CDAA diet containing L-carnitine (200mg/kg/day) and DEN injection, the other group received a CDAA diet and DEN injection without L-carnitine as controls. Liver fibrosis was analyzed by Azan, Sirius–red, a-SMA, ED-1 expression. Development of preneoplastic lesions was assessed by glutathione S-transferase placental form (GST-P) expression. The change of laboratory data was analyzed. Type I procollagen, TIMP-2, aSMA,TGF-b, AFP, TNF-a, MCP-1,IL-6,EpCAM mRNA expression were analyzed using real-time RT-PCR system.

Results: After 16, 20 weeks, L-carnitine prevented liver fibrosis in a dose-dependent manner by Azan, Sirius-red expression ($p < 0.05$). Furthermore, L-carnitine reduced the area of GST-P positive lesions known as preneoplastic lesions ($p < 0.05$). Administration of L-carnitine significantly reduced levels of serum alanine aminotransferase (AST) (mean value: L-carnitine 239.3 vs Control 391.3 IU/l, $p < 0.05$), serum albumin (mean value: L-carnitine 4.2 vs Control 3.9 g/dl, $p < 0.05$). L-carnitine significantly inhibited Type 1 procollagen, TNF-a, IL-6, AFP mRNA expression (all of $p < 0.05$).

Conclusion: Our results indicated that L-carnitine prevented liver fibrosis and inflammation. We suggested that L-carnitine will be the new drug for NASH.

Contact E-mail Address: nic.weiss@wanadoo.fr

Introduction: Hepatic encephalopathy (HE) is a neurological complication of cirrhosis, impairing survival and quality of life. Its incidence is growing because of the improved prognosis of other complications of cirrhosis, and of the widespread use of TIPS. However, besides hyperammonemia which is often pointed out as a cause of HE, the pathophysiological mechanisms of HE remains poorly understood, which prevents the development of therapeutic strategies. To address this issue, metabolomics was used to identify dysfunction of metabolic pathways in cerebrospinal fluid (CSF) samples of cirrhotic patients suffering from HE.

Aims & Methods: The aim of this study was to detect new therapeutic targets for HE associated with cirrhosis.

Cerebrospinal Fluid (CSF) samples were collected on 14 cirrhotic patients admitted in ICU for HE, in whom infection of central nervous system has to be ruled out, and were compared to CSF of 27 control patients without any proven neurological disease. Metabolomic analysis was performed using 3 liquid chromatographies coupled to high resolution mass spectrometry methods (LC-HRMS). Informatic data processing tools were used.

Results: LC-HRMS methods led to the characterization of 150 metabolites in CSF samples of HE patients, which were mainly amino acids and organic acids. Interestingly, according to human metabolome database, 40% of those metabolites had never been retrieved were not reported as present in CSF before. HE patients could be easily discriminated from controls on the basis of

metabolomicic information. Concentrations of 102 metabolites were found to be significantly altered in HE patients: metabolotypes displayed alterations in several major metabolite classes such as ammoniac, bile acids, but also amino-acids, acylcarnitines, and nucleosides. Accumulations of acetylated compounds, which could be due to a defect of the Krebs cycle, were reported for the first time in HE patients, and could constitute interesting therapeutic targets.
Conclusion: By enabling the simultaneous monitoring of a large set of metabolites in cirrhotic patients with HE, CSF metabolomics highlighted several altered metabolite pathways linked to ammonia metabolism, neurotransmission and energy metabolism. The pharmacological relevance of our findings has to be explored on animal models, as they could constitute interesting new therapeutic targets.

P0649 FREQUENCY OF HEPATIC HYDROTHORAX AND ITS RELATIONSHIP WITH SERUM ALBUMIN IN LIVER CIRRHOSIS PATIENTS

D. A. Kalhoro[1]
[1]*Medicine, Dow University of Heailth Sciences Karachi, Karachi, Pakistan*

Contact E-mail Address: draman_ullah2000@yahoo.com
Introduction: Cirrhosis is defined as the development of regenerative nodules surrounded by fibrous bands in response to chronic liver injury, which leads to portal hypertension and end-stage liver disease[1]. Patients with cirrhosis can develop several pulmonary conditions related to portal hypertension, including hepatopulmonary syndrome, porto pulmonary hypertension, spontaneous bacterial empyema and hepatic hydrothorax[2]. Hepatic hydrothorax (HH) is defined as the accumulation of significant pleural effusion (>500ml) in patients with cirrhosis without primary pulmonary or cardiac disease[3].
Aims & Methods: All patients with established diagnosis of decompensated chronic liver disease were included in study after getting a written informed consent.
After detailed history, thorough physical examination and routine laboratory investigations, chest X-ray chest and abdominal ultrasound were carried out in all patients to find out the presence of pleural effusion and ascites respectively. Fifty milliliters of pleural fluid was aspirated in all patients with pleural effusion using the transthoracic approach, taking ultrasound guidance wherever required. Fluid was sent for microscopic, biochemical, microbial analysis. SBEM defined when if pleural fluid with polymorphonuclear (PMN) cell count >500 cells/mm3 or positive culture with PMN cell count >250 cells/mm3 with exclusion of a parapneumonic effusion.
Results: Two hundred and six patients who met the inclusion criteria were included in the study with mean age of 41.25 ± 13.593 years. Among those 149 (72.3%) were males and 57 (27.7%) were females. Twenty three (11.2%) had hydrothorax; with right sided involvement was in 18 (78.3%) subjects, 3 (13%) had left sided while bilateral pleural effusion was found in 2 (8.7%) cases. SBEM was found in 07 (30.43%) cases. Mean serum albumin 3.125 ± 0.718 gram/dl. There was lack of correlation between serum albumin levels and hydrothorax but significant association with Child Pugh scoring system.
Conclusion: Our study highlighted the high frequency of hepatic hydrothorax having a significant association with hepatic function as assessed by Child Pugh scoring system but lack of correlation with serum albumin.

P0650 COMPARATIVE EVALUATION OF MELD AND CHILD-PUGH SCORES IN PROGNOSIS OF CIRRHOSIS

M. Fragaki[1], D. Sifaki-Pistolla[2], A. Afgoustaki[1], A. Voumvouraki[1], M. Koulentaki[1], D. Samonakis[1], **E. Kouroumalis**[1]
[1]*Gastroenterology,* [2]*Social Medicine, University of Crete Medical School, Heraklion, Greece*

Contact E-mail Address: kouroum@med.uoc.gr
Introduction: The existence of reliable prognostic indices is of paramount importance in the management of cirrhosis. The MELD score and its modifications are widely used. However there have been reports that the older Child-Pugh scores are equally effective and due to their simplicity they should be used instead.
Aims & Methods: The aim therefore was to compare the prognostic accuracy of MELD,MELDNa, Child-Pugh and the corrected for Creatinine Child-Pugh score in a genetically homogeneous Cretan cirrhotic population. 195 cirrhotics (127 males, Median age 66 years) hospitalized in the past 2 years were studied and MELD, MELDNa, Child-Pugh (CP-I) and Child-Pugh adding 0-4 points according to Creatinine value (CP-II) was calculated. 142 were presented with decompensated cirrhosis.
Results: Median values were: MELD 14 (range 6-30), MELDNa 17 (range 6-33), CP-I 7 (range 5-13) and CP-II 8 (range 5-17). ROC curves for 6 and 12 months mortality showed that MELD and MELDNa were significantly better ($p < 0.001$) for prognosis. Areas under the curve for 6 and 12 month mortality were 0.776 and 0.766 for MELD and 0.798 and 0.786 for MELDNa. There was no difference between the two. MELD and MELDNa were also superior to CP-I and CP-II when only decompesated cirrhosis was evaluated.
Conclusion: MELD and MELDNa are better prognostic indicators of mortality in cirrhosis and should be preferred to the Child-Pugh scores.
Disclosure of Interest: None declared

P0651 KIDNEY DISFUNCTION: MAIN MARKER OF INTRA-HOSPITAL MORTALITY ASSOCIATED WITH SPONTANEOUS BACTERIAL PERITONITIS

E. Gravito-Soares[1], M. Gravito-Soares[1], C. Lérias[1], C. Sofia[1]
[1]*Gastroenterology, Centro Hospitalar e Universitário Coimbra, Coimbra, Portugal*

Contact E-mail Address: es18497@gmail.com
Introduction: Liver cirrhosis is often complicated by spontaneous bacterial peritonitis (SBP), being the kidney dysfunction common and associated with elevated mortality. Risk stratification improves prognosis. Some studies assessed predictors of severity in SBP, with controversial results.
Objective: To evaluate the predictive factors and prognosis scores in SBP.
Aims & Methods: A retrospective study of 143 consecutive episodes of SBP, between 2009 and 2014. It was evaluated the association between intra-hospital mortality and clinical and analytical variables (serum and ascitic fluid) in the diagnosis of SBP and prognostic scores: the modern acute kidney injury network (Akin) criteria, Akin progression in the first 48 hours, the simplified model of prognosis (PCR >6, age >6years and Platelet <100000) and the Model 11/22 (White blood cell >11000 and MELD >22).
Results: At admission, kidney dysfunction (Cr > 1.5 and/or urea > 30) was presented in 55.9% of patients (oligoanuric in 38.8%). The progression of kidney dysfunction in first 48 hours occurred in 50.0% of patients. The intra-hospital fatal outcome occurred in 35.0% of the cases and 80.0% in the first 30 days. The mortality associated with Akin 0, 1, 2, and 3 was respectively 10.1%, 33.3%, 57.1% and 66.7%. Oligoanuria at admission (OR 4.950; $p = 0.008$), lower serum sodium (OR 1.094; $p = 0.031$), higher total bilirubin (OR 1.166; $p = 0.002$), higher serum urea (OR 1.042; $p = 0.001$), higher Akin at admission (OR 3.144; $p = 0.009$) and Akin progression (OR 3.607; $p = 0.010$) were independent predictors of poor prognosis. Of prognostic scores, the progression of Akin (AUROC 0.779; $p < 0.001$) and Akin at admission (AUROC 0.672; $p = 0.001$) had more accuracy to prognosis assessment of SBP, followed by the Model 11/22 (AUROC 0.641; $p = 0.006$).
Conclusion: Kidney dysfunction is common in liver cirrhosis complicated by SBP, being the main predictor of intra-hospital mortality. The Akin has good applicability in the selection of patients with severe SBP. Therapy with albumin, vasopressors and admission in the intensive care unit should be early started in cases of kidney dysfunction at admission and progression of that within the first 48 hours.

P0652 SECONDARY BACTERIAL PERITONITIS IN CIRRHOSIS LIVER: A RARE OR UNDERDIAGNOSED CONDITION?

E. Gravito-Soares[1], M. Gravito-Soares[1], C. Lérias[1], C. Sofia[1]
[1]*Gastroenterology, Centro Hospitalar e Universitário Coimbra, Coimbra, Portugal*

Contact E-mail Address: es18497@gmail.com
Introduction: Secondary bacterial peritonitis (SeBP) in liver cirrhosis represents an often underdiagnosed entity with high morbidity and mortality. It early recognition improves the prognosis. Studies about this clinical condition are scarce.
Objective: To determine the frequency, clinic and prognosis of SeBP in liver cirrhosis.
Aims & Methods: A retrospective study of 250 cirrhotic patients admitted for bacterial peritonitis, between 2006 and 2014. These were selected all patients with SeBP (G1: 19patients) and compared with patients with spontaneous bacterial peritonitis (SBP) (G2: 143patients).
Results: The secondary etiology of bacterial peritonitis occurred in 7.6% of patients (male: 63.2%, mean age 60.58 ± 12.06 years). This condition was not recognized in 26.3% of cases. At admission, 47.4% showed signs of peritoneal irritation. Relatively to Runyon's criteria, 73.3% had ≥2 criteria and 40.0% all criteria, with a sensitivity of 73.3% and specificity of 86.9%. The culture of ascitic fluid was polymicrobial in 69.2%(vs 14.3%; $p < 0.001$). The factors associated to SeBP were an increased LDH and Glucose < 50 in ascitic fluid (1219.79 ± 185.47 and 1632.02 vs 168.05 ± 46.7% vs 8.04%; $p < 0.001$). For patients with SeBP undergoing surgery (42.1%) appears to be a tendency to lower mortality (62.5% vs 72.7%; $p = 0.275$), with a surgical timing higher in patients who did not survive (18.00 ± 23.43 vs 3.83 ± 13.91; $p = 0.047$). The intra-hospital mortality associated with SeBP was 68.4%(vs 34.96%; $p = 0.005$). The corticosteroids (30.0% vs 0.0%; $p = 0.035$), higher serum LDH (292.70 ± 297.38 vs 165.33 ± 48.24; $p = 0.048$), ascitic glucose < 50 (77.8% vs 0.0%; $p = 0.012$), higher INR (2.33 ± 1.28 vs 1.48 ± 0.33; $p = 0.022$), higher MELD-Na (27.31 ± 8.46 vs 20.50 ± 4.23; $p = 0.037$) and higher CLIF-SOFA (11.15 ± 4.52 vs 6.17 ± 1.60; $p = 0.012$) were associated

with higher risk of mortality. The CLIF-SOFA and MELD-Na scores were good predictors of intra-hospital mortality by SeBP (AUROC 0.859[0.000;1.000]; p = 0.014 and 0.750[0.531;0.969]; p = 0.047).
Conclusion: Although infrequent, the SeBP have the double mortality of SBP. The Runyon's criteria and polymicrobial culture are good indicators of presence of intra-abdominal infection. Corticosteroid therapy, elevated INR, MELD-Na > 22.5 and CLIF-SOFA > 6.5 allows identify the patients at higher risk of mortality, that will benefit from more timely combined approach (medical and surgical).

P0653 EFFECT'S EVALUATION OF THE TREATMENT WITH CARVEDILOL VERSUS PROPRANOLOL PLUS LOSARTAN ADMINISTRATION ON HEPATIC HAEMODYNAMIC PARAMETERS IN PATIENTS WITH LIVER CIRRHOSIS

E. Tcaciuc[1], S. Matcovschi[1], D. Medvetchi-Munteanu[1], A. Tcaciuc[1], N. Nacu[1], L. Vlasov[1]
[1]*Chair of Internal Medicine, State University of Medicine and Pharmacy ''Nicolae Testemitanu", Chisinau, Moldova, Republic of*

Contact E-mail Address: eugentcaciuc@yahoo.com
Introduction: Primary prevention of variceal bleeding is an important and long-debated topic in the management of patients with cirrhosis and portal hypertension. Non-selective β-blockers are recommended for primary prophylaxis of variceal bleeding in patients with oesophageal varices. Carvedilol appears to be more effective than propranolol in the treatment of portal hypertension in cirrhotic patients [1,2]. Losartan, a specific angiotensin II receptor antagonist, has beneficial effects on splanchnic hemodynamics and liver fibrosis [3].
Aims & Methods: We have examined the efficacy of the treatment with Carvedilol versus combination therapy with Propranolol plus low dose Losartan on hepatic haemodynamic parameters in patients with liver cirrhosis. The study included 64 patients with liver cirrhosis of viral HBV or HCV etiology with different cirrhotic stage. We evaluated the portal system and hepatic artery before and after 6 months of treatment using duplex Doppler ultrasonography. 34 patients (gr. 1) received Carvedilol (6.25 - 25 mg/day) and 30 patients (gr. 2) received Propranolol (30 - 120 mg/day) plus Losartan (12.5 - 25 mg/day).
Results: Administration of Carvedilol, such as administration of Propranolol and Losartan improves hepatic haemodynamics parameters in cirrhotic patients. The diameter of portal vein the same decreased in gr. 1 and gr. 2 (15.1 ± 0.6% vs 15.8 ± 0.7%, p > 0.05). Portal blood flow velocity significantly increased in gr. 2 versus gr. 1 (15.3 ± 0.8% vs 11,2 ± 0.6%, p < 0.05) and hepatic artery resistance index significantly decreased in gr. 2 versus gr. 1 (16.1 ± 0.9% vs 10.7 ± 0.8%, p < 0.05). The mean arterial pressure insignificantly decreased in both groups (p > 0.05).
Conclusion: Our study indicates that the combination treatment with Propranolol and Losartan in patients with liver cirrhosis significantly improve portal blood flow velocity and hepatic artery resistance index, probably, because Losartan contributes to decrease the intrahepatic vascular resistance in cirrhotic patients more than Carvedilol.

P0654 HOW TO PREDICT NONINVASIVELY THE PRESENCE OF OESOPHAGEAL VARICES?

F. Dias De Castro[1], P. Boal Carvalho[1], C. Marinho[1], J. Cotter[1,2]
[1]*Gastroenterology, Centro Hospitalar do Alto Ave – Guimarães, Portugal, Guimarães,* [2]*Life and Health Sciences Research Institute, Universidade do Minho, Braga/Guimarães, Portugal*

Contact E-mail Address: franciscadcastro@gmail.com
Introduction: Upper gastrointestinal endoscopy, despite being an invasive diagnostic procedure, is yet the gold-standard to evaluate the presence oesophageal varices in cirrhotic patients. Non-invasive methods are currently being developed in order to obviate the need for endoscopy.
Aims & Methods: The aim of our study was to assess the diagnostic accuracy of non-invasive methods that quantify hepatic fibrosis in predicting the presence of oesophageal varices.
Retrospective study including 150 patients with compensated cirrhosis of various aetiologies who performed upper endoscopy to assess the presence of oesophageal varices. Clinical, laboratorial, ultrasonography and endoscopic features were analyzed. The non-invasive methods evaluated were APRI score (AST/ platelet ratio index), SPRI score (spleen size/ platelets ratio), Fib-4 score (based on patients' age, platelet count, AST and ALT) and FibroQ (based on patients' age, platelet count, AST, ALT and INR).
The ability of the scores to predict oesophageal varices was assessed by the area under the ROC curve (AUROC).
Results: 150 patients included, 75% male with mean age 59 ± 10 years. On upper endoscopy, 120 patients (80%) had oesophageal varices. The APRI score better predicted oesophageal varices (AUROC 0.737; CI 95% 0.628-0.847), followed by Fib-4 (AUROC 0.709; CI 95% 0.606-0.813), SPRI (AUROC 0.706; CI 95% 0.596-0.816) and finally FibroQ (AUROC 0.678; CI 95% 0.572-0.785). For APRI score the best *cut-off* values were 0.87 with a sensitivity of 71%, specificity of 80%, positive predictive value of 93% and negative predictive value of 41%.
Conclusion: Among the studied scores, the APRI score proved to be a non-invasive method with good ability to predict the presence of oesophageal varices - an APRI value greater than 0.87 predicts the identification of oesophageal varices on endoscopy in 93% of the cases. This score, easy to use and readily accessible in clinical practice, may be valuable in a careful selection of patients with cirrhosis for early referral to upper gastrointestinal endoscopy.

P0655 DEVIATIONS IN PERIPHERAL BLOOD CELL POPULATIONS ARE ASSOCIATED WITH THE STAGE OF PRIMARY BILIARY CIRRHOSIS

H. Cichoż-Lach[1], E. Grywalska[2], A. Kowalik[1], J. Roliński[2], K. Celiński[1], B. Kasztelan-Szczerbińska[1]
[1]*Department of Gastroenterology,* [2]*Department of Clinical Immunology, Medical University of Lublin, Lublin, Poland*

Contact E-mail Address: lach.halina@wp.pl
Introduction: Primary biliary cirrhosis (PBC) is a chronic cholestatic liver disease characterized by progressive destruction of small size intrahepatic bile ducts leading to cirrhosis. Among genetic, environmental, also immunological factors have conclusively been shown to contribute to the pathogenesis of PBC. The role of peripheral blood cell subpopulations, particularly Treg and Th17 in PBC pathogenesis remains still uncertain.
The aim of this research was to describe the percentages and absolute counts of Th17, Treg in patients with newly diagnosed PBC and the relationships between analyzed cell subsets and selected clinical parameters (itching and the degree of PBC severity).
Aims & Methods: The frequencies of Treg and Th17 were measured by flow cytometry in 40 previously untreated female patients with PBC. The control group consisted of 20 healthy age- and sex-matched volunteers.
The diagnosis of PBC was based on the common known criteria. The degree of severity of PBC was evaluated in each patient by histologic examination.
Results: Significantly lower frequencies and absolute counts of CD4(+)CD25(+)FoxP3(+) Treg cells were found in the study group in comparison with controls (p < 0.0001).
Higher percentages and absolute counts of IL-17A(+)CD3(+)CD4(+) Th17 lymphocytes were found in the PB of PBC patients than in the control group (p < 0.0001).
Among 40 patients with PBC, 7 showed the I stage of severity- portal stage, 16 patients the II stage- periportal stage, 11 the III - septal stage, and 6 patients the IV stage – cirrhosis. Itching of the skin was observed in 18 patients with PBC.
The frequencies and absolute counts of CD4(+)CD25(+)FoxP3(+) Treg cells correlated with the degree of severity of PBC however not with itching. The correlation between frequencies and absolute counts of IL-17A(+)CD3(+)CD4(+) Th17 lymphocytes and histological stage of PBC and/ or presence of itching was not observed.
Conclusion: The study demonstrates that both Treg and Th17 cells might play an important role in the pathogenesis of PBC. The reduced number of Treg cells and higher levels of Th17 cells in PBC could be responsible for the loss of immune tolerance and development of inflammatory and autoimmune process in PBC. The counts of Treg cells correlates with the degree of severity of PBC but no with presence of itching. Th17 cells did not show association between histologic stage of PBC and presence of itching.

P0656 RELIABILITY OF SERUM VONWILLBRAND FACTOR ANTIGEN IN PREDICTION OF ESOPHAGEAL VARICES IN PATIENTS WITH LIVER CIRRHOSIS

H. Mahmoud[1], A. Gweil[1], S. Bazeed[1], H. Fayed[2], M. Abdel Meguid[2]
[1]*Tropical Medicine and Gastroenterology,* [2]*Clinical Pathology, South Valley University, Qena, Egypt*

Contact E-mail Address: hassan_sedeek@yahoo.com

Introduction: Bleeding esophageal varices (OV) due to portal hypertension is one of the major complications with high mortality in liver cirrhosis. So, early detection and management is mandatory.

Aims & Methods

Aim: To evaluate the role of Vonwillbrand factor in predicting the presence of OV.

Patients and methods: 62 patients with liver cirrhosis representing different Child-Pugh classes were included. The diagnosis of liver cirrhosis was based on the combination of clinical, laboratory and US examinations. All included patients were underwent the following investigations: complete blood count, liver function tests (ALT, AST, serum bilirubin, albumin and total protein, prothrombin time (PT) and concentration (PC), INR and serum alkaline phosphatase), serum creatinine, Vonwillbrand factor antigen measurement and abdominal US. Upper endoscopic evaluation was done to detect presence or absence of varices (oesophageal or gastric) and/or PHG.

Results: 38 males and 24 females with their main age 46± 12 years old were included. Absence of OV (NO) was found in 22(35.5%) patients and presence of OV were found in 40(64.5%) patients; whom were as follow: 12(19.3%) patients were G1, 14(22.6%) were G2 and 14(22.6%) were G3. Gastric varices were found in 5(8%) patients and portal hypertensive gastropathy in 40(64.5%) patients. Serum Vonwillbrand factor-Ag level was significantly higher in patients with O.V than those without varices (p value = 0.000). Also, its level was significantly higher in patients with higher grade of OV; G3 than those with G1 or G2 (p value = 0.000). Patients with large OV including those with G2 and G3 showed statistically significant higher values of Vonwillbrand factor than those with small OV (NO and G1) (p value = 0.000). Vonwillbrand factor was independent predictor for detecting the presence of OV with good sensitivity (90), specificity (77.3) and accuracy (85.5) when its cutoff value was at 1.74. Also it was independent predictor for detecting the presence of large OV with good sensitivity (91.2), specificity (85.7) and accuracy (88.7 when its cutoff value was at 2.16.

Conclusion: Vonwillbrand factor antigen could be used as non invasive laboratory independent predictor for the presence of esophageal varices.

P0657 THE EFFECT OF NON-SELECTIVE BETA-BLOCKERS ON SURVIVAL IN DECOMPENSATED LIVER CIRRHOSIS PATIENTS

I. Girleanu[1], A. Trifan[1], C. Cojocariu[1], A. M. Singeap[1], A. Rohozneanu[1], S. Chiriac[1], C. Stanciu[1]
[1]*Gastroenterology, University of Medicine and Pharmacy Iasi, Romania, Iasi, Romania*

Contact E-mail Address: gilda_iri25@yahoo.com

Introduction: Recent studies evaluating outcomes associated with nonselective beta-blockers (NSBB) in cirrhosis have yielded mixed results (1). Due to their effect on cardiac output and on intestinal permeability, NSBB have been hypothesized to increase the risk of mortality especially in advanced liver disease (2). The aim of this study was to assess the effect of NSBBs on survival in decompensateted liver cirrhosis patients.

Aims & Methods: Liver cirrhosis patients who were admitted to our tertiary center from January 2005 to December 2005 were enrolled, and survival data until December 2014 was measured. Stratified randomization according to the Child–Pugh class and age was done and a total of 702 patients were divided into beta-blocker group (Propranolol, 40 mg/day) and non beta-blocker group. Overall survival and predictors of mortality were evaluated.

Results: There were 702 cirrhotic patients included in the study, mean age 55.82 ± 11.52 years, 392 (55.8%) males. Out of these 340 patients (48.8%) received NSBB treatment. There was no significant difference of survival (P = 0.321) and infection free survival (P = 0.910) between two groups. Two subgroups analyses according to the Model of End Life Disease (MELD) (MELD < 15, and MELD ≥ 15) also showed no significant difference of survival and infection free survival. Significant univariate predictors of death were age, Child–Pugh score, MELD score, prothrombin time, total bilirubin, albumin, and aspartate aminotransferase. The independent predictors of mortality were Child–Pugh score, and MELD score. Presence of esophageal varices was not predictor of mortality.

Conclusion: Non-selective beta-blockers have no effect on survival and infection free survival in cirrhotic patients. That means that NSBBs may not be used for the purpose of improving survival in decompensated liver cirrhosis patients.

P0658 TERLIPRESSIN-INDUCED HYPONATREMIA IN CIRRHOTIC PATIENTS WITH VARICEAL BLEEDING

I. Girleanu[1], A. Trifan[1], O. C. Stoica[1], C. Cojocariu[1], A. M. Singeap[1], C. Sfarti[1], C. Baluta[1], C. Stanciu[1]
[1]*Gastroenterology, University of Medicine and Pharmacy Iasi, Romania, Iasi, Romania*

Contact E-mail Address: gilda_iri25@yahoo.com

Introduction: Terlipressin is frequently used in acute variceal bleeding due to its important effect on vasopressin V1 receptors. Terlipressin has agonistic effects on the V1 receptor and partial agonistic effects on renal vasopressin V2 receptors. However, its effects on serum sodium concentration are controversial. The aim of this study was to examine the effects of terlipressin on serum sodium concentration in cirrhotic patients with variceal bleeding.

Aims & Methods: All consecutive cirrhotic diagnosed with variceal bleeding treated with terlipressin were investigated Terlipressin induced hyponatremia was defined as a decrease in serum sodium (Na) level of >5 mEq/L from the baseline level. Main outcome measure was fall in Na level during and up to 5 days post therapy.

Results: The study included 214 patients (mean age, 54.3 ± 10.7 y) with male predominance (60.7%). Median Na pretreatment was 130.0 ± 6.5 mmol/L and 126/214 (58.87%) had existing hyponatraemia. Serum sodium level was at the baseline 130.0 ± 6.5 mmol/L and 131.4 ± 6.2 mmol/L after 5 days of terlipressin treatment (P = 0.758) in all patients. Changes in serum Na levels from baseline were 0.2 ± 1.2 whereas the frequencies of terlipressin-indiced hyponatremia was 6.07% (13 patients). Occurrence of hyponatremia was related neither to duration or dosage of terlipressin treatment but with the severity of the underlying chronic liver disease. No complications of hyponatremia were observed.

Conclusion: Terlipressin-induced hyponatremia was uncommon in cirrhotic patients with variceal bleeding. Hyponatremia was related with the severity of the underlying liver cirrhosis.

P0659 ANTIVIRAL THERAPY IMPROVES POST-TRANSJUGULAR INTRAHEPATIC PORTOSYSTEMIC SHUNT SURVIVAL IN PATIENTS WITH HEPATITIS B VIRUS-RELATED LIVER CIRRHOSIS

J. Lin[1], B. Wei[1], C. Tang[1]
[1]*Department of Gastroenterology, West China Hospital, Sichuan University, P. R. China, Chengdu, China*

Contact E-mail Address: shcqcdmed@163.com

Introduction: Antiviral treatment has been shown to be effective in patients with hepatitis B virus (HBV)-related decompensated cirrhosis. However, the effect of antiviral therapy in the subset of post-transjugular intrahepatic portosystemic shunt (TIPS) patients with HBV-related decompensated cirrhosis is uncertain.

Aims & Methods: From January 2007 to December 2012, a total of 211 patients who underwent TIPS for variceal bleeding or refractory cirrhosis due to HBV-related cirrhosis were included in this prospective cohort study. Of these, 124 (58.7%) patients started antiviral therapy before or after TIPS foremed the antiviral group, and the remaining 87 (41.3%) patient formed untreated group. The primary endpoint was transplant-free survival. The secondary endpoints included recurrent variceal bleeding, occurrence of complications and shunt dysfunction.

Results: The baseline characteristics were comparable in the two groups. Antiviral used included adefovir (n = 49), entecavir (n = 36), lamivudine (n = 29), telbivudine (n = 2), combination of lamivudine and adefovir (n = 7), and combination of lamivudine and telbivudine (n = 1). Among the patients in antiviral group, 20 died during the study period, as compared with 33 patients in the untreated group. Patients in antiviral group had a significantly better transplant-free survival ($P = 0.004$, by the log-rank test). The cumulative survival rates at 1, 2, and 3 year were 93.742%, 89.466% and 85.671% in the antiviral group, and 86.207%, 71.034% and 64.284% in the untreated group, respectively. Patients who started antiviral therapy before TIPS had better survival than post-TIPS antiviral patients. The use of antiviral therapy, age and MELD score were the independent predictors for survival. The incidence of HCC tend to be lower in the antiviral group, and the difference was borderline significant ($P = 0.053$). The cumulative incidence of HCC at 1, 2, and 3 year were 2.639%, 6.291% and 9.836% in the antiviral group, and 3.949%, 14.970% and 19.118% in the untreated group, respectively. The incidence of variceal rebleeding and primary shunt patency were not significantly different between the two groups (P = 0.126, P = 0.330 respectively).

Conclusion: Antiviral interventions improves survival in post-TIPS patients with HBV-related decompensated cirrhosis, especially in those with early treatment. This result underscore the use of antivirals as a mandatory etiology treatment in patients who underwent TIPS.

P0660 HIGH INCIDENCE OF RESISTANCE TO THIRD-GENERATION CEPHALOSPORINS IN CIRRHOTIC PATIENTS IN A PORTUGUESE GASTROENTEROLOGY DEPARTMENT

J. Carmo[1], M. A. Túlio[1], S. Marques[1], M. Bispo[1], M. A. Pessanha[2], C. Toscano[2], C. Chagas[1]
[1]*Gastroenterology,* [2]*Microbiology, Hospital Egas Moniz, Lisboa, Portugal*

Contact E-mail Address: joanavcarmo@gmail.com

Introduction: Bacterial infections are one of the main causes of decompensation in cirrhosis and contribute significantly for morbidity and mortality in cirrhotic patients.

Aims & Methods

Aims: Characterize the infections and microbiological agents in patients admitted for decompensated cirrhosis in a Gastroenterology Department in Portugal. Analyze the antibiotic therapy used in these patients and its effectiveness.

Methods: Retrospective analysis of incoming patients admitted for decompensated cirrhosis in 2013 in a Portuguese Gastroenterology Department. Clinical/demographic (cirrhosis' etiology, Child-Pugh score, previous hospitalizations,

antibiotic therapy, inpatient outcome) and microbiologic (infections' focus, agents and its sensibility profile) data were analysed.
Results: 95 patients were admitted for decompensated cirrhosis. Bacterial infections were the cause of decompensation in 54% (n = 51). Average age: 67 years; > 50% with advanced (Child-Pugh C, 71%) and alcoholic cirrhosis; average time of hospitalization: 11 days. We diagnosed 30 cases of health care-associated infections, 16 community-acquired infections and 5 nosocomial infections. The most frequent infection was urinary tract infection (47%, n = 24), followed by spontaneous bacterial peritonitis and respiratory tract infections, with the same incidence (22%, n = 11). The most commonly used empirical antibiotic therapy was third-generation cephalosporins (35%, n = 18), amoxicillin/clavulanic acid (22%, n = 11) and quinolones (17%, n = 9). In 45% of the patients, no agent was isolated. In the remaining patients, 36 agents were isolated. Two thirds were Gram negatives and *E. coli* was the most frequent. 40% of the agents were resistant to third-generation cephalosporins. Ten agents were multiresistant bacteria (four *extended-spectrum β-lactamase-producing enterobacteriaceae* and one *vancomycin-resistant enterococcus*). Hospitalization in the previous 90 days was related with infection by multiresistant agents ($p < 0.05$).
Conclusion: The difficulty in obtaining a microbiological isolate, makes antibiotic choice more challenging. Although third-generation cephalosporins continue to be a first-line antibiotic in patients admitted for decompensated cirrhosis, we found a significant resistance rate to these antibiotics. In the choice of antibiotic therapy, hospitalization in the last 90 days should also be considered because multiresistant bacteria involvement is more probable.

P0661 LIVER CIRRHOSIS DOES NOT IMPAIR THE SHORT-TERM OUTCOME IN PEPTIC ULCER BLEEDING

J. M. Petersen[1], A. Krag[1], O. B. Schaffalitzky de Muckadell[1], S. B. Laursen[1]
[1]*Department of Medical Gastroenterology, University of Southern Denmark, Odense, Denmark*

Contact E-mail Address: jmpetersen@health.sdu.dk

Introduction: Variceal bleeding in patients with liver cirrhosis is associated with a considerable mortality around 10-20%. The outcome of peptic ulcer bleeding (PUB) in patients with liver cirrhosis compared to patients without cirrhosis has not been studied in detail.
Aims & Methods: Data were prospectively collected from consecutive patients admitted with PUB at our department through an 11-year period. We compared patient characteristics, bleeding episode, and outcome between patients with liver cirrhosis and patients without cirrhosis.
Results: A total of 1002 patients were admitted with PUB during the period of inclusion. Thirty-five (3.5%) patients had cirrhosis. Compared to patients without liver cirrhosis patients with cirrhosis were younger (mean age: 58 vs 73 years; $p < .001$), were more often males (74% vs 54%; $p = .02$), more frequently had hemodynamic shock at time of admission to hospital (46% vs 29%; $p = .039$), a higher ASA-score ($p = .005$), high intake of alcohol (79% vs 12%; $p < .0001$), high frequency of daily smokers (78% vs 32%), and a longer duration of admission to hospital (mean: 7.5 vs 5.6 days; $p = .018$). However, patients with cirrhosis was only rarely diagnosed with cardiac disease (5.7% vs 42%; $p < .0001$) and only few had intake of aspirin (14% vs 50%; $p = .001$). There were no differences in B-hemoglobin (5.1 vs 5.4mmol/L), duodenal ulcer location (71% vs 57%), high-risk stigmata of bleeding (37% vs 39%), rate of rebleeding (20% vs 16%), or in-hospital mortality (8.6% vs 5.3%).
Conclusion: Patients with PUB and cirrhosis are younger and only rarely diagnosed with cardiac comorbidity compared with PUB-patients without cirrhosis. Nevertheless, patients with cirrhosis and PUB have a high level of non-cardiac comorbidity and negative lifestyle factors that may explain the lack of difference in short-term mortality. Beside a difference in rate of hemodynamic shock, that may be explained by impaired cardiac response in cirrhotics, the character and severity of PUB seem similar in both groups of patients.

P0662 THE PREVALENCE, PROGNOSIS AND OUTCOME OF SIRS, SEPSIS AND SEVERE SEPSIS IN PATIENTS WITH CIRRHOSIS OF THE LIVER

S. Sheetal[1], **K. T. Shenoy**[2]
[1]*Neurology, Pushpagiri Medical College and Hospital, Tiruvalla,*
[2]*Gastroenterology, Sree Gokulam Medical College and Research Foundation, Venjaramoodu, India*

Contact E-mail Address: drktshenoy@gmail.com

Introduction: Cirrhotic patients are particularly susceptible to bacterial infections. Once an overt infection occurs, it may lead to systemic inflammatory response syndrome (SIRS)/sepsis which can precipitate hypotension (severe sepsis), renal dysfunction, encephalopathy, and coagulopathy, that is, multi organ failure. We studied sepsis and severe sepsis in a tertiary hospital in S India.
Aims & Methods
Aims: To estimate the prevalence of SIRS, sepsis and severe sepsis in patients with cirrhosis of liver and to study the pattern of clinical presentation; to assess the correlation between CRP and clinical outcomes in these patients and to elucidate the prognostic factors related to progression of disease and/ or death.
Methods: 70 patients with cirrhosis were prospectively evaluated at baseline, 3, 6, 9 and 12 months of follow up for sepsis, severe sepsis and septic shock and complications related to cirrhosis such as SBP, hepatorenal syndrome and mortality. Sepsis was diagnosed by CRP levels and culture of blood and urine. Data were analysed for study variables and survival.
Results: 70 patients (64 males and 6 females)in the age group of 30 -80 years were studied. 32.9% belonged to the 40-50 year age group. The mean age was 55.6 ± 10.1 years.The clinical presentation of patients with cirrhosis were as follows: melena in 57.1%; hematemesis and abdominal distension in 39 patients (55.7%). Alcohol consumption accounted for cirrhosis in 72.9%, Hepatitis B infection and concomitant alcohol intake in 11.4%, isolated Hepatitis B infection in 2.9% and Hepatitis C infection in 1.4%. No cause could be identified 10%.2 patients (2.9%) had SIRS, 12 patients had sepsis (17.1%), 6 had severe sepsis (8.6%), and 7 had septic shock (10%). Spontaneous bacterial peritonitis accounted for 48% of infections, followed by equal percentage of urinary tract infection, pneumonia and cellulitis (16% each), bacteremia was seen in 4%. CRP was positive in 25 patients (35.7%) and negative in 45 (64.3%). 29 patients (41.4%) hepatic encephalopathy; 18 had hepato renal syndrome (25.7%) and a total of 24 patients expired (34.3%). A statistically significant correlation was noted between CRP positivity and sepsis (p value- 0.000), severe sepsis (p value -0.001) and septic shock (p value -0.007), SBP (p value 0.000), UTI (p value -0.014) pneumonia (p value -0.014), hepatic encephalopathy (p value 0.000), hepatorenal syndrome (p value 0.000) and death (p value 0.000). A statistically significant correlation with mortality was established for severe sepsis (p 0.016), septic shock (p-0.000), SBP (P value 0.000), UTI (p 0.012), hepatic encephalopathy and hepatorenal syndrome. (p value- 0.000). 12 patients had SBP during their initial presentation. The prevalence of SBP at 3, 6,9,12 months was 7(10%), 8(11.4%), 3(4.3%), 5(7.1%). 24 patients had expired at the end of 1 year and 4 were lost to follow up.malaena was the presenting feature in 40 patients.
Conclusion: There was high prevalence of sepsis and severe sepsis with a high mortality at 1 year of follow up.
Disclosure of Interest: None declared

P0663 THE EFFECT OF LACTULOSE, RIFAXIMIN, L-ORNITHINE L-ASPARTATE, THEIR COMBINATION ON MINIMAL HEPATIC ENCEPHALOPATHY TREATMENT

K. Elnoemany[1], A. Alghoraieb[1], N. shebl[1], T. salman[1], E. reweisha[1], on behalf of National Liver Institute
[1]*Hepatology, National Liver Institute, Shebin Elkom, Egypt*

Contact E-mail Address: dr_kareemn@yahoo.com

Introduction: Minimal hepatic encephalopathy (MHE) is observed in 84% of patients with liver cirrhosis without the presence of overt HE. It adversely affects health-related quality of life (HRQOL).
Aims & Methods
Aim: to compare lactulose, rifaximin, L-Ornithine L-Aspartate (LoLa), their combination on MHE treatment and HRQOL.
Methods: After screening for MHE, 126 patients with MHE were assigned for the following treatment regimens; 30-60 ml lactulose twice daily (n = 31), 200 mg rifaximin thrice daily (n = 32), 6 g LoLa thrice daily (n = 32), and combined therapy (n = 31). All patients were assessed by critical flicker frequency (CFF), number connection test (NCT), serial dotting test (SDT), ammonia and sickness impact profile (SIP) questionnaire at baseline and two consecutive months.
Results: By repeated measure ANOVA test, there was favorable treatment induced changes in all groups concerning the three consecutive values of CFF (36.6 vs. 31.33 vs. 38.09 Hz; $p = 0.001$ except LoLa; $p = 0.167$), NCT (-2.5 vs. -1.15 vs. -0.9 SD; $p = 0.001$), SDT (-2.6 vs -1.27 vs. -1.07 SD; $p = 0.001$), ammonia (85.75 vs. 76.93 vs. 69.65 mmol/l; $p = 0.001$ except rifaximin; $p = 0.50$) and SIP questionnaire score (24.75 vs. 16.1 vs. 16.31; $p = 0.001$). The overall comparison of all groups was insignificant ($p > 0.05$). The predictors of MHE were age (odds = 1.069), bilirubin (odds = 5.254), albumin (odds = 0.163), INR (odds = 73.816) and Child-Pugh score (odds = 2.459).
Conclusion: Lactulose, rifaximin, LoLa, their combination are the same on MHE treatment and HRQOL.

P0664 NUTRITIONAL STATUS OF CIRRHOTIC PATIENTS IN A REFERRAL CENTRE FOR LIVER DISEASE IN CRETE GREECE

D. Sifaki-Pistolla[1], A. Markaki[2], J. Galanos[2], M. Christodoulaki[2], A. Mantaka[3], A. Augoustaki[3], V. Zafiropoulos[2], **E. Kouroumalis**[3], M. Koulentaki[3]
[1]*Clinic of Family and Social Medicine, Faculty of Medicine University of Crete, Heraklion,* [2]*Nutrition & Dietetics, Technological Educational Institute of Crete, Sitia,* [3]*Gastroenterology, University Hospital Heraklion Crete, Heraklion, Greece*

Contact E-mail Address: mkoulentaki@yahoo.gr

Introduction: Prognosis of cirrhotic patients is related to their nutritional status even in the compensated stages. Protein-energy malnutrition is not always recognized by attending physicians.
Aims & Methods: We aimed to assess the nutritional status of Greek cirrhotic patients, followed at the Department of Gastroenterology and Hepatology of the University Hospital of Heraklion (Crete, Greece).

We studied 101 cirrhotic patients (48 compensated, 52 females), median age 67.07 (31-88) years and 71 healthy controls (35 females), median age 66.04 (37-94) years. Cirrhosis etiology was viral hepatitis 43 pts. (23 HCV, 20 HBV), 20 non alcoholic steatohepatitis (NASH), 14 primary biliary cirrhosis (PBC), 5 autoimmune hepatitis (AIH), 14 alcoholic and 3 cryptogenic. Patients with hepatic encephalopathy or active alcohol drinking were not included in the study. MELD score was calculated to assess the severity of liver disease. Nutritional assessment included Body mass index (BMI), anthropometry, handgrip strength, bio-impedance analysis (BIA), the mini nutritional assessment (MNA) questionnaire, the Subjective Global Assessment (SGA) and the Malnutrition Universal Screening Tool (MUST) evaluation.
Comparisons were made by Student's T-test for continuous variables. Fisher's exact probability test and the $\chi 2$ test for the analysis of categorical variables. Spearman's rank coefficient was used for correlations. All tests were made at a 0.05 level of significance.
Results: Median MELD score was 14.6 (SD 2.43),
Parameters with significant differences between groups are shown in the table. MUST score and SGA score also differ significantly between groups ($p < 0.001$). A strongly positive correlation between MELD & MNA (rho = 0.87, p = 0.01) and strongly negative correlations between MELD and phase angle (ϕ) (rho = -0.80, p = 0.01) and MELD & handgrip (rho = -0.79, $p < 0.001$) were found.

Parameters	PatientsMean (SD)	ControlsMean (SD)	p value
BMI	29.85 (5.93)	28.08 (5.68)	**0.04**
MAMC	21.68 (3.29)	23.11 (3.44)	**0.007**
Handgrip (kg)	27.26 (11.61)	42.90 (10.34)	**0.002**
Handgrip <85%	70%	30%	**<0.001**
(BIA) ICW%	45.41 (10.58)	48.93 (9.81)	**0.04**
(BIA) BCM%	46.21 (11.74)	51.61 (11.55)	**0.01**
(BIA)Muscle mass%	37.13 (8.71)	42.90 (10.34)	**0.02**
(BIA) Phase angle (ϕ)	4.9 (1.15)	5.67 (1.22)	**<0.001**
MNA	21.78 (3.94)	23.39 (3.91)	**0.01**

Conclusion: BMI and most anthropometric measurements, except MAMC, did not detect the protein malnutrition of Greek cirrhotic patients. MUST, SGA, MNA, BIA, and handgrip were found all sensitive tools for its detection, the last three also correlating with the severity of liver disease.

Contact E-mail Address: marquarj@uni-mainz.de
Introduction: Untreated hepatorenal syndrome (HRS) is associated with a very bad prognosis in patients with advanced liver cirrhosis. Hepatorenal syndrome is subdivided into a HRS type 1 with a rapid-progressive loss of renal function and a HRS type 2, characterized by chronic ascites and persistently but moderately elevated renal parameters. While treatment with terlipressin and albumin improves renal function in patients with type 1 HRS, it is less clear if this treatment is effective in type 2 HRS.
Aims & Methods: Aim of this study was to examine the effect of treatment with terlipressin and albumin on renal function and survival in patients with HRS type 2.
All patients who presented to our center between April 2013 and February 2015 with a first episode of HRS type 1 or type 2 and who were treated with terlipressin and albumine were included in this observational study. Relevant clinical and laboratory parameters were prospectively examined – e.g. HRS type, baseline liver function, patient characteristics, side effects, renal function and overall survival as well as survival free of renal replacement therapy or liver transplantation.
Results: Overall 80 patients with liver cirrhosis and a first episode of HRS were prospectively followed over a median of 76 days. Most patients had advanced liver disease (Child-Pugh C: 67; 84%). 29 patients had HRS type 1, while 51 patients were diagnosed with a type 2 HRS (36%; 64%). Baseline patient characteristics such as etiology of cirrhosis, Child-Pugh stage, degree of ascites or hepatic encephalopathy grade were similar in both subgroups. As expected, median serum creatinine concentration was significantly higher in patients with HRS type 1 (3.1 vs. 2.4 mg/dl; p = 0.0003). Complete or partial response to terlipressin treatment was observed in 38 and 4 of 80 patients (CR: 48%; PR: 5%). Overall response rates were not significantly different between patients with HRS type 2 and type 1 (52% vs. 53%; p = 0.92). Overall survival and survival free of renal replacement therapy or liver transplantation was comparable too. Response to terlipressin treatment in HRS type 2 was associated with a significantly improved median survival ($p < 0.0001$).
Conclusion: Terlipressin in combination with albumine is effective in HRS type 2 – a response to treatment can be expected in approximately 50% of patients. Response to treatment is an important prognostic indicator as it is associated with improved survival.

P0666 SCREENING FOR HEPATOPULMONARY SYNDROME IN CIRRHOTIC PATIENTS: DIAGNOSTIC APPROACH AND CLINICAL CORRELATIONS

M. Fragaki[1], D. Samonakis[1], S. Koukouraki[2], D. Sifaki-Pistolla[3], M. Koulentaki[1], E. Matrella[1], E. Kouroumalis[1]
[1]*Department of Gastroenterology & Hepatology,* [2]*Department of Nuclear Medicine, University Hospital of Heraklion,* [3]*Department of Social Medicine, University of Crete, Heraklion, Greece*

Contact E-mail Address: mgfragaki@yahoo.gr
Introduction: Hepatopulmonary syndrome (HPS) affects 10-30% of patients with cirrhosis and/or portal hypertension, but is frequently underdiagnosed. It is characterized by the triad of advanced liver disease, arterial hypoxemia and intrapulmonary arteriovenous shunting in absence of primary cardiopulmonary disease. The aim of the study was to screen cirrhotics with arterial blood gases and albumin perfusion scan, identify those fulfilling the classic HPS criteria and correlate with clinical parameters.
Aims & Methods: Data on 102 patients presenting to the Liver Clinic or hospitalized in the Gastroenterology wards within one year and were analyzed. Clinical, metabolic and biochemical variables were measured, as well as MELD MELDNa, and Child-Pugh score, arterial blood gases, alveolar-arterial oxygen gradient [P(A-a)O2] were recorded. All patients underwent Technetium 99m-macroggregated albumin perfusion lung scan (Tc-MAA) and a subset of those had contrast-enhanced transthoracic echocardiography with saline (microbubbles >10μm in diameter). Diagnosis of HPS was based on the presence of the quantitative index Tc-MAA ≥ 6% and a $[P(A\text{-}a)O_2] \geq 15$mmHg ($\geq$20 mmHg for patients over > 64 years).
Results: 61 were male (59.8%) .Median age 66.5 years (range, 31-84). Mean BMI was 27.5 (SD 4.7) and median MELD was 12 (range, 6-22). 66 patients presented with decompensated cirrhosis, 10 with HCC. The mean P(A-a)O2 and P02 were 24 (SD14.1) and 81.3 (SD13.6) mmHg respectively. Patients with concomitant respiratory disease had all P(A-a)O2 > 20mmHg and were not evaluated further for HPS. Average P(A-a)O2 did not differ according to decompensation status (P = 0.6).
Quantitative median index in the Tc-MAA was 6% (range, 1-17). Diagnosis of HPS was made on 24/94 patients. In 8 patients the Tc-MAA scintigraphy could not be interpreted. In the multivariate analysis only the quantitative index was significant for the diagnosis of HPS. (p = 0.001, OR; 95% CI: 7,05; 2,27-21,87) Three patients with positive bubble echo had all quantitative index > 9% in Tc-MAA. The latter index was not statistically correlated with P(A-a)O2, PO2, or MELD score (p = n.s). Five patients died over the short follow-up period with no significant differences in survival time according to P(A-a)O2 or the results of Tc-MAA.
Conclusion: Tc-MAA is a useful screening tool in patients with arterial hypoxemia for complications as HPS which is a frequent complication of cirrhosis. Qualitative analysis is not reliable with false negative and positive results. Quantitative analysis should always be performed.

sCD163 by ELISA. Detailed clinical phenotypes regarding first decompensation event (ascites formation, variceal bleeding[VB], hepatic encephalopathy or systemic bacterial infection[INF]), development of hepatocellular carcinoma[HCC] and mortality were determined prospectively during the follow-up (median[IQR], 778[182-1720] days). Control group comprised 150 healthy subjects (HC).
Results: Serum levels of sCD163 were significantly higher in patients with LC compared to HC (median, 3724 vs. 1104 ng/ml,$p < 0.001$). In LC, sCD163 levels were associated to disease severity, as rated by the Child-Pugh stage ($p < 0.001$) but not to the presence of varices or prior VB. In non-AD patients, sCD163 levels were not able to predict the advent of the first decompensation events, development of HCC and also not the long-term mortality. In patients with AD episodes, sCD163 levels were significantly higher compared to non-AD patients but only in the presence of INF (AD-INF: 4969, AD-NON-INF: 3497 and NON-AD: 3471 ng/ml, $p < 0.001$ for both). Furthermore, during INF episodes ($n = 119$), sCD163 levels were significantly higher in those complicated with organ failure (31%) and increased gradually according to ACLF grade (No-ACLF: 4121, ACLF gr1: 7335, gr2: 7490, gr3: 12610 ng/ml, $p = 0.001$). Rate of 28-day mortality was higher among patients with sCD163 level > 7110 ng/ml compared to those with ≤ 7110 ng/ml (46.5% vs. 15.8%, $p < 0.001$). This cut-off level of sCD163 was associated with a shorter time to death (pLogRank < 0.001) in Kaplan-Meier analysis and was identified as an independent predictor in multivariate Cox- regression model (HR:2.91, 95%CI:1.34–6.32,$p = 0.007$) comprising age, gender, etiology, co-morbidity and MELD score as covariates.
Conclusion: Admission sCD163 levels may be an additional help in rapid identification of patients with high-risk for death during AD epsiodes complicated with INF in LC.

Introduction: The interferon-free 3 direct-acting antiviral (3D) regimen of ombitasvir (an NS5A inhibitor), paritaprevir (an HCV NS3/4A protease inhibitor identified by AbbVie and Enanta, boosted with ritonavir [r]) and dasabuvir (a non-nucleoside NS5B RNA polymerase inhibitor) is approved to treat patients infected with HCV genotype (GT) 1. Using pooled data from four phase 3 studies in treatment-naïve and prior pegIFN/RBV-experienced patients with GT1a infection, with or without cirrhosis, we report the safety and efficacy in patients who received the label-recommended 3D regimen plus ribavirin (RBV).
Aims & Methods: Genotype 1a-infected patients from the PEARL-IV, SAPPHIRE-I, SAPPHIRE-II, and TURQUOISE-II studies were included in this post-hoc analysis. Efficacy was assessed by the proportion of patients achieving sustained virologic response (HCV RNA <25 IU/mL) 12 weeks after completion of treatment (SVR12). Per the US Prescribing Information and European SmPC, the label-recommended regimen for GT1a infection is 3D + RBV for 12 weeks in non-cirrhotic patients, and 3D + RBV for 24 weeks in patients with cirrhosis. Adverse events (AEs) and laboratory measures are reported for all patients receiving the label-recommended regimen.
Results: Among 714 HCV GT1a-infected patients treated with the label-recommended 3D + RBV regimen, 64% were male, 33% were treatment-experienced, 17% had cirrhosis, and 85% had baseline viral loads ≥800,000 IU/mL. Sustained virologic response was achieved in 96% (95% CI, 94-97%) of patients (**Table**). Response rates were similar regardless of the presence or absence of cirrhosis (95 versus 96%, respectively). Virologic failure was observed in 18 (2.5%) patients, 5 (0.7%) with on-treatment breakthrough and 13 (1.8%) with post-treatment relapse. Seven patients (1.0%) discontinued treatment due to AEs, 4 of whom subsequently achieved SVR12. The most common AEs were fatigue (41%), headache (33%), nausea (23%), and insomnia (17%). Grade 3+ laboratory abnormalities were infrequent for ALT (0.9%), AST (0.6%), haemoglobin (0.3%), and total bilirubin (2.8%).
Conclusion: In HCV GT1a-infected patients, the label-recommended 3D regimen with RBV achieved high SVR12 rates, including historically difficult-to-cure subgroups of patients with prior PR null response and/or cirrhosis.

laboratory measures are reported for all patients receiving the label-recommended regimen.
Results: Among 369 HCV GT1b-infected patients treated with the label-recommended 3D ± RBV regimen, 50% were male, 37% were treatment-experienced, 18% had cirrhosis, 83% had an IL28B non-CC genotype, and 78% had baseline viral loads ≥800,000 IU/mL. Sustained virologic response was achieved in 368/369 (99.7%; 95% CI, 98.2-99.9%). One patient experienced post-treatment relapse, a 56 year-old white male with cirrhosis who received 3D + RBV. The majority of AEs were mild to moderate in severity, and most common AEs were headache (24%), fatigue (22%), and asthenia (9%). Grade 3 laboratory abnormalities were infrequent for ALT (0.3%), AST (0.3%), and total bilirubin (2.2%). No patient experienced a grade 3 haemoglobin decline and no patient discontinued treatment prematurely due to an AE.

Conclusion: Patients with HCV GT1b infection treated with the label-recommended 3D regimen, with or without RBV, achieve very high SVR12 rates, including those with historically difficult-to-cure disease characteristics such as prior pegIFN/RBV null response and cirrhosis.

P0670 HEPATITIS C VIRUS–ASSOCIATED B-CELL NON-HODGKIN LYMPHOMAS – AN ALTERNATIVE THERAPEUTIC APPROACH?

J. Castela[1], P. Sousa[1], C. Leitão[1], S. Mão de Ferro[1], S. Ferreira[1], M. Cunha[1], M. Silva[1], A. Dias Pereira[1]
[1]*Instituto Português de Oncologia de Lisboa Francisco Gentil, Lisboa, Portugal*

Contact E-mail Address: joanarocastela@gmail.com
Introduction: The most compelling argument for a causal relationship between hepatitis C virus (HCV) infection with B-cell non-Hodgkin Lymphoma (B-NHL) results from the demonstration of regression of some indolent B-NHL with the eradication of HCV. The role of HCV treatment as a first line therapy remains to be defined, particularly with the availability of new antivirals.
Aims & Methods: Clinical and demographic characterization of population with B-NHL and hepatitis C. Evaluation of eligibility for HCV therapy as the first line treatment for B-NHL.
Retrospective study of patients with B-NHL anti-HCV+, followed in a clinical center for 11 years. The clinical and demographic characteristics were analysed. Eligibility criteria for HCV therapy: indolent lymphomas, unless bulky or symptomatic disease.
Results: Of 2826 patients with B-NHL 37 were anti-HCV+, 17 men, mean age 60 ± 16 years. Viral load determined in 21 patients, detected in 16 (HCV-RNA +).
Fifteen patients had indolent lymphomas (non-classifiable-5, extranodal marginal-2, chronic lymphocytic leukemia-4, lymphoplasmacytic lymphoma-2, follicular lymphoma-2). Eleven were HCV-RNA+. According to the eligibility criteria, one would be excluded for being bulky and the remaining 10 would be candidates for primary therapy of HCV (only 7 eligible for INFpeg and ribavirin: 2 non responders to prior treatment and 1 anemia). No patient was treated for HCV as first-line therapy for lymphoma. 10/15 patients received chemotherapy (CT). Two patients had elevated transaminases during chemotherapy that did not require dose reduction.
Conclusion: Given the low prevalence of HCV infection, the number of patients who could benefit from anti-HCV therapy as primary treatment for B-NHL is reduced. However, given the possibility of regression of indolent lymphomas and the availability of new drugs for HCV with fewer side effects and greater efficiency, this therapy should be offered to eligible patients before chemotherapy.

Contact E-mail Address: marcosanduzzizamparelli@yahoo.it
Introduction: Hepatitis C virus (HCV) infection has been associated with several extrahepatic manifestations in a variety of tissues and organs, including the myocardium. Reduced myocardial perfusion or increased pro-B-type natriuretic peptide (NT-proBNP) have been described in HCV-infected individuals but, until now, no study clearly demonstrated the occurrence of myocardial dysfunction in the early stages of HCV-related liver diseases
Aims & Methods: Aim was to evaluate the impact of HCV infection on ventricular geometry and function by a standard 2D and 3D echocardiography.
50 out of 125 consecutive genotipe 1 HCV infected patients with histologically proved HCV-related chronic hepatitis and 30 Healthy Controls (HCs), comparable for age and gender prevalence were enrolled in the study. Laboratory tests, abdominal utrasonography, liver biopsy or FibroScan and ecocardiography were performed in all the patients. The echocardiography protocol consisted of: standard echo Doppler plus LV volumetric and systolic function analysis through 3D echocardiography. Left ventricular systolic function thorough 3D echo was evaluated by Speackle tracking echocardiography (STE) derived global longitudinal strain (GLS), global circumferential strain (GCS), global area strain (GAS) and global radial strain (GRS).
Results: Overall we enrolled 28 males and 22 females with HCV (genotype 1) related chronic liver disease. Mean age was 59.8 ± 6.9yrs. Age, gender distribution, body mass index, heart rate and blood pressure did not significantly differ between patients and controls. In HCV infected subjects standard 2D echocardiography point out a transmitral E/A ratio marginally lower (0.84 ± 0.2) compared to HC (1.01 ± 0.3) (p = 0.04). Moreover, more detail 3D STE showed in 38 (76%) of the cases a subclinical alteration of LV function, documented by lower GCS (HCV = -15.3 ± 2.2%, HC = -17.6 ± 3.9%, p = 0.02), GAS (-25.2 ± 2.6%, HC -29.9 ± 5.2%, p = 0.03), and GRS (37.6 ± 4.6% vs 44.9 ± 12%, p = 0.04) whereas HCV-releated changes of GLS were not significant. Interestingly, myocardial impairment was independent of viral load and staging of liver biopsy.
Conclusion: HCV infected patients show a subclinical myocardial dysfunction independently of viral load and liver fibrosis; circumferential fibers of the left ventricular mid wall are primarily involved in LV subclinical dysfunction.

Abstract number: P0674 Table 1: Week zero and week 72 values of different biomarker panels among group 1 (SVR) and groups 5 (control) patients.

Biomarker panels	Week zero(95 % CI)	Week 72(95 % CI)	P-value
APRI (mean ±SD)- SVR- Control	1.14±1.160.9 ±0.92	0.44± 0.41.14±1.27	<0.0010.004
FIB-4 (mean ±SD)- SVR- Control	2.13±1.462.52±2.25	1.52±0.892.86± 2.5	<0.0010.058*
PLASA(mean ±SD)- SVR- Control	0.53±1.180.53±1.04	-0.29±0.630.71±1.19	<0.0010.008
FRT(mean ±SD)- SVR- Control	10.0± 3.511.8± 6.5	8.4 ±1.913.6±10.1	<0.0010.034

Introduction: The degree of liver fibrosis is a major issue for making decision of therapeutic strategies on chronic liver diseases. Recently glyco-isomer of serum Mac-2-binding protein (M2BPGi) could be supposed to be a novel and useful biomarker to assess liver fibrosis. However little is known about its usefulness for diagnosis of CHC patients.

Aims & Methods: In this study, we were trying to reveal the significance of serum M2BPGi for assessment of liver fibrosis. One hundred twenty seven CHC patients (male/female = 67/60, mean age 58 y.o.) scheduled for the anti-viral therapy were enrolled. Liver biopsies were undertaken in all of the patients. We evaluated the relation between liver fibrotic degrees and the serum levels of M2BPGi, and the correlation between the serum levels of M2BPGi and examined liver function tests, i.e. T-Bil, AST, ALT, GGT, platelet, AFP, γ-globulin and hyaluronic acid (HA). Additionally we evaluated the ability of M2BPGi by Receiver Operating Characteristic (ROC) analysis compared with the serum levels of HA and Fib4 index.

Results: The patients were classified into two groups according to liver fibrosis stage, F0 (n = 34) and F1/2 (n = 93). The serum levels of M2BPGi were significantly higher in F1/2 group (median = 1.73C.O.I.) than in F0 group (median = 0.85C.O.I.), ($p < .0001$). Among the other serum liver tests, the levels of serum HA were strongly related with liver fibrosis stage (F0 = 23.0ng/ml vs F1/2 = 93.5ng/ml, $p < .0001$), and the serum levels of AST (F0 = 32IU/L vs F1/2 = 50IU/L, $p < .0005$), ALT (F0 = 36IU/L vs F1/2 = 59IU/L, $p < .01$), platelet (F0 = 21.0×10^4/μl vs F1/2 = 16.9×10^4/μl, $p < .001$) and γ-globulin (F0 = 18.6% vs F1/2 = 21.1%, $p < .001$) also indicated significant difference between the two groups. The serum levels of M2PBGi showed the positive correlation with the serum levels of AST (R = 0.32), ALT (R = 0.26), GGT (R = 0.29), γ-globulin (R = 0.38) and HA (R = 0.70), and the negative correlation with the serum levels of platelet (R = -0.28), respectively. ROC analysis showed that both serum HA (AUC = 0.830) and the Fib4 index (AUC = 0.809) were the most useful determinants of liver fibrosis comparing between the two groups. The serum levels of M2BPGi (AUC = 0.759) showed the possible indicator for liver fibrosis staging as well.

Conclusion: In this study, we could demonstrate that the serum M2BPGi was a potentially significant biomarker for liver fibrosis, even in minimal or mild liver fibrosis. The serum M2BPGi could be one of the most useful tools for assessment of liver fibrosis in CHC patients.

P0673 RESPONSE TO HEPATITIS B VACCINE IN CHRONIC HEPATITIS C EGYPTIAN PATIENTS

E. M. Said[1], **M. A. Metwally**[1], D. M. Abd El Hassib[2], R. M. Elsawi[3], M. M. E. Atta[1]
[1]*Hepatology, Gastroenterology, and Infectious Diseases,* [2]*Clinical and Chemical pathology,* [3]*Pathology, Benha University, Benha, Egypt*

Contact E-mail Address: mohamed.metwally@fmed.bu.edu.eg

Introduction: Egypt is cursed with the highest worldwide prevalence of chronic hepatitis C (CHC). Patients with CHC are advised to be vaccinated against hepatitis B virus (HBV) infection. Response to vaccination and risk factors for weak response are not clearly identified.

Aims & Methods

Aim: To assess response to hepatitis B vaccination in CHC patients and identify predictors of weak response.

Patients and methods: This prospective study included 112 consecutive adult, treatment- naive patients with CHC (cases group) and 54 non HCV subjects (control group). Demographic and laboratory variables including HCV-viral load and antischistosomal antibody beside histopathological examination were all collected. Three doses (0, 1 & 6 months) of HBV-vaccine (Euvax B, LG Life Sciences, Korea) were given and hepatitis B surface antibody (HBs-Ab) titre was evaluated 1.5 - 2 months after the 3rd dose.

Results: Out of 112 patients with CHC, 5 (4.5%) had HBs Ab titre less than 10 IU, 20 (17.9%) had less than 100 IU, and 50 (44.6%) had more than 1000 IU. In comparison, out of 54 controls, one (1.9%) had less than 10 IU, 2 (3.8%) had less than 100 IU, and 41 (75.9%) had more than 1000 (P = 0.001). CHC patients had highly significant lower mean antibody titre than controls ($P < 0.001$). In univariate regression analysis, HBs Ab titre was negatively associated with age ($P < 0.001$), ALT (P = 0.03), AST (P = 0.03), FIB4 score (P = 0.008), and antischistosomal antibody titre (P = 0.007) and positively associated with platelet count (P = 0.01). There was no association with gender, body mass index, viral load or other variables (including METAVIR grade or stage). Multivariate regression analysis in CHC patients showed that age (P = 0.02) and antischistosomal antibody titre (P = 0.04) were the independent predictors for HBs Ab titre response.

Conclusion: CHC patients have a significantly weak response to HBV-vaccine, particularly those with older age and schistosomiasis.

Introduction: Treating chronic hepatitis C (CHC) is associated with improving long-term outcomes and health-related quality of life. Monitoring fibrosis regression in response to treatment is important to identify patients with residual cirrhosis after CHC cure as they need long-term surveillance for hepatocellular carcinoma (HCC). Due to limitations of repeating liver biopsy after treatment; surrogate biomarkers can be an alternative to monitor fibrosis regression and to identifying patients with residual cirrhosis.

Aims & Methods: We aimed at monitoring regression of fibrosis in a group of CHC patients in response to treatment by calculating six different panels (APRI, FIB-4, PLASA, FRT, Fibro-alpha and BRC) used as non-invasive markers of hepatic fibrosis. Data of 363 CHC patients (140 males) were retrospectively analyzed. Data included pretreatment and post treatment laboratory parameters according to the national guidelines for treating CHC in Egypt (2007-2014). Patients were classified into 4 groups according to treatment response; patients who had sustained virologic response (group 1; n = 90), relapsers after treatment (group 2; n = 65), patients who had breakthrough during treatment (group 3; n = 12) and null responders (group 4; n = 71) in addition to a control groups (group 5; n = 125) of CHC patients whom were in eligible or refusing to receive standard of care treatment. All treated patients received pegylated interferon and ribavirn combination. APRI, FIB-4, PLASA, FRT, Fibro-alpha and BRC were calculated at weeks 0 and 72 for all groups and correlated to fibrosis stage by METAVIR and to treatment outcome in different groups.

Results: APRI, FIB-4, PLASA, FRT, Fibro-alpha and BRC could predict significant hepatic fibrosis (≥F2 METAVIR), advanced hepatic fibrosis (≥F3 METAVIR) and cirrhosis (F4 METAVIR) accurately. All panels showed significant decrease of their values in group 1 (sustained virologic response) in response to treatment. On the contrary; APRI, PLASA, FRT and BRC showed significant increase of their values in the control group (table 1). FIB-4 and Fibro-alpha had increase in their values in the control group but this was not significant. There were no other significant changes in the values of the studied panels in other treatment groups.

Conclusion: All of the studied biomarker panels for liver fibrosis assessment were useful in monitoring regression of fibrosis in treated CHC patients and most of them were useful in monitoring progression of fibrosis in untreated patients.

Introduction: Remission in autoimmune hepatitis (AIH) is defined as normal aminotransferases and normal IgG levels and no or only slight inflammation in liver biopsy. Transient elastography (TE) has become a useful method in measuring fibrosis, but biopsy has remained the gold standard in revealing both fibrosis and inflammation of the liver. Liver biopsy is invasive, costly, and subject to complications and sampling variability. The information about inflammation in addition to fibrosis is important in clinical decision of continuing or stopping the treatment. Thus, a non-invasive and accurate test for diagnosis of inflammation would be of great value and we have tested ^{31}phosphorus magnetic resonance spectroscopy (^{31}P MRS) in this setting.
Aims & Methods: Twelve consecutive AIH patients (mean age 42.8 years, eleven women) who underwent liver biopsy for disease staging, were evaluated with TE and ^{31}P MRS. Inflammation and fibrosis in liver biopsy were categorized according to Metavir score. ^{31}P-MRS of liver was performed on a 3 Tesla clinical imager (Philips, Achieva). A 125-216 cm3 voxel was placed in the center of right liver lobe and proton decoupled 31P-MR spectra were obtained using image selective in vivo spectroscopy (ISIS) with TR of 6000 ms and 128 acquisitions. 31P-MRS data was collected with a circular 31P transmit receive loop coil. Body coil was used for obtaining localizer images and for proton decoupling.
Phosphoenolpuryvate (PEP)/phosphatidylcholine (PtdC), phosphoethanolamine (PE), glyserophosphoethanolamine (GPE), total phosphomonoester level (PME), total phosphodiester level (PDE), and PE/PC, PE/GPE, and PC/(PME + PDE) ratios were compared to Metavir grade and stage, stiffness in TE and alanine aminotransferase (ALT), aspartate aminotransferase (AST), immunoglobulin-G (IgG), alkaline phosphatase (ALP), thrombolastin time (TT), and albumin (Alb). Spearman's and Pearson correlations were used to assess statistical relationships. $p < .05$ was considered statistically significant.
Results: PEP/PtdC correlated with inflammation grade ($r = .663$, $p = .019$) and ALP ($r = .598$, $p = .040$). PE/PC ($r = .764$, $p = .006$), PE/GPE ($r = .618$, $p = .043$), and PC/(PME + PDE) ($r = -.636$, $p = .035$) correlated with inflammation, as measured with IgG ($r = .764$, $p = .006$; $r = .618$, $p = .043$; and $r = -.636$, $p = .035$), respectively. There was no correlation between phosphorus metabolites and TE, histological fibrosis and aminotransferase levels.
The histological inflammation correlated with ALT and AST ($r = .800$, $p = .002$ and $r = .673$, $p = .023$ respectively) and IgG ($r = .604$, $p = .049$). TE did not correlate with phosphorus metabolites, liver histology, or laboratory parameters.
Conclusion: ^{31}P MRS measures inflammatory activity in AIH patients. TE and MRS were not effective in fibrosis quantification.
Disclosure of Interest: None declared

P0676 THE ROLE OF POINT SHEAR WAVE ELASTOGRAPHY TECHNIQUE (ELASTPQ) IN THE NON-INVASIVE ASSESSEMENT OF LIVER FIBROSIS IN VARIOUS LIVER DISEASES

M. Garcovich[1], M. Pompili[1], E. Di Stasio[1], L. Riccardi[1], M. E. Ainora[1], A. Grieco[1], G. L. Rapaccini[1], M. Siciliano[1], A. Gasbarrini[1], M. A. Zocco[1]
[1]*Catholic University of Sacred Heart, Rome, Italy*

Introduction: Point shear wave elastography (PSWE) is a novel non-invasive technique that assesses liver fibrosis by measuring liver stiffness (in kPa) with few studies published so far. The aim of this study was to determine the accuracy and the feasibility for the assessment of liver stiffness in comparison to the fibrosis stage in patients undergoing liver biopsy (LB) for various etiologies.
Aims & Methods: Consecutive patients scheduled for LB were studied by using the iU22 Philips ultrasound system with ElastPQ technique. The correlations between laboratory findings, liver stiffness and the Metavir score were analyzed using Spearman correlation and ROC curve analyses were performed to calculate AUC for $F \geq 2$, $F \geq 3$ and $F = 4$.
Results: We enrolled 217 patients (140/77 males/females) who underwent LB for viral or non-viral chronic hepatitis (HCV 44%; NASH 21%; AIH/PBC 18%; other 17%). Liver stiffness measurements performed on the right lobe were reliable in all cases but two (due to morbid obesity and narrow intercostal spaces). After univariate and multiple regression analysis PSWE showed a strong correlation with the fibrosis stage; no significant correlation was found with the degree of necroinflammation or steatosis. Mean kPa values in the whole cohort were 4.01 (range 2.30–5.69) for F0, 4.89 (range 2.62-9.68) for F1, 8.00 (2.81-20.79) for F2, 10.98 (3.88-21.44) for F3 and 18.61 (9.51-31.34) for F4 in the right lobe. AUROCs were 0.90 (±0.02), 0.91 (±0.02) and 0.97 (±0.01), when comparing F0-F1 vs F2-F4, F0-F2 vs F3-F4 and F0-3 vs F4, respectively. The optimal cut-off values for different levels of fibrosis were 6.03, 7,63 and 9.47 kPa for $F \geq 2$, $F \geq 3$ and F4, respectively. When analyzing PSWE values according to different etiologies, AUROCs were 0.85 (±0.04), 0.97 (±0.29) and 0.94 (±0.03) for $F \geq 2$; 0.88 (±0.04), 0.95 (±0.03) and 0.95 (±0.03) for $F \geq 3$; 0.98 (±0.01), 0.99 (±0.01) and 0.99 (±0.01) for F4 in HCV, NASH and AIH/PBC patients, respectively.
Conclusion: PSWE with ElastPQ appears to be a useful tool for non-invasive evaluation of fibrosis not only in patients with viral chronic hepatitis, but also for patients with different liver diseases. In order to validate such a non-invasive technique these findings need to be confirmed in larger studies.

P0677 PHARMACOKINETICS, RADIATION DOSIMETRY AND TOXICOLOGY STUDIES OF 111IN-DTPA HEXA-LACTOSIDE IN NORMAL MICE

M. H. Wang[1], C.-Y. Chien[1], H.-M. Yu[1], W.-J. Lin[1]
[1]*Isotopes, Institute of Nuclear Energy Research, Taoyuan, Taiwan, Province of China*

Contact E-mail Address: mhwang@iner.gov.tw
Introduction: Asialoglycoprotein receoptors residing on hepatocyte membrane has been known to specifically bind with GalNAc or Gal terminal glycoligands. ^{111} In-DTPA hexa-lactoside with Gal termini were developed as a biomarker for liver reserve measurement. In previous study, 111In-DTPA hexa-lactoside has been validated as a specific imaging biomarker for asialoglycoprotein receptors on hepatocyte membrane.
Aims & Methods: To advance ^{111} In-DTPA hexa-lactoside to first-in-human trial, pharmacokinetics, radiation dosimetry and toxicology studies of ^{111}In-DTPA hexa-lactoside in normal mice were performed to meet the requirements of regulatory approval for Investigational new drug (IND). The pharmacokinetic parameters were calculated according to the radioactivity elimination curve with the assistance of PK-Solver 2.0 software. The radiation exposure dose was measured by the OLINDA/EXM program on the basis of residence time of radioactivity in each organ, radiation energy of radionuclide, radionuclide type and tissue-weighting factor of International Commission on Radiological Protection (ICRP). A 14-day GLP extended acute toxicity was evaluated in male Sprague-Dawley (SD) rats via single intravenous injection administration of DTPA-hexa-lactoside.
Results: ^{111}In-DTPA hexa-lactoside exhibited biexponential elimination from the blood in normal mice following tail vein i. v. administration. The distribution half-life (α-phase) was 0.42 min. The elimination phase half-life (β-phase) was 11.46 min. The highest concentration of radioactivity was mostly found in liver (up to 55.48 ± 8.19 %ID/g) within 30min p. i. The mean residence time in blood and liver were 8.22 min and 22.44 h, respectively. The estimated total body dose was 2.86E-05 mSv/MBq which corresponds to a whole body dose of 1.0582 mSv per 1 mCi administered dose, i.e. 1/10 exposure dose of Chest X ray. No significant differences were observed for hematology and serum biochemistry parameters. The physiological functions of all animals were remaining normal during the study period. All parameters of clinical pathology were within the range of historical data.
Conclusion: Our data indicates ^{111}In-DTPA hexa-lactoside is suitable for advancement to a first-in-humans clinical trial.

P0678 NEAR INFRARED FLUORESCENCE DYE LABELED MULTIVALENT DEOXYGLUCOSE AS AN IMAGING AGENT FOR DETECTION OF LIVER CANCER

M. H. Wang[1], Y.-F. Chiang[1], R.-Y. Chen[1], C.-Y. Chien[1], W.-J. Lin[1]
[1]*Isotopes, Institute of Nuclear Energy Research, Taoyuan, Taiwan, Province of China*

Contact E-mail Address: mhwang@iner.gov.tw
Introduction: According to the statistics of American Cancer Society, one-fourth quarter of deaths are due to cancer in US. There is still a lot of unmet need in medical technology, especially in early diagnosis and therapeutic monitoring of liver cancer. Although F-18 FLT is very good as cell proliferation agent, we did not see good image in the orthotopic SK-HEP-1 bearing hepatoma mice in our preliminary experiment because the high unwanted interference in the abdomen.
Aims & Methods: In this study, we develop a fluorescent imaging biomarker with multivalent deoxyglucoside to see its feasibility for hepatoma targeting. Trivalent deoxyglucoside was made by a nitrile-triacetic acid linking three aminohexanoyl-deoxyglucoside. Hexa-deoxyglucoside was synthesized by dimerization of trivalent deoxyglucoside via amide bond formation with cy dye. The fluorescence imaging was performed in the Xtreme system. Biodistribution study was studied by imaging individual organ in vitro after sacrifice mice by cervical dislocation.
Results: Both Cy dye and cy dye-hexa-deoxyglucose performed accumulation in the tumor site bearing SK-HEP-1; however, cy dye-hexa-deoxyglucoside showed more specific for hepatoma targeting than cy dye only. The biodistribution imaging indicated there is highest absorption in the hepatoma region than normal region. Kidney was the next high accumulation organ, which revealed its water solubility property. There is low absorption in the other major organs such as heart, normal liver region, spleen and lung etc.
Conclusion: Our preliminary data indicated the cy dye-hexa-deoxyglucoside has hepatoma targeting property and was possible a good predictor for surgery-guided therapy.

Introduction: Simple hepatic cysts are benign congenital cysts with a prevalence of 2.5-4.25%. very few cases of simple hepatic cysts need treatment. Ethanol is the most commonly used agent for percutaneous sclerotherapy. Pain is a common complication with ethanol sclerotherapy and is related to the injected amount.
Aims & Methods: our aim is to evaluate the safety and efficacy of the combination of tetracycline and ethanol for percutaneous sclerotherapy of simple hepatic cysts. A total of 34 adult patients with symptomatic simple hepatic cyst underwent clinical evaluation, laboratory evaluation, radiological evaluation and diagnostic cyst aspiration. They were divided into 2 groups. The first group was treated by percutaneous ethanol sclerotherapy and the second was treated by combined ethanol and tetracycline sclerotherapy.
Results: Combined ethanol and tetracycline sclerotherapy was associated with fewer sessions than ethanol sclerotherapy($P = \leq 0.001$) and higher rate of sustained cyst size reduction on follow up ($P = \leq 0.001$). There was no significant difference between the two procedures regarding the complications. Hepatitis C virus infected patients and those with hepatic steatosis had non-significant changes in the serum transaminases with the two procedures.
Conclusion: percutaneous sclerotherapy of simple hepatic cysts using tetracycline and ethanol is more effective than ethanol sclerotherapy.

P0680 FACTORS THAT INFLUENCE THE CONTROLLED ATTENUATION PARAMETER (CAP) VALUE IN CHRONIC LIVER DISEASE PATIENTS

P. Andrade[1], E. Rodrigues-Pinto[1], R. Gaspar[1], S. Lopes[1], G. Macedo[1]
[1]*Gastroenterology Department, Centro Hospitalar São João, Porto, Portugal*

Contact E-mail Address: anapatriciarandrade@gmail.com
Introduction: Controlled Attenuation Parameter (CAP) measured by transient elastography has been suggested as a non-invasive method for detection and quantification of hepatic steatosis. Factors that influence the assessment of steatosis by CAP are not well established.
Aims & Methods: To evaluate the factors influencing the CAP value in a group of patients with chronic liver disease (CLD). This study included CLD patients who underwent CAP measurement using the M probe of Fibroscan (Echosens, Paris, France).
Results: We included 159 patients (61% men, mean age 47.9 ± 12.9 years). CLD aetiology was non-alcoholic fatty liver disease (34.8%), viruses (28.3%), autoimmune hepatitis (10.7%), alcohol (8.7%) and others (17.5%). CAP value was related to the degree of steatosis in liver histology ($p < 0.001$) and ultrasound ($p < 0.001$). The value of CAP was significantly higher in patients with hypertension (267.5 vs. 234.8 dB/m, $p = 0.007$), dyslipidaemia (273.5 vs. 212.1 dB/m, $p < 0.001$), type 2 diabetes mellitus (280.9 vs. 234.8 dB/m, $p = 0.001$), body mass index (BMI) > 25 Kg/m^2 (277.8 vs 213.0 dB/m, $p < 0.001$) and non-alcoholic fatty liver (290.8 vs 212.6 dB/m, $p < 0.001$). In the multivariate analysis, BMI > 25 Kg/m^2 (OR 48.4, 95% CI: 23.78 - 72.95, $p < 0.001$), serum cholesterol [OR 3.803, 95% CI: 2203-13889, $p < 0.008$) and non-alcoholic fatty liver aetiology (OR 40.8, 95% CI: 15.01 - 66.66, $p = 0.002$) were independently associated with higher CAP values; CAP was not influenced by the degree of fibrosis ($p = 0.794$) or inflammatory activity ($p = 0.893$) in histology, triglycerides ($p = 0.104$), glucose ($p = 0.871$), ALT ($p = 0.817$) or AST ($p = 0.372$).
Conclusion: CAP mean value increases according to the degree of steatosis in histology and ultrassonography. NAFLD, BMI > 25 kg/m^2 and serum cholesterol were independently associated with higher values of CAP. The degree of fibrosis and inflammatory activity in histology, triglycerides, blood glucose and transaminases did not influence the value of CAP.

P0681 ALTERATIONS IN THE PORTAL VENOUS SYSTEM IN IDIOPATHIC NON-CIRRHOTIC PORTAL HYPERTENSION: A PROSPECTIVE LONG-TERM FOLLOW-UP STUDY

A. Krishnan[1]
[1]*Department of Clinical Medicine, Windsor University School of Medicine, St.Kitts and Nevis, Saint Kitts and Nevis*

Contact E-mail Address: dr.arunkumarpillai@gmail.com
Introduction: Idiopathic Non-Cirrhotic Portal Hypertension (INCPH) is a group of diseases that are characterized by an increase in portal pressure, due to intrahepatic or prehepatic lesions, in the absence of cirrhosis of the liver. INCPH includes Extra Hepatic Portal Vein Obstruction (EHPVO) and Non-Cirrhotic Portal Fibrosis (NCPF). The natural history of INCPH is still not clear.
Aims & Methods: Aim of the present was to determine prospectively the changes in the portal venous system in patients with NCPH. Patients with a diagnosis of NCPF and EHPVO registered since 2001 were serially followed at an yearly interval for changes in liver size, its echotexture, and in the intra and extrahepatic portal venous system. Baseline demographic details, LFT, and co-morbid illness including virological profile were noted. Patients with co-morbid illness and those with known etiology of cirrhosis were excluded from the study.
Results: There were 34 patients with NCPF (M: F 1:1.8) and 30 patients with EHPVO (M: F ratio 1.6:1). The mean age was 24.9 yrs and 41.2 yrs respectively. During follow up, 20 out of 34 and 16 out of 30 patients with NCPF and EHPVO respectively had no progression of disease. 14 patients with NCPF progressed to cirrhosis over a mean period of 5.21 years. Eight patients developed ascites and required diuretics. 14 patients with EHPVO progressed to NCPF over the mean period of 8.6 years, 12 patients further progressed to cirrhosis over a mean period of 5.1 years. Overall 40% of patients with EHPVO progressed to cirrhosis over a mean period of 13.7 years.
Conclusion: INCPH is a spectrum wherein EHPVO progresses to NCPF and further to cirrhosis over a period of 13.7 years at least in a proportion of patients. So our report clearly emphasizes that INCPH is a spectrum of disease, so this patients should monitored periodically to observer the changes in the portal venous system.

Contact E-mail Address: blinov2010@gmail.com
Introduction: Prevalence of suspected Non-alcoholic fatty liver disease (NAFLD) has more than doubled over the past 20 years and currently affects nearly 11% of adolescents and one-half of obese males. In Russia prevalence of NAFLD is increasing from 26,1 to 37,3% during last 7 years. The rapid increase among those obese, independent of body mass index, suggests that other modifiable risk factors have influenced this trend. For a better understanding of the disease etiology and its correlations with risk factors it is necessary to conduct epidemiological studies in Russia. This study was funded and managed by Sanofi Russia.
Aims & Methods
Objective: To evaluate the hierarchy of risk factors of NAFLD in general and within the every age subgroups in GP's and gastroenterologist's patient flow.
Materials and methods: A total of 50145 patients meeting the inclusion/exclusion criteria in 16 Russian cities were enrolled in the Program. The investigators were 1031 qualified doctors (GPs \ therapists \ gastroenterologists \ pediatricians), providing outpatient care for the population. The epidemiological data were obtained, recorded during two routine patient visits to investigating centers.
Results: The patients with Non-cirrhotic non-alcoholic fatty liver disease (NANCFLD) had significant elevated weight, BMI and WC in both gender groups and in total. Among the adult population with NANCFLD, it is important to note a higher and significant value of glucose, insulin, total cholesterol, TG, and HDL cholesterol when compared with participants who had normal liver data. Additionally, patients with NANCFLD resulted in major and significant value of AST, ALT and GGT compared with patients without liver

diseases.The more frequent risk factors for females with NANCFLD were: abdominal obesity, BMI ≥ 27kg/m2, menopause, hypertension and metabolic syndrome. The prevalence of reduced High Density Lipoprotein within NANCFLD female patients was 58,0%. The more frequent risk factors for males with NANCFLD were: BMI ≥ 27kg/m2, abdominal obesity, hypertension, hypertriglyceridemia and metabolic syndrome. The prevalence of reduced High Density Lipoprotein within NANCFLD male patients was 40,2%. The main 4 risk factors for NAFLD in males and females were the same and were ranged by odds ratio values as the following: hypertriglyceridemia, metabolic syndrome, BMI ≥ 27kg/m2, abdominal obesity.
Conclusion: NAFLD is closely associated with hypertriglyceridemia, metabolic syndrome, BMI ≥ 27kg/m2, abdominal obesity. It has been confirmed the hypothesis that for each studied risk factor the proportion of patients with NANCFLD is higher than the proportion of patients with the same risk factor in the population without liver diseases.

Introduction: Up to 90% of patients with extrahepatic cholangiocarcinoma (ECC) have no identifiable risk factors; genetic background (genes programmed to halt proliferation in damaged cells, involved in DNA repair), geographical and environmental factors are considered to play a role in carcinogenesis.
Aims & Methods: The aim was to establish if XRCC1rs1799782, rs25487, rs25489 and hOGG1rs1052133 SNP are susceptibility to ECC. Multicenter, case-control study performed in Mexico between May 2011- December 2013, included adults diagnosed with ECC (cases), benign pathology of the bile duct and asymptomatic patients (controls) matched by sex, age (± 5 years) and place of residence. Genomic DNA was extracted from peripheral blood using QIAamp DNA, quantified using the PicoGreen kit, and stored at -20º C. All SNPs were done with 10 ng genomic DNA in 384-well plates, using TaqMan technologie. The order of DNAs from cases and controls was randomized, for quality control duplicates 10% of the samples were done, PCR reactions were performed using a Hydrocycler instrument and the GeneAmpVR PCR System, PCR plates were read on a ViiA7 real time instrument, the ViiA7 RUO Software, version 1.2.2 was used to determine the genotypes. Hardy-Weinberg equilibrium was tested; logistic regression analyses were used for association between genetic polymorphisms and ECC. Odds ratios (OR) and 95% confidence intervals (95% CI) were calculated for each genotype under a codominant, dominant, recessive and additive inheritance model.
Results: Included 391 Mexican patients, 98 EEC: 63 common bile duct, 9 gallbladder and 26 of Vateŕs papilla. Mean age of cases (62.2 ± 14.36), 40 men, 58 women. Controls; 92 benign biliary pathology (C1) and 201 asymptomatic blood donors (C2). XRCC1rs1799782_AG, rs25489_CT and hOGG1rs1052133_CG SNP no showed significant differences among groups. rs25487_CT was present in 18.36% of cases (18/98), 38.89 % of C1 (35/90), p = 0.0031, OR = 0.35 (0.17-0.72) and 34% of C2 (69/199), p = 0.056, OR = 0.42 (0.23-0.79). XRCC1rs1799782 genotype A/A was observed in 7.94% of choledochal cancer (5/63) vs 1.54% of C2 (2/130) p = 0.0385 OR = 5.52 (0.91-42.4), genotype A/G was present in 88.89% of gallbladder cancer (8/9) vs 27.77% (5/18) of C2, p = 0.0039 OR = 20.80 (1.70-587.88) In choledochal cancer, rs25487_CT was observed in 15.87% (10/63) vs 40% of C1 (24/60), p = 0.0052, OR = 0.28 (0.11-0.71) and 36.92% of C2 (48/130), p = 0.0047, OR = 0.32 (0.14-0.73), while C/C genotype, 74.60% of (47/63) vs 57.69% of C2 (75/130), p = 0.0335, OR = 2.15 (1.06-4.43).
Conclusion: In Mexican population, our results suggest that XRCC1rs1799782 genotype A/A is risk factor in choledochal cancer, and SNP rs25487 is protective factor while in gallbladder cancer, SNP rs1799782 is a risk factor.

Introduction: Extrahepatic cholangiocarcinoma (ECC) is a rare but a highly lethal malignancy due to difficulties of early diagnosis and lack of effective therapies. In Mexico endoscopic retrograde cholangiopancreatography (ERCP) still is considered a valuable tool for assessing biliary tract strictures because it allows obtain radiological images biliary tract, therapeutic interventions, and collection of brushing cytology specimens although highly specific, has low/moderate sensitivity (15% > 68%). The progress in molecular biology of human cancers along with increased understanding of oncogenic mutations and cell signaling pathways, led to the successful application of mutation analysis as a part of diagnostic techniques as well as new targeted therapies in many solid tumors. The mass spectrometry technique, matrix-assisted laser desorption/ionization–time of flight, has been used to assess tumors for point mutations and small deletions in commonly altered oncogenes.
Aims & Methods: The goal was determine the frequency of somatic mutations in common oncogenes in ECC in epithelial cells obtained by scraping the biliary ducts. Multicenter study performed in Mexico between May 2012 December 2013, included adults with diagnosis of ECC by ERCP, plus endoscopic ultrasound, intraductal biliary ultrasound and direct cholangioscopy. All cases were confirmed by brush cytology, histopathology and clinical course. Epithelial cells were obtained by scraping the biliary ducts during ERCP and the brushes were suspended in buffer solution at -80°C until tested. DNA was extracted from brushed cells using the QIAamp DNA easy kit and quantified using the PicoGreen kit, and evaluated using the Sequenom MassARRAY and OncoCarta v1.0 Mutation Profiler Panel.
Results: Included 28 cases: 17 woman and 11 men, mean age 64.41 ± 14.74, the ECC was distributed; 14 (50%) choledocho, 4 (14.29%) gallbladder and 10 (35.71%) in ampulla of Vater. Mutations were identified in 39.29% (11/28) of ECC in follow genes KRAS 28.57% (8/28); G12D, MET 7.14% (2/28); T992I, M1250T and PIK3CA 3.57% (1/28); P539R. The highest mutation rate was observed in cancer of choledocho 42.86% (6/14), followed by ampulla of Vater 40% (4/10) and gallbladder 25% (1/4). Follow-up was 30 months. Survival in patients without mutations was 9.25 ± 6.56 months and 9.78 ± 3.73 months in patients with mutations without significance.
Conclusion: Mutations in oncogenes as KRAS, MET and PIK3CA decrese efficacy of specific chemotherapies and in our study this frequency was 39.29% of ECC. MassARRAY technology can be used to detect mutations in a wide variety of oncogenes using epithelial cells obtained by scraping biliary ducts during ERCP and could be used for molecular profile in ECC protocol as diagnosis tool and individualized therapy.

Introduction: Chitosan is known as a natural and biocompatible polymer which has immune adjuvants and anticancer activities. Therefore, chitosan can be used in drug such as Ce6 that is adaptable to incorporate anionic drug because of the cationic properties of chitosan.
This study was produced using the water-soluble chitosan incorporated nanoparticles containing Ce6. Photodynamic potentials and physicochemical properties of Ce6-incorporated chitosan nanoparticles were studied against human cholangiocarcinoma cells in vitro and in vivo.
Aims & Methods: We purchased chitosan from Kittolife Co. Korea and Ce6 from Frontier Sci. Co. Ltd. USA.
We fabricated Ce6-incorporated nanoparticles using chitosan by dissolving 100mg of chitosan in 10ml of deionized water. Then 5-20 mg of Ce6 in 0.5ml DMSO was added to chitosan solution following sonication using bar-type ultrasonicator. To remove organic solvent and free drug, this solution was dialyzed against water.
Results: Ce6-incorporated nanoparticles was fabricated through ion-complexation formation between amine group of chitosan and carboxyl group of Ce6 using water-soluble chitosan. By simple mixing of Ce6 and chitosan, photosensitizer-incorporated were prepared following sonication and dialysis which has spherical shapes with less than 500nm. When Ce6-incorporated nanoparticles were treated to human cholangiocarcinoma cells with irradiation, they enhanced delivery of Ce6 to human cholangiocarcinoma cells and then enhanced ROS level in tumor cells rather than free Ce6. Futhermore, nanoparticles enhanced treatment efficiency. Photo-induced toxicity against human cholangiocarcinoma cells were increased compared to Ce6 only treatment. Nanoparticles enhanced delivery of Ce6 through bile duct in ex vivo study using porcine bile duct slice. Also, nanoparticles significantly enhanced delivery of Ce6 to tumor at in vivo animal study.
Conclusion: Ce6-incorporated nanoparticles using water-soluble chitosan were prepared. ChitoCe6 nanoparticles enhanced cellular uptake, phototoxicity, and ROS generation compared to Ce6i only. Also, Ce6-incorporated nanoparticles

enhanced delivery to human cholangiocarcinoma cells in vivo animal study and ex vivo porcine bile duct slice experiment.

P0686 PROMISING CANDIDATE FOR VORINOSTAT-INCORPORATED NANOPARTICLES AGAINST HUMAN CHOLANGIOCARCINOMA CELLS

K. Su Jin[1], O. Sook Kyoung[1], K. Dae Hwan[1], K. Hyung Wook[1], C. Cheol Woong[1], P. Su Bum[1], K. Min Dae[2], R. Dae Gon[1]
[1]*Department of Internal Medicine, Pusan National University, Yangsan Hospital, Yangsan,* [2]*Department of Internal Medicine, Bong Seng Memorial Hospital, Pusan, Republic of Korea*

Contact E-mail Address: gon22gon@naver.com
Introduction: This study evaluates the anticancer activity of vorinostat-incoporated nanoparticles (vorinostat-NPs) against cholangiocarcinoma cells.
Aims & Methods: By using a nanoprecipitation method, Vorinostat-NPs were fabricated and presented its spherical shapes with small particles size less than 100 nm. Also, Vorinostat-NPs were coated onto covered-stent. We observe the anticancer activity of Vorinostat-NPs and their coated stent in vitro and in vivo.
Results: Vorinostat and vorinostat-NPs have similar anticancer efficacy in terms of cytotoxicity, cell growth inhibition, and apoptosis of HuCC-T1 cholangiocarcinoma cells in vitro. Also, they have equal potency in inhibition of histone deacetylase (HDAC) expression, mutant type p53 suppression, increased p21expression, and PARP/cleaved caspase-3 expression. However, vorinostat-NPs and their coated stent showed improved antitumor activity against HuCC-T1 cancer cell-bearing mice compared to vorinostat itself, whereas empty nanoparticles had no effect on tumor growth. Vorinostat-NPs increased the expression of acetylated histone H3 in tumor tissue and suppressed HDAC expression in vivo. The improved anticancer efficacy of vorinostat-NPs was confirmed by molecular imaging studies using NIR-dye-incorporated nanoparticles.
Conclusion: This study shows the anticancer activity of vorinostat and vorinostat-NPs against HuCC-T1 cholangiocarcinoma cells by specific inhibition of HDAC expression. Therefore, vorinostat-NPs can be used in anticancer chemotherapy in cholangiocarcinoma.

P0687 PRE-EXPOSURE WITH SIMVASTATIN INHIBITS LIPOPOLYSACCHARIDE-INDUCED EPITHELIAL-MESENCHYMAL TRANSITION VIA DOWNREGULATION OF TLR4 AND NF-KB IN HUMAN BILIARY EPITHELIAL CELLS

S. M. Park[1], Y. Kim[2], B. Cho[1], Y. Oh[1]
[1]*Internal Medicine, Chungbuk National University Hospital,* [2]*Physiology, Chungbuk National University College of Medicine, Cheongju, Republic of Korea*

Contact E-mail Address: smpark@chungbuk.ac.kr
Introduction: Epithelial-mesenchymal transition (EMT) of biliary epithelial cells (BECs) plays a role in biliary fibrosis. Lipopolysaccharide (LPS) promotes EMT in BECs.
Aims & Methods: The present study investigated the effects of simvastatin on the EMT of BECs induced by LPS. Transformed human BECs (H69) were exposed with LPS (1μg/mL) or transforming growth factor-β1 (TGF-β1, 5 ng/ml) for 5 days. The expression of E-cadherin, vimentin, N-cadherin, and toll-like receptor 4 (TLR4) was determined by quantitative real-time PCR, western blotting, and confocal microscopy. The effect of simvastatin on the EMT induced by LPS or TGF- β1 was determined by the expression of E-cadherin, vimentin, and TLR4.
Results: After exposure to 1μg/mL of LPS for 5 days, E-cadherin decreased and vimentin increased in mRNA and protein levels. The mRNA expression of TRL4 was increased by the exposures of LPS and TGF-β1 (5ng/ml) for 5 days. As compared with BECs treated with LPS alone, co-treatment with simvastatin plus LPS showed a remarkable increase of E-cadherin and a slight decrease of vimentin. LPS-induced TLR4 slightly decreased by co-treatment with simvastatin and LPS. In the proliferation analysis, LPS-induced BECs growth was remarkably inhibited by the application of simvastatin (1μM). In BECs morphology analysis, as compared with BECs pre-treatment with simvastatin before LPS exposure (preSL), BECs pre-exposure with LPS (postSL) or co-exposure with LPS plus simvastatin (LS) were more potentiated EMT effects (cell morphology changes round shape to spindle like morphology). Furthermore, BECs pretreated with simvastatin (preSL) inhibited LPS-induced EMT by downregulation of NF-kB phsophorylation. These findings indicate that, while LPS or TGF-β1 promoted EMT, the BECs pre-treated with simvastatin (preSL) inhibited LPS-induced EMT by downregulation of TLR4 and NF-kB.
Conclusion: Our results demonstrate that pre-exposure with simvastatin (preSL) inhibits the LPS-induced EMT of human BECs. This finding suggests that simvastatin can be considered as a new agent to prevent biliary fibrosis associated with EMT of BECs.

Contact E-mail Address: thirky@hanmail.net
Introduction: Adenomyomatosis of gallbladder (GB) is considered as benign condition, but several reports suggest association with malignancies, especially for segmental subtype. Because of this chance, patients suspected to have segmental or diffuse type adenomyomatosis on the imaging study may undergo cholecystectomy. But, in some cases, histopathology reveals only chronic inflammation. In this study, we aimed to analyze radiologic and pathologic features of chronic cholecystitis and adenomyomatosis for more accurate diagnosis.
Aims & Methods: Patients who performed cholecystectomy during recent four years in one medical center were reviewed retrospectively. Among those, patients who were suspected to have adenomyomatosis on their abdominal imaging but with no adenomyoma detected on the histopathologic examination were analyzed for their radiologic, pathologic and clinical features compared to patients who had consistent results between abdominal imaging and histopathologic examination.
Results: Among 3144 patients who underwent cholecystectomy, 358 patients were suspected to have GB adenomyomatosis on the abdominal imaging study. Among them (358 patients), only 92 patients had histopathologic findings compatible with adenomyomatosis. Remaining 266 patients (74.3%) did not have adenomyomatosis. Instead, many GB specimens showed chronic cholecystitis. In this group, diffuse subtype of adenomyomatosis was significantly frequent compared to 92 patients who had coherent adenomyoma finding for both imaging study and pathology. The frequency of accompanying GB stones was significantly higher in mismatching group. Radiologically, contour of GB wall thickening, intralesional cystic area and inner layer enhancement pattern was helpful in differentiating adenomyomatosis from chronic cholecystitis.
Conclusion: Chronic cholecystitis mimicking adenomyomatosis is difficult to diagnose solely based on the abdominal imaging, and this can lead to unnecessary cholecystectomy. Existence of gallstones and several radiologic features can help differentiate these challenging entities.

Introduction: Various methods for endoscopic transpapillary sampling have been developed. However, the accuracy rate of these methods for bile duct cancer are controversial. The aim of the present study was to determine the factors affecting the accuracy of endoscopic transpapillary sampling methods.
Aims & Methods: We reviewed the results from 92 patients with bile duct cancer who underwent transpapillary sampling by aspiration bile cytology, brushing cytology, and fluoroscopic forceps biopsy. The final diagnosis of bile duct cancer was made on the basis of pathological evaluation of specimens obtained at surgery or the clinical course over at least 1 year in patients not operated. We carried out subgroup analyses for the factors affecting the accuracy of each transpapillary sampling method.
Results: Transpapillary biopsy (71.2%) had a significantly higher level of sensitivity for cholangiocarcinoma than brush cytology (58.8%) and bile cytology (62.5%). Bile cytology (85.7%) showed higer diagnostic yield for pancreatic cancer with bile duct invasion than transpapillary biopsy (60%) and brush cytology (66.7%). In patients with negative biopsy results, bile cytology had higher diagnostic yield than brush cytology.
Conclusion: Transpapillary bile duct biopsy is a simple, safe, and effective technique for diagnosing biliary malignant lesion. It showed more sensitive for cholangiocarcinoma than for pancreatic cancer with bile duct invasion. After negative biopsy result, bile cytology presented higher diagnostic yield.

P0690 MULTIPLE METAL STENTS FOR COMPLEX MALIGNANT HILAR STRICTURES: PATIENTS SURVIVAL, STENTS PATENCY AND OUTCOMES OF RE-INTERVENTIONS FOR OCCLUDED STENTS

I. Boskoski[1], S. Greco[1], P. Familiari[1], A. Tringali[1], V. Perri[1], G. Costamagna[1]
[1]*Digestive Endoscopy Unit, Catholic University of Rome, Rome, Italy*

Contact E-mail Address: ivoboskoski@yahoo.com
Introduction: Endoscopic biliary drainage of malignant hilar biliary strictures (MHS) with self-expandable metal stents (SEMS) is a well-established palliative

treatment for unresectable hilar tumors. Efficacy of SEMS has been well described in distal biliary strictures, but data in complex MHS are lacking.
Aims & Methods: Retrospective review of a prospective database of all patients with MHS that underwent ERCP for symptoms palliation. Of these, only patients with multiple SEMS placement were included. Survival-associated factors and stents patency were analyzed by Cox multivariate analysis. Patients survival, stents patency and outcomes of re-interventions for occluded stents were evaluated.
Results: Between January 1998 and June 2014, 740 patients with complex MHS that underwent ERCP for palliation were identified. Among these, 134 (18.2%) patients were treated with two or more multiple SEMS. Of the 134 patients, 76 (56.7%) previously had plastic stents, 34 (25.4%) had one or more percutaneous biliary drainages and 24 patients (17.9%) received SEMS as first treatment. Mean age at time of diagnosis was 67.2 (SD26.8) years, female patients were 53.7%. Histologically, cholangiocarcinoma was the cause of stricture in 59% of patients, while 28.3% had gallbladder carcinoma. Hilar compression by lymphnodes and hilar hepatocellular carcinoma had 9.7% and 3% respectively. Regarding the Bismuth type of hilar stricture, 25.3% had type II, type III had 50.7% and type IV had 24% of the patients. Chemotherapy was done in 38.3% of patients, external-beam radiotherapy in 12.7% and high-dose-rate brachytherapy in 10%. Multiple SEMS were placed "side-by-side" after 2 to 4 guidewires were left in place into the ducts to be drained. Post-procedure complications (5.2%: 4 sphincterotomy bleedings, 3 pancreatitis) were managed conservatively. No procedure-related mortality was observed. Histological and follow-up data were available for all of the 134 patients. Seventy-nine (59%) patients died without clinical signs of SEMS occlusion, while 55 (41%) patients had SEMS occlusions and underwent ERCP. Overall mean survival of the 134 patients was 380 days (28-1455). Survival was not influenced by tumor or Bismuth type, palliative chemotherapy, sex or age ($P = 0.5$). Longer survival was found in patients that underwent high-dose rate brachytherapy with Iridium 192 ($P = 0.02$), but not in those that underwent external beam radiotherapy ($P = 0.8$). The 55 patients that had SEMS occlusion underwent 93 endoscopic re-interventions (1-6/patient) after mean 201.3 days (32-867) from the first multiple SEMS insertion and mean 140 days (30-330) between further re-interventions. Main causes for SEMS occlusion were due to sludge, overgrowth and ingrowth. Sludge was removed with balloon and flushing with saline, while plastic stents or SEMS were placed into the previous SEMS in cases of ingrowth and overgrowth. Overall mean survival after re-interventions was 432 days (91-1425) and was prolonged compared to patients that died without signs of stents occlusion ($P = 0.001$).
Conclusion: Endoscopic insertion of multiple SEMS is safe and effective in patients with complex MHS. Survival is satisfactory independently from age, sex and type of tumor. High-dose rate brachytherapy and prompt recognition of signs of SEMS occlusion are associated with prolonged survival.

P0691 RISK FACTORS OF GALLBLADDER NEOPLASMS IN SUSPICIOUS ADENOMYOMATOSIS ON COMPUTED TOMOGRAPHY

J. Kang[1], J. Hwang[1], J. Kim[1], K. Paik[1], H. Kim[1], J. Lee[1]
[1]*Seoul National University Bundang Hospital, Seongnam-si, Republic of Korea*

Contact E-mail Address: bjpgr@naver.com
Introduction: Gallbladder (GB) adenomyomatosis is not uncommon findings on computed tomography (CT). Sometimes, the lesions are confirmed as GB neoplasms (adenoma or carcinoma). However, it is quite difficult to diagnose adenomyomatosis when showing GB wall thickness on CT.
Aims & Methods: The aim of this study is to find out predictors which may indicate GB neoplasms in suspicious GB adenomyomatosis on CT before cholecystectomy.
Patients with suspicious GB adenomyomatosis on CT (the presence of one or more of the following CT findings; mucosal epithelium with intramural diverticula, multiple intramural cysts, discrete hypoattenuating lesions) and underwent cholecystectomy between January 2010 and February 2015 were reviewed retrospectively. They were divided into three groups based on the pathologic findings: chronic cholecystitis group (n = 144), adenomyomatosis group (n = 92) and GB neoplasms group (n = 13). The clinical data and CT findings were compared between the three groups.
Results: A total of 249 patients were enrolled. There was no differences between chronic cholecystitis, adenomyomatosis and neoplasms groups in terms of clinical characteristics except age (50.4y vs. 50.6y vs. 64.3y, respectively, $p < 0.001$). Moreover, morphologic types (diffuse, fundal and segmental) on CT did not predict GB neoplasms. When further analyzing between adenomyomatosis group and GB neoplasms group, older age, combined GB polyp, and GB wall enhancement were independent risk factors on GB neoplasms with statistical significance.
Conclusion: We suggest that older age, combined GB polyp, and GB wall enhancement are independent risk factors on GB neoplasms in suspicious GB adenomyomatosis on CT. Therefore, the older with suspicious adenomyomatosis would be needed further evaluations, when combined GB polyps or GB wall enhancement.

P0692 PREDICTABLE FACTORS FOR PANCREATICOBILIARY MALIGNANCY IN PATIENTS WITH ANOMALOUS UNION OF PANCREATICOBILIARY DUCT

J.-S. Park[1], T. J. Song[2], D. H. Park[3], S. S. Lee[3], D. W. Seo[3], S. K. Lee[3], M.-H. Kim[3], D. Oh[3]
[1]*Gastroenterology, Inha University Hospital, Incheon,* [2]*Asan Medical Center, Seoul, Republic of Korea,* [3]*Gastroenterology, Asan Medical Center, Seoul, Republic of Korea*

Contact E-mail Address: pjsinha@naver.com
Introduction: Anomalous union of the pancreaticobiliary duct (AUPBD) is a rare congenital anomaly in which the pancreatic and biliary ducts join anatomically outside of the duodenal wall, usually forming a markedly long common channel. The most clinically important feature of AUPBD is frequently associated with carcinomas of the biliary tract, i.e., bile duct and gallbladder. Evaluation of AUPBD-related pancreaticobiliary malignancies is essential to determining appropriate treatment of anomalous union of pancreaticobiliary duct (AUPBD).
Aims & Methods: The aim of this study is to determine the incidence of AUPBD-related pancreaticobiliary malignancies and to propose their predictable factors. We retrospectively reviewed data from 229 patients with AUPBD between January 1999 and December 2013. The incidence of AUPBD-related pancreaticobiliary diseases, particullary according to the presence of bile duct dilatation and the predictable factors for pancreaticobiliary malignancies were evaluated.
Results: Among 229 patients with AUPBD, 152 patients had common bile duct dilatation (≥10 mm) (dilated group) and 77 patients did not have bile duct dilatation (<10 mm) (non-dilated group). Intrahepatic cholangiocarcinoma (ICC) occurred more frequently in the non-dilated group than in the dilated group (non-dilated group vs. dilated group; 3.9% vs. 0%, $P < 0.05$). On the other hand, although extrahepatic cholangiocarcinoma (ECC) tended to occur more frequently in the dilated group (1.3% vs. 3.9%, P *value* $= 0.271$), there were no significant differences in most pancreaticobiliary diseases between the two groups. In univariate analysis to determine predictable factors for AUPBD-related biliary tract cancer, age, type of AUPBD, and refluxed pancreatic enzyme level in bile duct showed significant differences. In multivariate analysis, age ≥45 years (OR, 1.042; 95% CI, 1.011-1.073; $P < 0.05$), P-C type (OR, 3.327; 95% CI, 1.031-10.740; $P < 0.05$), and a high level of biliary lipase (OR, 4.132, 95% CI, 1.420-12.021; $P < 0.05$) showed a significant association with AUPBD-related biliary tract cancer.
Conclusion: ICC may occur more frequently in AUPBD patients without bile duct dilatation. Age ≥45 years, P-C type, and biliary lipase level ≥45,000 IU/L are significantly related to AUPBD-related biliary tract cancer.

P0693 LONG-TERM FOLOW-UP OF ENDOSCOPIC PAPILLECTOMY (PE) IN PATIENTS WITH MALIGNANCY OF THE MAJOR DUODENAL PAPILLA

J. C. Ardengh[1,2], E. Taglieri[2], O. Micelli-Neto[2], E. T. Ardengh[2], R. Kemp[1], J. S. dos-Santos[1]
[1]*Surgery and Anatomy of HCFMRP-USP, HCFMRP-USP, Ribeirão Preto,* [2]*Endoscopy Departament, Hospital 9 de Julho, São Paulo, Brazil*

Contact E-mail Address: jcelso@uol.com.br
Introduction: The Endoscopic Papillectomy (EP) still is a controversial procedure used to treat malignancy of the major duodenal papilla. Nowadays, the treatment chosen is duodenopancreatectomy. The aims of of this transversal and multicentric study was to establish the endoscopic treatment parameters of malignancy of the major duodenl papilla in a controlled group of patients.
Aims & Methods: From January of 2008 to June of 2014, 54 patients were referred to undergo EP after staging by endosonography. We analyzed the occurrence of adverse events, relapses and the median follow-up results of 21.3 (3-96) months. We included those whose final diagnosis was adenocarcinoma, adenoma with high-grade dysplasia or neuroendocrine tumor of the major papilla.
Results: The endoscopic biopsy shown the diagnostic of malignancy in 45% (20/54) of cases. The majority (13/20 - 65%) had jaundice at the time of the exam. The total number of patients who met the inclusion criteria was 20: 15 with the histologic diagnosis of adenocarcinoma, three with neuroendocrine carcinoma and two with adenoma with high-grade dysplasia. The resection was complete in 18/20 (90%). Adverse events occurred in 7/20 (35%): the most frequent was bleeding (3/20 - 15%), followed by acute pancreatitis (2/20 - 10%). 14 (70%) of the selected patients keep monitoring and have no sign of the disease. Six patients were submitted to surgical treatment, and three of them had residual lesion (1 with pT1 and 2 with pT3) and metastatic lymph nodes in the surgical specimen (1 with pTxN1 and 2 with pT3N1). The main indication for surgery was the final diagnosis of EP product and the involvement of the lateral and deep margin of the lesion.
Conclusion: The EP is a safe and effective procedure for the treatment of the malignnacy of the papilla. The involvement of deep and lateral resection margins was determinant to the surgical indication. To optimize the approach of the carcinomas of major duodenal papilla endoscopically, we should expect a diligent patient selection, reference centers and specialized team.

P0695 OPTIMIZATION OF TISSUE ABLATION PARAMETERS FOR ENDOBILIARY RADIOFREQUENCY IN PORCINE LIVER, BILE DUCTS AND AMPULLA OF VATER

M. Barret[1], S. Leblanc[1], A. Vienne[1], A. Rouquette[2], S. Chaussade[1], F. Prat[1]
[1]*Gastroenterology,* [2]*Pathology, Cochin Hospital, Paris, France*

Contact E-mail Address: frederic.prat@aphp.fr

Introduction: The extent of thermal tissue injury induced by endoscopic endobiliary radiofrequency ablation has been described only for a select set of parameters designed to treat malignant strictures of the common bile duct. Since potential indications of this therapeutic modality may also include shallow intrahepatic or ampullary lesions, we sought to determine the optimal generator settings for such indications.

Aims & Methods: Endobiliary radiofrequency ablation was performed in live swine on the ampulla of Vater, in the common bile duct and hepatic parenchyma. Radiofrequency ablation time, "effect", and power were allowed to vary. The animals were sacrificed 2 hours after the procedure. Histopathological assessment of the depth of thermal lesions was performed.

Results: Twenty-five radiofrequency bursts were applied in three swine. In the ampulla of Vater (n = 3), necrosis of the duodenal wall was observed starting with an effect set at 8, power output set at 10 W and a 30s shot duration, whereas superficial mucosal damage of up to 350μm in depth was recorded for an effect set at 8, a power output set at 6W and a 30 s shot duration. In the common bile duct (n = 4), a 1070 μm safe and efficient ablation was obtained for an effect set at 8, a power output of 8W, and an ablation time of 30 s. Within the hepatic parenchyma (n = 18), the depth of tissue damage varied from 1620μm (effect = 8, power = 10W, ablation time = 15 s) to 4480μm (effect = 8, power = 8W, ablation time = 90 s).

Conclusion: The duration of catheter application appeared to be the most important parameter influencing the depth of thermal injury during endobiliary radiofrequency ablation. In healthy swine, currently recommended settings of the generator may induce severe, supratherapeutic tissue damage in the biliary tree, especially in the high-risk area of the ampulla of Vater.

P0696 ROLE OF PROCALCITONIN AND C-REACTIVE PROTEIN AS BIOMARKERS OF INFECTION IN CHILDREN WITH LIVER DISEASE

A. Srivastava[1], R. Bolia[1], R. Marak[2], S. K. Yachha[1], U. Poddar[1]
[1]*Pediatric Gastroenterology,* [2]*Microbiology, Sanjay Gandhi Postgraduate Institute of Medical Sciences, Lucknow, India*

Contact E-mail Address: avanianshu@yahoo.com

Introduction: Infection with organ failure is an important cause of mortality in patients with liver disease. Early and accurate identification of infection in these patients is challenging.

Aims & Methods: This study evaluated the role of procalcitonin (PCT) and C-reactive protein (CRP) as biomarkers of bacterial infection in children with liver disease.

Demographic and clinical data of consecutive children admitted with acute liver failure (ALF) or decompensated chronic liver disease (DCLD) were collected prospectively. Children were evaluated for infection at admission with hemogram including total and differential leukocyte count, PCT, CRP, blood and urine culture, chest X-ray and ascitic fluid analysis including culture in those with ascites. Systemic inflammatory response syndrome (SIRS) and severe sepsis were defined as per the International pediatric sepsis consensus definition[1].

Results: 164 children (113 boys, age 76(0.5 – 204) months, ALF = 69, DCLD = 95) were enrolled. 77 (47%) subjects had infection, most common site being ascitic fluid (AFI, n = 35), followed by urinary tract (UTI, n = 26), pneumonia (n = 22) and blood stream infection (BSI, n = 16). 21 children had multiple site infections, 18 had severe sepsis and 36 had SIRS.

Subjects with infection had significantly higher PCT (1.7 [0.1 – 38.1] ng/ml vs.0.3 [0.1 – 6.8] ng/ml; p = 0.00), CRP (1.82 [0.3 – 24] mg/dL vs. 0.33 [0.1 – 4.2] mg/dL, p = 0.00) and TLC (14,000 [3600 – 43800] /mm^3 vs. 8800 [3800 – 39600] / mm^3, p = 0.00) as compared to those without infection. Presence of fever did not

help in differentiating patients with and without infection (27/77 vs. 20/87, p=0.1). PCT and CRP values were not different in patients with various sites of infection i.e. BSI, AFI, UTI or pneumonia. PCT and CRP correlated with infection severity, highest in severe sepsis [8.3(3.5 – 38) ng/mL and 4.1(0.3 – 13.8) mg/dL] than infection [0.89 (0.1– 8) ng/mL and 1.7 (0.32-24) mg/dL] than no infection [0.3 (0.1 – 6.75) ng/mL and 0.3 (0.1 – 4.16 mg/dL). Sensitivity, specificity and likelihood ratio (LR) of CRP, PCT and TLC in identifying infection in children with liver disease is shown in Table 1. SIRS was commoner in patients with infection (31/77 vs. 5/87, p = 0.00). PCT (> 0.5 ng/ml) and CRP (>0.6 mg/dL) performed better in DCLD (AUC of 0.90 and 0.83) as compared to ALF patients (AUC of 0.73 and 0.69).

Conclusion: PCT and CRP are reliable markers of infection and correlate with infection severity in children with liver disease. Their diagnostic accuracy is better in DCLD than ALF cases. SIRS is significantly more common in patients with infection.

Introduction: Due to the modulatory effect on intestinal microflora, probiotics could be potentially used to prevent complication after hepatoportoenterostomy in children with biliary atresia, which can lead to progression of liver disease and require liver transplantation.

Aims & Methods: In this study we aimed at evaluating LGG probiotic treatment during the course of biliary atresia after the hepatoportoenterostomy in respect of clinical outcomes, liver function tests, gut microflora and intestinal barrier.

The patients were randomly assigned to two groups ingesting probiotic or placebo (1:1). The active preparation was the LGG probiotic (Lactobacillus GG) administered as capsuled powder (Dicoflor 60 preparation) for 6 months. Initially, after 3, 6 and 9 months the following parameters were assessed: A. anthropometric B. laboratory C. stool examination:- quantitative assessment of the gut microbiota composition by growing methods with the use of non-selective (differential) and selective growth media; quantitative assessment of the short-chain fatty acids (acetic, butyric and priopionic) and lactic acid; Alpha-1 Antitrypsin (A1AT) concentration in stool as a marker of intestinal barrier permeability.

The study included 30 children: 13 girls and 17 boys aged <4 months suffering from chronic cholestasis in the course of bile duct obstruction. In all patients, the bile duct obstruction diagnosis was intraoperatively confirmed and the Kasai portoenterostomy was performed.

Results: After 6 months there were 3 children in the LGG group suffering from at least one ascending cholangitis episode compared to 8 children in the placebo group, which was not statistically different. The number of all infections amounted to 6 in the LGG group and 12 in the placebo patients (ns). During the intervention, 7 out of 14 patients taking LGG and 5 out of 16 placebo patients were qualified for liver transplantation (no statistical difference).The level of conjugated bilirubin decreased below 2 mg/dl during the 6 months long trial in 6 patients in the LGG group and in 8 patients in the placebo group (ns) .After the intervention, clinical parameters (weight, height) and biochemical parameters (liver enzymes activity, the level of total and conjugated bilirubin, total protein and albumins, vitamin A and E) were similar both in the LGG and placebo groups. The level of Alpha-1 Antitrypsin (A1AT) concentration in stools was within normal limits. Also, the statistical differences between groups were not revealed.The gut microbiota and gut microbiota metabolisms of both groups measured with the use of SCFA did not differ after 6 months.

Conclusion: The LGG supplementation after the Kasai portoenterostomy in children suffering from the bile duct obstruction in the pilot study did not significantly influence the incidence of ascending cholangitis, the course of cholestatic liver disease, the death risk and the liver transplantation necessity.The LGG supplementation did not significantly influence gut microbiota and its metabolism.

Introduction: The incidence of pediatric pancreatitis (PP) has increased in the last decade. Some of the recent studies showed that the occurrence of the disease has grown over 10/100,000 which is not much less than in adults. We have established the Paediatric Section of the Hungarian Pancreatic Study Group in order to organize nationwide data collection and improve themanagement of the disease.

Aims & Methods: Our aim was to analyse the epidemiology, risk factors, management and clinical outcome of PP in Hungary. 56 children suffering from PP were enrolled from 7 centres between 2012 and 2014.

Results: 61% of the children were female. 31 acute (AP), 11 recurrent acute (RAP) and 14 chronic pancreatitis (CP) cases were recorded in the registry. 84% of the AP patients had mild and 16% moderate episodes, however, no severe AP was observed. In RAP patients pancreatitis seemed to be more severe than in patients having isolated episodes (mild: 73% moderate: 18%, severe: 9%). Mortality was not observed at all. Without genetic testing we could identify the etiological factors only in 44% of the cases, the others remained idiopathic. In 17 cases, genetic analyses of PRSS1, SPINK1, CFTR and CTRC genes have been completed. Genetic alterations in PRSS1 were found in 3 cases (all CP), in SPINK1 in 4 cases (1 RAP and 3 CP), in CFTR in 1 case (CP) and in CTRC in 10 cases (3 AP and 7 CP). In 5 CP patients mutations in two genes were observed (3 SPINK1-CTRC, 1 PRSS1-SPINK, 1 CFTR-CTRC).

Conclusion: Genetic testing is essential to identify the etiological factors in children with pancreatitis.

Introduction: The documented incidence of pediatric pancreatitis (PP) is very low, less than 1/100,000 in almost all European countries, whereas it is around 3.6-13.2 in the USA and Australia. Moreover, there are unexpectedly large differences between the incidences of PP among the countries and hospitals in Europe.

Aims & Methods: The aim of the PINEAPPLE study (ISRCTN35618458) is to understand the current practice of diagnosis of PP and to develop EBM guidelines that helps to evaluate (in a reliable and cost efficient way) the necessity of pancreatic enzyme measurement (PEM) and abdominal ultrasonography when a child has abdominal pain.

PINEAPPLE is a registered, multinational observational clinical trial. The PINEAPPLE-R subtrial is a retrospective review on children (patients under 18) records appearing at ER units, whereas, the PINEAPPLE-P subtrial is a prospective part of the study where detailed patients data (concerning medical history, complaints, symptoms, physical examination) are collected and PEM and abdominal imaging are performed in all cases. Until now 6012 patients records/PINEAPPLE-R and 90 patients/PINEAPPLE-P were enrolled from five pediatric centres.

Results: PINEAPPLE-R: 12% (710/6012) of the patients appearing at ER unit had abdominal pain. Only 2,5% (18/710) of them had PEM, whereas 30% (213/710) had transabdominal ultrasonograpy. Pancreatitis was diagnosed in one case only. PINEAPPLE-P: 1 pancreatitis of 90 patients with abdominal pain was diagnosed.

Conclusion: The PINEAPPLE-R study clearly shows that the number of PEM performed at ER units are unacceptably low in children, which could be the reason of low incidences of PP. More patients are crucially needed for PINEAPPLE-P in order to develop EBM guidelines.

Contact E-mail Address: j.vangrinsven@pancreatitis.nl
Introduction: Infected necrotizing pancreatitis is nearly always an indication for invasive treatment. Percutaneous catheter drainage (PCD) is now well established as the first intervention in a 'step-up approach'. It has been suggested that a drain upsizing strategy might obviate the need for additional surgical necrosectomy and improve clinical outcome, but studies on this topic are lacking.
Aims & Methods: We retrospectively identified patients with necrotizing pancreatitis from in-hospital databases (2004-2014) in four tertiary referral centers. Patients who underwent PCD as primary treatment for suspected infected necrosis were included. We compared patients' outcomes of a single center that attempted to routinely upsize in case of lack of clinical improvement with those of patients treated in the three centers where this strategy was not used routinely. Primary outcome was the need for additional surgical necrosectomy following PCD. Secondly, we compared complications including mortality and new onset (multi) organ failure.
Results: Of 1427 consecutive patients with acute pancreatitis, 369 patients (26%) were diagnosed with necrotizing pancreatitis, of which 117 patients (32%) underwent primary PCD for suspected infected necrosis. Infected necrosis was ultimately proven in 82 of these patients (70%). In total 42 patients (36%) were treated in the drain upsizing strategy center versus 75 patients (64%) in the non-upsizing strategy centers. Patient characteristics were similar in baseline, except for differences in age and timing of first PCD for which we corrected in the analyses. The median of drain procedures was 3 (interquartile range (IQR) 2-4) in the upsizing strategy center versus 2 (IQR 1-2) in the non-upsizing strategy centers, $P < .001$. The maximal drain size was median 16 French (IQR 14-20) compared to 14 French (IQR 12-14), $P < .001$, respectively. Additional surgical necrosectomy was required in significantly less patients in the upsizing strategy center, 29% vs. 52% $P = .045$. Mortality was comparable in both groups, 17% vs. 19%, $P = 0.79$. New onset (multi) organ failure after PCD occurred in 5% of patients in the upsizing strategy center compared to 20% of patients in the non-upsizing strategy centers, $P = 0.11$.
Conclusion: A PCD upsizing strategy for patients with suspected infected necrotizing pancreatitis appears to reduce the need for surgical necrosectomy. Future studies will have to demonstrate the true clinical value of PCD upsizing and whether this should be performed on indication or preemptively.

Introduction: Acute lung injury (ALI) is the commonest organ failure in patients with acute pancreatitis (AP). It is a major cause of early mortality in such patients and cytokines play a major role in its pathophysiology.
Aims & Methods: Aim & Methods: To study the predictive role of inflammatory cytokines in development of ALI in patients with AP.
In this prospective study between July 2013 and December 2014 consecutive eligible patients of AP underwent complete demographic, clinical, biochemical and radiological evaluation. Severity classification was done using revised Atlanta classification and also systemic inflammatory response score (SIRS) and Bedside Index of Severity of Acute Pancreatitis(BISAP), CT Severity Index (CTSI) and APACHE II scores were used. Serial arterial blood gas (ABG) analyses were done and ALI severity defined as per Berlin Classification using PaO_2/FiO_2 ratio. Development of ALI was monitored in all the patients. Serum levels of interleukin (IL)-6, IL-8, IL-10, IL-1b and TNFa were measured at baseline (day 1) for all patients and on day 3 in those who had ALI. For comparative analysis patients were divided into 2 groups: with and without ALI. The ALI cohort was further subdivided into persistent ALI (P-ALI) and transient ALI (T-ALI). A subgroup of ALI patients who developed ALI later during hospital stay was defined as "late onset" ALI (LO-ALI) to devise a predictive model for ALI using cytokine levels. Statistical analysis was done using SPSSv22.0
Results: Of the 107 patients (mean age of 38.4 yrs, 64.5% males, etiology: alcohol 36.4% gallstone disease 26.2% and others 51.4%), ALI developed in 51 (47.7%) of whom 40(78.4%) had ALI on admission while 11(21.6%) had LO-ALI. T-ALI was seen in 16(31.4%) while 35 (68.6%) had P-ALI. Patients with ALI had significantly higher IL-1b ($p < 0.0001$), IL-6 ($p < 0.0001$), IL-8 ($P < 0.001$) and TNFa ($P < 0.0001$) and lower IL-10 ($p < 0.0001$) levels on day 1, when compared to non-ALI group. In the ALI group, day 3 levels of IL-1b ($p = 0.001$), IL-6 ($p = 0.02$), IL-8 ($p = 0.006$) and TNFa ($p = 0.006$) were significantly higher than day 1 levels. Significant rise on day 3 of only IL-1b ($p = 0.04$) was observed in T-ALI group as compared to both IL-1b ($p = 0.001$) and TNFa ($p = 0.02$) in the P-ALI group. Day 1 levels of IL-6 and IL-8 had strong positive correlation with severity indices such as SIRS ($p < 0.001$), BISAP ($p < 0.001$) and CTSI ($p < 0.0001$) as also with outcome measures such as need for intervention ($p < 0.0001$), hospital stay ($p < 0.0001$) and intensive care stay ($p < 0.0001$). LO-ALI group had significantly higher levels of IL-6 ($p < 0.0001$), IL-8 ($p < 0.0001$), TNFα ($p < 0.0001$) and IL-1β ($p < 0.006$). IL-6 at cut off levels of 84.85 pg/mL (AUC = 0.94, sensitivity & specificity 91%) and IL-8 at cut off level of 112.5 pg/mL (AUC = 0.909, sensitivity 91% specificity 94.6%) predicted subsequent development of ALI.
Conclusion: Rising levels of IL-1b and TNFα suggest development of persistent ALI. IL-6 and IL-8 levels at admission can predict the future development of late onset ALI.

Introduction: The commonest organ failure in patients with acute pancreatitis (AP) is acute lung injury (ALI). Data on pulmonary function tests (PFT) in AP is limited.
Aims & Methods: To study PFT in patients with AP and evaluate the role of PFTs in predicting ALI.
In this prospective study between July 2013 and December 2014 consecutive patients of AP underwent complete demographic, clinical, biochemical and radiological evaluation. Severity classification was done using revised Atlanta classification and also systemic inflammatory response score (SIRS) and Bedside Index of Severity of Acute Pancreatitis (BISAP), CT Severity Index (CTSI) and APACHE II scores were used. Serial arterial blood gas (ABG) analyses were done and ALI severity defined as per Berlin classification using PaO_2/FiO_2 ratio. Development of ALI was monitored in all the patients. PFTs were done by spirometry as soon as possible after admission. Forced expiratory volume in first second (FEV_1), forced vital capacity (FVC) and FEV_1/FVC ratio were used as basic parameters for interpretation and all measurements were expressed as a percentage of their predicted values (FVC%, FEV_1%). Patients were divided into 2 groups: with and without ALI. The ALI cohort was further subdivided into persistent ALI (P-ALI) and transient ALI (T-ALI). A subgroup of ALI group which developed ALI later during hospital stay was defined as "later onset" ALI (LO-ALI) to devise a predictive model for ALI with PFT parameters. Statistical analysis was done using SPSSv22.0
Results: Of the 107 patients (mean age of 38.4 yrs, 64.5% males, etiology: alcohol 36.4% gallstone disease 26.2% and others 51.4%), ALI developed in 51 (47.7%) patients of whom 40 (78.4%) had ALI on admission while 11 (21.6%) had LO-ALI. T-ALI was seen in 16 (31.4%) while 35 (68.6%) had P-ALI. PFT could be performed in 87 patients (52 non-ALI, 35 ALI including 9 from LO-ALI subgroup). ALI group had significantly lower FVC% ($p < 0.0001$) and FEV_1% ($p < 0.0001$) signifying higher lung dysfunction compared to those without ALI. Similarly, P-ALI had lower FVC% (58.9 ± 14.8 vs. 69.6 ± 17.2, $p = 0.06$) and lower FEV_1% ($p = 0.04$) than T-ALI. A significant correlation existed between PaO_2/FiO_2 ratio and FVC% ($r = 0.513$, $P < 0.0001$) and FEV_1% ($r = 0.488$, $p < 0.0001$). Both FEV_1% and FVC% showed significant correlation with other severity parameters such as SIRS ($p < 0.0001$), BISAP ($p < 0.00011$), CTSI ($p < 0.0001$) and APACHE II ($p < 0.002$) and also with need for intervention ($p = 0.04$), hospital stay ($p < 0.0001$) and intensive care stay ($p = 0.001$). LO-ALI (9) had significantly lower FVC% ($p = 0.02$) and FEV_1% ($p = 0.03$) as compared to those without ALI, but a predictive cut off could not be achieved (AUC = 0.257, $p = 0.021$) due to small numbers.
Conclusion: Patients who eventually develop ALI later have more severe lung dysfunction at baseline than those who do not and PFTs can act as a tool to predict it.

Introduction: Use of a pancreatic stent (PS) to facilitate biliary cannulation is one of the so called pancreatic techniques in which the pancreas serve as a step to gain the Common Bile Duct (CBD). We report on the performance characteristics of using a new plastic PS to facilitate CBD cannulation in difficult ERCP.
Aims & Methods: CBD cannulation was attempted with a sphincterotome loaded with a guidewire controlled by the endoscopist. In cases of difficult biliary access in which the Pancreatic Duct was cannulated, an straight Advanix PS (Boston Scientific), having 5 french, and 4 cm in length without inner barbs was placed. This PS has a proximal radiopaque marker that facilitates recognition of the indwelling position. After this, physician-controlled guidewire was attempted by using the PS to direct the sphincterotome into the CBD.
Results: Among 98 ERCPs in patients with naïve Papilla, 16 (16.3%) received an Advanix PS to facilitate biliary cannulation. Successful cannulation was achieved in 16 (100%) without the need of Needle-Knife-Precut. In one patient the PS dislodged from the Papilla during cannulation attempts. No postERCP pancreatitis was observed. There were eight patients with CBD stones, three with pancreatic head cancer and five with type I sphincter of Oddi dysfunction after cholecistectomy. On radiological follow-up, 7/15 (47%) PS had spontaneouly passed after two weeks, whereas 8/15 (53%) remained still in place and had to be removed by gastroscopy. No pancreatitis occurred after removal.
Conclusion: Endoscopist-controlled guidewire over this new PS facilitates biliary cannulation and appears to prevent from postERCP pancreatitis. The PS althougth has no inner barbs, remained in place for more than two weeks in half of the patients and had to be removed by gastroscopy. The inner radiopaque marker results very useful to know its position.

P0704 GHRELIN MOLECULAR SYSTEM IN THE PROTECTION OF PANCREATIC ACINAR CELLS

J. Bonior[1], **J. Jaworek**[1], M. Kot[1], P. Pierzchalski[1]
[1]*Department of Medical Physiology, Faculty of Health Sciences, Jagiellonian University Medical College, Krakow, Poland*

Contact E-mail Address: joanna.bonior@uj.edu.pl
Introduction: Ghrelin (GHRL), an endogenous ligand for the growth hormone (GH) secretagogue receptor (GHS-R) has been isolated from the stomach and identified in the pancreas. GHRL has been demonstrated to protect pancreatic tissue from caerulein-induced acute pancreatitis (CIP).
Aims & Methods: To investigate the effect of GHRL and caerulein on gene expressions and on protein signals of GHRL, GHS-R1 and of an antioxidant enzyme: superoxide dysmutase (SOD) in the isolated pancreatic acini.
Pancreatic acini were isolated by collagenase digestion from control rats and from rats pretreated with GHRL (50,0 μg/kg i. p.) administered 48 hours before the isolation. Isolated acini were incubated with high concentration of caerulein (10^{-8}M). The gene expressions were determined by RT-PCR, whereas the protein contents were assessed employing Western-blot.
Results: Protein expressions and mRNA signals for GHS-R1a receptor, GHRL and for SOD-3 have been detected in the pancreatic acini under basal conditions and have been significantly upregulated following application of GHRL to the rats. Incubation with caerulein markedly downregulated signals of GHS-R1a and SOD-3 in pancreatic acini, but failed to affect these for GHRL. Pretreatment of rats with GHRL prevented caerulin-induced suppression of GHS-R1a and SOD-3 signals.
Conclusion: Caerulein overstimulation is able to modify the GHS-R1a receptor in the pancreatic acini and this effect could be prevented by pretreatment of rats with GHRL. Protective effect of GHRL on caerulein-induced pancreatitis could be dependent, at least in part, on the activation of SOD and improvement of antioxidant system in the pancreas.

Contact E-mail Address: jcelso@uol.com.br
Introduction: The surgical necrosectomy (SUR-N) of walled-off pancreatic necrosis (WOPN) has high morbidity and mortality rates. The new options of treatments have been increasingly used such as step-up approach and endoscopic drainage. The endoscopic approach is not yet defined as a first option for this treatment, but have been increasingly used for its efficacy, safety and the possibility of necrosis approach in any situation with the aid of endoscopic ultrasonography (EUS).
Aims & Methods: The objective was to study and compare the characteristics, clinical course, the immediate and late adverse events in patients with WOPN treated by SUR-N and EUS-guided necrosectomy (EUS-N). 63 patients with WOPN were treated by SUR-N (35) and EUS-N (28) from Aug/90 to Jul/2014.
Results: The mean age was higher in the EUS-N ($p < 0.01$). Sex, ASA index, diabetes, obesity, and cardiovascular risk factor before treatment were similar to the SUR-N and EUS-N groups ($p > 0.05$). Cause of AP ($p = 0.06$), infected necrosis ($p = 0.13$) and median time from onset of symptoms to treatment ($p = 0.34$) were similar for both groups. The Marshal ($p < 0.01$) and CT Balthazar score ($p < 0.01$) were significantly higher for SUR-N. Acute adverse events were statistically significant for the EUS-N vs SUR-N (71% vs 37%, $p < 0.01$). Despite the occurrence only in SUR-N group of sepsis, post-operative hernia, bowell obstruction, pneumonia, fistula (pancreatic and biliary) and chylous ascites there was no statistical difference compared to EUS-N group. The late adverse events were statistically significant for patients undergoing SUR-N vs EUS-N in relation to bowell and biliary obstruction (21% vs 0%, $p = 0.04$ and 27% vs 0%, $p = 0.01$, respectively) and required surgery (36% vs. 8%, $p = 0.02$, respectively). The average follow-up was 493 days, there was no difference between patients who underwent SUR-N and EUS-N in relation to pancreatic sequelae, including pseudocyst ($p = 0.62$), cases of onset diabetes ($p = 0.31$) or need for pancreatic enzymes ($p = 0.29$).
Conclusion: Compared to SUR-N, the EUS-N showed a lower rate of adverse events. EUS-N appears to be a safe and effective procedure must be included in the therapeutic algorithm patients with WOPN.

Introduction: Excessive ethanol consumption is one of the most common causes of acute and chronic pancreatitis. It is also documented that genetic defects of CFTR can lead to pancreatitis, however the effects of alcohol consumption on CFTR function in the pancreas is not known.
Aims & Methods: Our aim was to investigate the effects of ethanol and ethanol metabolites on the exocrine pancreatic fluid and bicarbonate secretion and on CFTR function and expression. Intra/interlobular pancreatic ducts were isolated from guinea pigs to study the effects of ethanol and ethanol metabolites on the *in vitro* pancreatic fluid and bicarbonate secretion. In vivo exocrine pancreatic secretion of anesthetized mice has been investigated using magnetic resonance cholangiopancreaticography (MRCP). The effects of ethanol and ethanol metabolites on CFTR activity pancreatic ductal epithelial cells (PDEC) was measured by patch clamp. CFTR expression in human tissue samples were assessed by immunohistochemistry in control human pancreatic tissue and in acute and chronic alcohol-induced pancreatitis. The mechanism of the decreased CFTR expression has been characterized in MDCK cell by western blot, cell surface elisa and pulse chase experiments.
Results: The administration of 100mM ethanol, or the non-oxidative ethanol metabolite palmitoleic acid (POA; 200μM) markedly reduced the *in vitro* fluid and bicarbonate secretion of isolated guinea pig pancreatic ducts. Moreover MRCP showed that the total excreted volume (used as a marker of the *in vivo* pancreatic fluid secretion) was significantly decreased after the i.p. injection of 1.75g/kg ethanol and 750mg/kg palmitic acid (PA). Exposure of guinea pig PDEC to 100mM ethanol or 200μM POA significantly decreased the forskolin-stimulated CFTR currents. Next we evaluated the effect of ethanol on the CFTR expression. Using human tissue samples we showed that CFTR expression was significantly decreased in acute or chronic alcohol-induced pancreatitis both at mRNA and protein levels. Similar decrease of pancreatic ductal CFTR expression has been observed in guinea pigs after the i.p. injection of 1.75g/kg ethanol and 750mg/kg PA. Experiments on MDCK-II cell expressing WT human CFTR revealed that ethanol and its metabolites decrease CFTR expression and plasma membrane density via accelerated channel plasma membrane turn over and damaged protein folding.
Conclusion: The findings indicate that alcohol and alcohol metabolites induce a loss of CFTR function and expression, which in turn impairs pancreatic ductal fluid and bicarbonate secretion. We suggest that the correction of CFTR function and expression should offer therapeutic benefit.

Contact E-mail Address: dhakanaren@gmail.com
Introduction: Necrosis in patients of pancreatitis can be either pancreatic, peripancreatic or both. However the impact of site of necrosis over collection location and disease outcome is still unknown.
Aims & Methods: To evaluate the impact of site of necrosis upon location of collections and outcome in patients of Acute Necrotizing Pancreatitis (ANP).
161 Patients with ANP (Mean age-39.91 ± 13.78 yrs) were classified according to the site of necrosis [Pancreatic (Group I), Peripancreatic (Group II) or both (Group III)]. They were managed as per institute protocol (Step up), followed up for development of fluid collections and then categorized according to locations of collections within the abdominal cavity [Pancreatic (A), Peripancreatic (B), both (C), Peripancreatic with distant (D) and at all sites (E)]. Outcome variables were hospital stay, ICU stay, need for pigtail drainage, surgery and mortality. Data was recorded in excel sheet and statistical analysis was done using SPSS v17.0.
Results: Type III necrosis was the commonest type of necrosis (n = 69, 42.8%), followed by type II (n = 46, 28.57%) and type I necrosis (n = 46, 28.57%). Type I necrosis was significantly associated with collection location C [32(82.6%)], whereas type II necrosis had significant association with location D [20(43.47)] and Type III necrosis had association with location E [59(85.5%)] ($p < 0.001$). Surgery, mortality and need for percutaneous drainage were exclusively seen in type III necrosis [7(10.14%), 14(20.28%), 54(78.26%)]. Duration of hospital and ICU stay were significantly associated with type III compared to type I necrosis (34.28 ± 24.88 vs. 13.26 ± 7.46 days, 8.17 ± 12.96 vs. 0.89 ± 2.72 days, $p < 0.001$).
Conclusion: Collections develop in a compartment more than the area of necrosis. Outcome of patients with necrosis involving both pancreas and peripancreatic region is worst followed by only peripancreatic necrosis and pancreatic necrosis alone in sequence.

Introduction: We have previously described a multi-step high-content screening approach to identify novel functionally relevant target genes in pancreatic ductal adenocarcinoma (Buchholz et al. 2015, *PLoS-One*, 10:e0122946). The results of these analyses predicted an unexpected and previously undocumented role for the small actin-binding protein cofilin-1 in growth control of pancreatic cancer cells.
Aims & Methods: Multiple tissue arrays, RNAi, cell proliferation and viability assays, FACS analysis, Western blot, inducible shRNA clones, reporter gene assays.
Results: Cofilin-1 is strongly overexpressed in human pancreatic ductal adenocarcinoma both at the mRNA and at the protein level. RNAi-mediated knockdown of cofilin-1 gene expression in four different pancreatic cancer cell lines resulted in significantly reduced cell viability and proliferation rates, while apoptosis was not induced. Further, the capacity for anchorage-independent growth was strongly reduced in the absence of cofilin-1 expression. Moreover, stable repression of cofilin-1 expression in pancreatic cancer cell clones significantly decreased the growth of xenograft tumors *in vivo*. Flow cytometric analyses indicated that these effects were primarily mediated by attenuation of G1/S transition during cell cycle. Mechanistically, CFL1 knockdown resulted in simultaneous overactivation of the MAL/SRF transcription factor complex and downregulation of expression of the Hedgehog pathway effector Gli1, which is well known to regulate pancreatic cancer cell growth.
Conclusion: In addition to its previously known roles in actin dynamics and cell motility, cofilin-1 has a direct and essential role in growth regulation of pancreatic cancer cells. The clinical significance of this observation is emphasised by the strong and widespread overexpression of cofilin-1 in human PDAC.

Contact E-mail Address: elena.rangelova@ki.se
Introduction: Active cellular therapy (ACT) using *ex-vivo* expanded T-cells from patients with cancer, obtained by apheresis, can represent a viable source for anti-cancer directed cellular therapy. The objective was to establishe a T-cell expansion protocol using two rounds of re-stimulation with TAA peptides along with IL-2, IL-15 and IL-21. In order to gauge the ex-vivo cellular reactivity as well as the potential to successful expand antigen-specific T-cells from patients with pancreatic cancer, a screening assay using whole-heparin blood, to gauge for TAA reactivity (NY-ESO-1, survivin, mesothelin) and control antigens (EBNA-1, EBNA-3, CMVpp65) was established.
Aims & Methods: Fresh blood samples were obtained from 24 patients with pancreatic cancer and from 6 individuals with pre-malignant lesions and tested for anti-TAA reactivity defined by CD3 + CD4+/CD3 + CD8+ T-cell proliferation and IFN- γ production. T-cells were expanded without cytokines, with IL-2 and IL-7, or with IL-2, IL-15 and IL-21. For T-cell expansion, PBMCs were expanded by adding cytokine and TAA peptides. CD3, CD4, CD8, CD45RA and CCR7 were determined by flow cytometry and TAA-reactive T-cells were identified by ICS (IL-2, TNF, IFN and IL-17).
Results: IFN-γ responses were detected in 90% (27 of 30) in blood samples for mesothelin, 55.3% (16 of 30) for survivin and 43.3% (13 of 30) for NY-ESO-1 (without adding cytokines). Cellular responses could be augmented by adding cytokines, i.e. IL-2 and IL-7 (to favor CD4+ T cell proliferation) or IL-2, IL-15 and IL-21 (to favor CD8+ T cell proliferation). IFN-γ responses were detecetd in 100% (30 of 30) in blood samples for EBNA1, 100% (30 of 30) for EBNA3 and 93.3% (28 of 30) for CMV without the addition of cytokines and the cellular responses could be augmented by adding cytokines. TAA-reactive T cells could be successfully expanded ex vivo and exhibited TAA-specific production of IFN-γ and TNF-α and a CD8 + CD45RA-CCR7+ phenotype.
Conclusion: A TAA-specific whole blood assay can be used to gauge the potential for expansion of TAA-reactive T-cells in peripheral blood from patients with pancreatic cancer. TAA-reactive T-cells can be successfully expanded in IL-2, IL-15 and IL-21 and could represent a viable source for the cellular therapy of patients with pancreatic cancer.

P0711 GENERATION OF TUMOR-INFILTRATING LYMPHOCYTE CULTURES FROM PANCREATIC CANCER FOR ADOPTIVE TRANSFER THERAPY

E. Rangelova[1,2], Q. Meng[3], L. Zhiang[4], T. Poiret[4], C. Verbeke[5], E. Dodoo[6], R. Segersvärd[1,2], M. Del Chiaro[1,2], M. Maeurer[4]
[1]*Division of Surgery, Karolinska University Hospital,* [2]*CLINTEC,* [3]*Karolinska Institute, Stockholm, Sweden,* [4]*Therapeutic Immunology, Karolinska Institute,* [5]*Division of Pathology,* [6]*Department of neurosurgery, Karolinska University Hospital, Stockholm, Sweden*

Contact E-mail Address: elena.rangelova@ki.se
Introduction: The generation of T-lymphocyte cultures with specific reactivity against autologous tumor is a prerequisite for effective adoptive transfer therapies – among the most successful of immune therapies. Pancreatic cancer-specific tumor-infiltrating lymphocyte (TIL) cultures are difficult to obtain, but can represent a viable T-cell source for cellular therapy of patients with pancreatic cancer. The objective was to optimize the method for generation of T-lymphocyte cultures from pancreatic cancer TILs.
Aims & Methods: Pancreatic cancer tissue was obtained by excision or core biopsy from the fresh surgical specimens of 30 patients and cultured for 10 days with cytokines (IL-2, IL-15, and IL-21). TILs were extracted and expanded using OKT-3 and irradiated allogenic peripheral blood mononuclear cells. The specific activity of TILs for recognition of tumor-associated antigens (mesothelin, survivin, and NY-ESO-1) was evaluated by IFN-γ production and intracellular cytokine production and detected by ELISA and ICS. Clonal T-cell populations were tested by a panel of TCR Vβ-specific antibodies and by TCR CDR3 PCR-guided analysis, along with T-cell differentiation and exhaustion markers by flow cytometry.
Results: TILs from all 30 patients, up to 10e11 cells, could successfully be expanded using the combination of IL-2/15/21. Even the core biopsy specimens yielded at least 1.5 x 10e9 CD8 + TILs. Four-week TIL-cultures showed up to 90% CD8 + T-cells, yet one culture exhibited exclusively CD4 + TILs with a CD45RA-CCR7+ phenotype. The majority of the CD8+ and CD4+ TILs resided in the central memory and effector memory subsets (CCR7 + CD45RA- and CCR7-CD45RA-). Some TIL cultures showed preferential expression of TCR-Vβ families - in CD8 + TILs 99.3% in Vβ13.2, 77% in Vβ1, 68.7% in Vβ22, 64% in Vβ14 for individual patients. 30% of the expanded Vβ families were monoclonal. ICS analysis showed a low frequency (up to 2.5%) of mesothelin, survivin or NY-ESO-1 reactive CD8 + TILs. TILs from one patient showed up to 15% NY-ESO-1 specific IFN-γ and TNF-α production in CD4+ and CD8 + TILs. Specific T-cell killing of autologous tumor cells could be demonstrated by chromium-51 release essay – up to 70% cancer cell death with 25:1 TIL-to-tumor cell ratio.
Conclusion: The methods for the robust and fast TIL-generation from pancreatic cancer tissue were optimized using a cytokine cocktail of IL-2/IL-15/IL-21 even for small biopsies. TILs show a central-memory and effector memory phenotype and are monoclonal, which is a good prerequisite for efficient T-cell therapy.

Introduction: Pancreatic cancer is a uniformly lethal disease that is difficult to diagnose at an early stage and even more difficult to cure. The current methods for diagnosing pancreatic cancer are ineffective and/or impractical for identifying smaller, potentially curable lesions. Gastrokine (GKN1-3) is a secreted auto-/paracrine protein in the gastric mucosa which shows growth factor or 'cytokine-like' activity toward gastric epithelial cells. GKN expression has so far been shown predominantly in the stomach, except for trace levels in the uterus and placenta and in the duodenum. In the stomach, GKN expression is confined to the gastric epithelium, where individual paralogs (GKN1-3) manifest remarkable cell-type-specific localization on different mucus-secreting epithelial lineages. Definitive physiological functions have not been formally ascribed to GKNs. The limited published evidence suggests fundamental roles in regulating gastric epithelial homeostasis and tumor suppression. While current research focuses on the exploration of tumor-suppressive properties of GKN1 regarding gastric tumors, nothing is known about GKN expression and function in other organ systems. Within the frame of a whole genome microarray analysis of a mouse model for pancreatic carcinogenesis (KrasxPtf1a), we have found gastrokines strikingly upregulated in the pancreas during pre-neoplastic conversion.

Aims & Methods: The aim of the study is to investigate gastrokine expression and function during pancreatic carcinogenesis. Gastrokine mRNA expression was confirmed by RT-PCR in human patients and different mouse models (pancreatitis and pancreatic carcinogenesis). Data mining of human microarray results focused on benign and malignant pancreatic diseases. Gastrokines were visualized by immunohistochemistry. The presence of GKNs in different stages of pre-malignant lesions was defined by IHC and mucin co-expression analysis. Secretion of GKNs in mouse pancreatic juice was shown by proteomic analysis. In vitro acinar assays were performed to analyze GKN expression during acinar transdifferentiation.

Results: Gastrokine expression is highly upregulated during the early stages of mouse pancreatic carcinogenesis. GKN transcripts are also increased in human patients in peri-tumoral tissue and in benign pancreatic tumors. GKN expression is neither detected in healthy pancreas nor in samples with pancreatic inflammation. Immunohistochemistry reveals strong GKN expression in pre-malignant PanIN lesions. GKN1 is abundant in the cytoplasm of dysplastic epithelium whereas GKN2 is localized to associated inflammatory cells. GKNs are absent from mouse and human PDAC. GKNs are co-expressed with Muc5ac and Muc2 in human patients indicating an expression on intestinal type IPMNs. ELISA and proteomic analysis in mice confirmed the secretion of GKN1 into pancreatic juice but not serum.

Conclusion: We identified for the first time gastrokine expression in neoplastic human and mouse pancreatic tissues. GKN expression is specific for premalignant PanIN lesions and it is secreted into the pancreatic juice during pancreatic carcinogenesis. Therefore, gastrokine could serve as a potential biomarker for early pancreatic pre-neoplastic lesions and benign tumors. Furthermore, determination of GKNs in pancreatic juice may provide a tool to identify patients at risk.

Introduction: Pancreatic cystic lesions (PCL) are increasingly being diagnosed in clinical practice. However the efficacy of several methods in differential diagnosis is still uncertain and differs between centers. We investigated the role and contribution of endosonography (EUS) and EUS-guided fine needle aspiration (EUS-FNA) in the differential diagnosis of PCL.

Aims & Methods: We identified all patients who underwent EUS and EUS-FNA for PCL in our center from 2011 to 2014. Data were collected on demographics, clinical, laboratory and imaging, the results of biochemical and cytological evaluation of cyst fluid, in case it is available.

Results: There were 379 patients (45% male, mean age 57,6 ± 14,6 years, range 17-90). PCL were more commonly diagnosed between the ages of 60-69: 28% and 50-59: 23%. Three in four of the patients were symptomatic (excluding pseudocysts, 42%) and diabetes mellitus was present in 1/3. The mean cyst size was 38.2 ± 31,1 mm (median: 30 mm, range; 4-220 mm). A total of 268 FNAs were attempted, 3 of which were unsuccessful. In cytology, 15(10%) showed insufficient, and 41 (27%) non-specific findings. Out of 154 cytological examination, a specific diagnosis was reached in 98 (63%). Overall, out of 379 cases, a specific diagnosis could be reached in 274 (73%) patients: 95 (25%) were pseudocysts, 78 (21%) mucinous cysts, 40 (11%) cystic tumors, 38 (10%) serous cystadenomas (SCA), and 23(6%) other cystic lesions. In 51 cases surgery was performed. Diagnosis included, mucinous cystic tumor (MCN) (6), intraductal papillary mucinous neoplasm (10), cystic neuroendocrine tumor (2), SCA (3), solid pseudopapillary tumor (4), pseudocyst (4), cystic tumor (12), solid tumours with cystic degeneration, and cysts of different origin (10). The kappa value for the diagnosis of mucinous cyst between imaging-surgery were 0.688 and EUS-surgery, 0.658, respectively.The kappa level between EUS vs. imaging in making a diagnosis of pseudocyst was %77,7 (p: 0.001). In all serous cysts, the cyst amylase level was below 2000 U/L and CEA was below 5 ng/ml but the levels of amylase and CEA showed a wide variation in all other types of cysts. In 9% of pseudocyst, the amylase were below 2000 U/L. In two surgically diagnosed MCN, the cyst CEA were below 5 ng/ml, and in one of them amylase was over 20.000 U/L. In another MCN, CEA was 40 ng/ml and amylase was over 20.000 U/L. While in all serous cysts the serum CA19-9 was below 37 U/L. In 80 % of cystic malignancies it was over 37 U/ml.

Conclusion: The diagnostic value of imaging and EUS towards PCL seems to be similar. EUS-FNA obtained cyst cytology reached a specific diagnosis in 63% of the cases. While cyst CEA and amylase levels showed a variable diagnostic capacity and were sometimes, misleading, serum CA 19-9 level seemed to be discriminatory between benign and, already, malignant lesions.

Introduction: Pancreatic cancer (PCa) is characterized by increased intratumoral nerve density and nerve hypertrophy. Conversely, the density of vessels and tumor perfusion in PCa were reported to be decreased when compared to normal pancreas, creating a hypoxic tumor microenvironment. This observation raises the question whether neurogenesis and angiogenesis in PCa behave oppositely or even suppress each other.

Aims & Methods: The current study aimed to elucidate the interaction between neurogenesis and angiogenesis and to decipher the molecular actors that drive generation of nerves and vessels in PCa. Human PCa specimens (UICC stages II-III, n = 57) were analyzed for the density of all ($CD31^+$) vessels and all ($S100^+$) nerves in the whole tumor area via a novel triple immunofluorescence/immunohistochemistry analysis that additionally co-labeled cancer cells via cytokeratin-19 (CK19). The density of nerves and vessels were correlated to each other and to the severity of neural invasion (NI) and angioinvasion. The transcriptomic profile within tumor tissue of patients with strong neurogenesis or strong angiogenesis was compared to that of patients with little neuro- or angiogenesis via profiler PCR arrays.

Results: 41 out of 57 patients exhibited NI, whereas angioinvasion was detected in only one out of 57 patients. The mean vessel size and mean nerve size correlated positively (Sperman's coefficient $r = 0.43$, $p = 0.0013$), and the total area of nerves increased in parallel with the total area of vessels in the analyzed specimens ($r = 0.28$, $p = 0.04$). The frequency of NI increased in concordance with the amount of tumor innervation ($r = 0.25$, $p = 0.059$). There was no association between vessel density and NI. Patients with more pronounced tumor angiogenesis had greater intratumoral amounts of matrix metalloproteinase (MMP9), beta-III-integrin, TgfbetaR1, CXCL9, and lower levels interferon-alpha-1 (Ifna1) and LECT1. Furthermore, patients with more neurogenesis exhibited intratumoral upregulation of interleukin-6, TrkA, Nr1I2, NGF, CXC3CR1, and Neurotrophin-3, and downregulation of ciliary neurotrophic factor (CNTF).

Conclusion: Angiogenesis and neurogenesis behave concordantly in PCa. Interleukin-6 and neurotrophic factors may be responsible for the remarkably high prevalence of NI in PCa.

P0715 TM4SF1 PROMOTES INVASION AND METASTASIS OF PANCREATIC CANCER VIA REGULATING THE EXPRESSION OF DDR1

J. Yang[1], J. Cao[1], Z. Li[2], L. Xu[1]
[1]Digestive Endoscopic Diagnosis and Treatment Center, Xinhua Hospital, Shanghai Jiaotong University School of Medicine, [2]Dept of Gastroenterology, Changhai Hospital, Second Military Medical University, Shanghai, China

Contact E-mail Address: emmafcwf@126.com

Introduction: Pancreatic ductal adenocarcinoma (PDAC) has increasingly mortality rates because it has highly invasion and metastasizes rapidly. We previously found that Transmembrane-4-L-six-family-1(TM4SF1), a four-transmembrane L6 family member, was highly expressed in human pancreatic cancer tissues and PDAC cell lines. Also, TM4SF1 promoted cancer cells invasion and metastasis *in vitro* and *in vivo*. Here, we investigated the mechanism of TM4SF1-mediated invasion and metastasis in PDAC.

Aims & Methods: We used small interfering RNAs in PANC-1, AsPC-1 to study the function of TM4SF1 on regulating invadopodia, which mediated the extracellular matrix (ECM) degradation to support cancer cells invasion. We investigated the ability of TM4SF1 to regulate the expression of discoidin domain receptor 1 (DDR1) using real-time PCR, immunoblot, immunofluorescence and coimmunoprecipitation analyses. And the effects on cell migration and invasion were analyzed by Transwell chambers and Matrigel invasion chambers. Finally, the clinical relevance of TM4SF1 and DDR1 was investigated using adjacent normal pancreatic tissues and pancreatic cancer specimens.

Results: In human PDAC cell lines, TM4SF1 facilitated the activation of matrix metalloproteinase 2 (MMP2) and matrix metalloproteinase 9 (MMP9) by western blot and gelatin zymography analysis. We found that the number of invadopodia reduced by 73% and the area of the ECM degradation decreased by 63% in PANC-1 when TM4SF1 was silenced compared to the control cells. Silencing of TM4SF1 reduced the percentage of cells with invadopodia by approximately 70% and decreased the ECM degradation by 46% in AsPC-1.

Also, TM4SF1 silencing down-regulated the expression of DDR1 and inhibited cancer cells migration and invasion. TM4SF1 expression colocalized with DDR1 in PANC-1 and AsPC-1 cells by immunofluorescence analysis. Coimmunoprecipitation assays showed an interaction between TM4SF1 and DDR1. Overexpressed DDR1 rescued the inhibitory effect of TM4SF1 silencing on PDAC cell lines migration and invasion, suggesting that DDR1 was involved in TM4SF1-mediated migration and invasion. When DDR1 was overexpressed in PANC-1 and AsPC-1, MMP2 and MMP9 protein expression levels increased. Moreover, TM4SF1 and DDR1 mRNA expression levels were both found to be almost 2 fold high in PDAC compared with adjacent normal pancreatic tissues. The scatter plots showed that TM4SF1 and DDR1 mRNA expression levels were positively correlated in PDAC tissues.
Conclusion: Taken together, our data suggest that a novel regulatory pathway involving TM4SF1, DDR1, MMP2 and MMP9, which mediates the ECM degradation and promotes invasion and metastasis in PDAC. Thus, TM4SF1 may be a potential therapeutic target.

P0716 NOVEL BIOMARKER PANEL FOR THE EARLY DETECTION OF PANCREATIC CANCER IN THE BLOOD

J. Namkung[1], Y. Choi[1], W. J. Lee[2], J. S. Heo[3], J. K. Park[4], D.-Y. Oh[4], S. C. Kim[5], C. M. Kang[6], T. Park[7], Y. Kim[4], J.-Y. Jang[4]
[1]*IVD Business Unit, SK Telecom, Seoul,* [2]*National Cancer Center, Koyang,* [3]*Samsung Medical Center,* [4]*Seoul National University College of Medicine,* [5]*Asan Medical Center,* [6]*Severance Hospital,* [7]*Seoul National University, Seoul, Republic of Korea*

Contact E-mail Address: Novel biomarker panel for the early detection of pancreatic cancer in the blood.
Introduction: Current pancreatic cancer marker, CA19-9 has limited diagnostic accuracy. In this study, we aimed to identify a multi-marker panel capable of detecting early stage pancreatic cancer eligible for surgical treatment, with high sensitivity and specificity. We conducted a thorough candidate marker screening and then validated the final panel in a large multicenter clinical study.
Aims & Methods: Pancreatic cancer biomarker candidates from data mining of commercial and public databases were listed. Additional candidates were recruited by identifying differentially expressed genes from our tissue microarray experiments. Initially 1000 candidates with supporting evidence from more than two sources were selected and their serum protein levels were measured using Multiple Reaction Monitoring Mass Spectrometry (MRM-MS) in 50 resectable pancreatic ductal adenocarcinoma (PDAC) samples and 50 healthy or benign samples. Of the candidates, 54 proteins with high ranked diagnostic performance were selected for further investigation. Using MRM-MS, the candidate markers were evaluated in blood samples from five major clinical centers in Korea. The study subjects included 401 cases of PDAC patients (232 in stage I-II), and 458 controls (300 normal individuals and 158 benign diseases including pancreatitis and non-malignant pancreas cystic tumors). All the possible biomarker combinations consisted of up to 5 proteins among 54 candidates were investigated using Support Vector Machine. Then, 7 multiple marker combinations were selected by 10 fold cross-validation to have sensitivity greater than 0.85 at a fixed specificity of 0.9. The final panel was selected by considering biological relevance with cancer development, dynamic ranges in the blood and reliability of the measurements. The panel was validated using ELISA and an automated immunoassay system in the 859 multicenter case-control samples and additional 149 other cancer samples.
Results: A panel comprising CA19-9, LRG1 and TTR was determined to be the best biomarker. This triple marker panel significantly improved diagnostic performance of CA19-9 and we obtained consistent results from the immunoassay analyses. The area under the ROC curve (AUC) of the panel was 0.941 and the sensitivity was 0.850 whereas those of CA19-9 alone were 0.847 and 0.746, respectively. Even in cancer samples of stage I-II, the performance was significantly improved to AUC 0.921 and sensitivity 0.820 whereas CA19-9 had 0.82 and 0.677 respectively. The increase in AUC was greater than 10% (Delong's test p-value < 0.001). Additionally, the panel was highly selective for PDAC and had AUC of 9% greater than CA19-9 in the analysis of PDAC vs. other cancers.
Conclusion: A new diagnostic panel showed advantages over CA19-9 in terms of sensitivity and specificity as a pancreatic cancer specific tumor marker. Noticeably, this panel consistently performed well for detection of relatively early stage pancreatic cancer samples, which suggests potential of the panel as a screening test for early detection of PDAC.

P0717 THE ANTI-DIABETIC DRUG METFORMIN INHIBITS PANCREATIC CANCER CELL PROLIFERATION IN VITRO AND IN VIVO: STUDY OF MICRORNAS ASSOCIATED WITH THE ANTI-TUMOR EFFECT OF METFORMIN

K. Kato[1], H. Kamada[1], K. Kobayashi[1], T. Fujimori[1], T. Masaki[1]
[1]*Gastroenterology and Neurology, Kagawa University, Kagawa, Japan*

Introduction: Recent studies suggest that metformin, which is a commonly used oral anti-hyperglycemic agent of the biguanide family, may reduce cancer risk and improve prognosis, but the detailed mechanisms by which metformin affects various cancers, including pancreatic cancer, remain unknown.
Aims & Methods: The goal of the present study was to evaluate the effects of metformin on human pancreatic cancer cell proliferation *in vitro* and *in vivo*, and to study microRNAs (miRNAs) associated with metformin's anti-tumor effect. We used the human pancreatic cancer cell lines Panc1, PK1 and PK9 to study the effects of metformin on human pancreatic cancer cells. Athymic nude mice bearing xenograft tumors were treated with or without metformin. Tumor growth was recorded after 5 weeks, and the expression of cell cycle-related proteins was determined. In addition, we used miRNA array tips to explore the differences among miRNAs in Panc1 cells bearing xenograft tumors treated with or without metformin *in vitro* and *in vivo*.
Results: Metformin inhibited the proliferation of Panc1, PK1 and PK9 *in vitro*. Metformin blocked the cell cycle in G0/G1 *in vitro* and *in vivo*. This blockade was accompanied by a strong decrease of G1 cyclins, especially in cyclin D1, cyclin-dependent kinase 4 (Cdk4), and Cdk6, and by a decrease in retinoblastoma protein (Rb) phosphorylation. In addition, metformin reduced the phosphorylation of EGFR and IGF-1R *in vitro* and *in vivo*. Moreover, metformin reduced the phosphorylation of EGFR at Tyr845. The miRNA expression was markedly altered by the treatment with metformin *in vitro* and *in vivo*. Various miRNAs altered by metformin may also contribute to tumor growth *in vitro* and *in vivo*.
Conclusion: Our results revealed that metformin inhibits human pancreatic cancer cell proliferation and tumor growth, possibly by suppressing the cell-cycle-related molecules via alteration of miRNAs.

P0718 EPITHELIAL-TO-MESENCHYMAL TRANSITION (EMT) IN HUMAN PANCREATIC CANCER: ASSOCIATION WITH DISEASE DISSEMINATION AND RECURRENCE

M. Tacelli[1], A. Gallioli[1,2], S. Magri[1], F. Gavazzi[2], A. Zerbi[2], P. Spaggiari[3], M. Roncalli[3], P. Bianchi[1,4], G. Basso[1], G. Celesti[1], M. Montorsi[2,5], A. Malesci[6], L. Laghi[1]
[1]*Laboratory of Molecular Gastroenterology,* [2]*Departments of General Surgery,* [3]*Pathology,* [4]*Analytical Laboratory,* [5]*Hunimed University Chancellor, Humanitas Research and Clinical Hospital, Rozzano,* [6]*Dept. of Translational Medicine, University of Milan, Milan, Italy*

Contact E-mail Address: matteo.tacelli@gmail.com
Introduction: EMT is an emerging mechanism underlying cancer cell dissemination. EMT is driven by transcription factors (TFs; *TWIST1*, *ZEB2*, *SLUG*) coupling the expression of M genes (*VIMENTIN, CDH2*) with the repression of E ones (*CDH1*), thus conferring to cancer cells fibroblast-like morphology and enhanced migratory properties. Although EMT occurs early in mouse model of pancreatic cancer (PC), evidence in human PC remain scattered.
Aims & Methods: Human PC cell-lines (HPAF-II, HPAC, PANC-1, MIAPaCa-2) were characterized as to the expression of *CDH1-2* and EMT-TFs mRNA. In tissue specimens from PC patients, the presence of stromal cells expressing TWIST1 was assessed by immunohistochemistry at the tumor center (^{CT}; n = 99) and at the posterior resection margin (^{PRM}; n = 79). Association between TWIST1+ cells, clinical-pathological features, and disease-free survival (DFS) were assessed by logistic regression, Cox model (N-adjusted, stage IV and DFS < 90 days excluded), and Kaplan-Meier curves. The levels of EMT-TFs mRNA in the bloodstream of PC patients were measured by qRT-PCR (n = 45; heathy controls, n = 30), and circulating tumor cells (CTCs) were searched by combining in-situ hybridization (chromosome 7 and 20) with VIMENTIN/CDH1 immune-reactivity (n = 10).
Results: *CDH1*+ PC cells (HPAF-II, HPAC) did not show EMT-TFs, while *CDH1*-negative cells (PANC-1, MIAPaCa-2) expressed *TWIST1* and *SLUG*. Most (71/99; 72%) specimens harbored TWIST1^{CT+} cells; the only pathological feature associated with TWIST1^{CT+} cells was neural invasion [71/71 TWIST1^{CT+} cases *vs* 23/28 (82%) negative ones; p = 0.001]. In pathological specimens, the presence of TWIST1^{PRM+} (51/79; 64.5%), was significantly lower than that of TWIST1^{CT+}cells (42/51, 82%, showing TWIST1$^{CT+/PRM+}$, but 14/28, 50%, TWIST1 $^{PRM\text{-}negative}$ harboring TWIST1^{CT+}; p = 0.003). TWIST1^{CT+} cells had no prognostic value [(HR&95%CI) 1.27, 0.65-2.48; p = .47], while TWIST1^{PRM+} cells increased the risk of recurrence (3.12, 1.35-7.26; p < .008), either local (3.35, 1.25-9.0; p = .017), either metastatic (5.8, 1.32-25.6; p = .02), and were associated with a worse DFS (log-rank test, p = 0.002). In patient bloodstream, we detected increased mRNA levels of *CDH1* ($2^{-\Delta CT}$median, 2.03E-07 *vs* 8.37E-08, in controls; p = 0.03), but also of *TWIST1* (3.95E-08 vs 2.06E-08; p = 0.06), *ZEB2* (1.52E-05 vs 3.63E-06; p = 0.006), and *SLUG* (2.36E-08 vs 9.09E-13; p < 0.001). Eventually, aneuploid CTCs expressing VIMENTIN (1.7 cells/ml) or CDH1 (2.1/ml) were detected.
Conclusion: A set of established PC cells, shows no E but M hallmarks and expresses EMT-TFs. The association between TWIST1^{PRM+} cells and disease recurrence suggests the involvement of EMT in PC progression. EMT-TF mRNA levels and aneuploid M-CTCs in the bloodstream indicate ongoing EMT in a subset of PC cells into the circulation. PC comprises cell populations with M features, ignored so far but likely relevant for local and distant dissemination.

P0719 IMPACT OF PHARMACOLOGICAL MACROPHAGE DEPLETION ON THE PROGRESSION OF PANCREATIC NEUROENDOCRINE NEOPLASMS

S. Krug[1], R. Abbassi[2], H. Griesmann[1], M. Egidi[1], A. Rinke[2], T. Gress[2], P. Michl[1]

Introduction: Pancreatic neuroendocrine tumors (PNETs) are a heterogeneous group of neuroendocrine neoplasms with distinct biological behaviour and response to treatment. Efforts have been taken to improve the survival for patients at advanced stage, however, conventional chemotherapy is still recommended as standard treatment with limited efficacy. Previous reports indicate that the infiltration of tumor-associated macrophages (TAMs) in PNETs strongly correlates with proliferation and metastases.
Aims & Methods: Evaluation of the impact of the liposomal clodronate as pharmacological tool for macrophage depletion *in-vitro* and *in-vivo*.
The effect of liposomal clodronate on cell-viability was analysed in J774 and RAW myeloid cells and isolated murine bone macrophages as well as CD11b+cells of RIP1-Tag2 pancreata which were evaluated by FACS. RIP1-Tag2 mice were treated with either clodronate or liposomes alone to evaluate tumor progression, proliferation, angiogenesis and macrophage infiltration by FACS and immunohistochemistry.
Results: Liposomal clodronate inhibited the proliferation of monocytic J774 and RAW cells and murine bone macrophages. In contrast, cell-viability of neuroendocrine BON-1 and QGP-1 cells was not affected by this treatment. FACS analyses of RIP1-Tag2 mice treated with clodronate confirmed the selective depletion of macrophages. In RIP1-Tag2 mice liposomal clodronate reduced the evolution of invasive beta-cell tumors. Furthermore, proliferation of tumor cells and angiogenesis within the tumors were markedly reduced.
Conclusion: Liposomal clodronate selectively depletes macrophages and disrupts tumor progression in the RIP1-Tag2 neuroendocrine tumor model associated with reduced angiogenesis.

Contact E-mail Address: t.komura0507@gmail.com
Introduction: Pancreatic ductal adenocarcinoma (PDAC) is the lethal malignancy with extremely poor prognosis due to difficulty of diagnosis in early stage as well as the high grade of malignant potential. Therefore, detailed biological features including the immune-pathology are to be examined for development of the novel diagnostic method and therapeutic approach including immunotherapy.
Aims & Methods: We here examined the peripheral blood of PDAC patients in the context of programmed cell death-1 (PD-1) molecule, which is expressed on activated lymphocytes and regulate host immune response, and their clinical features. Fifty PDAC patients (Age; 68.0 ± 10.1, Gender; Male/Female = 29/21, Stage I/II/III/IV = 7/12/13/18) and twenty seven healthy volunteers (Age; 64.1 ± 8.7, Gender; Male/Female = 13/14) were enrolled with the informed consent of the study. Peripheral blood mononuclear cells (PBMCs) were isolated from heparinized venous blood using Ficoll-Hypaque density gradient centrifugation. Obtained PBMCs were incubated with fluorescent antibodies, PD-1, CD4, CD8, CD25, CD127, and these expression levels were analysed using flow cytometry. Furthermore, we extracted RNA from CD4+ T cells using anti-CD4 magnet beads from PBMCs, and examined the expression level of PD-1 and FoxP3, which is transcriptional factor for regulatory T cells, on these cells.
Results: Flow cytometry analysis showed that the frequency of CD4 + PD-1+ cells, not CD8 + PD-1+ cells, was significantly increased in the PBMCs of PDAC patients (6.4 ± 2.9%), compared to healthy volunteers (3.8 ± 2.1%, p = 0.001). Then, PD-1 mRNA expression level was also increased in CD4+ cells of PDAC patients. On the other hand, CD4 + CD25 + CD127low/- cells, which is representative regulatory T cells, was increased in the PBMCs of PDAC patients (3.8 ± 1.4%), compared to healthy volunteers (2.9 ± 1.4%, p = 0.022), while FoxP3 mRNA expression level was not increased in CD4+ cells of PDAC patients.
We observed that the frequency of CD4 + PD-1+ T cells and regulatory T cells was no correlation with clinical stages as well as serum CEA and CA19-9 values in PDAC patients. We examined whether the frequency of these populations were correlated with clinical outcome of PDAC patients or not, among the enrolled 35 PDAC patients who underwent chemotherapy. The frequency of CD4 + PD1+ T cells was significantly increased in patients with poor response to chemotherapy (p = 0.002), although the frequency of regulatory T cells was not. There was no significant difference in overall survival among the frequency of CD4 + PD1+ T cells as well as regulatory T cells populations.
Conclusion: The frequency of CD4 + PD-1+ T cells was increased even in early stage of PDAC patients, implying assessment of the frequency of CD4 + PD-1+ T cells in PBMCs is the possible novel diagnostic approach in early stage. In addition, the high frequency of CD4 + PD-1+ T cells population of PDAC patients was predictive of poor response of chemotherapy.

Contact E-mail Address: i.konings@erasmusmc.nl
Introduction: There is growing interest in surveillance for pancreatic cancer (PC) in high-risk individuals to detect early stage PC or precursor lesions. When assessing the feasibility of such surveillance, it is important to also address participants' psychological burden. Previously, we reported that repeated participation in annual surveillance imposes low psychological burden. However, a subgroup of individuals showed intermediate to high levels of cancer worry. The aim of this study was to evaluate possible factors associated with these cancer worries.
Aims & Methods: High-risk individuals (estimated lifetime risk of PC ≥ 10%), participating in an annual prospective multicenter Dutch EUS-MRI based PC surveillance program, were invited to complete an annual questionnaire to assess their cancer worries with the Cancer Worry Scale (CWS). The questionnaire was sent after genetic counseling (T0), after intake for participation but prior to the first MRI and EUS (T1), and thereafter annually after MRI and EUS (T2-T7). Individuals who scored ≥ 12 points on the CWS on each available questionnaire were defined as having intermediate to high cancer worries.
Results: A total of 688 out of 763 questionnaires were returned (90%) by 166 out of 178 participants (93%): 41, 92, 149, 123, 106, 81, 64 and 32 questionnaires at each of the eight time points respectively. The mean age of participants was 52 years with a mean follow-up of 49 months. The mean CWS-score was 12.8 (range 8-26). A total of 66 individuals (40%) scored ≥ 12 points on the CWS at each available questionnaire. Both univariate and multivariate analysis showed three factors to be associated with intermediate to high cancer worries: proven carriers of a PC-associated gene mutation (as opposed to familial pancreatic cancer individuals in whom no known gene mutation could be detected) ($P = 0.04$); scoring ≥ 20 points on the Hospital Anxiety and Depression Score (HADS) at least once ($P = 0.05$); and having a family member affected with pancreatic cancer < 50 years of age ($P < 0.01$). Not associated were gender, education level, marital status, a personal history of cancer, the detection of a cystic lesion nor a shortened interval during surveillance.
Conclusion: A total of 40% of individuals participating in annual pancreatic cancer surveillance had intermediate to high cancer worries at all available psychological questionnaires. We identified three factors to be associated with these worries: carriership of a pancreatic cancer associated gene mutation, a high HADS score, and a family member affected with pancreatic cancer under 50 years of age. These associated factors can help to identify patients 'at risk' for experiencing cancer worries who might benefit from psychosocial support.

P0722 PREVALENCE AND PROGRESSION OF CYSTIC PANCREATIC PRECURSOR LESIONS DIFFER BETWEEN TWO GROUPS AT HIGH RISK OF DEVELOPING PANCREATIC CANCER

I. C. Konings[1], F. Harinck[1], J.-W. Poley[1], C. M. Aalfs[2], A. van Rens[3], N. C. Krak[4], A. Wagner[5], C. Y. Nio[6], R. Sijmons[7], H. van Dullemen[8], F. P. Vleggaar[9], M. G. Ausems[10], P. Fockens[11], J. E. van Hooft[11], M. J. Bruno[1], on behalf of behalf of the Dutch Research Group on Pancreatic Cancer Surveillance in High-Risk Individuals

Contact E-mail Address: i.konings@erasmusmc.nl
Introduction: Individuals at high risk of developing pancreatic ductal adenocarcinoma (PDAC) are (1) carriers of a mutation that predisposes to PDAC, and (2) individuals who have no known gene mutation but who have a strong family history of PDAC (familial pancreatic cancer, FPC). The genes involved in the

development of FPC are unknown. Consequently, given the presumed autosomal dominant inheritance pattern of FPC, by definition half of these FPC-individuals are not at increased risk. It is still unclear whether the prevalence and natural progression of cystic precursor lesions are equal in both risk groups. The aim of our study was therefore to compare prevalence and progression of lesions between the two groups.

Aims & Methods: Individuals with an estimated lifetime risk of developing PC ≥10% underwent annual pancreatic surveillance with magnetic resonance imaging (MRI) and endoscopic ultrasound (EUS) in an ongoing prospective multicenter study. Individuals included are (1) first degree relatives (FDR) of FPC cases, defined as families with PDAC in ≥2 FDR, in ≥3 relatives, or in ≥2 relatives with ≥ 1 case aged < 50 at diagnosis, and (2) mutation carriers of PC-prone gene mutations (all *CDKN2A* mutation carriers and Peutz-Jeghers patients; *BRCA1* or *2* mutation carriers, *p53* mutation carriers and Lynch syndrome patients with ≥2 family members affected with PDAC). Progression of a lesion was defined as growth ≥4 mm or the development of malignant features.

Results: We included 172 individuals, of whom 90 (52%) were mutation carriers and 82 (48%) were FPC individuals. There was no significant difference in follow-up between groups (mean 41 months vs 44 months respectively, $P = 0.35$). A total of 36 cysts were detected in 90 mutation carriers (40%) and 47 cysts in 82 FPC-individuals (57%, $P = 0.12$). Significantly more cysts ≥10 mm were detected in FPC individuals than in mutation carriers (15% vs 4%, $P = 0.05$). However, the cystic lesions detected in mutation carriers were significantly more likely to progress than those in FPC individuals (19% vs 2%, $P = 0.04$). The number of lesions per individual, the presence and number of chronic pancreatitis features, and the age of individuals at diagnosis of a cystic lesion did not differ between both groups.

Conclusion: FPC individuals had a higher prevalence of cystic lesions ≥10 mm, which is remarkable given the fact that half of these FPC individuals are probably not at increased risk to develop pancreatic neoplasia (presumed autosomal dominant inheritance of unknown mutation). However, the lesions in mutation carriers were more likely to progress during follow-up. These results could lead to better tailored surveillance strategies, to identify high-grade dysplastic lesions or PDAC more adequately.

Introduction: Careful selection for surgical intervention or radiologic and clinical surveillance is important in the management of patients with pancreatic cystic neoplasms (PCNs). Although some PCNs require surgical resection, they are slow growing and have a favorable prognosis in contrast to ductal adenocarcinoma.

Aims & Methods: We aimed to evaluate natural course of PCNs and the detection of malignant transformation during follow-up according to the risk factors. We retrospectively reviewed the records of 301 patients with PCN incidentally diagnosed by using abdominal US, CT, or MRI. Cyst size was recorded as the maximum dimension measured on cross-sectional imaging. Presence of cyst features that are known potential risk factors for malignancy, such as thickened enhanced cyst walls, main pancreatic duct size > 5 mm, non-enhanced mural nodules, abrupt changes in the main pancreatic duct caliber with distal pancreatic atrophy, and enhanced solid component, were also recorded. Patients were followed-up after an initial 3-month interval and then followed-up at 6 months and 12 months, followed by an annual follow-up. Malignant transformation of PCN during follow-up was defined as either histologic confirmation after surgical resection or evidence of metastatic or invasive disease from a suspected primary PCN on radiologic imaging.

Results: Of 301 patients, 19 were excluded (15 less than 1 year of follow-up, 4 underwent surgery for malignancy at initial diagnosis). Data from 282 patients were analyzed (mean age: 59.4 years, median follow-up: 28.5 months); 97 patients had risk factors such as cyst > 3 cm or the presence of mural nodule. During surveillance, 41 patients showed changes in cysts (median duration: 24 months); 32 showed an increase in cyst size, and 9 showed a change in cyst characteristics. Cyst-related malignancy occurred in 5 patients (2.5%, 5/203), all who had risk factors and whose cysts showed changes. Post-operative morbidity was observed in 30 of 93 patients (32.3%); 2 died (1, intra-abdominal infection; 1, mechanical obstruction). Mortality was observed in 9 patients, with disease-specific death in only one.

Conclusion: Although the risk of malignant transformation was higher in patients with incidental PCNs than in the general population, the detection of malignancy or disease-specific mortality during surveillance was low, even in the high-risk group. Continued surveillance is important whether there are significant changes in PCNs.

P0724 EFFICACY OF PROPHYLACTIC GASTROJEJUNAL BYPASS IN PREVENTING GASTRIC OUTLET OBSTRUCTION SYMPTOMS IN UNRESECTABLE PERIAMPULLARY CANCER

J. Eden[1], S. Sanjeevi[1], A. Noorani[1], E. Rangelova[1], J. Blomberg[1], J. Tsai[1], M. Del Chiaro[1], L. Lundell[1], **C. Ansorge**[1]

[1]*Department of Surgical Gastroenterology, Karolinska University Hospital, Division of Surgery, Department of Clinical Science, Intervention and Technology (CLINTEC), Karolinska Institutet, Stockholm, Sweden*

Contact E-mail Address: christoph.ansorge@ki.se

Introduction: Up to 33% of patients with preoperatively considered resectable periampullary cancer are deemed unresectable at laparotomy due to unexpected locally advanced or metastasized disease. The conversion from curative to palliative intent usually leads to the construction of a concomitant prophylactic gastrojejunal bypass (PGJB) as part of a double bypass to prevent eventual duodenal / gastric outlet obstruction (GOO) symptoms that may occur with further tumour progression. How PGJB subsequently affects the adequacy of oral intake in a palliative setting has not been fully clarified.

Aims & Methods: To investigate the effect of PGJB on GOO symptoms using established scoring systems. Observational study on patients with periampullary adenocarcinoma found to be unresectable at exploratory laparotomy between 2004 and 2014. The patients were grouped according to the palliative surgical management they had received into PGJB or exploration (EXP) alone. Data on oral intake before operation, at discharge and at follow up was retrieved from the patient's medical records and classified according to the GOO scoring system. Postoperative complications were classified according to Dindo-Clavien and delayed gastric emptying (DGE) according to the ISGPS consensus definition.

Results: A hundred-eight patients were included, 94 underwent PGJB (14 EXP). The groups were comparable regarding demographical data and and, except for severe complications (17% PGJB vs 7% EXP), had similar postoperative outcomes and long-term survival. Clinically significant DGE occurred in 18 % of the PGJB group and in 7.7 % of the EXP group. Length of hospital stay was longer in the PGJB group (9 vs 6 days). Improved rates of oral intake could not be demonstrated for PGJB when compared to EXP. Regarding therapeutic efficacy, 40 % of patients with preoperative GOO symptoms had improved oral intake at discharge after PGJB and 46 % had full oral intake on follow up. 43 % had a sustainably improved oral intake (at discharge and follow up). Regarding prevention of GOO symptoms, 32 % of the non-symptomatic patients developed a temporarily decreased and 7% a prolonged decrease of oral intake. At a median follow-up time of 47 days, 73 % of patients had regained full oral intake; however, only 49 % had full oral intake at both discharge and follow-up after PGJB compared to 73 % with full oral intake at discharge and follow-up after EXP.

Conclusion: Prophylactic gastrojejunal bypass, usually part of a double bypass, is a major surgical procedure with high rates of associated morbidity and mortality. For this procedure, the present study failed to demonstrate acceptable results for the treatment and effective short-term / long-term prevention of gastric outlet obstruction symptoms. Since primary gastric outlet obstruction develops in only 10-20 % of all patients with periampullary cancer, less invasive on-demand strategies may be discussed as alternatives to prophylactic surgery.

Contact E-mail Address: jcelso@uol.com.br

Introduction: The anatomic classification of intraductal papillary mucinous tumor (IPMT) is difficult to understand. Despite the involvement of the main pancreatic duct (MPD) having a greater chance of malignancy, the branch duct remains a major challenge in relation to diagnosis and the decision of the treatment to be performed. There are several factors to predict the presence of malignancy, but they are still intense debate about, and there are many questions regarding which is the best malignancy predictor?

Aims & Methods: The aim of this study was to evaluate the effectiveness and accuracy of the latest international consensus to predict malignancy of IPMT. Data from 203 patients with pancreatic mucinous neoplasm identified by imaging and referred to the endoscopy department were prospectively collected to undergo endosonography-guided fine needle aspiration (EUS-FNA), between January 2008 and April 2014. We evaluated and compared the malignancy predictors factors described by the Fukuokás International Consensus described in 2012.

Results: According to the EUS images, results of laboratory tests and microhistology obtained by EUS-FNA, it was observed that the larger cysts > 2.5 cm have a higher chance of malignancy (50% versus 19%; $p < 0.001$), with sensitivity and a specificity of 70% and 69.2%, respectively. The solid component was present in 30% of malignant tumors compared to 11.9% of benign ($p = 0.006$). The presence of solid component cysts larger than 2.5 cm has preditive positive value (PPV) 68% ($p = 0.001$) while his absence of cysts of any size has a PPV of 88% ($p = 0.006$). The MPD was normal in patients with no invasion (86% vs 60%, $p < 0.0001$). The BD-IPMT had more results benignity (88.1%) while the MD-IPMN had the highest frequency among malignant lesions (41.2%) [$p < 0001$]. The presence of one major criteria is associated with the presence of tumor by 55% ($p < 0.001$).

Conclusion: The frequency of malignancy found in patients with MPD diameter between 5-9mm and also in cysts 2.5cm in diameter suggests that there is space for discussion of reducing the cutoff for the diameter lesions were classified as at high risk for malignancy. Furthermore, the presence of vegetation within cysts larger than 2.5 cm has a high PPV for the presence of malignancy, validating the proposed consensus.

Contact E-mail Address: katarzyna.winter@vp.pl
Introduction: The involvement of the Hedgehog pathway in pancreatic carcinogenesis has been suggested. Hedgehog signaling molecules, such as Sonic hedgehog (Shh), Smoothened (Smo) and Glioblastoma transcription factor 1 (Gli1) are proposed as biomarkers for cancer detection and prognosis.
Aims & Methods: The aim of the study was to evaluate the Hedgehog signaling pathway molecules, α smooth muscle actin (αSMA) and Ki67 in patients with PDAC and CP.
We enrolled 114 patients undergoing pancreatic resection: 83 with PDAC and 31 with CP. Normal control pancreatic tissue was obtained from autopsy material from 21 patients. The immunoexpression of Shh, Smo, Gli1, αSMA and Ki67 were detected in tissue specimens by immunohistochemistry (Abcam antibodies, GB). The intensity and extend of staining of Shh, Smo, αSMA were recorded semi-quantitatively and for nuclear expression of Gli 1 and Ki67 labeling index was calculated.
Results: Mean Shh staining score in PDAC was: 2.24 (+0.57), which was significantly higher than in CP patients: 1.17(+0.25) and in control group: 0.79(+0.34) ($p = 0.000$). Smo protein expression was 2.62(+0.34) in PDAC, 1.21(+0.23) in CP and 0.94(+0,15) in control group ($p = 0.000$). Likewise Gli1 protein expression was higher in PDAC: 1.74(+0.74) than in CP: 1.15(+0.72) and in control group: 1(+0) ($p = 0.000$). In addition, Shh and Smo immunoreactivity in CP was significantly higher than in the control group ($p = 0.024$; $p = 0.007$ respectively). Significant correlation was found between immunoexpression of Shh, Gli and Ki67 in PDAC group ($r = 0.379$; $r = 0.28$, respectively; $p < 0.05$).
Conclusion: Presented findings support the hypothesis on the role of Hedgehog pathway in pancreatic carcinogenesis as well as cell hyperproliferation in CP.

P0728 POOR SURVIVAL IN PANCREATIC MALIGNANCY ASSOCIATED WITH TROPICAL PANCREATITIS. IS IT A BIOLOGICALLY DIFFERENT DISEASE?

K. B. Leena[1], K. T. Shenoy[2]
[1]*Senior Research Manager, Population Health and Research Institute, Trivandrum,* [2]*Gastroenterology, Sree Gokulam Medical College and Research Foundation, Venjaramoodu, India*

Contact E-mail Address: drleenakb@yahoo.com
Introduction: Malignancy in tropical pancreatitis is associated with high chance of mortality and has higher rates of hepatic and or distant metastasis. In a prospective cohort with pancreatic malignancy, we studied the tumor size and survival.
Aims & Methods
Aims: To evaluate the operability, risk factors and survival of pancreatic malignacy in tropical pancreatitis.
Methods: In this prospective study, 1480 subjects with tropical pancreatitits were studied in a tertiary referral centre attached to Trivandrum Medical College in S India recruited between January 1980 and March 2006. On follow up, 164 developed malignancy. The diagnosis was estalished by CT/MRI and MRCP followed by either FNAC pancreas or at surgical resection. Abdominal pain, diabetes and duration, alcohol abuse, tobacco smoking were evaluated in detail. Univariate analysis, Cox Proportional Hazard regression and Kaplan Meir Survival curves were plotted and analysed.
Results: Pancreatic malignacy occured at an younger age of 45 ± 12.4 years. The tumor was confined to head region in 130 subjects and tail and or body in the rest. Mean size was 4.2 cms and lymph node metastasis was present in 60%. 38 percent had hepatic/ distant metastasis and were inoperable. CA 19-9 level was over 1000 units in 80%. Duration of diabetes and abdominal pain didnot affect survival.The relative risk of mortality for: age over 50 was 4.97 (95% CI 3.7-6.67); for smoking 1.39 (95% CI 1.01-1.89). KM survival probability were 0.55 (95% CI 0.42-0.66) at 3 months; 0.24 at 6 months and 0.13 at 9 months.
Conclusion: The survival in pancreatic malignancy associated with tropical pancreatitis is poor and the biological behaviour is different; there was high regional and distant metastasis.

Contact E-mail Address: maiken.t.joergensen@rsyd.dk
Introduction: Pancreatic cancer (PC) is the fourth leading cause of cancer death worldwide, symptoms are few and diffuse, and when the diagnosis has been made only 10-15% would benefit from resection [1]. Surgery is the only potentially curable treatment for PC, and the prognosis seems to improve with early detection [2]. A hereditary component has been identified in 1-10% of the PC cases [3]. To comply with this, screening for PC in high-risk groups with a genetic disposition for PC has been recommended in research settings [4].
Aims & Methods: Between January 2006 and February 2014 31 patients with or with a disposition for HP and 40 first-degree relatives of patients with FPC were screened for development of PDAC with yearly endoscopic ultrasound and fine needle aspiration when needed. Total pancreatectomy was performed when 1) PDAC 2) PanINIII or 3) Main-duct IPMN was verified by histology. The cost-effectiveness of screening in comparison with no-screening was assessed by the ICER.
Results: By screening the FPC group we identified 2 patients with PDAC who were treated by total pancreatectomy. One patient is still alive, while the other died after 7 months due to cardiac surgery complications. The cost per PDAC identified was 132.899 US$, the cost per life-year saved was 37.994 US$ and the cost per QALY gained was 50.329 US$. Stratified analysis of patients with HP and FPC provided ICERs of 47.156 US$ vs. 35.493 US$ per life-year and 58.647 US$ vs. 47.867 US$ per QALY. Including only PDAC related death changed the ICER to 31.722 US$ per life-year and 42.128 US$ per QALY. The ICER for patients with FPC was estimated at 28.834 US$ per life-year and 38.785 US$ per QALY.
Conclusion: With a threshold value of 50.000 US$ per QALY this screening program appears to constitute a cost-effective intervention although screening of HP patients appears to be less cost-effective than FPC patients. These results are sensitive to appropriate stratification of the patients and the effectiveness of the treatment modalities offered. Both screening and surgery should be performed in specialized, research-based centres with many patients and a dedicated multidisciplinary approach and expertise.

Introduction: The glycosaminoglycan chondroitin sulfate E (CS-E) is known to promote tumor invasion by cleaving CD44 on pancreatic cancer cells. Interference with CS-E has been shown to inhibit tumor invasion and metastasis in nonclinical studies. CS-E is upregulated in pancreatic cancer tissue and its biosynthesis is mediated by specific enzyme carbohydrate sulfotransferase 15 (CHST15). CHST15 mRNA is reported to be upregulated and to correlate with poor prognosis in several types of cancer. We have shown that synthesized CHST15 dsRNA can inhibit the expression of CHST15 mRNA in human pancreatic cancer cells in vitro. In this study, we conducted an investigator initiated trial of CHST15 dsRNA through EUS-guided intratumoral injection in patients with unresectable pancreatic cancer.
Aims & Methods: Primary outcome measures were safety, feasibility, and tolerability. Secondary outcome measures were response in tumor size, overall survival (OS) and disease-free survival. Histopathologically, tumor specimens were also evaluated with CHST15 immuno-stain before and 1 month after injection.
Results: A total of five stage IV pancreatic cancer patients with a median age of 75.8 years (male: female = 3:2) were enrolled. Four of them had undergone standard chemotherapy including gemcitabine or S-1 regimen, and the other patient refused chemotherapy. For all patients, a total of 16 ml (250nM) of dsRNA was successfully injected into the tumor under EUS guidance using a 22 gauge needle without related adverse events. Mean tumor size changed from 29.0 (21-39) mm to 29.6 (23-45) mm in diameter one month after the first injection. Histopathologically, all patients (100%) were CHST15 positive in the primary specimen, and one patient's specimen revealed CHST15 weakness

one month after the first injection, suggesting the effectiveness of dsRNA injection.
Conclusion: This was the first-in-patient trial of EUS-guided injection of dsRNA against glycogene in unresectable pancreatic cancer in the world. A single-dose administration of CHST15 dsRNA showed no drug-related adverse effects at the tested concentration. High safety and feasibility were demonstrated, which will contribute to further clinical trials investigating this anti-tumor agent.

Contact E-mail Address: jmgonza05@yahoo.fr
Introduction: Gastroparesis is a motility disorder affecting 4% of the population with symptoms related to pathological gastric emptying. Therapeutic options remain limited with many patients refractory to the medical treatment. 2 series reported the effectiveness of laparoscopic pyloroplasty. Recently, endoscopic per oral pyloromyotomy after tunnel creation (G-POEM) has been attempted (3 cases: US, Brazil and our team) with excellent results.
Aims & Methods: Five patients, 3 men and 2 women, with mean age of 58 years old [42 – 76], were managed in our center for refractory gastroparesis. Two were due to diabetes, two were post operative consequences (Heller), and one idiopathic. All the patients underwent a G-POEM procedure after multidisciplinary discussion and giving informed consent. Four of them have had a pre-operative gastric emptying scintigraphy. The procedures were performed by an endoscopist expert in esophageal POEM, on patients under general anesthesia, intubated and in supine position. We used a large operating channel gastroscope (Pentax, Japan) with CO_2 and a Triangle Tip knife (Olympus, Japan). The steps of the procedure were: 1/ mucosal incision after submucosal injection (posterior wall, 5cm upstream the pylorus); 2/ Tunnel creation by dissection (Swift Coag 35 W); 3/ Pyloric 3cm complete incision; 4/ Closure of the mucosal flap. An antibiotic prophylaxis and PPI were administrated daily. They were followed-up clinically at 1 month and associating a gastric emptying scintigraphy at 3 months.
Results: A complete procedure could be performed on all the patients but one (4/5). The failed patient had a fibrotic stomach and was mistakenly performed with a regular channel scope resulting in difficult access to the pylorus. The mean duration was 100 minutes without per- or post-operative complication. All the patients could drink at POD 2, eat gradually at POD 3, and were discharged at POD 6. The patients with technical success reported a mean improvement of quality of life of 73% [65-90%] and of gastric emptying symptoms of 60% at 1 month, persisting at 3 months. Regarding the scintigraphy, the baseline evaluation showed a mean half gastric emptying time (HGET) of 139 min [104-188] and a mean residual percentage at hour 4 (RPH4) of 25% [6-45%]. After the G-POEM, the mean HGET and RPH4 were normalized, decreasing to 81 min [77-85, $p = 005$] and 4% [1-9, NS], respectively.
Conclusion: Endoscopic pyloromyotomy with the G-POEM technique is feasible, reproducible, and safe. This approach seems effective clinically in terms of quality of life and specific symptoms, which was confirmed by the scintigraphy. A prospective study will soon start in our department to clearly confirm its great potential on patient with refractory severe gastroparesis.

P0732 PREDICTORS OF MORTALITY IN CAUSTIC INGESTION: A SINGLE, TERTIARY CENTER STUDY

J. M. Libuit[1], G. C. Carpio[1], S. Macalindong[1], J. P. Ong[1]
[1]*Medicine, Philippine General Hospital, Manila, Philippines*

Contact E-mail Address: jefflibuitmd@gmail.com
Introduction: Caustic ingestion, whether accidental or intentional, causes severe injury to the esophagus and the stomach, and may be associated with significant morbidity and even mortality. The severity of caustic injury depends on the following factors: corrosive properties of the ingested substance, amount, concentration, and physical form of the agent and duration of contact with the mucosa.
Aims & Methods: This is a retrospective cross-sectional study which included all adult patients who ingested caustic agents who were admitted at the Philippine General Hospital Acute Care Unit from January 1, 2008 to December 31, 2012. This study aimed to determine the predictors of mortality; determined the incidence of caustic ingestion and surgical and mortality rates; and characterized patients admitted for caustic ingestion.
Results: There were 303 cases of caustic ingestion admitted over a five-year study period. The mean age was 36 ± 13 years. There were slightly more male patients. Ingestion of acidic corrosive agents was more common than alkaline substances Majority were intentional in nature. The average amount of ingested substance was 74.9 ± 84.9 ml. Psychiatric disorder was the most commonly identified co-morbidity and was the only co-existing illness recognized among patients who expired. The most common symptoms were vomiting and abdominal pain. Among 154 patients who underwent esophagogastroduodenoscopy, half had mild (Zargar grades 1-2b) mucosal injury. One-third had severe (Zargar grade 3) mucosal injury. Around 10% had no signs of mucosal injury. Metabolic acidosis and leukocytosis were common laboratory findings. There were 13 cases of perforation (perforation rate of 4.5%). Surgery was performed in 56 (19.2%) patients. There were 23 recorded cases of death (8.1% mortality rate). Only metabolic acidosis, presence of a psychiatric disorder, need for surgical intervention, and presence of documented perforation were significantly different between patients who expired and who survived. On univariate analysis, presence of psychiatric abnormality did not show significant association with mortality (Table 1). Multivariate analysis revealed that surgery was the most consistent predictor of mortality. Perforation had no effect in the absence of metabolic acidosis.

TABLE 1: Univariate Analyses on the Effects of Metabolic Acidosis, Presence of Psychiatric Disorder, Need for Surgery, and Perforation on Mortality

Clinical /Parameter	Odds Ratio	95% CI	P-value
Metabolic Acidosis	10.6	2.17, 76	0.006
Presence of Psychiatric Disorder	4	0.55, 20.4	0.108
Need for Surgery	13.3	3.9, 44.6	< 0.001
Perforation	22.2	8.3, 70.4	< 0.001

Conclusion: The clinico-demographic profiles of the adult subjects, distribution of severity of mucosal injury, all-cause mortality rate and surgery rate in this study are similar to the other publication. Patients with metabolic acidosis on admission, undergoing surgical intervention, and with perforation are at higher risk of death. Among these, institution of surgical intervention was the most consistent predictor of mortality. We recommend that these patients be closely monitored during their hospital stay in order to lower the possibility of mortality.

Introduction: Endoscopic submucosal dissection (ESD) has been widely accepted as an established treatment modality for gastric neoplasms. With regard to patient selection for ESD, an exact histologic diagnosis before treatment is essential. However, there is often a discrepancy between results from endoscopic forcep biopsy and resected specimen.

Aims & Methods: We aimed to identify endoscopic predictors for undifferentiated histology in differentiated gastric neoplasms prior to endoscopic resection. Medical records of the patients who underwent ESD for biopsy-proven differentiated gastric neoplasms at Seoul National University Hospital between July 2005 and July 2014 were retrospectively reviewed. The lesions were divided into two groups based on the histologic result of ESD: differentiated adenocarcinoma (DA group) and undifferentiated histology (UDH group). The discordant rate, clinicopathologic characteristics and endoscopic factors were analyzed.

Results: A total of 1,641 early gastric cancers from 1,615 patients were included. Of these, 1,556 (94.8%) were diagnosed as DA and 85 (5.2%) as UDH. The mean age was significantly lower and number of women was higher in the UDH group than in the DA group. On multivariate analysis, age <65 years (odds ratio [OR] 1.75, 95% confidence interval [CI] 1.10–2.80), female sex (OR 3.19, 95% CI 2.00–5.08), endoscopic size >10 mm (OR 1.81, 95% CI 1.12–2.92), depressed type (OR 2.85, 95% CI 1.56–5.21), nodularity (OR 2.83, 95% CI 1.59–5.05), and whitish discoloration (OR 19.64, 95% CI 6.98–55.25) were independent predictors.

Table 1: Multivariate analysis of clinicopathologic and endoscopic characteristics associated with undifferentiated histology in endoscopic submucosal dissection

Characteristics	OR (95% CI)	*P* value
Age		
≥65	1.00 (reference)	
<65	1.75 (1.10 – 2.80)	0.019
Sex		
Male	1.00 (reference)	
Female	3.19 (2.00 – 5.08)	< 0.001
Endoscopic size		
≤10 mm	1.00 (reference)	
>10 mm	1.81 (1.12 – 2.92)	0.016
Macroscopic type		
Elevated	1.00 (reference)	
Flat	1.49 (0.70 – 3.14)	0.298
Depressed	2.85 (1.56 – 5.21)	0.001
Gross morphology		
Ulcer	1.97 (0.76 – 5.07)	0.161
Erosion	0.71 (0.41 – 1.26)	0.241
Whitish discoloration	19.64 (6.98 – 55.25)	< 0.001
Nodularity	2.83 (1.59 – 5.05)	< 0.001

Conclusion: Female sex, age <65 years, large endoscopic size, depressed morphology, surface nodularity, and whitish discoloration were predictors for UDH. Meticulous attention should be paid to the lesions with these endoscopic predictors for determining the risk of UDH prior to endoscopic resection.

Introduction: Endoscopic resection (ER) has been widely accepted as a curative treatment strategy for early gastric cancer and gastric adenoma. However, no residual disease (NRD) can be found in the specimen after ER of biopsy-proven gastric neoplasm.

Aims & Methods: This study aimed to evaluate the endoscopic and pathologic characteristics of patients with NRD, and identify the cause and long-term prognosis. Medical records of patients who underwent ER for biopsy-proven gastric neoplasms at a single tertiary hospital between January 2005 and November 2014 were retrospectively reviewed. Patients whose post-ER histology was revealed as NRD were included in the study. Overall incidence, clinicopathologic characteristics, cause, and long-term prognosis were analyzed.

Results: NRD was detected in 138 (3.2%) of 4,318 cases of gastric neoplasms treated with ER. Mean endoscopic size of the initial lesion was 8.27 ± 6.73 mm; in 92 cases (66.7%), the lesion was located in the lower third of the stomach. Initial pathologic diagnosis was as follows: adenoma (n = 108), carcinoma (n = 26), and atypical gland (n = 4). The causes of NRD were minute lesions removed by biopsy in 135 patients, pathologic misdiagnoses in 2, and localization error in 1. Local recurrence was detected in 5 patients (3.7%) with minute lesions during follow-up and treated with argon plasma coagulation (n = 4) or re-ER (n = 1). Synchronous (n = 5, 3.7%) and metachronous gastric lesions (n = 6, 4.4%) were also detected during follow-up.

Conclusion: The main cause of NRD was minute lesions, which might be completely removed by initial diagnostic biopsy; these cases showed a minimal rate of local recurrence and synchronous or metachronous gastric neoplasms. Careful follow-up is also mandatory for detection of residual disease.

P0735 ENDOSCOPIC FULL-THICKNESS RESECTION WITH DEFECT CLOSURE USING AN OVER-THE-SCOPE CLIP FOR GASTRIC SUBEPITHELIAL TUMORS

J. Guo[1]
[1]*Endoscopy Center, Shengjing Hospital of China Medical University, Shenyang, China*

Contact E-mail Address: guojt@sj-hospital.org

Introduction: Endoscopic full-thickness resection (EFTR) is a mini-invasive technique for gastric subepithelial tumors originating from the muscularis propria, which enables a full-thickness resection of tumors and can provide a complete basis for pathological diagnosis. Gastric fistula closure after EFTR is a challenge for endoscopists. In this study we introduced EFTR with fistula closure using the over-the-scope clip (OTSC) system for gastric subepithelial tumors originating from the muscularis propria.

Aims & Methods: Objectives: To evaluate the feasibility and safety of fistula closure with OTSC by a retrospective analysis on the cases of EFTR with defect closure using OTSC for gastric subepithelial tumors originating from the muscularis propria in our hospital.

Methods: The patients were selected who underwent EFTR for gastric subepithelial tumors originating from the muscularis propria (tumor diameter ≤2cm) in our hospital from October 2013 to March 2014. After a full-thickness resection of tumors, the OTSC was released to close the defect. The success rate of defect closure with OTSC was observed and the endoscopic follow-up was performed at 1 week, 1 month and 6 months after operation to check OTSC closure.

Results: Totally 23 patients were included into the study. The full-thickness resection rate of gastric tumors in the muscularis propria was 100% (23/23), the success rate of defect closure was 100%, and the average time of defect closure was 4.9 min (range: 2-12 min). All patients experienced no postoperative complications such as bleeding and perforation. The postoperative follow-up time was 1-6 months (mean: 3 months), and no OTSC detachment was found.

Conclusion: OTSC can be used to perform EFTR with defect closure for gastric tumors in the muscularis propria (tumor diameter ≤2cm). It is simple, convenient, safe and effective.

P0736 FINDINGS IN GASTROSCOPY WITH BIOPSY AS A PREDICTOR OF RESECTABILITY OF GASTRIC CANCER

J. J. Vila[1], A. Borda[1], **I. Fernández-Urién**[1], J. Jiménez-Pérez[1], J. M. Zozaya[1], A. Guerra[1]
[1]*Gastroenterology, Complejo Hospitalario De Navarra, Pamplona, Spain*

Contact E-mail Address: abordamartin@yahoo.es

Introduction: Gastric cancer diagnosis is usually performed by gastroscopy with biopsies, but reports about its predictive value for cancer resectability are scarce.

Aims & Methods: To analyze endoscopy findings predictive value concerning resection possibilities with curative intention in gastric cancer.

264 gastric carcinomas, consecutively diagnosed by endoscopic biopsy, were retrospectively reviewed. Non operated cases due to causes not related to the tumor (age and/or comorbidities) were excluded. Thus, frequency of the following parameters were compared between resected and non resected cases: Size > 5cm, macroscopic type (Japanese classification of gastric carcinomas), Lauren histological subtype and differentiation grade (I-IV). The group of variables with $p < 0.05$ was considered as a predictive diagnostic test for resectability and its sensitivity (S), specificity (Sp), positive (PPV) and negative predictive value (NPV) and diagnostic accuracy (DA) were calculated.

Results: 154 patients were operated with curative intention. Of the rest, 11 were operated without resection and 62 were inoperable due to their tumoral stage. 37 inoperable cases were excluded for the statistical analysis because of their age and/or comorbidity. No significant differences in resectability were registered regarding tumoral location: p= 0.25 or histological type. Tumors < 5cm showed a higher resectability rate: 88.2% versus 48.7%; [OR = 7.69; IC95% = (3.85-128.2); p = 0.000]. Carcinomas with an infiltrative component (ulcerated infiltrative-diffuse infiltrative) registered a lower resectability rate: 53% vs the rest: 73.9%.[OR = 2.51; IC95% = (1.32-4.77); p = 0.002]. According to the differentiation grade the resectability was: grade I-II (well-moderately differentiated) = 86% vs III-IV (poorly-undifferentiated) = 56.4% [OR = 5; IC = (2.38-111.1); p = 0.000]. If tumors < 5cm, with no macroscopically infiltrative type and well-moderate differentiation grade were considered as positive diagnostic test for resectability we obtained a S = 0.80; Sp = 0.95; PPV = 0.98; NPV = 0,63 y DA = 0.84.

Conclusion: 1. Among all parameters which can be evaluated with a gastroscopy plus biopsies, size < 5 cms, a macroscopically non infiltrative type and a well-moderate differentiation grade showed a significant predictive value for gastric cancer resectability with curative intention.

2. High specificity rate and positive predictive value were registered considering as a positive diagnostic test for resectability the presence of a tumor < 5cm, with no endoscopic infiltrative component and with a well-moderate differentiation grade.

Disclosure of Interest: None declared

P0737 GENTAMICIN SUBMUCOSAL LAVAGE DURING PER ORAL ENDOSCOPIC MYOTOMY (POEM): IS IT NECESSARY?

J. Bayer[1], Z. Vacková[1], J. Špičák[1], H. Švecová[1], J. Martínek[1]
[1]*IKEM, Prague, Czech Republic*

Contact E-mail Address: busta-bayer@web.de

Introduction: Per oral endoscopic myotomy (POEM) is an evolving therapeutic modality for achalasia. According to the original Inoués technique, lavage with gentamicin (80 mg) into the submucosal tunnel before starting the myotomy has been practiced due to the fear of infection. Since the number of infectious complications during POEM has been negligible, several centers (including our own) discontinued the use of gentamicin. However, there is no data assessing the clinical utility of gentamicin lavage yet.

Aims & Methods: The aim of this study was to compare outcomes of patients who received gentamicin lavage vs. patients who did not.

A retrospective analysis of prospectively collected data. POEM was performed in 86 patients (median age 46). Before the procedure, all patients were given intravenously ceftriaxone 2 g and metronidazole 500 mg; ceftriaxone was further administered on POD 2 and 3. In 60 patients (69.8%), a lavage with 80 mg of gentamicin diluted in 10 mL of normal saline was performed into the submucosal tunnel before starting the myotomy (= group A). In 26 patients (30.2%), gentamicin lavage was not performed (= group B). The main outcome variables were CRP level, WBC level, infectious complications and postprocedural fever and pain.

Results: The treatment success at 12 months (defined as an Eckardt score < 3) did not differ between the two groups (group A 98.3% vs. 100% group B). We did not experience any clinically significant infectious complications, such as mediastinitis, peritonitis or abscesses, in either group. In group A (with gentamicin), there was a trend for lower CRP levels and lower WBC count after POEM (POD 1, median with IQ range: CRP: 52.6 (34.8) mg/L vs. 68.2 (34.1) mg/L, p= 0.1; WBC: (10.9 (3.3) vs. 12.4 (3.7) (p= 0.05). Regarding all remaining parameters, we did not detect any differences between the two groups (group A vs. group B, median with IQR: RBC 4.2 (0.6) vs. 4.3 (0.7), Hb 129.5 (18) vs. 133 (22), length of hospitalization 2.0 (1) vs. 2.0 (0) days. The post POEM fever was present on POD 1 and/or POD 2 in 10% of patients in the group A and in 11.5% of patients in the group B (NS).

Conclusion: During POEM, submucosal lavage with gentamicin prior to myotomy does not seem to play a role in the prevention of clinically significant infectious complications, although the systemic inflammatory response may be decreased.

P0738 ENTERAL ACCESS FOR DUODOPA INFUSION: THE ROLE OF THE ENDOSCOPIST

J. Cheron[1], P. Eisendrath[1], D. Blero[1], O. Le Moine[1], J. Devière[1], E. Toussaint[1,2], A. Ballarin[2], D. Zegers De Beyl[3], A. Van Gossum[1,2], M. Arvanitakis[1,2]
[1]*Gastroenterology Department,* [2]*Nutrition team,* [3]*Neurology Department, Erasme University Hospital, ULB, Brussels, Belgium*

Contact E-mail Address: jcheron@ulb.ac.be

Introduction: In patients with advanced Parkinson's disease, the continuous delivery to the jejunum of levodopa/carbidopa (Duodopa) represents a new therapy, which results in less motor fluctuations than oral administration, but requires insertion of a percutaneous endoscopic gastrostomy with a jejunal extension (PEG-J). In this study, outcome of patients undergoing PEG-J placement for Duodopa infusion was analysed.

Aims & Methods: A prospective trial regarding Duodopa treatment is on-going in our institution. All patients had a nasojejunal tube placed initially to assess Duodopa efficiency and dosage, following by a PEG-J after 9 weeks, which was used exclusively for Duodopa infusion. We report the results (technical success, complication rate and outcome), regarding endoscopic management. Complications were defined as adverse effects that required specific treatment (surgery, endoscopy) and/or prolonged hospitalisation.

Results: 27 patients (17 men, median age: 64 (42-80)) were included for long-term Duodopa treatment requiring PEG-J placement, from June 2007 to April 2015. The nasojejunal tube (Freka intestinal tube CH15) was inserted under sedation (n = 11) or general anaesthesia (n = 16). This was performed either from the nasal route with a paediatric scope and the use of a guidewire (n = 17), either with a standard scope and a biopsy forceps (n = 10). No complications were noted. The PEG-J (Freka PEG CH15) was placed under general anaesthesia in all patients. The jejunal extension was inserted during the same procedure in the majority of the patients (n = 25, 93%).

Complications (n = 17) were reported in 12 patients (44%) including J-tube migration (n = 4, during first 3 months after insertion), J-tube impaction in the jejunum (n = 1), J-tube dysfunction (n = 5), Buried Bumper Syndrome (n = 2), duodenal ulcer (n = 2), covered duodenal perforation (n = 1), peritonitis (n = 1), and jejunal perforation with duodenal fistula (n = 1). Complications occurred after a mean follow-up of 17 months (0-54 months). All complications were managed successfully medically (n = 3), by endoscopy (n = 13), or by surgery (n = 1).

The mean number of repeat endoscopy was 2.60 (0-9) (including scheduled procedures for tube replacement and procedures for complications management) during a mean follow-up of 51 months (1-94 months).

All patients responded well to Duodopa regarding neurological outcome. There were no mortalities related to nasojejunal tube or PEG-J during follow-up.

5 patients required PEG-J definitive removal because of cognitive defect (n = 2), psychological trouble (n = 1) and gastrointestinal complications (n = 2, jejunal perforation with duodenal fistula; duodenal ulcer). This PEG-J withdrawal occurred after a mean follow-up duration of 27 months (1-72 months).

Conclusion: Placement of a PEG-J tube for Duodopa jejunal treatment in patients with advanced Parkinson's disease is an effective and noninvasive technique but which carries a high risk of gastro-intestinal complications, probably linked to the overall fragility of these patients. Patients should be fully informed of procedure-related complications and should be followed-up accordingly in referral centres.

P0739 RECURRENCE OF ZENKER'S DIVERTICULUM IS MORE FREQUENT IN MEN WITH SEVERE SYMPTOMS

J. Brueckner[1], H. Messmann[1], S. K. Goelder[1]
[1]*Gastroenterology, Klinikum Augsburg, Augsburg, Germany*

Contact E-mail Address: juliane.brueckner@klinikum-augsburg.de

Introduction: Zenker's diverticulum (ZD) is an illness of the middle-aged and elderly, with a 1.5-fold predominance in men. It develops over time through increased pressure at the Kilian triangle due to impaired relaxation of the upper esophageal sphincter. Nowadays, endoscopic treatment is well established offering various techniques. However, some 20 – 30 % of patients experience recurrence of symptoms after successful treatment. The objective of this study was to identify predictive factors for development of recurrence in order to optimize surveillance for patients at risk.

Aims & Methods: A patient cohort of 25 male and 21 female patients, mean age 67 years, with symptomatic ZD was retrospectively analyzed for pre-treatment differences between patients who experienced or did not experience recurrence. In this cohort 12 out of 47 patients experienced recurrence of symptoms. We examined descriptive factors such as sex, age, multimorbidity, prior treatment and altered local anatomy, as well as severity, duration and frequency of pre-treatment clinical symptoms and complications due to ZD.

Results: Most strikingly, we observed a higher pre-treatment prevalence of severe symptoms such as vomiting (frequency score 2.25 vs. 0.26; $p < 0.01$) and symptom-related insomnia (1.71 vs. 1.04, n. s.) in the recurrence group. Likewise, the dysphagia score was markedly higher (2.27 vs. 1.61, n. s.). Upon further stratification of the recurrence group by No. of sessions (2 or 3 sessions total), the patients with 3 sessions had even more pronounced symptoms. However, due to the small number of these cases there were no significances. Also, duration of symptoms was longer (24.1 vs. 19.6 months, n. s.) and weight loss was more pronounced (3.6 vs. 0.9 kg) in the recurrence group. Analysis of the descriptive

factors showed more male patients in the recurrence group (80 % vs. 47 %; $p < 0.05$), whereas old age and multimorbidity did not show a relevant difference.
Conclusion: Male patients with a high dysphagia score and high frequency of severe symptoms are more likely to experience recurrence of symptoms from ZD and should be monitored more closely following successful endoscopic treatment.

Introduction: Cancer can develop in the operated stomach after partial gastrectomy and in the reconstructed gastric tube after surgery for esophageal cancer. It is considered that endoscopic therapy is more safe and suitable for the early gastric cancer developed in such stomah than opration. To investigate the efficacy of endoscopic submucosal dissection (ESD) for cancer of the operated stomach.
Aims & Methods: Subjects were 669 gastric cancer patients who underwent ESD: 22 patients (23 lesions) had surgically altered gastric anatomy, whereas 647 patients (727 lesions) had normal gastric anatomy. In the altered gastric anatomy group, 13 patients, 6 patients and 3 patients had previously undergone distal gastrectomy, gastric tube reconstruction, and proximal gastrectomy, respectively. Rates of complete *en bloc* resection and curative resection were compared between the two groups. Influence of an anastomotic site and/or a suture line on ESD outcomes was examined in the altered gastric anatomy group.
Results: The rate of complete *en bloc* resection by ESD was 82.6% (19/23) in the altered gastric anatomy group and 92.3% (671/727) in the normal gastric anatomy group. The rate of curative resection and incident rates of complications were not significantly different between the groups. In the altered gastric anatomy group, the rate of complete *en bloc* resection was significantly lower when a lesion had spread across an anastomotic site and/or a suture line ($P = 0.0372$). Furthermore, duration of ESD was significantly longer ($P = 0.0276$), and resection efficiency was significantly lower (13 mm^2/min, $P = 0.0283$), when treating lesions with an anastomotic site and/or a suture line than when treating isolated lesions.
Conclusion: Outcome of ESD for cancer of the operated stomach compares with that in normal stomach anatomy. Anastomotic site/suture line within a lesion influenced the ESD procedure.

P0741 METHYLENE BLUE CHROMOENDOSCOPY AND MAGNIFICATION ENDOSCOPY ARE NOT USEFUL FOR DIFFERENTIATING TYPES OF INTESTINAL METAPLASIA IN THE STOMACH

J. Wasielica-Berger[1], A. Pryczynicz[2], A. Kemona[2], A. Dabrowski[1]
[1]*Department of Gastroenterology and Internal Medicine,* [2]*Department of Pathomorphology, Medical University of Bialystok, Bialystok, Poland*

Contact E-mail Address: jwasielica@o2.pl
Introduction: Intestinal metaplasia (IM) in the stomach is a precancerous state often presenting as foci. IM can be divided into complete and incomplete, the latter bears greater risk of malignant transformation. Methylene blue (MB) chromoendoscopy can detect IM in the stomach, but sensitivity of this method is low. We hypothesised that those two types of IM have different ability to absorb MB which may be the cause of false negative results of chromoendoscopy. Previous studies suggested that complete and incomplete IM in the stomach present with different mucosal surface pit patterns.
Aims & Methods: We aimed to check if absorption of MB depends from the type of IM and if mucosal pit pattern evaluation may be helpful to discern complete and incomplete IM in the stomach. 37 patients with previously diagnosed IM in the stomach underwent gastroscopy with 0.5% MB staining and evaluation of gastric mucosal pit pattern in magnification up to x115 (Olympus GIF Q160Z). Biopsies were collected from antrum and corpus of the stomach, separately from the areas that stained and did not stain with MB. If intestinal metaplasia has been found in H&E histology, it was further differentiated into complete and incomplete by histochemistry (Alcian Blue PAS pH 2,5).
Results: We collected biopsies from 127 areas (34 stained and 93 unstained). Intestinal metaplasia was found in 57 bioptates (44.9%). IM was found more often in specimens collected from areas stained with MB (27 out of 34 – 79.4%) than in specimens collected from areas that did not stain with MB (30 out of 93 – 32.3%), $p < 0.001$. MB chromoendoscopy had 47.4% sensitivity and 90.0% specificity in detecting IM. There was no difference in the frequency of positive MB staining between complete and incomplete IM ($p = 1.0$). Comparing specimens containing IM collected from stained and unstained areas, the percentage of metaplastic cells in gastric mucosa was significantly higher in the first group (56.06%) than in the latter (28.17%, $p < 0.001$). IM was significantly less common in dot pit pattern (7.1%) than in tubular (38.9%, $p < 0.05$), villous (48.7%, $p < 0.0005$), foveolar (53.3%, $p < 0.005$) and cobblestone pit pattern (67.7%, $p < 0.0005$). The differences in frequency of IM between tubular, villous, foveolar and cobblestone pit patterns were not significant. The proportion of complete and incomplete intestinal metaplasia was similar in all pit patterns.
Conclusion: Positive MB staining and other than dot pit pattern correlate positively with the presence of IM. Positive or negative MB staining of metaplastic areas in the stomach may depend from percentage of metaplastic cells in gastric mucosa. Neither MB chromoendoscopy nor mucosal pit pattern evaluation are helpful in discerning complete and incomplete IM in the stomach.

P0742 IS THERE ANY VALUE OF ENDOSCOPY FOR GORD IN PATIENTS UNDER 45?

A. S. Solomon[1], **K. Besherdas**[1]
[1]*Royal Free Hospital, Enfield, United Kingdom*

Contact E-mail Address: kalpesh.besherdas@nhs.net
Introduction: For gastro-oesophageal reflux (GORD), upper endoscopy may be indicated in men older than 50 years with chronic GORD symptoms (symptoms for more than 5 years) and additional risk factors (nocturnal reflux symptoms, hiatal hernia, elevated body mass index, tobacco use, and intra-abdominal distribution of fat) to detect oesophageal adenocarcinoma and Barrett oesophagus. In addition, upper endoscopy is indicated in patients with heartburn and alarm symptoms, such as dysphagia, bleeding, anaemia, weight loss, and recurrent vomiting. However, upper endoscopy is not an appropriate first step in most patients with GORD symptoms and is indicated only when empirical PPI therapy for 4 to 8 weeks is unsuccessful. Furthermore, inappropriate use of upper endoscopy does not improve the health of patients, exposes them to preventable harms, may lead to additional unnecessary interventions and results in unnecessary costs with no benefit.
Aims & Methods: The aim of the study was to assess the findings at upper endoscopy in patients under 45 years endoscoped for reflux without alarm symptoms. A single centre retrospective analysis in a North London NHS Trust Hospital was performed. Patients endoscoped for reflux were identified using the Unisoft Endoscopy reporting software, across a period of 10 years (June 2005 - May 2015). Data from the patients' electronic records were scrutinized if Barrett's was detected.
Results: A total of 1772 patients underwent upper endoscopy for reflux within the study period. 478/1772 patients were under 45 years of age. 124/ 1772 were found to have Barretts (7%). The age distribution was: under 45 years old: 16 patients (13%), 45-55 years: 20 patients (16%), 55-65 years old: 31 patients (24.8%), over 65: 57 patients (45.6%).
Out of the 478 patients under 45 undergoing endoscopy, 16 had Barrett's (3%), and no patient had cancer of oesophagus/stomach. All the 16 patients with Barrett's under 45 years had a short segment Barrett's without dysplasia (8 patients with 1 cm, 7 patients with 2 cm maximal length, 1 patient with 3 cm maximal length.
Conclusion: From this study, no patients under 45 undergoing upper endoscopy for GORD had upper GI cancer and only 3% had Barrett's, all short segment (<3 cm). The yield of upper GI endoscopy in this group is very low. In austere times where supply of endoscopy is overstretched it is important not to overburden the service with unnecessary procedures. From this study, we do not advocate performing upper GI endoscopy in patients under 45 years of age with reflux without alarm symptoms.

Contact E-mail Address: kazarchery@yahoo.co.jp
Introduction: Acute upper gastrointestinal (UGI) ulcers is a major cause of morbidity and mortality, as well as a common medical emergency. Endoscopic hemostasis is the first treatment for UGI ulcer, and it can avoid emergency surgery. However, it can be difficult to completely achieve in some patients, and excessive hemorrhage from UGI ulcers can be fatal. Endoscopic treatment of UGI bleeding has recently advanced along with the administration of high dose intravenous proton pump inhibitors. Despite improvements in endoscopic hemostasis and pharmacological therapies, UGI ulcers repeatedly bleed in 10% to 20% of patients, and those without early endoscopic reintervention or definitive surgery might be at a high risk for mortality. Therefore, determining which factors are involved in rebleeding after an initial endoscopic hemostasis is extremely important for patients with bleeding UGI ulcers. In addition, understanding the factors that contribute to intractable or in sufficient initial endoscopic hemostasis is needed to advance the management of such ulcers.
Aims & Methods: This study aimed to determine the risk factors for intractability to initial endoscopic hemostasis. We analyzed 558 patients who underwent emergency endoscopic for bleeding UGI ulcers within 24 hours of arrival at our hospital between April 2000 and October 2014. We retrospectively documented the patients' backgrounds, and evaluated the ulcer location, size of exposed vessels on the bottom of the ulcer size, and Forrest bleeding patterns. To determine the factors involved in intractability to the initial endoscopic hemostasis, we compared patients whose bleeding UGI ulcers were successfully treated with the hemostasis with those who were intractable.
Results: Durable hemostasis was achieved in 477 patients (84.5%) by using initial endoscopic procedures. Seventy-six patients (14.6%) with Forrest types

Ia, Ib, IIa, and IIb at the second look endoscopy were considered intractable to initial endoscopic hemostasis. Three patients (0.6%) who underwent emergency surgery because of failure to the initial endoscopic hemostasis and two patients (0.4%) who died right after the initial endoscopic hemostasis because of heart failure were also considered intractable to initial endoscopic hemostasis. Multivariate analysis indicated that smoking (odds ratio [OR], 1.94; 95% confidence interval [CI], 1.16 to 3.24), shock on admission (OR, 2.68; 95% CI, 1.35 to 5.31), hemoglobin upon admission < 8.0 mg/dl (OR, 1.87; 95% CI, 1.02 to 3.42), serum albumin upon admission < 3.3 g/dL (OR, 2.05; 95% CI, 1.07 to 3.90), exposed vessels with a diameter of ≥ 2 mm on the bottom of ulcer (OR, 2.79; 95% CI, 1.65 to 4.72) predicted intractable endoscopic hemostasis, but Forrest types Ia was not the predictive factor of intractable endoscopic hemostasis.

Conclusion: Smoking, shock upon admission, hemoglobin < 8.0 mg/dL, serum albumin < 3.3 g/dL, and exposed vessels ≥ 2 mm on the ulcer bottom were identified as independent risk factors associated with initial intractable endoscopic hemostasis in patients with peptic UGI bleeds. Careful observation after initial endoscopic hemostasis is important for patients at a high risk for incomplete hemostasis.

Introduction: Gastric or pancreatobiliary cancer patients sometimes suffer from gastric outlet obstruction due to gastric or duodenal stenosis. Recently the through-the-scope gastroduodenal stenting for malignant gastric outlet obstruction has become more effective, but the gastroduodenal stenting is sometimes ineffective, and stent dysfunction and complications occur. Many previous studies have analyzed the clinical efficacy, but not much has been available on the predictive factors.

Aims & Methods: The purpose of the present study was to retrospectively evaluate the clinical effectiveness of the gastroduodenal stenting with malignant obstruction and to identify predictive factors associated with ineffectiveness, stent dysfunction and complications. Between March 2009 and March 2014, 278 patients who underwent through-the-scope gastroduodenal stenting at four tertiary medical centers in west Japan were analyzed retrospectively. Primary aim was to investigate predictive factors for the outcomes such as clinical ineffectiveness, stent dysfunction and complications. The ineffective group was defined as the group without achievement of the GOOSS of 2 or more and relief of symptoms of GOO after stenting on the day 7 after stenting.

Results: The mean age of patients was 71.7 ± 11.4 years old. The patient etiology was; pancreatic cancer in 121 (43.5%) and gastric cancer in 87 (31.3%). Technical success was achieved in 277 of 278 patients (99.6%). Clinical effectiveness was achieved in 242 of 277 patients (87.4%), while stenting was ineffective in 32 patients (11.6%) and 3 patient (1.1%) died within 7 days after stenting. Stent dysfunction (ingrowth, overgrowth, migration and others) occurred in 46 patients (16.6%) (16, 11, 11 and 8 patients, respectively). Complications (jaundice, bleedings, perforation and others) occurred in 54 patients (19.5%) (23, 15, 6 and 10 patients, respectively). Number of stenosis regions ≥ 3 (odds ratio 6.11; 95% CI 2.16-17.30; $p < 0.01$) and KPS ≤ 50 (odds ratio 6.63; 95% CI 2.89–15.20; $p < 0.01$) were the significant predictive factors for clinical ineffectiveness. KPS ≤ 50 (hazard ratio 4.10; 95% CI 1.80–9.32; $p < 0.01$) and covered stent (hazard ratio 2.05; 95% CI 1.07–3.93; $p = 0.03$) were the significant predictive factors for stent dysfunction. Type II stenosis (hazard ratio 40.94; 95% CI 2.58-649.90; $P < 0.01$), covered stent (hazard ratio 87.14; 95% CI 6.16-1232.81; $P < 0.01$) and ascites (hazard ratio 0.13; 95% CI 0.02-0.96; $P < 0.05$) were the significant predictive factors for stent migration. Deployment of 2 stents in the same session (hazard ratio 1554.78; 95% CI 12.63-191364.4; $P < 0.01$) was the significant predictive factor for perforation.

Conclusion: The gastrodudenal stenting tends to be ineffective in patients with poor performance status and long stenosis regions. Stent dysfunction occurs more frequently with using covered than uncovered stents and in patients with poorer performance status. Uncovered stent is recommended in case of type II stenosis and non-ascites. We have to pay attention to prevention of perforation during deployment of 2 stents.

P0745 ENDOSCOPIC ENBLOC RESECTION OF SUB EPITHELIAL TUMORS: A SINGLE-CENTRE STUDY

A. Bapaye[1], N. A. Dubale[1], **K. Sheth**[1], J. A. Bapaye[1], M. Kulkarni[1], R. Jajoo[1]
[1]*Shivanand Desai Center for Digestive Disorders, Deenanath Mangeshkar Hospital and Research Center, Pune, India*

Contact E-mail Address: amolbapaye@gmail.com

Introduction: Sub epithelial tumors (SETs) are soft tissue tumors arising from the sub mucosal or muscluaris propria layers of luminal organs. Enbloc resection of these lesions is desirable; often using surgical methods. Endoscopic techniques for resection of these lesions include endoscopic submucosal dissection (ESD) for lesions originating in the sub mucosal layer or endoscopic full thickness resection (EFTR) or submucosal tunneling endoscopic resection (STER) for lesions arising in the muscularis propria layer. This study describes our experience of endoscopic treatment of SETs.

Aims & Methods: Data of all consecutive patients undergoing endoscopic resection of SET in the period 2012 – 2014 was analyzed. All patients underwent pre procedure screening esophagogastroduodenoscopy (EGD) and endoscopic ultrasound (EUS) for assessment of the SET. One of following 3 procedures – ESD, EFTR or STER was performed for resection of the SET. ESD was performed for SET's arising in sub mucosal layer whereas EFTR or STER was performed for lesions in the muscularis propria layer. All patients underwent follow up EGD at 4 - 6 weeks. Parameters recorded were – location of lesion, layer of origin, procedure performed (ESD, EFTR or STER), technical success, margin positivity on histology, complications and their management, final histopathology.

Results: 29 consecutive patients with sub epithelial tumors underwent endoscopic resection during study period. Mean age – 56 years (range 29-78) and 21 male patients. ESD was performed in 23 patients, EFTR in 4 and STER in 2. Location of SET's was stomach (14), colon (6), duodenum (5), esophagus (3) and rectum (1). The mean area of sub epithelial tumors was 14.11 cm^2 (range 1-110). Histology was neuroendocrine tumors – 9, lipoma – 7, gastrointestinal stromal tumors – 6, leiomyoma – 5, ectopic pancreatic rest – 1 and duplication cyst – 1. Technical success of resection was 100%. 3 complications: perforation – 2 patients, 1 required surgery; bleeding – 1 patient, managed endoscopically. Histopathology of all specimens showed en-bloc excision with negative tumor margins.

Conclusion: Endoscopic en-bloc resection using ESD, EFTR or STER is a safe and effective therapy for SETs. Pre procedure EUS must be used to detect the layer of origin of SET. Based on EUS findings, the appropriate excision procedure can be selected.

P0746 PREDICTIVE FACTORS FOR LYMPH NODE METASTASIS AND LONG TERM OUTCOMES IN NON-CURATIVE PATIENTS WITH EARLY GASTRIC CANCER AFTER ENDOSCOPIC SUBMUCOSAL DISSECTION

K. Nakamura[1], H. Kinugasa[1], K. Miyahara[1], M. Nakagawa[1]
[1]*Internal Medicine, Hiroshima City Hospital, Hiroshima, Japan*

Contact E-mail Address: kami_hi_koki@yahoo.co.jp

Introduction: Endoscopic submucosal dissection (ESD) is now widely employed and accepted in Japan as a less invasive treatment for early gastric cancer.

Aims & Methods: Endoscopic submucosal dissection (ESD) for gastric cancer has been familiarized broadly and rapidly. However risk factors and long-term outcomes in patients with non-curative resection after ESD remain to be elucidated. We evaluated predictive factors for lymph node metastasis (LNM) and long-term outcomes for these patients.

We analyzed 859 patients with early gastric cancer (1074 lesions) who underwent endoscopic submucosal dissection (ESD) from June 2001 through August 2011 in Hiroshima Citizens Hospital. Among 128 patients of non-curative resection, pathological factors have been analyzed. Ninety-nine patients (group A) have undergone an additional surgical gastrectomy with lymph node dissection and 29 patients (group B) have received no additional surgical gastrectomy due to their comorbidities. Seven hundred thirty one patients have had curative resection (group C). We have revealed risk factors for LNM and compared long-term outcomes in three groups.

Results:

The incidence of LNM was 8% (8/99) in group A. Pathological factors such as size, histology (pure differenced type, dominant type, pure undifferenced type), depth of submucosal invasion, ulceration, lymphatic involvement (LI), and venous involvement (VI) were examined for LNM. Decision tree analysis showed that the highest LNM risk combination was LI and ulceration. The frequency of LNM was 31% (3/9) in the patients LI and ulceration. Univariate analysis revealed that LI was only significant prognostic factor ($p = 0.005$). Kaplan-Meier demonstrated that there was a significant difference of group A and Group B ($p = 0.0002$) to group B and group C ($p = 0.005$).

Conclusion: LI was a only risk factor for LNM in patients with non-curative resection after ESD and additional surgical gastrectomy with lymph node dissection was recommended to them if possible.

P0747 CREATING AND ASSESSING EX-VIVO MODELS FOR SIMULATION ENDOSCOPIC TRAINING

I. Chizhikova[1], A. Ivanov[1], **K. Petrova**[1], E. Fedorov[2]
[1]*Training Center of Innovative Medical Technologies,* [2]*Pirogov Russian National Research Medical University (RNRMU), Moscow, Russian Federation*

Contact E-mail Address: i.o.tsukurova@gmail.com

Introduction: While virtual reality and plastic models are essentially similar for all training centers, ex vivo models are centers' proprietary work, making it impossible for a student to assess the quality of a center's model before taking the course. At the same time, lack of standards in the area of ex-vivo modelling directly affects the quality of trainings provided. In view of this, standards must be set to maximize the quality of ex-vivo models, both in terms of the organ and pathology representation and imitation of surgical manipulations.

Abstract number: P0747 Ex-vivo Model Assessment Chart: Gastrointestinal Hemorrhage

Criteria		Not achieved	Partially achieved	Fully achieved
Organ modeling	Organ integrity			
Mucous membrane of natural color, with changes corresponding to the simulated pathology				
Pathology modeling	Hemorrhage intensity true to type			
Vessel wall condition				
Surgery simulation	Supporting the whole range of surgical techniques			
	Ease of access			
Model supporting several types of hemorrhage				

Aims & Methods: To optimize the process of creation of ex-vivo models (illustrated with the example of the gastrointestinal hemorrhage model), we have developed the following methods:
1. Organ modeling: A) To ensure the stomach integrity, we recommend forming an artificial gastroesophageal sphincter imitation from polymers. B) To preserve the natural colour of the mucous membrane, we recommend treating it with NaCl isotonic solutions and storing the abdominal organs in a 20% ethanol, 10% glycerine solution, at -10 to -15 C.
2. Pathology modeling: A) To simulate Forrest I arterial hemorrhage, we recommend using a pulse pump, and a drip set to imitate a vein hemorrhage. B) We recommend using the vessels: animal's own spleen artery and vein to imitate the vascular wall condition for this pathology.
3. Surgical manipulations imitation: A) The model supports the whole range of surgical techniques owing to the properties of the mucous membrane treatment solution and the natural properties of the animal's vessels, which ensure good contact between the tissue and a plate electrode, and adequate electrocoagulation. B) To provide access to the abdominal organs, we recommend forming a polymer port in the upper esophagus, wide enough in diameter to the surgical tools to be used. C) To create a model that would support several types of gastrointestinal hemorrhage, we recommend modeling up to 20 Forrest Ia/b bleeding points in the organ's wall.
Results: Based on four years of surgical gastroenterology work at the Training Center and on the feedback received individually and through polls from RNRMU professors, our international partners (including World Endoscopy Organization (WEO) experts) and students, we developed a set of performance criteria for ex-vivo models for each type of training.
Conclusion: Based on these criteria, the key requirements to each ex-vivo model were identified and have been implemented in a targeted manner.
This paper exemplifies successful use of feedback from simulation training students to find solutions to the key problems of biomodelling.

Contact E-mail Address: lpoincloux@chu-clermontferrand.fr
Introduction: Using a self-expandable metallic stent (SEMS) in the cervical esophagus is controversial due to increased risk of complications. Here we assessed a new type of SEMS purpose-designed for the cervical esophagus area.
Aims & Methods: This study included patients with malignant or benign stenosis within 4 cm distance of the upper esophageal sphincter (UES) who underwent placement of an SEMS with a shorter proximal funnel (Niti-S Esophageal Covered Stent—Cervical-type, NSCSC), Taewoong Medical). Main outcome measures were functional outcome, tolerance, complications, recurrent dysphagia and survival.
Results: 37 patients had a NSCSC placed between April 2008 and June 2013 for esophageal stenosis (20 malignant = 20, benign = 17), 5 with associated tracheoesophageal fistula. Average distance between UES and upper taper of the stenosis was 1.86 ± 1.27 cm. Median follow-up was 150 days. Dysphagia improved in 27/37 cases (73%). Short-and long-term tolerance without needing stent removal was 92% and 82%, respectively. Complication rate was 59% (22/37): 32% (n = 12 patients) major complications (fistula (3), perforation (3), aspiration pneumonia (5), laryngeal dyspnea (2) and bleeding (1)), and 27% (n = 10 patients) pain (7) or dysphonia (3). 84% of major complications occurred after 49 days. Multivariate analysis found a higher risk of major complications in cases of benign stenosis ($p = 0.04$). Recurrent dysphagia occurred in 15 (40%) patients due to obstruction (7) or migration (8).
Conclusion: NSCSC placement in the cervical esophagus effectively palliates dysphagia and is well-tolerated, but carries a high rate of complications. It does not seems to be less morbid than standard SEMS in this indication. The use of this device in benign strictures beyond six weeks is not recommended.

P0749 WHEN TO DRIVE SAFELY AFTER SEDATED ENDOSCOPY: A PROSPECTIVE PILOT STUDY ACCESSING THE DRIVING SKILLS RECOVERY AFTER ENDOSCOPIC SEDATION BY DRIVING SIMULATOR

L. Peng[1], Z. yuanlin[1]
[1]*Department of Gastroenterology, Beijing Friendship Hospital,Capital Medical University, Beijing, China*

Contact E-mail Address: 15011299045@163.com
Introduction: Patients after endoscopic sedation were recommended not driving in 24 hours.
Aims & Methods: Assessing patients driving skills recovery after endoscopic procedures with propofol sedation to determine when to drive safely. Outpatients range in age from 20 to 70 years old and hold legitimate licenses. Volunteers were recruited to have a gastroscopy or colonoscopy under intravenous anesthesia with propofol, and measured driving ability by driving simulator before, and 2h, 4h after endoscopy. Meanwhile, blood samples were collected respectively before, and 2h, 4h after endoscopy for propofol concentration, which was determined by High Performance Liquid Chromatography. Driving simulation scenes were designed as low, moderate and high risk. The low risk scene simulated S curve driving, the moderate risk scene evaluated overtaking ability, and the high risk one assessed emergency collision avoidance capacity.
Results: Thirty volunteers met the inclusion criteria and participated in preoperative driving simulation, but eight of them had symptoms of dizziness, nausea or vomiting in the driving simulation test and were excluded from the study. The rest twenty two cases completed preoperative driving simulation test, but four of them refused the next gastrointestinal endoscopy. Eventually, eighteen cases completed gastroscopy or colonoscopy with propofol sedation, the driving simulation and blood collection 2h, 4h after endoscopy. Repeated measures was used for analyzing the variables of low risk, medium risk and high risk driving scenes. In low risk S curve scene, average acceleration (cm/s2) before endoscopy, 0.016 ± 0.010 VS 2h after endoscopy, 0.029 ± 0.016, $P = 0.001$; the average lane deviation (cm) before endoscopy, 42.50 ± 16.91 VS 2h after endoscopy, 53.80 ± 18.85, $P = 0.014$; the maximum lane shift (cm) before endoscopy, 113.70 ± 31.91 VS 2h after endoscopy, 157.00 ± 62.27, $P = 0.024$; the times of deviating from pathway before endoscopy, 0.83 ± 1.65 VS 2h after endoscopy, 2.06 ± 1.80, $P = 0.022$. In moderate risk scene and emergency collision avoidance high risk scene, there were no significant differences between before endoscopy and 2h after endoscopy. All variables of low, moderate and high risk scenes between before endoscopy and 4h after endoscopy, were no significant differences. The average blood concentration of propofol 2h after endoscopy was 0.81 ± 0.40 ug/ml, and propofol blood concentrations of blood samples collected 4h after endoscopy were below the limit of detection.
Conclusion: Subjects driving ability 2h after endoscopy was not recovered to baseline completely, but being fully restored 4h after endoscopy. Propofol had a certain impact on driving ability 2h after endoscopy.

Introduction: The key stage of the EFTR procedure is the successful closure of the gastric wall defect left after full-thickness resection and thereby avoid surgical intervention. This report presents a new method of closing large gastric defects left after EFTR, using LeClamp™ endoloops and metallic clips by means of single-channel endoscope.
Aims & Methods: We retrospectively analyzed 68 patients who presented at four institutes between April 2014 and October 2014 with gastric fundus GISTs arising from the MP and who consequently underwent EFTR, with the resulting large gastric defects being closed using novel endoloops (Loop-20 and Loop-30, LeClamp™, Changzhou, China) and metallic clips (HX-600-135; Olympus). The key steps of closure were (1) An endoloop was inserted into the gastric cavity by forceps through the single-channel therapeutic endoscope; (2) The endoloop was anchored onto the full thickness of the defect's distal margin with the clip, followed by insertion of several additional clips to anchor the endoloop at different sides of the margin; (3) The delivery system was inserted and a removable hook was connected with the endoloop; (4) The endoloop was tightened by slight pulling of all the edges together; (5) Other clips were used if any clip was not accurately positioned or the purse-string suture was not tight. Patient characteristics, tumor size, en bloc resection, and postoperative complications were evaluated.
Results: A total of 68 patients (27 men [40%], 41 women [60%]; median age 55 years, range 38–67) were successfully underwent EFTR and the en bloc resection rate was 100%. Completely closure of all the gastric full-thinkness defects was achieved (success rate 100%). The median suture operation time was 13 minutes (range 9–21min). The mean maximum size of the lesions was 2.3cm (range 1.5–3cm). Pathological examination determined that all of the lesions were GISTs. The tumors were all low risk or very low risk, with a low mitotic index. No further treatment was given. The median hospital stay after the procedure was 5.4 days (range 3–9). None of the patients experienced severe complications, such as delayed bleeding, peritonitis or abdominal abscesses. Contrast roentgenography on post-procedure day 3 showed that no patients had gastrointestinal tract leakage or disturbed gastric emptying. None of the 68 patients underwent any surgical operations for the treatment of their lesions. All the patients had follow-up visits and the wounds were healed in all cases 1 month after the procedure. No residual tumor or tumor recurrence was observed during the follow-up period (range 6–12 months).
Conclusion: The use of LeClamp™ endoloops and metallic clips is a relatively safe, easy, and feasible method for repairing gastric defects resulting from EFTR.

P0751 ESD TRAINING IN CHINA: EXPERIENCE FROM HYBRID KNIFE HANDS-ON WORKSHOPS IN ZHONGSHAN HOSPITAL

Y. Zhong[1], J. Li[1], **L. Yao**[1]
[1]*Zhongshan Hospital of Fudan University, Endoscopy Center, Shang hai, China*

Contact E-mail Address: lijian15952870985@163.com
Introduction: Endoscopic submucosal dissection (ESD) is the gold standard technique for en bloc resection of superficial tumors of the gastrointestinal tract [1]. Hands-on endoscopy workshops are popular and valuable source for training of ESD. In China, ESD experience remains limited. Endoscopy Center, Zhongshan Hospital was the first endoscopy center to provide ESD in China back in 2006 [2], and has been a destination for ESD training since 2009.
Aims & Methods: The aim of the study is to evaluate the efficacy and safety of short-term hands-on workshops in ESD and to assess the progress of ESD practice in China following endoscopic training at the Zhongshan Hospital, with special attention to both short-term outcomes during the course and to the later ESD experience of the trainee's hospitals, in order to help setting the standards for adequate training and certification for ESD. From 2009 to 2013, ESD hands-on workshops have been held at Zhongshan Hospital. The workshops included lectures, ESD live demonstrations and hands-on training on live porcine models. Follow up questionnaires were sent to all 550 trainees at 464 hospitals in October 2014, with 460 trainees responding.
Results: There were 550 doctors who were trained during the 23rd hands-on workshops held Zhongshan Hospital, the median number of course trainees was 25 (ranging between 7-32). Completed questionnaires were returned by 460 (83.6%) trainees. There were 417 trainees who started performing ESD after the course. 28 doctors attended the workshop twice, and performed better than trainees who attended once in the hands-on practical session. Performance in the practical session has a significant difference both in the trainees GI experience ($>$ 5years vs$\leq$ 5years) and GI endoscopies ($>$4000 vs $\leq$4000). Following up the trainees within 1-year, there were 378 (82.2%) respondents from high-volume medical centers, with one-third of the respondents had experience in ESD.
Conclusion: Hands-on endoscopy workshops are useful in introducing ESD for trainees. Results showed that our training model is safe and enable novice endoscopists to start performing ESD. Requirements for starting ESD training include prior GI endoscopy experience, intensive learning and simulated ESD on live animal models under instructor's supervision. Essential requirements for trainees starting ESD remain to be established, but our system provides a step on the way.

P0752 ENDOSCOPY IN VARICEAL BLEEDING: OPTIMAL TIME TO RESCOPING

L. Nunn[1], C. Shekhar[2], R. Mohammad[3], N. Fisher[3], S. Ishaq[3]
[1]*Medical School, University of Birmingham, Birmingham,* [2]*Gastroenterology, Manor Hospital, Walsall,* [3]*Gastroenterology, Russells Hall Hospital, Dudley, United Kingdom*

Contact E-mail Address: drcshekhar@gmail.com
Introduction: Variceal haemorrhage is a common and potentially lethal complication of cirrhosis (1). Variceal rebleeding can occur in 20% of cases in the first week following the acute episode (2). BSG guidelines published in 2000 suggested endoscopy at weekly interval, whereas the AASLD guideline from 2007 suggest at 1-2 week interval and most recent ASGE guideline suggests optimal rescoping intervals of 1-8 weeks, a wide-ranging time scale recommendation classified as low-grade evidence (3,4,5). There is also primary literature that indicates that rescoping in less than 3 weeks might increase risk of harm (6).
Aims & Methods: We reviewed our practice to assess compliance with guidelines.
Method: We carried out a retrospective review of endoscopic procedures and follow up after oesophageal variceal bleeds at a DGH in the West Midlands over a 12-month period from August 2012 onwards. We recorded the date of their first variceal bleed (index bleed) and the scheduled follow up endoscopy procedure. We also recorded any adverse events such as rebleeds (bleeds in $<$7 days since the index bleed) or interval bleeds (bleeds that occurred $>$7 days post index bleed).
Results: 31 patients identified during 12month period had total 45 acute variceal bleeds, requiring urgent endoscopy. Haemostasis was achieved in all but one occasion 97.8% (44/45), with the majority (32) receiving band ligation and remaining receiving sclerotherapy or combination of therapies. 20% of total bleeds had rebleeds or died within 7 days. Of the remaining 36 bleeds, 14% had scheduled repeat endoscopy in $<$7 days as per last BSG guidelines, 29% had scheduled endoscopy between 1-8 weeks, which conforms to the standards suggested in new ASGE guideline, 20% had follow up endoscopy after 8 weeks, and 37% had no follow up endoscopy. The mortality rates of the people rescoped within 0-2 weeks and 2-8 weeks were 78% and 23% respectively with multiple reasons contributing.
Conclusion: There is inconsistency in the duration to follow up endoscopy practice perhaps due to wide discrepancy in available guidance and patient compliance. It is likely that in real-life practice in UK, rescoping interval is variable and inconsistent. It would be helpful to reassess current BSG guidelines and consider follow up endoscopy within 3-8 weeks after an index variceal bleed, with ongoing prospective review and audit to inform future adjustment.

P0753 ENDOSCOPIC SUBMUCOSAL DISSECTION FOR GASTRIC SUPERFICIAL NEOPLASTIC LESIONS: A EUROPEAN II LEVEL CENTER EXPERIENCE

L. Petruzziello[1], M. Campanale[1], G. Andrisani[1], G. Gullo[1], S. Greco[1], C. Spada[1], G. Costamagna[1]
[1]*Endoscopy Unit, Catholic University of Rome, Rome, Italy*

Contact E-mail Address: chiaracampanale@hotmail.com
Introduction: Endoscopic dissection for the treatment of gastric superficial neoplastic lesions is an established first-line treatment in Eastern countries, its role has yet to be considered in Western guidelines, mostly due to a lack of long-term studies. The aim of this study was to describe the efficacy, safety and long-term outcomes for endoscopic submucosal dissection (ESD) in the treatment of gastric lesions in our center.
Aims & Methods: This was a single-center, retrospective, cohort study between November 2007 and November 2014. A total of 60 consecutive patients with 61 gastric superficial lesions underwent ESD and were followed up for a median of 27 months.
Results: In total 60 ESD were performed. 44 (73.3) lesions matched Extended Criteria, 16 (26.7%) Guideline Criteria (standard criteria). ''En bloc'' resection was feasible in 95%, with R0 resection rates of 86.6% (Ext-G 38/44 86.4% vs St-G 14/16 87.5% p:n.s). In total, 60 gastric lesions were classified as 33 (55%) adenocarcinomas intestinal type according to Lauren classification, 2 (3.3%) adenocarcinomas diffuse type according to Lauren classification, 7 (11.67%) adenomas with low-grade dysplasia (LGD), 10 (16.67%) high-grade dysplasia (HGD), 3 (5%) ectopic pancreas, 2 (3.3%) hyperplastic lesions, 3 (5%)

neuroendocrine tumors. Mean lesion size was 25.5 mm with a difference between two groups (Ext-G 28.77 vs St-G 16.50 mm, $p < 0.001$). 78.3% of lesions were located in third lower of stomach. Type 0-IIa + IIc according to Paris classification was the most frequent lesion in Extended group (54.5%). The recurrence rate was 18.18% (10/55 lesions of Ext-G, p:ns) at follow up of 27 months. We observed only 1 (1.6%) serious adverse events, a perforation treated with surgical resection. 9/10 complications were treated endoscopically without sequels. Surgery was performed in 7 cases (11.67%) : 5/7 after non curative endoscopic resection and 1/7 after histological evaluation (adenocarcinomas diffuse type according to Lauren classification), 1/7 due to complications.
Conclusion: ESD is a highly effective treatment for gastric superficial lesions, without compromising cancer survival. Endoscopic resection should also be considered as first-line treatment for gastric neoplasias in Western countries.

Contact E-mail Address: majagr@net.hr
Introduction: Hemospray is a novel hemostatic agent for the management of gastrointestinal bleeding (GIB). Herein we describe the experience with Hemospray in our cohort of patients with GIB.
Aims & Methods: This was a binational multicentre observational study done at three tertiary hospitals in Croatia and Bosnia and Herzegovina. Consecutive patients with GIB refractory to standard endoscopic hemostasis were included in the study. The patients referred for surgery, or in whom the informed consent for endoscopy was not obtained, were excluded from the study.
Results: There were 16 patients (median age 66.5 yrs, range 47-91, 11 males) with active GIB in whom Hemospray was applied. Lesions in the upper GI tract included: peptic ulcer bleeding (n = 4), Cameron lesion (1), Mallory-Weiss (1), GAVE (1), esophageal cancer (3). Lesions in the lower GI tract included: post-polypectomy bleeding (n = 5), bleeding polyp (1) Severity of bleeding was classified as spurting in 5 pts, oozing (7), visible vessel (1) and can't tell (3). A total of 6 patients were receiving anticoagulant or/and antithrombotic therapy. Bleeding with spurting vessel was in 31.25% of patients, in the form of oozing in 43.75%, and 25% of patients had visible blood vessel. Previous endoscopic treatment was recorded in 10 pts (clips = 7, nylon snare = 1, injection therapy = 1). Rebleeding at 7 days was noted in one patient (6%) with the post-polypectomy bleeding, who was referred to surgery. During the follow-up period (median 3 months, range 1-6), no re-bleeding episodes were recorded and two GIB-unrelated deaths occurred (12.5%). During study period we did not observe any side-effects of Hemospray.
Conclusion: In our cohorts of patients the use of Hemospray was efective treatment option for patients with GIB.

Contact E-mail Address: makotabe7@gmail.com
Introduction: With the development of image-enhanced endoscopy and endoscopic diagnosis, the number of superficial cancer in the oropharynx and hypopharynx is increasing. The endoscopic submucosal dissection (ESD), endoscopic mucosal resection, or endoscopic laryngopharyngeal surgery is performed for these superficial squamous cell carcinomas. Because of complicated structure of pharynx, when ESD was performed for the lesion near the pyriform sinus, postoperative adhesion was observed. It impairs swallowing function and becomes the cause of aspiration pneumonitis. And similar to the esophageal ESD, postoperative stricture is observed when a large area of mucosa was removed. Some study showed the endoscopic transplantation of fabricated autologous epithelial cell sheets prevent postoperative stricture. It is expected same effect after the ESD of the oropharynx and hypopharynx. However, because of the narrow and complicated 3-dimensional structure of pharynx, we can transplant the cell sheets on only a limited area by using existing transplant method and devices. So, it was impossible to investigate an effect of the cell sheet transplantation in the field of the pharynx.
Aims & Methods: To transplant cell sheets to entire field of the oropharynx and hypopharynx after ESD, The novel devices were designed and developed with a computer-aided design system, and the three-dimensional data were transferred to a 3-D printer. And then, primary epidermal cells were isolated from the lower abdominal skin of miniature pigs, cultured for 14 days at 37°C on temperature-responsive culture inserts. Transplantable cell sheets were harvested from the inserts by reducing temperature to 20°C. We performed pharyngeal ESD and cell sheets transplantation with this device in a porcine, and investigated the feasibility of these in the field of the oropharynx and hypopharynx.
Results: Developed novel endoscopic delivery device was consisted of a cell sheet carrier and an air tube. A cell sheet carrier was spoon-shaped and covered by balloon, and connected to an air tube. It could attach the cell sheets by inflating the balloon that inflated only one side. It could deliver the cell sheets without contacting the mouth and laryngopharyngeal mucosa, and deliver the cell sheets on any areas of the pharynx after circumferential ESD. Required cell sheets were successfully transplanted to cover the ulcer site.
Conclusion: The novel device was very useful. Owe to this device, now we can investigate an effect of the cell sheets transplantation after pharyngeal ESD.

P0756 SUCCESFUL TREATMENT OF ACHALASIA BY POEM IN ROMANIA: A REPORT ON THE FIRST 30 CASES

M. Tantau[1], A. Tantau[2], C. Tefas[1], C. Buzas[1], A. Hadade[1], G. Mester[1]
[1]*Gastroenterologie, Institutul Regional de Gastroenterologie i Hepatologie Prof. Dr. Octavian Fodor,* [2]*Spitalul Universitar CF, Cluj Napoca, Romania*

Contact E-mail Address: tefascristian@gmail.com
Introduction: Peroral endoscopic myotomy (POEM) is now the proposed method to replace laparoscopic mytomy in the treatment of achalasia, being less aggressive, with lower morbidity and similar or even higher efficiency. Thus, POEM is reserved for expert endoscopists.
Aims & Methods: The main purpose was to analyze the efficacy and complications of the technique, while the secondary purpose was to evaluate the clinical, endoscopic and manometric improvement in patients after treatment. Endoscopic, radiological and manometric assessments were performed in all patients before and after the procedure. All POEMs were performed by a highly experienced endoscopist with no previous hands-on training. We evaluated the resolution of symptoms at 3 and 30 days after POEM using the Eckardt score. The technique, accessories and electrocautery settings used were those described by Prof. Inoue (1). An esophagography was performed in all patients after the procedure to rule out any leakage. All patients were allowed to eat 48 hours after POEM.
Results: From November 2013 to April 2015, thirty patients were treated by POEM, with a mean age of 43.7 years. Five patients had previous endoscopic balloon dilation. No patient had previous surgical myotomy. The average duration of the intervention was 87.5 minutes. We recorded five incidents, three in the form of esophageal and gastric mucosal microperforations, closed safely with endoscopic clips, one subcutaneous emphysema, for which temporary cessation of the intervention was necessary, and one pneumoperitoneum, for which transumbilical decompression using a Veress needle was necessary. We also recorded two complications in the form of postprocedural endoscopic clip slippage, which required endoscopic reintervention. We noted a decrease in Eckardt score from a mean 7,7 before POEM to a mean 0,8, 30 days after POEM. We also recorded a decrease in LES pressure from a mean 35,5 mmHg before the procedure to 3 mmHg, 30 days after the procedure.
Conclusion: POEM is an effective and safe technique. An experienced gastroenterologist can perform it without the need for hands-on training in advance, due to a reduced learning curve.

P0757 OUTCOMES OF ENDOSCOPIC INJECTION OF MITOMYCIN C FOR REFRACTORY RECURRENT BENIGN ESOPHAGEAL STRICTURES

M. I. Canto[1,2,*], K. Lynch[1], M. Khashab[1], E. J. Shin[1], P. Okolo[1], A. Kalloo[1]
[1]*Medicine (Gastroenterology),* [2]*Oncology, Johns Hopkins Medical Institutions, Baltimore, United States*

Contact E-mail Address: mcanto@jhmi.edu
Introduction: Benign esophageal strictures are a common problem characterized by luminal narrowing due to acid exposure, radiation, caustic injury, or post-surgical changes. The production of collagen and fibrous tissue stimulated by esophageal injury results in chronic stenosis. Up to 35% of benign strictures recur are recalcitrant. Mitomycin C is a chemotherapeutic agent that inhibits both DNA and protein synthesis following intracellular enzymatic reduction resulting in slowing of cell division and fibroblast proliferation [1]. Topical MMC has been used in children and adults to treat laryngeal and tracheal strictures [2,3]. Limited data of MMC topical mucosal therapy in children and adults suggests promising safety and efficacy for recalcitrant esophageal strictures [4].
Aims & Methods: We report the clinical outcomes of 9 patients with refractory benign esophageal strictures treated with endoscopic submucosal injection of MMC(0.4 mg/,l) after dilation[4].
Results: 9 symptomatic patients with 11 refractory esophageal strictures previously treated with numerous dilations (median 4), steroid injections and/or

stents underwent MMC treatment. A total of 16 intralesional endoscopic injections were made. 3 patients with complex strictures required more than 1 MMC treatment. Pre-MMC mean stricture length and diameter were 3.7cm (range 1-10cm) and 5.5mm (range 2-10mm), respectively. Mean patient follow-up time was 14 months (range 6.3-49.8 months). Symptomatic recurrence requiring unscheduled intervening therapy was observed in 4/9 patients within the first 3 months (2 dilation, 1 stent, 1 dilation + MMC). Partial response (post-MMC dysphagia score improved by at least 1 grade) was noted in all. A durable complete response was defined as no dysphagia and no intervening therapies at last follow-up. This was observed in all except 1 patient who required stenting within 6 months. MMC injection decreased pre-treatment intervention therapy from median 3.8 procedures per 6 months (interquartile range 3 to 4.5 per 6 months) to 0 procedures in 6 months ($p = 0.008$,Wilcoxon signed rank). There were no treatment-related adverse events with endoscopic injection of a total of 0.64 to 6.4 mg MMC per patient.

Conclusion: MMC injection for refractory recurrent benign esophageal strictures is safe, eliminates dysphagia, and significantly decreases symptom recurrence and the need for subsequent interventions.

P0758 NITROUS OXIDE CRYOTHERAPY FOR TREATMENT OF ESOPHAGEAL SQUAMOUS CELL NEOPLASIA (ESCN): INITIAL EXPERIENCE WITH A NOVEL PORTABLE CRYOBALLOON FOCAL ABLATION SYSTEM (CBFAS)

M. I. Canto[1], K. Lynch[1], E. J. Shin[1], J. A. Almario[1], H. Cosby[1], B. Jobe[2], Y. Komatsu[2]

[1]*Medicine (Gastroenterology), Johns Hopkins Medical Institutions, Baltimore,* [2]*Surgery, Allegheny Health Network, Pittsburgh, United States*

Contact E-mail Address: mcanto@jhmi.edu

Introduction: Early esophageal squamous cell neoplasia (ESCN) can be successfully treated with radiofrequency ablation (RFA), endoscopic mucosal resection (EMR), or endoscopic submucosal dissection (ESD), but strictures can develop[1]. Endoscopic cryotherapy can successfully eradicate neoplastic Barrett's esophagus[2, 3], including those that failed other treatments[2, 4]. A new portable battery-powered contact cryotherapy system using nitrous oxide (cryoballoon focal ablation system, CbFAS) has been used for Barrett's esophagus[5] with promising early results[6].

Aims & Methods

Aim: To determine the feasibility of endoscopic eradication of ESCN with nitrous oxide cryotherapy using a CbFAS.

Methods: Patients with ESCN who had failed or were ineligible for EMR/RFA (stricture, esophageal varices) were treated with nitrous oxide cryoballoon ablation using the CbFAS, which consists of a small hand-held device containing liquid nitrous oxide, which converts to gas within a low pressure compliant through-the-scope balloon. It freezes targeted mucosa in contact with the balloon, resulting in ablations of approximately 2 cm^2. After chromoendoscopy, all Lugol's voiding lesions (LGLs) were treated with multiple focal ablations (8-10 seconds of ice per site). Post-procedure adverse events were recorded. Patients were treated every 6-8 weeks until targeted and random biopsies demonstrated eradication of neoplasia.

Results: 3 male patients (mean age 66, range 55-76) with multifocal low-grade intraepithelial neoplasia (LGIN), high grade intraepithelial neoplasia (HGIN), or flat type ESCC involving 3 cm (Pt1), 4 cm (Pt2), and 10 cm (Pt3) of the esophagus had 3, 8, and 10 ablations at the index procedure, respectively. Residual LGLs were treated in a second (Pt2) and third procedure (Pt3). No device malfunction was noted. Aiming the cryogen at LGLs was relatively easy. Median procedure time was 34 min (range 18-57). No major adverse events occurred. One patient had mild odynophagia and chest pain. No strictures or bleeding developed. Squamous regeneration was seen in all treated areas with no LGLs and complete pathologic response achieved in all patients with short term follow-up (mean 165 days, IQR 35-316).

Conclusion: Our initial experience suggests that multifocal cryoballoon ablation is a promising portable, technically simple, well-tolerated, safe and effective endoscopic therapy for ESCN, including extensive disease refractory to EMR and RFA. Prospective studies are needed to optimize cryogen dosimetry and assess safety and long-term efficacy.

Introduction: Percutaneous transesophageal gastrotubing (PTEG) was developed as an alternative route to access the gastrointestinal tract for the patients that Percutaneous Endoscopic Gastrostomy was contraindicated with conditions such as prior gastrectomy, gastric anterior wall malignancies, or massive ascites. PTEG by endoscopic assistance may enhance the safety of the procedure.

Aims & Methods: The aim of this study is to evaluate the clinical usefulness of PTEG supported by endoscopy. A rupture-free balloon (RFB) catheter is inserted into the lower esophagus. Percutaneous balloon puncture with a specialized needle is then performed from the left side of patient's neck under ultrasonographic control. A guide wire is inserted through the needle into the RFB, followed by a dilator and sheath. A placement tube is then inserted through the sheath, and the sheath is removed. We started to perform PTEG under endoscopy or fluoroscopy in a total of 144 patients (93 men and 51 women, mean age 72.0 years) in whom PEG was not feasible. PTEG was performed for nutrition in 82 patients and for decompression in 62.Thirty patients were started by fluoroscopic assistance and 114 patients were started by endoscopic assistance.

Results: Satisfactory results were achieved in all 144 patients. Median follow-up was 64.0 days in patients who received decompression because of the obstruction due to malignancies and 255.5 days in those who received nutrition. Seven of 82 patients for nutrition were able to free from tube feeding due to PTEG tube feeding support. There was 1 patient with severe bleeding requiring blood transfusion in the fluoroscopy group. one patient had tracheal penetration, which was managed conservatively. Other complications were minor oozing bleeding in eight patients that did not require blood transfusion, subcutaneous emphysema in two patients, which were managed conservatively. The complication rate associated with fluoroscopically and endoscopically assisted PTEG was 20.0% and 14.1%, respectively. No patient required surgical treatment or died after PTEG.

Conclusion: PTEG is feasible, safe, and useful. PTEG could be an optimal procedure for long-term nutrition and/or decompression even for the patients who failed PEG insertion. The use of endoscopy enhances the safety of the procedure and allows better confirmation of each step involved.

Introduction: Endoscopic resections can remove superficial digestive neoplasia with low morbidity and mortality. Nevertheless, delayed bleeding has been reported in approximately 1, 5, 15 and 2% after resection in the esophagus, the stomach, the duodenum and the rectum, respectively, increasing with antiplatelet/anticoagulant therapy or in case of portal hypertension. A self-assembling peptide (SAP) forming a gel in appropriate conditions of ionization could protect the mucosal defect during the early phase of healing. The aim of this clinical trial was to assess the safety and efficacy of the SAP to prevent delayed bleedings after endoscopic resections.

Aims & Methods: Consecutive patients who underwent endoscopic resections for esophageal, gastric, duodenal or colic superficial lesions were enrolled in two university hospitals. We also included patients with high risk of bleeding like patients with antiplatelet agents, anticoagulation drugs with heparin bridge therapy and cirrhosis with portal hypertension. The SAP gel (Purastat®, 3D Matrix, Ltd) was apllied immediately after resection. The volume of gel depended of the resection size and was applied with a catheter aiming to cover all the ulcer bed.

Abstract number: P0762

Table 1: Mean ESD time of cases with pathology and invasion depth

		InspectionTime(min)	IncisionTime (min)	DissectionTime (min)	CoagulationTime (min)	TotalTime (min)
Pathology	Adenoma	3.54	15.97	30.12	6.98	56.36
	Adenocarcinoma	3.81	19.41	47.44	8.08	79.09
	P value	0.051	0.013	0.001	0.566	0.001
Invasion depth	M	3.62	17.93	36.68	7.04	65.09
	MM	3.58	18.38	37.46	6.32	66.00
	SM	4.71	19.75	77.92	6.08	110.33
	P value	0.383	0.767	0.001	0.659	0.001

Subsequent patient management included oral PPI after esophageal, gastric and duodenal resections. The primary endpoint was the rate of post resection bleeding. Ease of use and safety were also assessed.

Results: 37 patients were included with 42 lesions (8 esophagus, 10 stomach, 8 duodenum, 3 ampullary, 13 colorectal tumors). Among those 42 lesions, 28 were resected in high-risk situations (8 non-discontinued anti-platelets drugs, 6 heparin bridge therapies followed by anticoagulant drugs at day 1, 9 with cirrhosis and portal hypertension, 1 with both cirrhosis and antiplatelet therapy, 3 large duodenal lesions and 1 lesion of the anal canal surrounded by large hemorroids). The resection technique was ESD in 22 cases, en-bloc EMR in 9 and piecemeal EMR in 5. The mean lesion size was 17.1 mm (SD 18.4) with a mean area of 2.94 cm^2 (SD : 3.2). The mean volume of Purastat® used was 3.1 ml (SD : 1.5 ml) in a mean time of 2.0 min (SD : 1.2). No difficulty was noted during application. Four delayed overt bleedings occured (9.5 %) (3 hematochezia, 1 hematemesis) needing endoscopic hemostasis in 3 cases. The mean hemoglobin drop off was 0.8 g/dl (-0.1to 2.1 g/dl). There were no adverse events related to the gel.

Conclusion: The use of this novel EMS may help to reduce the post endoscopic resection bleedings including in high risk situations. Its use is easy and safe but further comparative studies are needed to fully evaluate its effectiveness.

P0761 PRELIMINARY EVALUATION OF SUBMUCOSAL TUNNELING ENDOSCOPIC RESECTION FOR THE TREATMENT OF LARGE SYMPTOMATIC SUBMUCOSAL TUMORS ORINGINATING FROM THE MUSCULARIS PROPRIA LAYER IN THE ESOPHAGUS AND CARDIA

M. Xu[1], C. Zhang[1], on behalf of Chen Zhang, Quan-Lin. Li, Mei-Dong. Xu
[1]*Endoscopy center, Zhongshan Hospital, Shanghai, China*

Contact E-mail Address: xumeidong@aliyun.com

Introduction: Submucosal tunneling endoscopic resection (STER) has been proved to have many advantages for small upper gastrointestinal (GI) submucosal tumors (SMTs) originating from the muscularis propria (MP) layer. Here, we report the clinical value of STER for huge (≥3cm) and symptomatic SMTs originating from the MP layer in the esophagus and cardia.

Aims & Methods: Our study aimed to evaluate the clinical value of STER for large symptomatic submucosal SMTs originating from the MP layer in the esophagus and cardia. A total of 72 large symptomatic SMTs originating from the MP layer in the esophagus and cardia were treated by STER between May, 2011 and December, 2013. Large symptomatic tumors referred to the tumors which were not less than 3 cm in maximum diameter and caused varying degrees of retrosternal or epigastric discomfort, regurgitation, odynophagia, and/or dysphasia. After located, a submucosal tunnel was created to expose the tumor. The lesion was then resected under direct endoscopic view and the tunnel entry was closed with several metal clips.

Results: STER was performed successfully in all cases, and the en bloc resection rate was 100%. The median maximum diameter of the specimens was 4.0 cm. Pathological results revealed 69 leiomyomas, 1 stromal tumor, 1 schwannoma and 1 cyst. STER-related complications were listed in Table 1. All of those complications were treated successfully after conservative treatments. No patient encountered massive and delayed bleeding, intra-tunnel infection or abscess, and procedure-related death. The symptoms of retrosternal or epigastric discomfort, regurgitation, odynophagia and/or dysphasia were relieved varying degrees after the procedures according to patients' subjective feelings. An objective relief of dysphagia was also achieved as assessed by Stooler's dysphagia score ($P < 0.001$). No tumor residual or recurrence was found during the follow-up period (range, 2-30 months)

Table 1 Clinicopathologic information of the 72 patients
. Patients N = 72
Age, median (range), years 46 (28-67)
Sex, n (%). Male 50 (69.4) Female 22 (30.6)
Lesion size, median (range) cm 4.0 (3.0-7.0)
Procedure time, median (range) min 70.0 (42-140)
Tumor location, n (%) . Esophagus 60 (83.3) Cardia 12 (16.7)
Chief complaint, n (%) . Retrosternal or epigastric discomfort 72 (100.0) Regurgitation 56 (77.8) Odynophagia 60(83.3) Dysphasia 72 (100.0)
EUS layer, n (%) . Superficial MP 31 (43.1) Deep MP 41 (56.9)
Pathologic diagnosis, n (%) . Leiomyoma 69 (95.8) GIST 1 (1.4) Schwannoma 1 (1.4) Cyst 1 (1.4)
Complications, n (%) .Substernal or epigastric pain Analgesics required Mucosal damage Closures required 41 (56.9) 3 (4.2) 4 (5.6) 4 (5.6)Pneumothorax Subcutaneous emphysema Diaphragmatic emphysema Pneumoperitoneum Pleural effusion Massive and delayed bleeding Intra-tunnel infection or abscess Surgical-related death Tumor residual or recurrence 9 (12.5) 18 (25.0) 19 (26.4) 9 (12.5) 34 (47.2) 0 (0) 0 (0) 0 (0) 0 (0) 0 (0)

Conclusion: STER is safe and effective for large symptomatic SMTs originating from the MP layer in the esophagus and cardia. The procedure can significantly relieve symptoms without severe adverse events. High en bloc resection rate and accurate histopathologic outcomes can also be achieved with the technique.

P0762 ANALYSIS OF CLINICOPATHLOGIC FACTORS THAT AFFECT ON PROCEDURE TIME OF ENDOSCOPIC SUBMUCOSAL DISSECTION

M. W. Jung[1], S. J. Shin[1], K. M. Lee[1], S. G. Lim[1]
[1]*Gastroenterology, Ajou University School of Medicine, Suwon, Republic of Korea*

Contact E-mail Address: jmw_81@hanmail.net

Introduction: Endoscopic submucosal dissection (ESD) has become a widely accepted therapeutic method for gastric adenoma and early gastric cancer. However, it takes a long time to perform ESD procedure because of technical difficulties. So there has been a lot of effort to analyze factors that have an affect on procedure time. Especially, in this study, we analyzed not only total procedure time but also subdivision of the time -inspection, incision, dissection, coagulation time.

Aims & Methods: We reviewed the data of 343 patients who underwent ESD for 378 lesions (gastric adenoma and early gastric cancer) from July 2006 to December 2012 by one skillful endoscopist. Clinical outcomes of ESD such as procedure time, location, pathology, size, invasion depth were analyzed.

Results:
Mean total procedure time was 64.9 min, and mean inspection, incision, dissection, coagulation time were 3.68, 17.27, 36.65, 7.32 min respectively. Univariate analysis showed the total ESD time was closely related to pathology ($p = 0.001$), tumor invasion depth ($p = 0.001$), location ($p = 0.002$), size ($p = 0.001$), ulceration ($p = 0.001$) and depression ($p = 0.001$). Especially, the pathology, location, tumor size, ulceration and depression were related to incision time and dissection time. Invasion depth was associated with dissection time ($p = 0.001$). When tumor size was controlled, incision time was positively correlated with dissection time ($p = 0.001$).

Conclusion: ESD procedure takes longer when the neoplasm is adenocarcinoma compared to adenoma. Deeper invasion depth, larger tumor size, presence of

Abstract number: P0763

Pre-ESD biopsy result (No.)		Post-ESD result	No. (%)	Discrepancy group
Gastric adenoma (837)	Low grade dysplasia (688, 82.2%)	Non neoplasia	51 (7.4)	Downgrade
		Low grade dysplasia	511 (74.2)	Concordance
		High grade dysplasia	43 (6.3)	Upgrade
			Adenocarcinoma	83 (12.1)
	High grade dysplasia (149, 17.8%)	Non neoplasia	3 (2)	Downgrade
	Low grade dysplasia	28 (18.8)		
	High grade dysplasia	36 (24.2)	Concordance	
	Adenocarcinoma	82 (55)	Upgrade

P0763 ANALYSIS OF DISCREPANCIES IN HISTOLOGIC DIAGNOSES OF GASTRIC NEOPLASM BETWEEN BIOPSY AND ENDOSCOPIC SUBMUCOSAL DISSECTION

M. W. Jung[1], S. G. Lim[1], K. M. Lee[1], S. J. Shin[1]
[1]*Gastroenterology, Ajou University School of Medicine, Suwon, Republic of Korea*

Contact E-mail Address: jmw_81@hanmail.net

Introduction: Endoscopic submucosal dissection (ESD) has become a widely accepted therapeutic method for gastric adenoma and early gastric cancer. A preoperative histologic diagnosis of neoplasia is a requirement for ESD. But, histologic discrepancies between endoscopic forcep biopsy (EFB) and ESD specimens have been reported at rates ranging from 2.7–49%.

Aims & Methods: Aim of this study was to analyze the prevalence of paradoxical (upgrade and downgrade) and concordant pathology results on ESD specimens and to compare their endoscopic characteristics among the each groups. Between February 2005 and December 2011, 1186 ESDs were done at Ajou University Hospital in Suwon, South Korea. Among these cases, 837 cases was diagnosed as adenoma in endoscopic forceps biopsy. We retrospectively reviewed these cases from our original database of gastrointestinal therapeutic procedures. The following variables were analyzed to document endoscopic characteristics such as size of lesion, sampling ratio and coexistence lesions.

Results: Compared with upgrade and concordance group, the downgrade group showed a meaningful smaller tumor size, surface area, and lower sampling ratios ($P < 0.001$). On the other hand, compared with concordance group, the upgrade group showed a significant larger tumor size and more frequent prevalence of ulcerative lesion (14.3%, concordance;4.0%) and depressed lesion (48.8%, concordance; 32.2%) ($P < 0.001$).

Conclusion: The tumor size and sampling ratio can be predictable value of downgrade group of histologic discrepancy after ESD. And the coexistant endoscopic finding such as ulcerative lesion or depressed lesion could be predictable value of upgrade group of histologic discrepancy after ESD.

P0764 HEMOSPRAY IN ACUTE NON-VARICEAL UPPER GASTROINTESTINAL BLEEDING: FIRST EXPERIENCES IN A UK TEACHING HOSPITAL

M. S. Hanna[1], P. Wurm[1]
[1]*Department of Gastroenterology, Leicester Royal Infirmary, Leicester, United Kingdom*

Contact E-mail Address: mina.hanna@nhs.net

Introduction: Acute Upper GI Bleeding (AUGB) is a common and serious medical emergency with an incidence ranging from 50 to 190/10 000/year in the UK.[1] Hemospray (TC-325), a hemostatic powder licensed for the treatment of non-variceal upper GI bleeding, was launched in the United Kingdom in June 2013. We introduced Hemospray into our practice at University Hospitals of Leicester [UHL] in December 2013.

Aims & Methods: The aim of our study was to assess the use of hemospray and its impact on our practice at UHL. We retrospectively reviewed our endoscopy reporting database [Unisoft- GI reporting tool] for all patients who underwent Upper GI endoscopy for AUGB [indications: melaena and/or haematemesis] and were treated with Hemospray between December 2013 and March 2015. Data was analysed for patient age, gender, endoscopic diagnosis, Monotherapy vs. combination therapy, concomitant anti-thrombotic agent use, rebleeding rate and 30 day mortality.

Results: From December 2013 until March 2015, 1299 Upper GI endoscopies were performed at UHL for AUGB. Hemostatic interventions were performed in 233 procedures [17.9%]. 19 patients were treated with Hemospray (14 male) in 21 procedures. In 19 endoscopies (90.5%) Hemospray was used at index endoscopy, while it was used at two (9.5%) second look endoscopies for rebleeding. The average age was 72 years (Range 34-94). The cause of AUGB was peptic ulceration in 78% of patients (n = 14) {duodenal ulcer 78.6% (n = 11) ; gastric ulcer 21.4%(n = 3)}, 10.5 % oesophageal ulceration (n = 2), 10.5 % gastric malignancy (n = 2), 5.3% post-sphincteromy bleeding (n = 1). The main reasons for Hemospray use by procedure (n = 21) were: 66.7% difficult endoscopic access (n = 14), 23.8 % difficulty in visualising exact bleeding point (n = 5), 9.5% patient intolerance of procedure (n = 2). Amongst peptic ulcers (n = 14), the Forrest classification breakdown was: 1A (4, 28.6%), 1B (8, 57.1 %), 2A (2, 14.3%). Immediate hemostasis was achieved in 18/21 endoscopies (85.7 %). 9/19 patients (47.4%) were on anti-thrombotic therapy (aspirin 66.6% (n = 6), clopidogrel 22.2% (n = 2) and therapeutic enoxaparin 11.1% (n = 1). Hemospray was used as monotherapy in 5 (23.8%) endoscopies and in combination with traditional modalities (adrenaline injection, heater probe, haemostatic clips) in 16 (76.1%) endoscopies. 5/19 patients developed rebleeding (26.4%). The average time to rebleeding was 5.8 days (Range 2-14 days). The 30 day mortality was 31.3% (n = 6). 3 deaths (50%) were directly related to uncontrolled gastrointestinal haemorrhage. No adverse events as the result of Hemospray use were noted.

Conclusion: Hemospray is a safe and useful adjunct to traditional hemostatic therapies with a high rate of immediate hemostasis. In our series, Hemospray accounted for about 8% of all endoscopic interventions and was only employed in 1.5% of all patients presenting with AUGB. There was a significant rebleed rate of 26%, likely to be a reflection of a very sick patient cohort. The majority of cases had high rebleeding risk (Forrest 1A and 1B ulcers, GI malignancy). The average time to rebleed was 6 days, which suggests that Hemospray is a useful bridging therapy to non-endoscopic GI bleed therapy (angiography/surgery). A formal RCT comparing Hemospray to conventional haemostatic methods is indicated to evaluate its efficacy and effect on mortality.

P0765 REFRACTORY GASTROPARESIS CAN BE SUCCESSFULLY MANAGED WITH ENDOSCOPIC TRANSPYLORIC STENT PLACEMENT AND FIXATION

M. Khashab[1], S. Besharati[1], **S. Ngamruengphong**[1], V. Kumbhari[1], M. H. El Zein[1], A. Abdelgelil[1], A. H. Tieu[1], G. E. Mullin[1], E. M. Stein[1], S. Dhalla[1], M. Nandwani[1], V. Singh[1], M. Canto[1], A. N. Kalloo[1], J. Clarke[1]
[1]*Gastroenterology, Johns Hopkins University, Baltimore, United States*

Contact E-mail Address: mkhasha1@jhmi.edu

Introduction: Medical treatment options for gastroparesis are limited. Data from studies of botulinum toxin and pyloroplasty suggest that disruption of the pylorus can result in symptomatic improvement in some patients with refractory gastroparetic symptoms. We previously performed a pilot study that demonstrated improvement of symptoms in 4 patients with gastroparesis treated with transpyloric stent placement (TPS).

Aims & Methods: To (1) determine safety and efficacy of TPS placement for refractory gastroparesis; and (2) evaluate whether various stent fixation techniques had impact on stent migration rate and clinical outcome. Patients with gastroparesis refractory to medical treatment were referred for TPS. A through-the-scope fully covered self-expandable metallic esophageal stent was deployed across the pylorus. In fixation group, the stent was anchored to the gastric wall with either endoclips, over-the-scope clip (OTSC) or endoscopic suture (ES: placed in 2 locations between stent and gastric wall). Self-reported symptom improvement, stent migration rate and post-stent gastric emptying study (GES) results were collected. Time to migration was compared using Kaplan Meier estimate.

Results: A total of 29 patients (20 female, mean age 39yr) with refractory gastroparesis (idiopathic 16, diabetic 8, post-surgical 5) underwent 47 TPS procedures. Of these, 25/47 (53%) were performed in patients admitted to the hospital with intractable symptoms. Most (n = 24, 83%) had predominant symptoms of nausea (N) and vomiting (V). Successful stent placement was achieved during 46 (98%) procedures. Most stents were anchored to the gastric wall using ES (n = 23), followed by OTSC (n = 18) and endoclip (n = 2). Three patients did not receive stent fixation. Overall, 20/27 (74%) patients had clinical response (2 patients were lost to follow-up). All inpatients were successfully discharged after stent placement. Clinical success was higher in patients with predominant N/V compared with those with abdominal pain/bloating (95% vs. 71%, p = 0.12) (table 1). Repeat GES was performed in 16 patients: mean 4hr GE normalized in 5 patients (76% vs. 98%, p = 0.2) and significantly improved in 4 (54% vs. 73%, p = 0.02). Stent migration occurred in 59% of procedures: 100% in the no fixation group, 50% in the endoclip group, 71% in the OTSC group, and 48% in the ES group ($p > 0.05$ for all comparisons). During a mean follow up of 146d, time to stent migration was not different between ES and other groups (P = 0.9).

Conclusion: TPS is a promising novel endoscopic treatment modality for gastroparesis and improves both symptoms and gastric emptying in patients refractory to medical treatment, especially those with N/V. TPS can be considered as salvage therapy for inpatients with intractable symptoms. Questions regarding long-term durability and stent migration risk remain.

Introduction: In the UK novice endoscopists must attain JAG certification in UGI endoscopy (portfolio > UGI 200 cases, trainer DOPS, achievement of performance indicators and JAG basic skills course attendance). Cases are recorded on the JETS e-portfolio (1). Barriers include need for dual accreditation in general medicine, service pressure, difficulty accessing courses and variable quality of hands-on training. In Wales we designed an accelerated national training pathway - SPRINT programme –delivering core elements with integrated simulator and lesion recognition training.
Aims & Methods: Efficiency of SPRINT training was determined by time to achieve numerical milestones, compared to previous cohorts of Welsh trainees using procedure logs from the JETS e-portfolio. SPRINT trainees evaluated each component of SPRINT training (Simulator, Lesion Recognition, endoscopic non-technical skills [ENTS]) plus an overall rating using a Likert Scale (0 = no help to 10 = extremely useful). Seven novice trainees were selected by GI and GI surgery training programme directors. The training programme was commenced in Sept 2014 and comprised structured induction and simulator training, JAG Basic UGI course and regional 'Endoscopy school' days. Data from a historical cohort of 14 trainees was used for comparison. Differences between groups were measured using a one-sided t-test ($p < 0.05$ significance level).
Results: Median time to each landmark was significantly faster at all stages in the SPRINT group – shifting learning curves to the left (Table) with a reduced range in completion times in the SPRINT cohort. Mean Likert scores were Simulation 7.8; Lesion Recognition 9.2; ENTS 8.8; Overall program 9.4. Trainee evaluation highlighted the main benefits as peer learning and support, faculty discussion, feedback and access to training opportunities.
Conclusion: A well-structured training pathway, incorporating evidence-based training methods can enhance training quality and experience for trainees and improve efficiency of training – in this case halving training time in UGI endoscopy compared to historic controls. All elements were valued by trainees. Regular contact with regional trainers acts to standardise training, improves discussion and feedback, allowing early identification and targeted support where progress is slower than expected.

Introduction: We formerly presented about the efficacy of magnifying endoscopy with blue laser imaging (M-BLI) in the diagnosis of early gastric cancers at this meeting (UEGW 2012). BLI is a novel image-enhanced endoscopy with two different lasers. In our previous presentation, we have showed that M-BLI can detect microsurface (MS) pattern at the same level of M-NBI and additionally, 75% of lesions which were showed absent MS pattern in NBI were detected irregular MS pattern in BLI. However, we couldn't quite understand the cause of that until now.
Aims & Methods: The aim of the present study is to clarify the pathological differences among these lesions which were showed absent MS pattern in NBI and irregular MS pattern in BLI. We retrospectively analyzed 20 early gastric cancers that were examined with M-BLI and NBI at the Hospital of Kyoto Prefectural University of Medicine between September 2011 and March 2014. All gastric cancers had been treated by endoscopic submucosal dissection. The following were selected on the basis of their appearance revealed by M-BLI and NBI performed beforehand: 11 lesions showing irregular MS pattern by M-BLI but absent MS pattern by M-NBI (Group A), 4 lesions with irregular MS pattern by both methods (Group B), and 5 lesions with absent MS pattern by M-BLI and NBI (Group C). The resected specimens were observed by a stereoscopic microscope, then photographed microscopic images were compared with endoscopic images. In all cases, it had been confirmed that the histological areas examined corresponded to the parts observed by both methods very closely. We examined the characteristics of the histopathological findings of each group. Furthermore, in Group A and B, the depths of three crypts in each lesion were measured using a viewer soft according to the method by Yagi (*Diagn Ther Endosc* 2012).
Results: In Group A, 6 of 11 lesions show histological feature that crypts were shallow, 3 lesions had histological feature that number of the ducts opens in the surface layer were few and 2 lesions had winding crypts. In Group B, all 4 lesions had deep and straight crypts. In Group C, 3 of 5 lesions were replaced with signet ring cell carcinoma in all mucosal layer, one lesion had very short intervening part and one lesion had pseudostratified cancer cells. Average depth of crypts of 6 lesions (65 ± 20 μm) in group A was significantly shallower than it of 4 lesions (265 ± 64um) in Group B ($p < 0.01$). Yagi reported that the depths of crypts in areas where the white zones were indistinct or invisible and those in lesions where the white zones were distinct were 81μm and 182μm, respectively in NBI. Since MS pattern is almost synonymous with white zone, it may be also that M-BLI can visualize even shallower crypt compared with M-NBI.
Conclusion: BLI may be useful for diagnosis of an extent and a submucosal invasion of early gastric cancers by visualizing the shallower crypt compared with NBI. Further study is necessary to clarify what differences of pathological findings except depth of crypts cause the differences in MS pattern findings between with BLI and NBI.

P0768 THE DIAGNOSIS OF INVASION DEPTH IN SUPERFICIAL ESOPHAGEAL SQUAMOUS CELL CARCINOMA: A COMPARISON BETWEEN A MAGNIFYING NARROW-BAND IMAGING OBSERVATION AND EUS

N. Matsuura[1], N. Hanaoka[1], R. Ishihara[1], S. Yamamoto[1], T. Akasaka[1], Y. Takeuchi[1], K. Higashino[1], N. Uedo[1], H. Iishi[1]
[1]*Gastrointestinal Oncology, Osaka Medical Center for Cancer and Cardiovascular Diseases, Osaka-city, Japan*

Contact E-mail Address: matuura-no@mc.pref.osaka.jp
Introduction: The diagnosis of cancer invasion depth is crucial for selecting the optimal treatment strategy for esophageal cancer. Endoscopic ultrasonography (EUS) is regarded as the standard modality for diagnosing invasion esophageal cancer depth in the West. In Japan, magnifying endoscopy has been used for diagnosis by observing the architecture of the esophageal microvasculature. This modality represents a rapid and simple diagnostic procedure without the need for any additional equipment. However, the accuracy of magnifying endoscopy has not been compared with that of EUS for the diagnosis of cancer invasion depth.
Aims & Methods: Patients with esophageal squamous cell carcinoma (SCC) suspicious for muscularis mucosa or submucosal invasion in non-magnifying white light imaging were included. All patients received white-light imaging (WLI), magnifying narrow-band imaging (NBI) observation followed by EUS. Magnifying NBI observation was performed by endoscope with magnification (GIF-Q240Z, or H260Z; Olympus, Tokyo, Japan). EUS was performed using a high-resolution probe by jelly-filled method. Before examination, several syringes (5 mL) containing sufficient amounts of jelly (K-Y Lubricating jelly, Johnson and Johnson, k. k.) were prepared. After endoscope insertion (GIF-2TQ260M; Olympus) into the target area within the esophagus, a 30 or 20-MHz miniature probe was then inserted through the left channel of the endoscope and 30 to 40 mL of echo jelly was instilled through the right channel until the esophageal lumen was filled. Cancer invasion depth was diagnosed as T1a or T1b using both modalities. The diagnostic accuracy of magnifying NBI observation was compared with that of EUS while the histologic diagnosis of resected specimen served as reference standard.
Results: From January 2011 to March 2014, 204 patients with esophageal SCC suspicious for muscularis mucosa or submucosal invasion in non-magnifying WLI were examined using the two modalities. Of the 204 patients, 108 treated with chemoradiotherapy or photodynamic therapy were excluded from analysis because histologic specimens were not obtained. Ninety-six patients with 97 lesions treated either by esophagectomy (n = 25) or endoscopic resection (n = 72) were included in the final analysis. Histologic diagnosis was T1a in 48 lesions, T1b in 47 lesions, and T2 in two lesions. 4 lesions couldn't be diagnosed by magnifying NBI because intra-epithelial papillary capillary loop couldn't be observed. The overall accuracy of diagnosing invasion depth was 67.7% (63/93 lesions) by magnifying NBI and 71.1% (69/97 lesions) by EUS ($P = 0.364$). The accuracy of diagnosing invasion depth in lesions with protrusions was 63% (29/46 lesions) and 80% (40/50 lesions) by magnifying NBI and EUS, respectively ($P = 0.07$).
Conclusion: EUS and magnifying NBI exhibited high diagnostic accuracy in esophageal SCC. Considering its simplicity of use, magnifying NBI has the potential to be the standard modality for diagnosing invasion depth of esophageal SCC. However, the diagnostic accuracy for esophageal SCC is not sufficient only with magnifying NBI. Compared with magnifying NBI, EUS has the potential to diagnose invasion depth more accurately lesions with protrusion.

P0769 COLON PREPARATIONS WITH PEG 4000 AND LACTULOSE: A PROSPECTIVE RANDOMIZED DOUBLE BLINDED TRIAL

K. Brescia[1], J. C. Coelho[1]
[1]*Endoscopy, Gastrocenter, Belo Horizonte, Brazil*

Contact E-mail Address: kbrescia@ig.com.br

Introduction: Colonoscopy represents nowadays one of the best diagnostic methods for colorectal diseases and for colorectal cancer screening. Good colon preparation is essencial for a high quality diagnostic examination and for the necessary therapeutic approaches. This study aims to compare two preparations regarding efficacy: The PEG 4000 preparation, which is the gold standard in the United States, and the 10% lactulose solution. Lactulose is an osmotic laxative still without formal indication as colon preparation.

Aims & Methods: It is a prospective randomized double blinded trial with 400 patients included, submitted to elective out-patient colonoscopies in private clinic. The patients were randomized in two 200 patients groups and in each one preparation was used. The Boston Bowel Praparation Scale was used in order to measure the colon preparation quality.

Results: In only 13 patiens the preparation was considered inadequate. In PEG patients only six (3%) and in lactulose patiens seven (3.5%) were considered inadequate. There was no statistical difference between both groups regarding efficacy ($P = 0.778$).

Conclusion: The study concluded that lactulose solution is as effective as PEG 4000 as bowel preparation for colonoscopic exams. The lactulose solution can be indicated as an option for colon preparation for colonoscopic exams. Its restrictions and contra-indications should be respected.

P0770 THE EFFICACY AND SAFETY OF ENDOSCOPIC SUBMUCOSAL DISSECTION USING THE "CLIP-FLAP METHOD" FOR LARGE SUPERFICIAL COLORECTAL TUMORS

K. Yamamoto[1], S. Hayashi[2], T. Nishida[2], H. Saiki[1], M. Kato[1], Y. Tokuda[1], M. Yamamoto[2], M. Naito[1], T. Michida[3], T. Ito[1]

Contact E-mail Address: yamamoto-kts@umic.ac.jp

Introduction: Endoscopic submucosal dissection (ESD) is technically difficult because of poor visualization and instability in the cutting area. Although the mucosal flap formation improves visualization of the cutting area, it is difficult to achieve, especially in colorectal ESD. To facilitate the mucosal flap creation, we developed the "clip-flap method" by initially substituting an endoclip for the mucosal flap until the flap is completed (K. Yamamoto, et al., *Endoscopy* 2012·2015).

Aims & Methods: We retrospectively studied 200 cases, in which ESD for large superficial colorectal tumors was performed at Toyonaka Municipal Hospital between 2009 and 2013. We compared the treatment outcomes after the adoption of the clip-flap method (Clipflap-ESD: 100 cases) with those before the adoption of the clip-flap method (Conventional-ESD: 100 cases) to evaluate the efficacy and safety of the clip-flap method. The procedure of the clip-flap method is as follows. After submucosal injection, the mucosa around the lesion on the anal side was incised with an adequate margin, and then the submucosal layer was cut deeply. The edge of the exfoliated mucosa was clipped with an endoclip (EZ CLIP, HX-610-135; Olympus). The distal attachment was inserted under the endoclip as well as under the mucosal flap, and then the submucosal layer was dissected with the endoknife. A single endoclip was generally used, and the cross pattern of endoclips, created by attaching one endoclip to another endoclip, was also used according to the situations. We mainly used a short-needle electrosurgical endoknife with a water-jet function (FlushKnifeBT; Fujinon), and also used other endoknives in some cases.

Results: Median tumor diameter, resected specimen diameter, procedure time, *en bloc* resection rate, and perforation rate of Conventional-ESD and Clipflap-ESD were 27mm vs 30mm, 34mm vs 37mm, 97minutes vs 70minutes, 91% vs 97%, and 4% vs 1%, respectively. The procedure time of Clipflap-ESD was statistically significantly shorter than that of Conventional-ESD ($P < 0.01$), and the differences in other parameters were not significant. Perforation was conservatively treated by clipping in 5 of 5 cases. In all cases which the clip-flap method was used, the exfoliated mucosa was lifted by the endoclip attached to the exfoliated mucosa after the distal attachment was inserted under the endoclip, allowing for clear visualization and efficient dissection of the submucosal layer, and effective creation of the mucosal flap.

Conclusion: The clip-flap method very effectively enabled the mucosal flap creation and allowed our treatment outcomes to be greatly improved. The present study demonstrates that the clip-flap method is a simple, safe, and very effective option for colorectal ESD.

Introduction: Interval colorectal cancer is an emerging issue in cancer screen and surveillance. The frequency and associated factors have not been well studied in Taiwan.

Aims & Methods: We plan to clarify the prevalence and associated factors with interval colorectal cancer. The Colorectal cancer with negative colonoscopy 6 months to 36 months before cancer diagnosis was defined as interval colorectal cancer. Patients' characteristics, past history, colon preparation, colonoscopy finding and pathology were retrospective evaluated. 670 patients with colorectal adenocarcinoma from Jan. 2005 to Nov. 2014 and who underwent colonoscopy before the diagnosis were recruited.

Results: Colorectal cancer with negative colonoscopy 6 months to 36 months before cancer diagnosis was defined as interval colorectal cancer. Patients' characteristics, past history, colon preparation, colonoscopy finding and pathology were retrospective evaluated. 670 patients with colorectal adenocarcinoma from Jan. 2005 to Nov. 2014 and who underwent colonoscopy before the diagnosis were recruited.

Results: 22 (3.28%) patients (65.7 ± 9.2 years old; 9 male) were diagnosed as interval colon cancer. The interval colorectal cancer were predominant located at rectum and cecum (rectum 50%, cecum 18.2%, transverse colon 13.6%, sigmoid colon 13.6%, descending colon 4.5%), presented with earlier tumor stage (stage I and stage II 86.4%, stage III and stage IV 13.6%). The associated factors of interval cancer include end-stage renal disease (HR:10.494, 95% CI: 2.131-51.681), and shorter withdraw time from cecum to hepatic flexure (interval cancer: non-interval cancer 2.00 ± 0.82:4.91 ± 3.74 min) (HR: 0.561, 95% CI:0.345-0.913). Prior polypectomy and tumor size showed a tendency to develop interval colorectal cancer.

Conclusion: The prevalence of interval colorectal cancer in present study is 3.28%. Comorbidity with end-stage renal disease and shorter withdraw time from cecum to hepatic flexure could be associated factors of interval colorectal cancer.

P0773 THE PROSPECTIVE STUDY OF THE RELATIONSHIP BETWEEN COLONOSCOPY AND INTESTINAL ADHESION

K. Takeda[1,2], S.-E. Kudo[1], K. Nakahara[1], D. Takayanagi[1], M. Misawa[1], Y. Mori[1], T. Kudo[1], K. Kodama[1,2], S. Mukai[1], K. Wakamura[1], T. Hayashi[1], H. Miyachi[1], E. Hidaka[1], F. Ishida[1]
[1]*Showa University Northern Yokohama Hospital, Yokohama city,* [2]*Kakunodate Municipal Hospital, Daisen city, Japan*

Introduction: When we feel scope decreased mobility at the colonoscopy, we often think that intestinal adhesion may be the reason for difficulty. But it is doubtful whether intestinal adhesion cause difficulties for endoscopy actually. We therefore sought to verify whether the scope decreased mobility is the findings as a result of intestinal adhesion prospectively.
Aims & Methods: 53 patients were performed colonoscopy and underwent laparoscopic surgery for colorectal cancer at Showa University Northern Yokohama Hospital from April 2012 to August 2012. All colonoscopist recorded the findings about colonoscopy such as time for total colonoscopy and degree of difficulty for colonoscopy (insertion grade1,2,3). And surgeon checked the location of intestinal adhesion at the laparoscopic surgery.
Results: 34 male and 19 female were included in this study. 18 cases have the abdominal surgical history and in all cases, intestinal adhesion was observed. On the other hand, intestinal adhesion was also observed in 28 cases have no surgical history. Five of 28 cases have the history of endoscopic treatment and adhesion was observed around the lesion of endoscopic treatment had been performed. There was no significant difference in the average time for reaching at cecum from anal between intestinal adhesion cases and no intestinal adhesion cases.
There were 27 cases that were evaluated as grade 2 or 3 in degree of difficulty for colonoscopy, and intestinal adhesion were observed in fifteen cases of them. We thought that insertion grade2 or 3 may be the bellwether of intestinal adhesion but result showed that insertion grade would not reflect the intestinal adhesion (sensitivity 56.4%, specificity 61.5%, PPV 81.4%, PPV 81.4%, NPV 32.0%).
Conclusion: Difficulties of colonoscopy do not always reflect the intestinal adhesion. But in case of additional intestinal resection for the lesion endoscopic treatment has been performed for colorectal cancer, we should be consider the possibility of intestinal adhesion around the target lesion.

Introduction: Endoscopic submucosal dissection (ESD) has recently become a standard treatment for colorectal epithelial neoplasms. Despite the success of ESD, incomplete resection has resulted when it has been applied to laterally spreading tumor (LST) of the colon with submucosal fibrosis which could complicate the separation of the submucosa from the muscular layer. Therefore, ESD for LSTs with submucosal fibrosis might cause high frequencies of incomplete en bloc resection of the tumor and intestinal perforation during ESD. In this study, we aimed to assess the relationship between the outcome of ESD for LSTs and the degree of submucosal fibrosis beneath the tumors. We also evaluated the relationship between the degree of submucosal fibrosis beneath the tumors and the features of LSTs.
Aims & Methods: We evaluated 114 colorectal LSTs larger than 20 mm in diameter between January 2010 and March 2015. LSTs were divided into granular (LST-G) (n = 78) and non-granular (LST-NG) (n = 36) tumors. LST-Gs were subdivided into homogenous-type tumors (LST-G-homo) (n = 34) and nodular-mixed-type tumors (LST-G-mix) (n = 44).The degree of submucosal fibrosis beneath the LSTs was determined on the basis of the following original classification system, which was based on the findings obtained at the time of injection of sodium hyaluronate with indigo carmine: F0, no fibrosis, which manifested as a blue transparent layer; F1, mild fibrosis, which appears as a white web-like structure in the blue submucosal layers; and F2, severe fibrosis, which appears as a white muscular like structure without a blue transparent layer in the submucosal layers. The relationship among characteristics of the LSTs, the degree of submucosal fibrosis beneath the LSTs and outcome of ESD for the LSTs were analyzed.
Results: The incidence of F2 fibrosis in LST-G-mix and LSTs-NG was significantly higher than that in LST-G-homo ($p < 0.05$, compared with F0/1). The tumor locations and sizes did not significantly differ between F2 and F0/F1 fibrosis beneath LSTs regardless of tumor growth patterns. There were no significant differences in the rate of complete en bloc resection and complications such as perforation or delayed bleeding between F2 and F0/1. However, severe bleeding during ESD strongly tended to be related to F2 fibrosis ($p = 0.06$, F2 vs. F0/F1), and the mean duration of the ESD procedure significantly differed between LSTs with severe fibrosis (F2) and LSTs with no or mild fibrosis (F0/ F1) regardless of tumor growth patterns (F2, 269.3 ± 114.4 vs. F0/1, 137.5 ± 80.2 min, $p < 0.0001$).
Conclusion: The LST-G-mix and LSTs-NG might harbor severe submucosal fibrosis which would predict outcome of ESD for colorectal LSTs. The more advanced the endoscopic submucosal fibrosis, the longer the time required for ESD and the higher the frequency of immediate bleeding during ESD. Further development of endoscopic devices are needed for safe and complete resection of colorectal tumors with severe fibrosis.

P0775 NOVEL BIO-MARKER FOR COLORECTAL NEOPLASIA: WHITE OPAQUE SUBSTANCE WITHIN COLORECTAL NEOPLASTIC EPITHELIUM AS VISUALIZED BY MAGNIFYING ENDOSCOPY WITH NARROW-BAND IMAGING

K. Imamura[1], K. Yao[2], T. Hisabe[1], T. Nagahama[1], F. Hirai[1], M. Nambu[3], A. Iwashita[3]

Contact E-mail Address: kentaro2316@ive.jp
Introduction: We previously reported the presence of a white opaque substance (WOS), opaque to the endoscope light, inside the epithelium when we use magnifying endoscopy (ME) to examine gastric epithelial neoplasia (adenomas and carcinomas) and chronic gastritis (intestinal metaplasia). Through further pathohistological study we elucidated that this substance is comprised of minute lipid droplets (LDs) accumulated within the mucosal epithelium of gastric epithelial neoplasia or intestinal metaplasia[1]. These minute LDs strongly backscatter the projected light, and are visualized as a white substance. When we examined colorectal neoplastic lesions (adenomas and carcinomas) using ME, we observed WOS as in the stomach. However, it is unclear whether WOS in colorectal epithelial tumors is in fact an accumulation of LDs as in the stomach.
Aims & Methods: Aims: To elucidate whether WOS observed in colorectal epithelial tumors (adenomas and carcinomas) is composed of LDs. We analyzed a continuous series of both 40 WOS-positive and 40 WOS-negative colorectal epithelial tumors. We examined colorectal neoplastic lesions (adenomas and carcinomas), prior to planned treatment, using ME with narrow-band imaging (NBI), determining whether WOS was present in the surface layers of the most anal part of the colorectal epithelial tumor. We took targeted biopsies from this part of the tumor. Biopsy specimens were immediately frozen, slices taken, and the slides were stained for lipids using oil-red O. Slides were examined using light microscopy immediately after staining for the presence of LDs within the neoplastic epithelium. Subsequently, we stained microdroplets of LDs using imunostaining by anti-adiphophilin antibody in formalin-fixed specimen. We investigated the correlation between the presence of WOS as visualized by ME with NBI and the presence of LDs in the histological specimens. And, we compared WOS-positive and WOS-negative about the density of adiphopilin.
Results: We analyzed a continuous series of both 40 WOS-positive and 40 WOS-negative colorectal epithelial tumors. Prevalence of LD as stained by oil red O staining in WOS-positive versus WOS-negative lesions was 47.5% (19/40) and 5% (2/40), respectively ($P < 0.001$, Fisher's exact test). Furthermore, WOS coincided with the expression of adipophilin. Namely, prevalence of LD as stained by anti-adiphophilin antiboy in WOS-positive versus WOS-negative lesions was 100% (40/40) and 62.5% (25/40), respectively ($P < 0.001$, Fisher's exact test). Mean density of adiphopilin was significantly greater in WOS-positive (10.8 ± 8.7 %) than in WOS-negative lesions (4.1 ± 4.1 %; $P < 0.001$).
Conclusion: LDs do not accumulate in the normal colorectal epithelium. However, this study elucidated for the first time that endoscopically visualized WOS may be composed of LDs accumulated in colorectal epithelium. This phenomenon has the potential to be a new biomarker for the pathology and diagnosis of colorectal neoplasia.

Introduction: Colorectal cancer (CRC) is one of the most common cancers in Sweden and CRC screening is a preventive action. At present, Sweden is running a national randomized study Screening of Swedish Colons (SCREESCO) to understand the decision to participate in CRC screening.
Aims & Methods: The questionnaire National Survey of Medical Decisions (DECISIONS) was developed for a US population and the aim was to translate and culturally adapt the DECISIONS questionnaire to the Swedish context. A qualitative design inspired by guidelines based on methods for cross-cultural

adaptation of questionnaires in the field of psychology and sociology were used. The guideline includes focus group discussions, individual and telephone interviews and Thinking Aloud (TA) sessions to culturally adapt questionnaires.
Results: The questionnaire: National Survey of Medical Decisions (DECISIONS) was translated and culturally adapted. The translation and adaptation process resulted in reformulation and rewording of 29 items, 11 items changed due to wording and two new items were added as a result of the qualitative interviews and group discussions. The present version of the DECISION questionnaire consists of 24 items concerning decision making.
Conclusion: Our study demonstrates the importance of implementing cultural adaptation to ensure the quality of a translated questionnaire and thereby its results. The major cause for removal and changing of items can be explained by different traditions in communicating with the health care system in Sweden and the US, communication about decision-making and how risk for cancer is communicated in general. The results have hopefully produced a questionnaire that can be used to evaluate decision-making in participation in CRC screening in a Swedish population.

Introduction: The recommended interval of surveillance colonoscopy for patients with adenomatous polyps is based on adenoma histology, size, and number; however, prospective studies on the impact of family history (FH) of colorectal cancer (CRC) are limited.
Aims & Methods: The aim of this study was to assess whether the interval of surveillance colonoscopy after removal of adenomatous polyps for patients with FH of CRC should be changed compared with patients without FH. The Japan Polyp Study (JPS) is a multicenter randomized control trial conducted at 11 participating centers to evaluate follow-up interval after polypectomy. Patients were eligible if they have had two complete colonoscopies (1st- and 2nd-CS: interval; 1 year) as baseline examination with removal of all neoplastic lesions. Following this they were randomly assigned to have follow-up colonoscopy at 1 and 3 yrs or at 3 yrs only. Main outcome measurements in this subanalysis were prevalence of advanced neoplasia (AN: $\geq$1 cm, villous histology, high-grade dysplasia, or invasive cancer), high-risk adenoma (HRA: AN or $\geq$3 non-advanced neoplasia) and low-risk adenoma (LRA: 1 or 2 non-advanced neoplasia) detected during 3 yrs after randomization in patients with first degree relatives with CRC.
Results: Among 3,926 patients with no history of FAP, HNPCC, IBD or colectomy, 1,847 patients (Aged 40-49 yrs: 252, 50-59 yrs: 677, 60-69 yrs: 918, mean age 56.0 yrs, 61.4% male) who underwent two-round complete colonoscopy before randomization and follow-up colonoscopy as scheduled were included. Among patients aged 40-49 yrs who had FH of CRC in first degree relatives or not, the prevalence of AN, HRA and LRA were as follows; AN (0%, 0/43: FH+ vs. 1.0%, 2/209: FH-) ($P=0.76$), HRA (4.7%, 2/43: FH+ vs. 2.9%, 6/209: FH-) ($P=0.90$), LRA (25.6%, 11/43: FH+ vs. 21.5%, 45/209: FH-) ($P=0.56$). Among patients aged 50-69 yrs, prevalence of them were; AN (4.1%, 9/220: FH+ vs. 1.5%, 20/1,375: FH-) ($P<0.001$), HRA (14.5%, 32/220: FH+ vs. 7.9%, 109/1,375: FH-) ($P<0.001$), LRA (25.9%, 57/220: FH+ vs. 32.3%, 444/1,375: FH-) ($P=0.06$).
Conclusion: Prevalence of AN and HRA of patients aged 40-49 yrs and 50-69 yrs without FH of CRC was significantly lower than that of 50-69 yrs patients with FH of CRC during 3 yrs follow-up period. Intensive surveillance colonoscopy namely 3-yrs interval after polypectomy should be recommended only for patients aged 50 yrs or older with FH of CRC; in contrast, there was no novel evidence of changing surveillance interval in patients younger than 50 yrs. Whether these results may affect the current surveillance programs remains uncertain and longer follow-up data might be necessary.

Introduction: Postplolypectomy coagulation syndrome (PPCS) has symptoms such as localized abdominal pain, fever, leukocytosis, and peritoneal inflammation without perforation, which occur less than 0.1%. However, post coagulation syndrome (PCS) after colorectal endoscopic submucosal dissection (ESD) is not known well. Here, we aimed to assess the clinical outcomes and factors associated with PCS after colorectal ESD.
Aims & Methods: Between January 2010 and July 2014, we performed ESD on 211 consecutive colorectal tumors in 207 patients. We investigated the incidence of PCS after colorectal ESD and conducted multiple logistic regression analysis of the following factors related to PCS after colorectal ESD: age, gender, location, tumor size (<40 mm vs. ≥ 40 mm), operation time (<120 min vs. ≥ 120 min), morphology (granular type laterally spreading tumor [LST-G], non-granular type laterally spreading tumor [LST-NG], or protruded type), fibrosis, and paradoxical movement during the procedure. PCS after colorectal ESD was defined as fever ($\geq 37.8^{\circ}$C) and abdominal pain or regional rebound tenderness in the absence of perforation during or after ESD.
Results: After exclusion of 4 of 211 cases with perforation, 207 patients were analyzed. In the treated epithelial lesions, 36 cases were located in the rectum (17.4%), 41 cases in sigmoid colon (19.8%), 44 cases in transverse colon (21.3%) and 51 cases in ascending colon (24.6%). PCS after ESD occurred in fifteen cases (7.2%). Of the fifteen cases of PCS, six cases (2.9%) occurred in cecum, four

cases (1.9%) in ascending, three cases (1.4%) in transverse and two cases (0.97%) in rectum.
Average tumor size was 30.9 ± 10.5 mm, and the average procedure length was 66.8 ± 45.1 min. The rate of en bloc resection was 96.6%, while that of en bloc curative resection was 87.4%.
Univariate analysis showed that tumor site in the cecum ($p = 0.0014$), tumor size (≥ 40 mm, $p < 0.001$), loner procedure time (≥ 120 min, $p < 0.001$) during the procedure and severe fibrosis ($p = 0.0161$) were significantly associated with PCS of colorectal ESD.
Multivariate logistic regression analysis revealed that tumor location in the cecum (odds ratio [OR] 17.58; 95% confidence interval [CI] 2.32–210.9, $p = 0.0043$), a tumor size exceeding 40 mm (OR 6.43 [95% CI 1.37-34.02], $p = 0.019$) contributed to PCS after colorectal ESD. A trend for PCS after the ESD procedure in the group which experienced longer procedure time during the procedure was also noted ($p = 0.0619$).
Conclusion: Tumors located in cecum, larger tumor size more than 40mm were independent factors contributing to the PCS of colorectal ESD.

P0779 DOES COLORECTAL ADENOMA INCREASE THE RISK OF GALL BLADDER POLYP?

K. O. Kim[1], S. B. Kim[1], K. H. Kim[1], S. H. Lee[1], B. Jang[1], T. N. Kim[1]
[1]*Division of Gastroenterology and Hepatology, Department of Internal Medicine, Yeungnam University College of Medicine, Daegu, Republic of Korea*

Contact E-mail Address: cello7727@naver.com
Introduction: Colorectal adenoma and gallbladder (GB) polyp share many risk factors. However studies concerning the association between colorectal adenoma and GB polyp has been rare.
Aims & Methods: The aims of this study were to evaluate whether colorectal adenoma increases the risk of GB polyp and analyze the risk factors associated with GB polyp. Health examinees who underwent both hepatobiliary sonography and colonoscopy in Yeungnam University Hospital health promotion center from January 2010 to December 2013 were included. Subjects with previous history of cholecystectomy and without pathologic report of colorectal polyp were excluded. To eliminating the confounding factors of GB polyp, age, gender and BMI was matched using propensity score. The clinical characteristics, colonoscopy and ultrasonographic findings of the subjects were reviewed and compared between colorectal adenoma and non-adenma group retrospectively.
Results: Among 4373 subjects, colorectal adenoma was detected in 1453 (33.2%) and colorectal cancer in 11 (0.3%). There were significant differences in age, gender and presence of fatty liver between subjects with or without colorectal adenoma. GB polyp was noted in 362 (8.3%) cases. After using propensity score matching, number of subjects in each groups with or without colorectal adenoma was 1453. Subjects with colorectal adenoma only or with concomitant colorectal cancer had tendency of more GB polyps than those without (145 (10.0%) vs 116 (8.0%), (p = 0.060)). Although mean age of the subjects was not significantly different depending on the presence of GB polyp, male was more common in subjects with GB polyp (218 (83.5%) vs 1976 (74.7%), p = 0.002). There was no significant difference in presence of GB stone and fatty liver and level of BMI and total cholesterol between two groups. Five (0.1%) subjects underwent operation of GB polyp and diagnosed as cholesterol polyp and/or adenoma. By multivariate analysis, the risk of GB polyp was higher in subjects with colorectal adenoma, however, it failed to show clinical significance (OR 1.28, 95% CI 0.99-1.65, p = 0.06) and the only significant risk factor of GB polyp was male gender (OR 1.72, 95% CI 1.22-2.40, $p = 0.002$).
Conclusion: Presence of colorectal adenoma was associated with higher tendency for GB polyp although it could not show statistical significance. Meticulous examination with ultrasonography of GB should be considered especially in male subjects with colorectal adenoma not to miss the GB polyps. Further studies concerning the common pathogenesis associated with both colorectal adenoma and GB polyp are warranted.

P0780 DIAGNOSTIC VALUE OF FUJINON INTELLIGENT COLOR ENHANCEMENT (FICE) TECHNOLOGY WITH AND WITHOUT MAGNIFICANTION TO DIFFERENTIATE BETWEEN HYPERPLASTIC AND ADENOMATOUS LESIONS ACCORDING TO THE NICE CLASSIFICATION - A PROSPECTIVE, RANDOMIZED, CONTROLLED STUDY

L. Madacsy[1], G. Gyimesi[1], I. Hritz[1], P. Hausinger[1], T. Velkei[1], B. Gellert[2], Z. Dubravcsik[1], A. Szepes[1]

Introduction: According to the resect-and-discard strategy the histological type of the colonic polyps (adenomatous vs. non-neoplastic or hyperplastic) is predicted in vivo by an appropriate endoscopic method, and based on this decision certain postpolypectomy pathologic specimens can be discarded rather than sent for histological assessment. The purpose of this prospective, non-interventional study was to validate the Narrow Band Imaging International Colorectal Endoscopic (NICE) classification for differentiating hyperplastic and adenomatous polyps by using Fuji Intelligent Color Enhancement (FICE) technology with high-definition with and without optical magnification.
Aims & Methods: 117 patients referred for outpatient colonoscopy were prospectively enrolled. All endoscopies were performed by experienced endoscopists. 61 patients were randomized to investigate with the Fujinon EC-600WM and 56 patients to investigate with the EC-600ZW/L series. In order to create a video-library of endoscopic cases, patients with at least one histologically verified polyp were included. A short HD video-clip (around 15-20 seconds) of each polyp and a HD DICOM still picture both at white-light and at FICE-virtual chromoendoscopy were recorded and stored in an anonymized video database. Histopathology of the lesions were confirmed by the blinded pathological evaluation of endoscopic resection, polypectomy or biopsy specimens. Finally NICE classification with FICE and histopathological results were compared.
Results: In the 117 patients we detected 247 polyps, all of them were endoscopically removed and sent to histological assessment. The average size of the polyps were 4,1 mm. According to the histopathological results, six early adenocarcinomas, 148 adenomas and 93 hyperplastic polyps were detected. There was a complete agreement between the NICE classification with FICE technology and histological results in 217 polyps (87,9%). 17 polyps classified as NICE type II despite non-neoplastic histology (6,9% false positive), whereas 14 polyps were classified as NICE type I despite adenomatous histology (5,7% false negative). No significant differences in the accuracy of NICE classification between standard and zoom HD colonoscopy compared to histology were detected.
Conclusion: FICE virtual chromoendoscopy in combination with HD colonoscopy with or without magnification is a promising tool for the differentiation of neoplastic from non-neoplastic colorectal polyps. High confidence predictions for adenomas such as NICE classification may provide precise diagnostic tool for real-time endoscopic diagnosis of neoplastic polyps.

P0781 LONG-TERM FOLLOW-UP AFTER ENDOMUCOSAL RESECTION FOR COLORECTAL POLYPS: A RETROSPECTIVE AUDIT OF EXPERIENCE AT A LARGE DISTRICT GENERAL HOSPITAL

J. Aldridge[1], T. Murugesan[1], **L. Burke**[1], D. Vani[1], S. Shah[1]
[1]*Gastroenterology, Pinderfields General Hospital, Wakefield, United Kingdom*

Contact E-mail Address: syed.shah@midyorks.nhs.uk
Introduction: Endomucosal resection (EMR) of colorectal polyps at lower GI endoscopy is becoming increasingly important, offering an effective means of removing large, obstinate polyps without resorting to surgery[1]. There is ample evidence on short-term recurrence post EMR but longer term data is missing[1,2]. We analysed our experience to fill this gap and provide follow-up data at 3 and 5 years post EMR.
Aims & Methods: Retrospective analysis was performed on endoscopy reports for all EMRs performed at lower GI endoscopies during a one year period in 2010 at a non-tertiary GI endoscopy unit. Reports were accessed from the hospital endoscopy reporting system (HICSS) and analysed for details of the EMR performed and follow up endoscopies for recurrence at the site of initial EMR. The location, size and morphology of polyp was recorded along with EMR details including completeness and need for APC. Polyp recurrence at subsequent endoscopies up to 5 years was also recorded.
Results: 188 lower GI endoscopies with EMR were performed. After exclusion for malignancy requiring surgery, incomplete follow up, polyp size < 1cm, 111 were analysed. Duration of follow up ranged from 3 to 60 months with a mean follow up of 32 months (median 35 months). Of the 111 polyps, 59% were 1-2cm, 36% 2-5cm, 5% > 5cm. Location was in the left colon in 59% of polyps and right-sided in 41%. The majority of polyps regardless of size were sessile (75%) with the remainder being flat (19%) or sub-pedunculated (6%).

Follow up endoscopy	6 months	1 year	3 years	5 years
No. performed	53	68	49	24
Recurrence (%)	7/53 (13)	5/68 (7)	5/51 (10)	0/25 (0)

Conclusion: This study confirms EMR is an effective alternative to surgery in the management of difficult colonic polyps. Our short-term recurrence rates are lower than those previously documented[2] and these low rates are maintained at long-term follow-up with a mean follow up duration of 32 months. Our results favour the confident use of EMR in the eradication of large and/or complex colonic polyps to achieve low long-term recurrence rates.

Introduction: A large UK study of single flexible sigmoidoscopy with adenoma clearance in patients aged 55-64, demonstrated a reduction in CRC incidence by 23% and mortality by 31% in intention-to-treat analyses.[1] This provided the rationale for provision of a new arm of the Bowel Cancer Screening Programme (BCSP), offering a single flexible sigmoidoscopy (FS) to all 55 year olds in England, known as BowelScope screening. BowelScope was introduced to 6 pilot sites, beginning in May 2013. It is to be rolled out across the country by 2016.

Aims & Methods: We aim to describe the findings, in terms of procedural data, from the first year of BowelScope screening at the pilot sites.

Data were obtained from the Bowel Cancer Screening System database for all participants who underwent FS between May 2013-May 2014. Procedural data were recorded, including entonox use, adenoma detection rate (ADR), cancer detection, complications and colonoscopy conversion rates.

Results: Overall uptake was 44.1%. 1 cancer was detected. Mean ADR was 9.2%. The mean number of patients requiring colonoscopy conversion was 4.2%. Mean complication rate was 0.1%, including bleeding, discomfort, difficult polyp excision and unwell patient. There was wide variation in entonox use. (Table 1)

Conclusion: Uptake has improved since the six month data were presented but remains lower than for the FOB arm of the BCSP, and varies between sites. The ADR is 9.2% (range 7.6% - 11.1%). This is lower than reported in the UK FS screening trial (12.1%[1]), however ADR calculations in BowelScope do not include adenomas not removed at FS but removed later at colonoscopy, whereas the FS trial did. The ADR is comparable to the BowelScope pathfinder project (9.6%[2]).

Further work is necessary to explore the variation in uptake rates. Variation in ADR exists between centres. Further analysis of endoscopist factors and patient groups may explain this. Entonox use varies widely but does not appear to correlate with ADR- further work may be required to investigate this.

Introduction: The traditional serrated adenoma (TSA) is the least frequent colorectal serrated polyp.

The prevalence of high-grade dysplasia (HGD) and adenocarcinoma in these polyps as well as association with colorectal neoplasia and malignant neoplasia has not been established.

Aims & Methods

Aim: To determine the prevalence of HGD and adenocarcinoma and to establish the association with synchronous (SNL) and metachronous neoplastic lesions (MNL) and other malignant neoplasm among patients with traditional serrated adenomas (TSA).

Methods: Reports from patients undergoing colonoscopy and polypectomy from January 2003 to September 2014, were retrospectively obtained from the electronic database of a teaching hospital. Personal and family history of colorectal cancer (CRC) and malignant neoplasm were consigned from medical records. TSA diagnosis was based on the presence of luminal serration, cytoplasmic eosinophilia and the presence of ectopic crypt foci. SNL were defined by adenomas, sessile serrated adenomas (SSA), cancer or advanced neoplastic lesions (ANL) (>1cm, HGD or >75% of villous component) in the same colonoscopy. Those lesions appearing after 12 months of index colonoscopy during surveillance were considered MNL. A multivariate analysis was performed, looking for independent predictors of HGD, cancer, SNL and MNL in patients with TSA.

Results: During the analyzed period a total of 101 STA were diagnosed in 89 patients. The prevalence of STA was 0.45% (101/ 22000 colonoscopies). The mean age was 62 years old (range: 32-90) and 55% of patients were men. A personal and family history of CRC was present in 4/89(4.5%) and 12/89 (13%) respectively. Personal history of malignant neoplasm was present in 8/89 (9%) patients (4/8 lung cancer and 4/8 skin cancer).

Familial adenomatous polyposis had been diagnosed in 1/89(2%) patients and 7/89 (9%) met the WHO diagnostic criteria for serrated polyposis syndrome. Regarding TSA characteristics, average polyp size was 9.61 mm (range 5-45) and the most frequent location was left-colon 89/101(88%). Polyps more frequent morphology were sessile 63/101(62 %) and pedunculated 33/101(33%). HGD was present in 6/101(6%). Regarding SNL 39% presented adenomas, 35% SSA, 19% ANL, and 4.5% adenocarcinoma on index colonoscopy. During surveillance colonoscopy 25% presented SSA, 31% adenomas, 44% ANL and 0% adenocarcinoma. Multivariate analysis revealed that polyp size >20mm was the only independent predictor of HGD (OR 25.14 CI 3.10-249, p 0.0001). We didńt find independent predictors for synchronous or metachronous neoplastic lesions.

Conclusion: We found low prevalence of TSA similar to reported. The frequent association of these lesions with synchronous and metachronous colonic neoplasia, intestinal polyposis syndromes and other malignant neoplasm, highlights the importance of detecting these lesions during routine colonoscopy.

Introduction: Serrated polyposis syndrome (SPS) is often under-diagnosed in a single colonoscopy. The low sensitivity of diagnostic criteria for SPS could impair the follow-up approach in high-risk patients who have not yet met them. Current surveillance recommendations concerning serrated polyps (SP) are insufficient.

Aims & Methods: We aimed to assess the yield of a second look colonoscopy (SLC) to diagnose SPS after a screening colonoscopy and to determine the optimal SP-threshold to indicate it.

From January 2010 to July 2013, individuals with ≥1 SP ≥5 mm proximal to splenic-flexure or ≥10 mm along the colon after a screening colonoscopy were retrospectively evaluated. Despite the standard surveillance recommendations based on adenomas, an early SLC was empirically scheduled to patients with concomitant SP to rule out SPS. SLC was performed with a special aim at detecting SP.

Results: 196/3444 patients fulfilled selection criteria. At screening colonoscopy, 11 were already diagnosed of SPS. Amongst the 185 remaining patients, 71 underwent SLC in 11.9 ± 1.7 months. According to SLC findings, individuals were grouped into: 1) SPS: 20 (28%) representing a 182% increase compared to baseline-colonoscopy diagnosis, 2) SPS-like (those with a high burden of SP and almost fulfilling SPS criteria): 15 (21%) and 3) Sporadic-SP: 36 (51%). SPS and SPS-like were considered High-Risk group. Independent colonoscopy baseline and individual predictive characteristics of High-Risk were: presence of ≥5 proximal-SP (OR 4.04 [1.2-13.5], p = 0.023), ≥2 sessile serrated polyps ≥10mm (OR 12.42 [1.39-110.72], p = 0.024) and high-definition endoscopy and/or conventional/virtual chromoendoscopy use at SLC (OR 7.43 [2.01-27.49], p = 0.003).

Conclusion: A SLC within one-year doubles the number of patients diagnosed with SPS after a screening colonoscopy. The presence of ≥5 proximal-SP or ≥2 sessile serrated polyps ≥10mm at baseline-colonoscopy is an optimal threshold to indicate a SLC. SLC has to be performed preferably using advanced endoscopic techniques. These findings provide rationale to adjust surveillance recommendations in individuals with concomitant SP.

P0785 THE NBI TECHNOLOGY COULD INCREASE THE OPTICAL DIAGNOSIS OF THE GASTROINTESTINAL GRAFT-VERSUS-HOST DISEASE

A. Maimone[1], C. Giardini[2], A. de Leone[1], M. T. Fabi[1], P. Lorenzini[3], M. L. Bianchi[1], S. Fiori[1], A. Isidori[2], G. Visani[2], **L. De Luca**[1]

Contact E-mail Address: antonellamaimone@yahoo.it
Introduction: Athough graft versus host disease (GVHD) is a complication relatively common after allogenic hematopoietic stem cell transplantation (HSCT), it infrequently evolves in severe gastrointestinal (GI) complications. The diagnosis of GI-GVHD is often elusive, due to variability of the clinical presentation and it is based upon histologic findings. The endoscopic intestinal lesions are macroscopically pleomorphic (i.e. mucosal erytema, aphthous ulcerations) and can be patchy or absent in early phases of the disease. The Narrow Band Imaging (NBI) is a simple "push-on-a button" technique that enhances mucosal and vascular details without the use of dyes, and has proven to be superior to only High-Resolution Endoscopy (HRE).
Aims & Methods: The aims of this pragmatic trial were to explore the role of NBI system in the diagnosis of GI-GVHD. Seventeen of 51 patients (33%) which received allogenic HSCT at Bone Marrow Transplant Unit of Pesaro, presented unexplained diarrhoea at risk for acute GI-GVHD. The median time from transplantation was 40 days and the diagnosis work-up for infection causes resulted negative. These patients underwent to colonoscopy using the Evis Exera II system (Olympus Medical Systems, Tokyo, Japan) and a High-Resolution endoscope (CF-H180AI/L), integrating NBI system by only pushing a button. The multiple biopsies of the ileum, right, transverse, left and rectosigmoid colon were performed by the same operator during each procedure. The histological diagnosis was carried by a skilled pathologist
Results: The histological diagnosis of intestinal GVHD was confirmed in 7/17 patients (41%). HRE have shown macroscopic findings in 2 patients, characterized by extensive mucosal hyperemia, nodularity, hemorragic spots, patchy erosions and multiple shallow ulcers. The NBI system identified minute changes of the mucosal surface as pattern thinning and microvascular network irregularities in 5 patients (M/F 3:2, mean age 39), in whom HRE was normal (Table 1).

Table 1: The relationship between histological evaluation and endoscopic findings of HRE and NBI technologies for GI-GVHD diagnosis.

Histological Diagnosis N. Patients		Endoscopic Findings HRE	NBI
GVHD	7	2	7
Normal	10	15	10

Conclusion: The NBI system could help to identify minute abnormalities suspicious for GI-GVHD, such as alteration of vascular pattern and mucosal micronodularity, not detected by HRE. This tool could increase the yield of endoscopic diagnosis of GI-GVHD by targeted biopsy compared to random biopsies at HRE. Further evaluation may be need to establish the correlation between endoscopic and histological findings.

P0786 BLUE LASER IMAGING: A NOVEL ENDOSCOPIC TOOL FOR PRECISE EVALUATION OF VASCULAR PATTERN OF COLORECTAL LESIONS

C. R. Teixeira[1], **L. F. Figueiredo**[1], M. Bonotto[1], J. Pereira-Lima[1], N. H. V. Coelho[1], M. Maia[1], C. R. F. Rodrigues[1], L. Conrado[1]
[1]*Endoscopic Unit, FUGAST, Porto Alegre, Brazil*

Contact E-mail Address: texcla@terra.com.br; luciana.gastro@gmail.com
Introduction: A new system using a laser light source, Blue Laser Imaging (BLI-Lasereo by Fujifilm), has been developed allowing an *in vivo* endoscopic observation of the surface and microvascular pattern of lesions. Colonoscopy with BLI-Lasereo and magnifying zoom enable the characterization of the fine superficial capillary pattern of normal mucosa and of colorectal lesions. The endoscopic distinction between the different capillary pattern can contribute to the differential diagnosis among normal, hyperplastic, serrated and other neoplastic lesions.
Aims & Methods: Applying this latest technology, the objective of this study is to evaluate the accuracy of the capillary-vessel pattern classification of colorectal lesions diagnosed during routine colonoscopy using BLI and magnifying zoom imaging.
A total of 91 colorectal lesions in 42 patients (23 men) were prospectively examined using Kudo's pit pattern classification and capillary-vessel pattern according to our previous published classification [1]. All lesions were endoscopically or surgically resected In summary, the capillary pattern was divided into 5 subtypes according to the number, morphology and architecture of the fine blood vessels. The presumptive endoscopic diagnosis of the lesions were correlated with the histopathologic findings, determining the sensitivity, specificity and accuracy of this method.
Results: The overall accuracy of the fine blood vessel classification by BLI and magnification in differentiating neoplastic and non-neoplastic colorectal lesions was 95.6% (87/91 lesions). The sensitivity, specificity, positive predict value and negative predict value of the capillary pattern classification for distinguishing neoplasia from non-neoplasia were, respectively, 98.5%, 90.9%, 97.1% and 90.9%
Conclusion: The endoscopic classification of the superficial capillary-vessel pattern of colorectal lesions using BLI - Lasereo technology is an accurate method to predict the histopathologic diagnosis. BLI - Lasereo system is a very promising technology for precise evaluation of fine blood vessel pattern.

P0787 ENDOSCOPIC MUCOSAL RESECTION OF LARGE COLORECTAL POLYPS: LONG-TERM PROSPECTIVE EVALUATION OF EFFECTIVENESS AND COMPLICATIONS

L. Elvas[1], M. Areia[1], D. Brito[1], R. Carvalho[1], S. Alves[1], S. Saraiva[1], A. T. Cadime[1]
[1]*Gastroenterology, Portuguese Oncology Institute - Coimbra, Coimbra, Portugal*

Contact E-mail Address: luisandreelvas@gmail.com
Introduction: Endoscopic mucosal resection (EMR) is a very important therapeutic procedure for large sessile and flat colorectal polyps. The aim of the study was to prospectively evaluate the success, complications and recurrence with EMR.
Aims & Methods: Prospective cohort study of patients referred for EMR of colorectal polyps ≥20mm at our gastroenterology department, between June of 2008 and February of 2015. Inject and cut technique was used and argon-plasma coagulation was applied in resection margin if any remnant tissue was suspected. Patients' and lesions' characteristics were collected, as well as complications and recurrence at 3, 12, 36 and 60 months. Statistical analysis was performed by logistic regression.
Results: A total of 155 colorectal polyps were removed in 148 patients (56% males; mean age 70 ± 10 years). Median polyp size was 30mm (20; 40) and 65% were sessile while 35% were flat polyps. Almost half of the lesions (47%) were located in rectum or sigmoid colon.
Median follow-up time was 24 months (12;41). Piecemeal resection was performed in 86%.
Recurrence rate was 19% (26/136) at 3 months, 6.3% (8/127) at 12 months and 2.7% (2/73) at 36 months. There was no recurrence after 60 months (0/36). Three polyps (1.9%) required surgery after non-complete resection/recurrence. The complication rate was 8.4% (13/155) and all complications were managed without surgery: bleeding – 10 (2 immediate and 8 delayed); perforation – 1 (0.6%); post-polypectomy electrocoagulation syndrome – 1; rectal ulcer – 1. Logistic regression identified distal rectal location of the polyp as the only risk factor for recurrence (OR 3.8, IC 95%: 1.5-10.2).
Conclusion: In our experience, EMR is a safe procedure for removing large colorectal polyp and all procedure-related complications were managed without surgical intervention. The possibility of recurrence implies an endoscopic long-term follow-up and, after 5 years, 98% of our patients were cured only with endoscopic therapy.

P0788 IMPACT OF PERSONALIZED PATIENT EDUCATION ON BOWEL PREPARATION FOR COLONOSCOPY – PROSPECTIVE RANDOMIZED CONTROLLED TRIAL

L. Elvas[1], D. Brito[1], M. Areia[1], R. Carvalho[1], S. Alves[1], S. Saraiva[1], A. T. Cadime[1]
[1]*Gastroenterology, Portuguese Oncology Institute - Coimbra, Coimbra, Portugal*

Contact E-mail Address: luisandreelvas@gmail.com
Introduction: An adequate bowel preparation is one of the most important quality factors of colonoscopy.
Aims & Methods: Our goal was to analyze the impact of personalized patient education on bowel preparation cleansing for colonoscopy.

We performed a single-blinded, single-center, prospective randomized controlled trial, where patients were allocated to "control" group, which received predefined oral and written information on bowel preparation from the gastroenterologist, or "intervention" group, that also had a 20-minute appointment with a nurse, receiving personalized education on all preparation steps. Primary outcome was the quality of bowel preparation (Aronchick Scale).

Results: A total of 229 patients were randomized, 113 to "control" group and 116 to "intervention" group. In intention-to-treat analysis, bowel preparation was "adequate" in 63% of colonoscopies of "intervention" group and in 40% of "control" group ($p = 0.001$). Subgroup analysis showed a significant impact of personalized education in patients under 65 years (67% vs. 35%; $p < 0.001$), males (60% vs. 33%; $p = 0.003$), those with higher educational levels (68% vs. 37%; $p = 0.002$), living in urban areas (68% vs. 40%; $p = 0.004$) and with previous colonoscopy (68% vs. 40%; $p = 0.001$). Risk factors for "inadequate" preparation were: male gender (OR = 2.1; 95% CI 1.1-4.1), diabetes mellitus (OR = 3.8; 1.2-11.6), chronic constipation (OR = 3.7; 1.7-8.2), absence of prior abdominal surgery (OR = 2.2; 1.2-4.1) and absence of personalized patient education (OR = 2.5; 1.4-4.4).

Conclusion: Personalized patient education on bowel preparation for colonoscopy significantly improved the quality of bowel preparation. We believe it should be applied in every gastroenterology department as it could improve the quality of colonoscopy.

Introduction: Endoscopic polypectomy of colonic polyps decreases morbidity and mortality of colorectal cancer. Bleeding and colonic perforation are the most common complications of this technique.

Aims & Methods: Our aim was to evaluate the complication rate of endoscopic polypectomy.

We conducted a prospective registry, from 2009 to 2015, of polypectomy procedures performed at our endoscopy unit and its complications. An appointment was scheduled around 1 month after the procedure so that every patient could report any delayed complications. Complication rate and risk factors were analyzed. Statistical analysis was performed with chi-square test and logistic regression.

Results: We included 2416 polypectomies (6.4% endoscopic mucosal resections) in 1052 patients (63% males; mean age 63 ± 11 years). Mean time for the post-polypectomy appointment with gastroenterologist: 44 ± 24 days. Polyp characteristics: mean size – 8.8 ± 7.0mm; left-sided – 61%; sessile type – 71%. Complication rate per-polyp was 1.4%: bleeding – 1%; perfuration – <0.1%; other complications – 0.3%. All complications were managed without surgery. Nineteen patients (0.8%) required in-hospital stay. Delayed complications occurred 4.1 ± 3.7 days after polypectomy. From the 23 cases of bleeding, 11 needed endoscopic hemostasis treatment and 4 required red cell transfusion. Delayed bleeding probability increased with polyp size ≥20mm (3.4% *vs.* 0.7%, $p < 0.001$), was higher in sessile versus pedunculated polyps (1.1% *vs.* 0.6%, $p = 0.21$) and in patients under 65 years-old (1.2% *vs.* 0.7%, $p = 0.19$). In multivariate logistic regression only polyp size reached statistical significance, OR 4.9 (IC 95%: 2-12).

Conclusion: Complication rate of our series is similar to published data. We point out that there were no deaths and all complications were managed without surgery.

P0790 DISTANCE FROM RECTAL AND SIGMOID TUMORS TO ANAL VERGE – EVERY CENTIMETRE COUNTS!

L. Elvas[1], D. Brito[1], M. Areia[1], S. Alves[1], S. Saraiva[1], A. T. Cadime[1]
[1]*Gastroenterology, Portuguese Oncology Institute - Coimbra, Coimbra, Portugal*

Contact E-mail Address: luisandreelvas@gmail.com

Introduction: An exact characterization of the distance from distal end of rectal and sigmoid tumours to anal verge is essential for an adequate staging and treatment decision, concerning neoadjuvant therapies and different types of surgery.

Aims & Methods: Our aim was to compare the measures from colonoscopies performed in ambulatory centre outside our hospital against a flexible sigmoidoscopy performed at our gastroenterology department.

We performed a prospective comparative study of patients with rectal and distal sigmoid malignant neoplasia, who were submitted to colonoscopy examination outside our institution and to flexible sigmoidoscopy at our endoscopy unit, to determine the distance from distal end of the lesion to the anal verge. The distance measured in pelvic magnetic resonance imaging (MRI) was used as reference. Statistical analysis performed with Mann-Whitney and Chi-square tests and Spearman correlation coefficient.

Results: We included 32 lesions from 32 patients (53% female; mean age 67 ± 12 years). In 5 (16%) of the ambulatory colonoscopies the distal end of the lesion was not reported. The median value of the difference between measured distances outside and inside our hospital department was 3.0cm (1;6). MRI and both endoscopic procedures were available in 22 of the 32 patients. Spearman correlation coefficient between endoscopic procedures and MRI was 0.68 for ambulatory and 0.93 for in-hospital flexible sigmoidoscopy. Comparing each procedure with MRI, there were statistically significant differences (ambulatory *vs.* MRI – 3.0cm; in-hospital *vs.* MRI – 0.0cm; $p = 0.007$). When using MRI as reference, the differences between distance to the anal verge would change the staging or treatment of a lesion in 5% of in-hospital exams *vs.* 37% of ambulatory colonoscopies ($p = 0.03$). In the latter, 7 out of 22 (32%) rectal tumours were wrongly classified as sigmoid (above 15cm from anal verge), which could change the staging and neoadjuvant therapeutic options, and 1 (5%) distal rectal tumour reported as proximal, which could be immediately directed to a centre with expertise in minimally invasive rectal surgical interventions.

Conclusion: Reporting the exact distance from distal end of rectal and sigmoid tumours to anal verge is important but it is endoscopist-dependent. A precise measure of these distances allows better staging options and adequate treatment decision.

Contact E-mail Address: araim-cib@umin.ac.jp

Introduction: Previous studies have shown that colonoscopy with water exchange technique is superior to air insufflation in attenuating insertion pain and that it is difficult for trainee colonoscopists to perform colonoscopy in elderly patients.

Aims & Methods: To assess comparative effectiveness in elderly patients, we conducted a randomized controlled trial with head-to-head comparison of these two methods. We did not enroll the following cases in this study: (1) patients received endoscopy for treatment, (2) patients were diagnosed with ileus, (3) patients wished to use a sedative agent before colonoscopy. A total of 447 patients in two centers were randomized to either water exchange (WE) or the standard air (CO_2) insufflation technique (AI). In WE, warm water was infused through the forceps channel of the colonoscopy using a foot-switch-controlled water pump. Water used to aid insertion was removed predominantly during the insertion phase. Suspended fecal matter and residual air pockets were removed by suction, followed by infusion of water to improve the view. The

primary outcome was patient intraprocedural pain and the secondary outcome was doctor comfort and satisfaction. These outcomes were evaluated using a questionnaire (Score 1 to 5). Clinical trial registry number is UMIN000009706. All authors declare that there are no conflicts of interest.
Results: Forty four patients were excluded for further analysis. As a result, 403 patients without sedation were analyzed. The number of elderly patients aged 75 years and over was 83 (20.6%). There were no differences in patient age (65.6 ± 12.0 vs. 63.1 ± 12.6 years) and body mass index (22.9 ± 3.8 vs 23.3 ± 4.2 kg/m^2) between WE and AI groups. Patients in WE group reported less intraprocedural pain than those in AI group (2.18 ± 1.15 vs. 2.42 ± 1.03; unpaired t-test, $p = 0.024$). In contrast, there was no statistically significant difference in elderly patients between WE and AI groups (2.10 ± 1.12 vs.2.21 ± 0.98). Colonoscopy by trainee colonoscopists (T group) who performed less than 500 colonoscopy was more painful than that by non-trainee (NT group) (2.44 ± 1.08 vs.1.59 ± 0.78; $p < 0.01$). In T group, there was no significant difference in pain during colonoscopy in elderly patients between WE and AI groups (2.18 ± 1.15 vs. 2.45 ± 1.11). On the contrary, in NT group, WE could reduce pain in elderly patients compared to AI (1.88 ± 1.04 vs. 2.25 ± 1.06; $p = 0.033$).
Conclusion: Although WE is superior to AI in attenuating real-time insertion pain during colonoscopy, the efficacy of WE is limited in elderly patients. Unlike trainees, colonoscopy experts can attenuate insertion pain of elderly patients by utilizing WE technique.
Disclosure of Interest: None declared

P0792 OPTICAL DIAGNOSIS OF T1 COLORECTAL CARCINOMA BY COLONOSCOPY EXPERTS, GENERAL GASTROENTEROLOGISTS AND GI-FELLOWS: IS IT FEASIBLE?

M. Van Der Vlugt[1], S. van Doorn[1], B. Bastiaansen[1], P. Fockens[1], E. Dekker[1]
[1]*Department of Gastroenterology and Hepatology, Academic Medical Center Amsterdam, Amsterdam, Netherlands*

Contact E-mail Address: m.vandervlugt@amc.uva.nl
Introduction: An increasing number of T1 colorectal cancers are diagnosed. It is important to endoscopically recognize these cancers correctly to establish an optimal treatment strategy. Asian studies show that colonoscopy experts can reliably recognize early cancers. In daily practice however, accurate optical diagnosis of T1 carcinomas still seems challenging.
Aims & Methods: To evaluate the performance of optical diagnosis of T1 cancers by colonoscopy experts, general gastroenterologists and GI-fellows. We selected good quality endoscopic images (white light and NBI images) without magnification of 43 lesions: 19 T1 carcinomas and 24 benign polyps (7 sessile serrated adenomas and 17 adenomas with low-grade dysplasia) ranging from 8-30 mm in size. Seven international colonoscopy experts, 7 general gastroenterologists and 14 GI-fellows assessed all images for an optical diagnosis and level of confidence (high/low). We calculated sensitivity, specificity, negative and positive predictive value (NPV,PPV) for optical diagnosis of T1 carcinomas using 2x2 tables. For fellows, this was also described according to years of training.
Results: Sensitivity was 60% for all endoscopists. Sensitivity was best for experts (67%) compared to general gastroenterologists and fellows (53% and 59% resp.). NPV was lowest for general gastroenterologists. Of all endoscopists, only two (1 expert and 1 fellow) reached a NPV of $\geq 90\%$. 645 (54%) optical diagnoses were made with high confidence. High confidence diagnoses correlated with higher overall sensitivity, specificity, PPV and NPV, especially for fellows.
Conclusion: Sensitivity for predicting a T1 carcinoma and NPV for excluding a T1 cancer was insufficient. Experts did best with sensitivity of 67% and NPV 78%, and the performance of fellows in their last year of training is comparable to that of experts. This indicates that training for optical diagnosis for malignant polyps is needed.

P0793 RESECTION OF LARGE COLONIC PEDUNCULATED POLYPS (PARIS IP)

M. A. Alburquerque[1,2], A. Smarrelli[1], L. Vidal[1], C. Ledezma[1], J. Chevarría[3], A. L. Vargas[2], M. Figa[2], F. Gonzalez-Huix[2]
[1]*Gastroenterology, Hospital de Palamós,* [2]*Gastroenterology, Clínica Girona,* [3]*Nephrology, Hospital de Palamós, Girona, Spain*

Contact E-mail Address: nictalope7@gmail.com
Introduction: There are some techniques to resect large colonic pedunculated polyps.
Aims & Methods: To compare the safety of the techniques commonly used to resect large colonic pedunculated polyps ≥ 20mm according to the stalk measures. Descriptive - prospective study (2010-2014) regarding the safety of the techniques to resect large colonic pedunculated polyps, usually used by four endoscopists. We registered: location and polyp features, resection techniques and complications. The polyps were classified in 4 groups according to the stalk measures. The immediate postpolypectomy bleeding (IPPB) was defined as the bleeding during the resection procedure in which was necessary an additional haemostatic technique. **Resection techniques**: **A)** Hot snare, **B)** Adrenaline (0,005-0,01%) injection in the stalk, cutting snare and close of the wound/remnant stalk with clips and, **C)** Clip (Quick Clip® Olympus and Resolution clip® Boston Scientific) or detachable snare placement (Endoloop MAJ-339 Olympus®) and cutting snare.
Results: There were resected 180 pedunculated polyps ≥ 20mm (Longest diameter $= 25.34 \pm 6.54$; 20–60mm) among 168 patients, women: 49(29.16%). Age: 63.53 ± 10.96 y. There were excluded 20 polyps by incomplete data. In the Group 1 ($n = 38$, stalk: Length < 15mm/Diameter ≤ 10mm) were resected with hot snare: 57.89%, while in the Group 2 ($n = 28$, Length ≥ 15mm/Diameter ≤ 10mm) with clip: 57.15%. In the Group 3 ($n = 30$, Length < 15mm/Diameter > 10mm) were resected with Adrenaline injection: 93.33% and in the Group 4 ($n = 64$, Length ≥ 15mm/Diameter > 10mm) with Endoloop®: 75%; $p = 0.001$. The IPPB was the most frequent global complication: 31.10%(56/180), highest in the Group 3: 63.3%, $p = 0.001$; and was resolved with clips with an effectiveness $= 91.10\%(41/45)$. In the Groups 1 & 2 (stalk diameter ≤ 10mm), the IPPB rate was 18.75%(6/32) in the resected polyps with only snare vs. 31.8%(7/22) in those with clip, $p = 0.270$. In the Groups 3 & 4 (stalk diameter > 10mm), the IPPB rate was higher in the resection with adrenaline injection than Endoloop®: 64.70%(22/34) vs. 10.20%(5/49), $p = 0.001$. In these groups the IPPB rate was not different between clips and adrenaline injection: 50%(3/6) vs. 64.7%(22/34), $p = 0.65$. In the polyps with stalk diameter > 10mm, in the multivariate analysis, the adrenaline injection was significantly associated to IPPB: $p = 0.0001$; OR = 15.23(IC95% 4.43–52.34). In the Group 4, the IPPB was higher with clips than with Endoloop®: 50%(3/6) vs. 10.4%(5/48), $p = 0.036$.
Conclusion: In large colonic pedunculated polyps ≥ 20mm with thinner stalk ≤ 10mm the resection with hot snare was acceptably safe. In thicker stalk > 10mm, the polypectomy with Endoloop® was significantly safer when the stalk length was enough to place it; and the adrenaline injection has shown a high risk to IPPB. Some clips type might not have been superior to prevent the IPPB although they are effective to resolve it.

P0794 IN VIVO DETECTION OF EARLY COLORECTAL CANCER BY FLUORESCENCE ENDOSCOPY TARGETING THE ENDOTHELIN-A-RECEPTOR

M. M. Mücke[1], D. Bettenworth[1], C. Geyer[2], K. Schwegmann[3], C. Poremba[4], M. Schäfers[3], D. Domagk[5], C. Höltke[2], P. Lenz[16]

Contact E-mail Address: lenzph@uni-muenster.de
Introduction: Patients suffering from ulcerative colitis are at an increased risk of developing colorectal cancer. Current guidelines recommend surveillance colonoscopy with chromoendoscopy or random biopsies to further improve detection rates of dyplastic lesions. ET-A receptor (ET_AR) expression is known to be significantly increased in various malignancies including colorectal cancer (1). The objective of this study was to evaluate ET_AR-guided fluorescence endoscopy (FE) *in vivo* and fluorescence reflectance imaging (FRI) *ex vivo* for detection and characterization of early dysplastic lesions in mice.
Aims & Methods: Colorectal cancer was induced in C57Bl/6 WT mice ($n = 15$) by single injection of azoxymethane (AOM) i.p. and cyclic administration of dextran sodiumsulfate (DSS) in drinking water. A Cy5.5-labeled nonpeptidic ET_AR imaging probe was intravenously injected 24 hrs before endoscopic examination. Tumor development was assessed *in vivo* by white light endoscopy and FE. Then colons were explanted and examined by fluorescence reflectance imaging using an MS-FX PRO optical imaging system to measure tracer uptake *ex vivo*. At the end of the experiment tumors were graded after HE staining and evaluated by an expert pathologist. Tumor biology was assessed utilizing the proliferation marker Ki-67 and ET_AR expression was visualized by immunohistochemistry and western blot analysis. Additionally, binding specificity of the tracer was evaluated by simultaneous injection of an equimolar amount of an unspecific fluorochrome (Cy3.5-glycin) and the specific ET_AR tracer.
Results: In 15 mice, 77 adenomas were confirmed up to high-grade dysplasia in standard histology. FE was able to detect ET_AR expression easily applying the fluorescent ET_AR imaging probe. A significant higher fluorescent contrast was observed in colonic adenomas as compared to adjacent non-malignant mucosa (63.4 ± 7.9 vs. 56.6 ± 7.0; $P < 0.001$). Correspondingly, *ex vivo* conventional molecular imaging showed significantly increased tracer uptake in colorectal adenoma as compared to healthy mucosa (1211.0 ± 557.4 vs. 509.7 ± 137.0; $P < 0.001$). Immunochemistry revealed an increased Ki67 and ET_AR expression in colonic dysplasia. Moreover, western blot analysis verified the detected ET_AR expression. No significant difference in tracer uptake between low and high-grade adenoma was found (tumor-to-background ratio: 2.3 ± 0.8 vs. 2.4 ± 0.7, $P = 0.589$). The tumor-to-background ratio of lesions imaged for Cy3.5 was significantly reduced as compared to Cy5.5 indicating the high binding-specificity of the utilized ET_AR tracer (1.4 ± 0.3 vs. 2.5 ± 0.7, $P < 0.001$).
Conclusion: In murine colorectal dysplasia ET_AR expression was significantly increased as compared to healthy mucosa. By detection of ET_AR via FE in live mice, a prognostic biomarker for colorectal cancer development is directly visualized during colonoscopy, thus facilitating *in vivo* tumor characterization on a molecular level.

P0795 SHOULD POLYP RESECTION BE PRIORITIZED ACCORDING TO LOCATION?

M. J. Silva[1], R. V. Loureiro[1], P. Russo[1], C. Bernardes[1], V. P. Borges[1], T. Capela[1], M. N. Costa[1], D. Carvalho[1], A. David Marques[1]
[1]*Central Lisbon Hospital Center, Lisboa, Portugal*

Introduction: Prediction of histology of colon polyps according to location and other macroscopic features is particularly relevant as colonographic techniques are becoming more widespread. Advanced polyps are smaller in the right colon[1] and right-sided lesions carry increased risk of recurrence of advanced adenomas.[2] Nevertheless, differences in histologies between right- vs left-sided colon polyps are not well characterized.[2] When available, such information may be used for prioritizing colonoscopies recommended after colonography (ie, when at least one polyp ≥6mm is observed).[3]
Aims & Methods: We aimed at characterizing colonic polyp histology according to patient and polyp macroscopic characteristics.
We reviewed all polyps observed in colonoscopies performed during 2013 in an Gastroenterology Department, whose location and histology (from biopsy or complete removal) are unequivocally known. We considered high risk traditional adenomas all those with ≥10mm at colonoscopy or with advanced histology (villous histology or high grade dysplasia).
We reviewed all polyps observed in colonoscopies performed during 2013 in an Gastroenterology Department, whose location and histology (from biopsy or complete removal) are unequivocally known. We considered high risk traditional adenomas all those with ≥10mm at colonoscopy or with advanced histology (villous histology or high grade dysplasia). Patient demographics, as well as polyp macroscopic and microscopic features, were analyzed with STATA® 12.1.
Results: In total, 1960 polyps were analyzed.In the rectum, the most frequent polyps were hyperplastic (53.3%; 218/409); while in the other segments the most common polyp type was tubular adenoma with low grade dysplasia: 48.3% (236/489) in sigmoid colon, 64.5% (158/245) in descending colon, 68.3% (293/429) in transverse colon, 70.6% (202/286) in ascending colon and 69.6% (71/102) in cecum.High risk traditional adenomas were more common in the sigmoid colon (33.5% of polyps; 164/489) and descending colon (26.9%; 66/245) than in other segments.Among polyps ≥6mm (N = 878), advanced histology in traditional adenoma was more prevalent in rectal polyps (33.3%; 42/126), followed by polyps in the sigmoid colon (23.8%; 62/260), descending colon (19.7%; 27/137), cecum (18.9%; 7/37), transverse colon (15.2%; 31/204) and ascending colon (14.0%; 16/114). Advanced histology was significant more frequent in distal compared to proximal polyps, both when comparing all polyps (11.9% vs 7.2%, $p = 0.001$) or only those ≥6mm (25.0% vs 15.2%, $p < 0.001$).
Conclusion: In this series, distal polyps carried a higher risk of advanced histology. Priorization for colonoscopic removal may consider polyp location.

Introduction: According to an ageing population, and increasing burden of colorectal cancer at an advanced age, colonoscopies are increasingly needed in the elderly. Polyethylene glycol electrolyte lavage solution containing ascorbic acid (PEG-ASC) has recently become available in Japan, as a low-volume lavage solution. However, in view of concerns of hypertonicity for PEG-ASC, we compared it to standard PEG electrolyte solution (PEG-ELS) and evaluated the hematological and biochemical change before and after taking PEG solution.
Aims & Methods: The aim of this study is to compare the efficacy, acceptability, tolerability, and safety of PEG + ASC and standard PEG-ELS, not only in the general population, but also in patients of advanced age. This was a single-blinded, non-inferiority, randomized, controlled trial including adult inpatients. Although 3–4 L of PEG-ELS is used in Western countries, approximately 2 L of PEG-ELS, along with a laxative, is usually considered adequate for bowel preparation in Japan. Subjects were randomized to receive 1.5 L PEG-ASC or 2 L PEG-ELS, and completed a questionnaire on the acceptability and tolerability of the bowel preparation process. Hematological and biochemical parameters were assessed at baseline, 3 hours, and 7 hours after beginning the preparation solution. The Boston Bowel Preparation Scale was used to evaluate bowel cleansing, and a 3-point scale was used to assess mucosal visibility.
Results: One hundred patients were randomized to either the 1.5-L PEG-ASC group (n = 50, males 66%, mean age 66.4 years) or the 2-L PEG-ELS group (n = 50, males 64%, mean age 67.9 years). Patients in 1.5-L PEG-ASC group were more willing to repeat the procedure than the 2-L PEG-ELS group (72% 1.5-L PEG-ASC group vs. 52% 2-L PEG-ELS group (95% lower confidence limit, for a difference of 1.4%)). No significant differences were found in bowel cleansing ($P = 0.889$) or mucosal visibility ($P = 0.063$) between the groups. Except for sodium bicarbonate in the 1.5-L PEG-ASC group, all hematological and biochemical parameter variations were within the normal range. However, we demonstrated significant statistical changes in the hematological and biochemical parameters such as sodium, chloride, albumin, hematocrit, and acid-base balance parameters after both type of preparation, regardless of patient age, which were not clinically significant.
Conclusion: The 1.5-L PEG-ASC regimen had higher patient acceptability than the 2-L PEG-ELS regimen. Tolerability, bowel cleansing, and safety were similar between regimens. No significant differences in the safety profile were found between subjects aged less than 70 years and those aged 70 years or more; nevertheless, regardless of age, proper hydration is needed throughout the bowel preparation process.

Introduction: Neoplastic colorectal polyps are precursor lesions recommended to remove. Both Narrow band imaging (NBI) and optical magnification have contributed to an accurate endoscopic diagnosis of the colorectal tumors. Recently, a simplified 45 times optical magnification (near-focus NBI) that is activated by only a switch has become commercially available. This near-focus NBI might help trainees to differentiate between neoplastic and non-neoplastic polyps.
Aims & Methods: The aim of this retrospective image evaluation study is to elucidate diagnostic accuracy of near-focus NBI for differential diagnosis of colorectal small polyp in trainees using western setting.
In the pre-study, education according to NICE classification was performed to 7 reviewers [6 trainees and 1 experienced endoscopists (control)] using 15 typical polyps. In Study 1, endoscopic images obtained by high-resolution white-light (WLI), NBI and near-focus NBI of 20 consecutive polyps removed between July and August 2014, were systematically assessed by the 7 reviewers. In study 2, two weeks after the study, endoscopic images of other consecutive 40 polyps removed between August and September 2014, were evaluated by the 7 reviewers after repeating the same lecture and verifying the pathological diagnosis of the 20 polyps in study 1. Diagnostic accuracy and rate of high confidence were analyzed. Trainees had performed < 100 colonoscopies and < 3 years' experience. All reviewers were blinded to clinicopathological data and evaluated the images in a random order. All images used in the study 1 and 2 were obtained by Exera III system (Olympus). All polyps were smaller than 10mm.
Results: Before the education, diagnostic accuracy for differentiating adenomas from hyperplastic polyps (HPs) of the trainees and rate of high confidence were 78% (47~87) and 67% (60~80).
Study 1) Overall diagnostic accuracy of WLI, NBI, and near-focus NBI for differentiating adenomas from HPs in trainees were 61% (55~65), 75% (65~85) and 80% (75~90), respectively. Overall rate of high confidence in WLI, NBI and near-focus NBI were 73% (35~90), 65% (45~95) and 68% (60~80). In the experienced endoscopist, diagnostic accuracies were high as 65%, 75% and 85%, and high confidence rate was 85%, 95% and 95%, respectively.
Study 2) Overall diagnostic accuracy of WLI, NBI, and near-focus NBI for differentiating adenomas from HPs in trainees were 50% (40~63), 65% (48~78) and 71% (53~83), respectively. Overall rate of high confidence in WLI, NBI and near-focus NBI were 68% (23~90), 80% (68~88) and 80% (60~80). In the experienced endoscopist, diagnostic accuracies were low as 45%, 45% and 60%, and high confidence rate was 83%, 88% and 88%, respectively.

Table: Diagnostic accuracies of the trainees.

	WLI (%)	NBI (%)	Near-focus NBI (%)
Study 1	61 (55~65)	75 (65~85)	80 (75~90)
Study 2	50 (40~63)	65 (48~78)	71 (58~83)

Conclusion: The present study clearly demonstrated that near-focus NBI was superior to WLI and NBI in differentiating neoplastic and non-neoplastic small lesions for the trainees. Near-focus NBI may help trainees to precisely manage colorectal polyps.

Introduction: Indications for colorectal endoscopic submucosal dissection (CR-ESD) include treatment of mucosal tumors with submucosal fibrosis i.e. after previous biopsy or after incomplete endoscopic mucosal resection, EMR. Little is known on the clinical outcomes of this procedure in a western setting.
Aims & Methods: The aim of our study was to evaluate feasibility of CR-ESD as a salvage endoscopic treatment for residual colorectal lesions after incomplete EMR. A retrospective study on a prospectively collected database of endoscopic procedures during period 2013-2015 was done. Data regarding lesion location, the ESD accessories used, procedure time, pathology, margin involvement (R0) and post-procedure complications, were collected.
Results: We identified 9 patients (6 male, 3 female, median age 71 years, range 39-79 years) with this clinical scenario. 8 lessions were located in rectum and 1 in sygmoid colon (median size 25 mm, range 15-80 mm). Lesions included residual adenomas (Paris Is, 7/9pts; Paris Is + IIc, 1/9 pts) and LST-NG (Paris Is + IIa, 1/9 pts). All procedures were done with Dual and Hook knife. Median procedure time was 240 min (range 60-600 min). Pathohistology specimens were: tubular adenoma with low-grade dysplasia (7/9) and villotubular adenoma with high-grade dysplasia (2/9). R0 resection was confirmed in 7/9 pts (78%). Endoscopic treatment of the intraoperative events included closure of perforation (2/9), and hemostasis (3/9). Two-step procedure was needed in 3 patients to complete the resection and post-procedural fever was observed in one patient. During median follow-up of 7 months (range 1-17 months) no delayed complications were observed.
Conclusion: CR-ESD after incomplete EMR is technically demanding and time-consuming procedure. However, in the hands of experienced endoscopist, it is a 'surgeon sparing' procedure that can achieve an acceptable rate of R0.

Contact E-mail Address: mathieu.pioche@chu-lyon.fr
Introduction: Endoscopic submucosal dissection is the reference method to achieve *en bloc* resections for large lesions of the digestive tract. Nevertheless, it is a difficult and risky technique with a long learning curve. To reduce first procedures morbidity, animal models like bovine colon were developed to teach the initial skills. Self-teaching program could be helpful in the western world but also in Asia even if the technique is more spread out. A self-learning software to assist students in the first steps of ESD has been developed by N. Yahagi jointly with Olympus®. We designed this study to evaluate the impact of such a tool on ESD learning curve using a bovine colon model developed previously(1).
Aims & Methods: A prospective randomized comparative study enrolled 37 students (29 in France and 8 in Japan) experienced in interventional endoscopy but not in ESD. Each student was randomized in one of the two groups and performed 30 ESD for a 30 mm simulated rectal lesion in retroflexed position. Group A used the self-learning software whereas group B only observed an ESD procedure movie. No other technical explanation was given to both groups. Procedure duration, resection completeness, perforation rate and the specimen size and surface were assessed. If the procedure exceeded 75 min, the trainee had to stop and we considered it as a failure.
Results: 39 students performed 1170 ESD (group A: 19 students, 570 ESD) (group B: 20 students, 600 ESD) with 57 failures (time out over 75 min) (group A : 26, 4.6%, group B: 31, 5.2%, $p = 0.26$). Among the 1113 resection of a specimen in less than 75 min, the complete resection rate was 76.2% in group A versus 67.4% in group B ($p = 0.001$). The rate of success defined by a complete procedure in less than 75 min without perforation was significantly superior with respectively 70.9% and 61.2% in group A and B ($p < 0.001$). The perforation rate and the procedure duration were not different with 6.0 vs 6.4 % ($p = 0.796$) and 35.7 vs 34.9 min ($p = 0.391$) respectively. Regarding only the 30th procedure of each student, the rate of complete resection was superior in group A with 84.2 versus 70% ($p = 0.292$). Other analyses (learning curve, french vs japanese trainees) are ongoing.
Conclusion: The use of an ESD self-learning software is effective to improve the quality of resection compared to a standard teaching with procedure movies. The main advantage is to save some supervision time. This result suggests to incorporate such a self-learning software in the ESD teaching program.

Contact E-mail Address: thierry.ponchon@chu-lyon.fr
Introduction: Multiple randomized studies have shown that changing certain features in imaging of colonoscopes (structure enhancement, wide angle view, HDTV) do not consistently improve adenoma detection rate. Similarly, change from one endoscope generation to the next one, implementing one or even several new features were not successful in achieving a rise in ADR either. There is however indirect evidence that it might need to skip one colonoscope generation (i.e. change from one generation to the next but one) may have this effect.
Aims & Methods: We therefore compared the latest generation Olympus colonoscopes (Exera III, CF- or PCF-190) with the next to last one (CF- or PCF 165) in a prospective randomized multicenter tandem study. Patients with increased risk for colorectal neoplasia (FOBT positive, personal or familial history of colorectal cancer or adenoma, rectal bleeding, recent change in frequency and consistency of stools) were included. Primary outcome was the adenoma miss rate with 190 colonoscopy in comparison to 165 colonoscopy.
Results: 848 patients (48% male, mean age 58.3 years, range 19-87) with personal (41%) or familial (38%) history of colorectal neoplasia, rectal bleeding (19%) and other indications were included. A total of 304 missed adenomas were found in 197 patients. Of the 425 patients in the intervention group (PC or PCF 190 first), 68 patients (16.0%; 95% CI: 12.5 % - 19.5%) had at least one adenoma missing during the 1st procedure, as compared with 129 of the 423 (30.5%; 95% CI: 26.1% - 34.9%) patients in the control group (PC or PCF 165 first). This difference was significantly different between the 2 study groups ($p < 10\text{-}3$). Adenoma detection rate (percentage of patients with at least one adenoma) during the first colonoscopy was 43.3% (184/425) in the intervention group (190 series) and 36.6% in the control group (165 series) ($p < 0.05$).
Conclusion: Also based on negative results of previous trials, this randomized tandem study shows that it may take two instrument generation improvements before an increase of adenoma miss rate can be observed.

Introduction: Endoscopic submucosal dissection is the reference method to achieve en bloc resections for large lesions of the digestive tract. Nevertheless, it is a difficult technique with long learning curve and relatively high risk of perforation. To reduce the risk of first procedures, animal models have been developed to teach the initial skills. In Japan, stomach ESD is the first step for students and pig stomach is a dedicated model to learn ESD in gastric conditions. In Europe, since the number of gastric lesions is low compared to colonic ones, we have to develop different strategies of teaching with dedicated models. Pig colon is a good model but thinner and more difficult than human and the caliber of the bowel is sometimes too narrow to work in retroflexed position. In this present work, we evaluated a bovine colon model to perform rectal ESD in retroflexed position.
Aims & Methods: In a first step we prepared 6 bowels to perform ESD using Dual Knife® and Nestis Enki II® in order to precise the preparation protocol. Using this protocol, two endoscopists unexperienced in ESD performed 62 procedures of 30 mm on 8 colon models. In parallel, we compared the ellipse

Abstract number: P0804

Parameter		Excellent / Good Bowel Preperation	Fair / Poor / Inadequate Bowel Preperation	OR / t	CI	p
Sex	Male	370	212	1.16	0.92-1.46	0.2
	Female	406	270	0.86	0.68-1.08	0.2
Polyp Detection	PDR	0.322	0.368	0.87	0.69-1.11	0.28
	ADR	0.166	0.191	0.87	0.64-1.20	0.4
Parameter		Excellent / Good / Fair Bowel Preperation	Poor / Inad equate Bowel Preperation	OR / t	CI	p
Sex	Male	500	42	0.79	0.50-1.26	0.33
	Female	540	36	1.26	0.79-2.0	0.33
Polyp Detection	PDR	0.337	0.342	0.98	0.61-1.59	0.94

formula evaluation of specimen area with measured area using a picture size software.
Results: A precise protocol to defrost and to prepare the colon was defined. The lesions were marked with a plastic circle of 28 mm diameter after inversion and swallowing of the bowel. The two students achieved complete en bloc resection in 89.1% of cases with 6.2% of perforations. A large heterogeneity appeared between the speed and the success rate depending on the age of the animal bowel. Using veal colon (animal under 8 months), the rate of failure was significantly higher ($p = 0.002$) and the speed of dissection was significantly lower ($p < 0.001$) than using adult bovine colon (aged between 12 and 24 months). The progression of dissection speed was significant between the first and the second half of the cases with respectively 0.49 and 0.59 cm^2/min using only the cases on adult bovine colon. No significant difference appeared between measured and calculated areas of the specimen.
Conclusion: Bovine colon model is a suitable model to teach ESD in the rectum. Nevertheless, adult bovine colon model is more homogeneous than veal ones and has to be used for comparative works. Calculated area using ellipse formula is a good way to evaluate the size of the specimen with no difference with measured areas using picture measurement software.

P0802 ENDOSCOPIC DIAGNOSIS OF COLORECTAL POLYPS USING BLUE LASER IMAGING AND MAGNIFICATION: IMPACT OF A SHORT TEACHING PROGRAM

M. Barret[1], D. T. Cao[1], S. Grabar[2], M. Camus[1], S. Leblanc[1], J. Dreanic[1], M. Dhooge[1], R. Coriat[1], F. Prat[1], S. Chaussade[1]
[1]*Gastroenterology,* [2]*Epidemiology and Biostatistics, Cochin Hospital, Paris, France*

Introduction: Blue Laser Imaging (BLI) is a new image-enhanced endoscopy technique, proven highly effective, in addition to magnification endoscopy, to differentiate between neoplastic and non-neoplastic colorectal polyps. We sought do determine if these results could be reproduced in a group of non expert western endoscopists after a short teaching program.
Aims & Methods: 120 endoscopic images, including white light endoscopic images, standard BLI, BLI-bright and magnified images of 62 small colorectal polyps were used for the study. These pictures were shown to a group of 138 gastroenterologists who were asked to score each polyp as an adenoma or an hyperplastic polyp. After a one hour teaching lesson dedicated to the diagnostic criteria of hyperplastic and adenomatous lesions under BLI or narrow-band imaging and magnification, a posttest was conducted with the same images arranged in a different order.
Results: 61 gastroenterologists, among which 29 residents and 32 seniors, filled the pre and posttest questionnaires. Only 31.7% had previously received a formalized teaching in any kind of virtual chromoendoscopy. The overall sensitivity, specificity, positive and negative predictive value, and diagnostic accuracy of BLI with magnification for the endoscopic diagnostic of small colorectal adenomas were 0.64 (95% CI = 0.63-0.66), 0.58 (95% CI = 0.55-0.6), 0.81, 0.37, and 0.63, respectively. These numbers were not significantly different in residents and senior endoscopists, and did not significantly improve after the teaching lesson. The proportion of diagnostic certainty improved from 31.5% to 41.9% ($p < 0.0001$) after training.
Conclusion: For non expert Western endoscopists, a one hour teaching lesson is insufficient to acquire basic knowledge in BLI and magnification endoscopy. Longer training programs might be required before such advanced endoscopic imaging techniques can be implemented in France.

P0803 EFFECTIVENESS OF A TRAINING SYSTEM FOR THE IDENTIFICATION OF DIMINUTIVE COLORECTAL POLYP HISTOLOGY USING NARROW BAND IMAGING

M. J. A. Oliman[1], E. M. Bondoc[1], I. Cua[1], A. Rastogi[2]
[1]*Institute of Digestive and Liver Diseases, St. Luke's Medical Center, Quezon City, Philippines,* [2]*Division of Gastroenterology, Veterans Affairs Medical Center, Kansas City, United States*

Contact E-mail Address: mjoliman@yahoo.com
Introduction: Patel et al developed a system that effectively trained gastroenterology fellows to identify diminutive colorectal polyp histology using Narrow Band Imaging (NBI).[1] It, however, requires the presence of an expert to provide active feedback during the training session, limiting its applicability. A modified version of the training system was thus developed and tested, which utilised a computer-based testing module, which provided automated feedback on participant performance.
Aims & Methods: A single-center, prospective, educational evaluation study was conducted among 16 gastroenterology consultants and fellows to assess if the modified training system is effective, and if its effects are durable for at least 3 months. Participants initially watched a teaching presentation that described the NBI findings that distinguish polyp histology. They then used a computer-based testing module, operable using a web browser, that showed 80 videos of diminutive colorectal polyps. Predictions of polyp histology and degrees of confidence were recorded. After each video, the module provided feedback by showing a representative picture of the polyp and providing the actual polyp histology and the NBI findings that support the prediction. Performance was evaluated by comparing predicted histology with actual histology. To evaluate durability of learning, after 3 months, the same videos were shown to the participants, and they were again asked to predict polyp histology.
Results: Participant performance and percentage of high-confidence predictions improved significantly as they progressed through video blocks. Predictions made with high confidence were statistically superior to those made with low confidence. All participants performed well during both study sessions, achieving > 90% accuracy, sensitivity, specificity, PPV, and NPV for high confidence predictions. The participants' experience in endoscopy did not affect performance or percentage of high-confidence predictions.
Conclusion: The modified training system effectively trained participants to identify diminutive colorectal polyp histology using NBI. Learning acquired from this system is durable for at least 3 months. This system is noteworthy in its ability to provide automated feedback and its potential to be used online, making it more applicable in a wider spectrum of clinical settings. Further studies that evaluate the long-term durability of learning from this system, as well as the *in vivo* real-time performance of trained endoscopists are recommended.

P0804 THE ADEQUACY OF BOWEL PREPARATION HAS NO IMPACT ON ADENOMA DETECTION RATES

C. D. Mills[1], A. Swaine[2], C. McCamley[3], V. Portelli[4], **M. Swan**[1]

Introduction: Bowel preparation is recognised as an important factor for the completion of colonoscopy. However, due to heterogenous methodologies of published literature, consensus agreement on the effect of bowel preparation on adenoma detection rate is unclear. There has been an unclear impact of the degree of colonic preparation in the literature, in part because of the differences in methodology between studies. The degree of bowel preparation is used as a marker of colonoscopic adequacy, with current guidelines suggesting shorter interval surveillance for those patients with inadequate bowel preparation at index colonoscopy.
Aims & Methods: To compare the polyp and adenoma detection rates of the adequacy of bowel preparation.
A retrospective study was performed from prospectively collected data from three day endoscopy centers involving 4 experienced gastroenterologists. Twelve hundred procedures were identified. Exclusion criteria included a previously performed partial or total colectomy or in the case of multiple

endoscopies, having a previous colonoscopy within the study period, or in the case where inadequate description of the degree of colonic preparation was found.
Results: A total of 1122 procedures were analyzed. Participants had an average age of 59.95 years, with 51.4% being female. There was no difference between the two groups in terms of demographics, indication or colonic insufflation method used. Results demonstrated there was no statistically significant difference in the adenoma detection rates dependent on the degree of bowel preparation, even when excellent, good and fair preparation were grouped together for subsequent analysis.
Conclusion: The degree of bowel preparation appears to have little bearing on the adenoma detection rate. This finding supports that the adenoma detection rate is independent of bowel preparation, and other factors affecting bowel preparation should be the subject of further study.
Disclosure of Interest: None declared

P0805 THE COLONOSCOPIC ADENOMA DETECTION RATE INCREASES DEPENDING UPON THE METHOD OF INSUFFLATION

C. D. Mills[1], A. Swaine[2], C. McCamley[3], V. Portelli[4], **M. Swan**[1]

Contact E-mail Address: chris.mills@monashhealth.org.au
Introduction: There has been an increasing use of carbon dioxide insufflation recently for colonoscopy as this has been shown to improve patient comfort, shorten procedure duration and decrease the use of post procedural analgesia. There have been no studies to date comparing the difference between adenoma detection rates of carbon dioxide or air insufflation.
Aims & Methods: To compare the polyp and adenoma detection rates of carbon dioxide compared to air insufflation for colonoscopy.
A retrospective study was performed from prospectively collected data from three day endoscopy centers involving 4 experienced gastroenterologists. Twelve hundred procedures were identified. Exclusion criteria included a previously performed partial or total colectomy or in the case of multiple endoscopies, having a previous colonoscopy within the study period.
Results: A total of 1163 procedures were analyzed. Participants had an average age of 59.9 years, with 51.4% being female. There was no difference between the two groups in terms of demographics, time of day of the procedure, and indication. Results demonstrated there was a statistically significant difference in the adenoma detection rates between the two groups. The carbon dioxide group had a significant positive advantage in the detection of adenomas. Other procedural parameters were not statistically different.

Parameter		CO2 Group	Air Group	OR / t	CI	p
Sex						
	Male	316	245	1.04	0.82-1.31	0.75
	Female	332	267	0.96	0.77-1.22	0.76
Age		60.3	59.5	0.978		0.33
Withdrawl Time		7.47	7.32	0.55		0.58
Bowel Preperation						
	Excellent	31	17	1.47	0.80-2.69	0.21
	Good	370	321	0.79	0.62-1.01	0.06
	Fair	180	124	1.21	0.92-1.57	0.17
	Poor	40	22	1.47	0.86-2.50	0.16
	Inadequate	13	4	2.6	0.84-8.03	0.10
Polyp Detection						
	PDR	0.36	0.33	1.13	0.84-1.51	0.41
	ADR	0.22	0.16	1.39	1.02-1.89	0.03

Conclusion: Carbon dioxide insufflation was shown to have better adenoma detection rates when compared with air insufflation. This finding further enhances the case for carbon dioxide insufflation in addition to already established procedural benefits.

P0806 CLINICOPATHOLOGICAL STUDY OF SERRATED LESIONS OF THE COLORECTUM

M. Sugimura[1], M. Iwabuchi[1], T. Fujiya[1], Y. Abe[1], H. Suzuki[2], J. Sakurada[2], K. Ukai[1], K. Tadokoro[1]
[1]*Gastroenterology,* [2]*Pathology, Sendai Medical Center, Sendai, Japan*

Contact E-mail Address: msugimura@snh.go.jp
Introduction: Serrated lesions of the colorectum are the precursors of microsatellite unstable carcinomas. However, their clinical and pathologic features are still unclear and need further exploration.
Aims & Methods: The aims of this study was to clarify the clinicopathological features of colorectal serrated lesions. We reviewed clinical charts and pathological files of 3591 endoscopically resected specimens during January 2007 and December 2014 in our hospital. A total of 282 serrated lesions resected were classified into three categories : HP (hyperplastic polyp), SSA/P (sessile serrated adenomas/ polyps), and TSA (traditional serrated adenoma), according to the WHO criteria. We examined the clinical features of these cases. Then we studied the expressions of Ki-67 and MUCs (MUC2, MUC5AC and MUC6) immunohistochemically to evaluate the differences of the distribution of proliferation and the profile of mucins in these serrated lesions.
Results: Of these 282 lesions, a total of 151 (53.6%) were HP, 63 (22.3%) SSA/P, and 68 (24.1%) TSA. Male to female ratio (M/F) was 2.60 for HP, 1.17 for SSA/P, and 2.40 for TSA. Mean size of SSA/Ps (11.3mm) and TSAs (9.5mm) were significantly larger than that of HP (7.9mm). SSA/Ps were located predominantly in the proximal colon, whereas HP and TSA were mainly located in the sigmoid colon and rectum. 85% of SSA/Ps were flat in macroscopic appearance. SSA/Ps and HPs were whitish or almost the same as adjacent mucosa in color, whereas TSAs had a tendency to be reddish. Magnified colonoscopy showed Type II open pit pattern as characteristic of SSA/Ps, whereas pine-cone-shaped pit pattern as that of TSAs. Incidences of concomitant carcinomas in HP, SSA/P, and TSA were 0% (0 out of 151), 3.2% (2 out of 63), and 2.9% (2 out of 68), respectively. Ki-67 positive cells in HP showed regular, symmetric distribution, and those in SSA/P did irregular asymmetrical pattern, whereas most of those in TSA were distributed in "ectopic crypts". Expression levels of MUC2, MUC5AC and MUC6 were significantly different between the serrated lesions ; SSA/Ps and HPs were positive for MUC5AC in comparison with TSAs.
Conclusion: Our studies showed the three types of serrated lesions have their own distinct features and could be helpful to distinguish between them. SSA/P and TSA are premalignant lesions of colorectum and we should detect these lesions and completely remove endoscopically.

P0807 FLEXIBLE ENDOSCOPY FOR DIAGNOSIS OF TUBERCULOSIS OF A LARGE BOWEL IN PATIENTS WITH HIV/TB CO-INFECTION

M. Reshetnikov[1], I. Sokolina[1], B. Bormotov[1], M. Synitsyn[1], M. Kalinina[1]
[1]*Moscow Government Health Department, Moscow Research and Clinical Center for Tuberculosis Control, Moscow, Russian Federation*

Contact E-mail Address: taxol@bk.ru
Introduction: In patients with HIV/TB co-infection TB-process is characterized by development of generalized and complicated forms with multiple localizations – in lungs, intrathoracic lymph nodes, in inraabdominal, mezenterial lymph nodes, bowel, peritoneum, spleen. Most of the patients of HIV/TB co-infection complain of the abdominal pain, alvine flux, which may be caused by any inflammatory process – both specific or nonspecific, adverse effects of TB-drugs and HIV-therapy. This problem demands attention and diagnostics. Diagnosis of large bowel tuberculosis and inflammatory bowel diseases can be difficult with patients HIV/TB co-infection. Flexible endoscopy and biopsy are necessary for revealing the pathology.
Aims & Methods: Data of 39 patients observed in the surgical department of Moscow Research and Clinical Center for Tuberculosis Control of the Moscow Government Health Department in the period from 2010 to 2014 with the suspecting on TB-process in bowel are examined. 32 (82,1%) patients had lung forms of tuberculosis, 7 (17,9%) patients were hospitalized with the suspecting on TB-process in bowel, these patients had no lung TB. Complex examination of all the patients included ultrasonography of abdominal cavity organs, oesophagogastroduodenoscopy, irrigoscopy, computer tomography of abdominal cavity organs and examination of fecal masses on Mycobacterium tuberculosis by the luminescent microscopy and cultural method. Colonoscopy was performed with biopsy for histological examination, microscopy, cultural method and PCR.
Results: Visual signs of large bowel tuberculosis were observed in 29 (74.4%) of patients. Types of tuberculosis lesions of large bowel are described: military form, infiltrative and infiltrative-ulcerous. They were described as erosion, infiltrative and infiltrative-ulcerous. Epithelioid-cellular granuloma was revealed in the material of biopsy in 19 (48.7%) cases. In 11 (28.2%) cases Mycobacterium tuberculosis was detected. In 2 patients (5,1%) adenocarcinoma of the large bowel was diagnosed, in 3 (7.7%) citomegaloviral ulcerative colitis was observed, in 15 (38.7%) nonspecific colitis was revealed. All the patient were treated with TB drugs, in 22 patients (56.4%) improvements, such as pain and alvine flux elimination were observed, defecation was normalized. 7 patient (17.9%) needed in the correction of TB drug therapy.
Conclusion: To sum up, colonoscopy is a rapid and valuable method of abdominal cavity organs tuberculosis diagnostic.

P0808 SYSTEMIC REVIEWS AND META-ANALYSIS: THE EFFECT OF PATIENT EDUCATION ON BOWEL PREPARATION FOR COLONOSCOPY

M.-J. Chen[1], C.-W. Chang[1], C.-H. Chu[1], T.-E. Wang[1], H.-Y. Wang[1], S.-C. Shih[1]
[1]*Division of Gastroenterology, Department of Internal Medicine, Mackay Memorial Hospital, Taipei, Taiwan, Taipei, Taiwan, Province of China*

Contact E-mail Address: mingjen.ch@msa.hinet.net
Introduction: Colonoscopy is a useful and widely available tool for diagnosing and managing colorectal diseases. [1] According to the US National Polyp Study, colonoscopy can reduce the incidence and associated mortality of colorectal cancer (CRC) and polypectomy can lower colorectal cancer death rates if polyps are detected during colonoscopy.
Aims & Methods: Effectiveness of bowel preparation is closely linked to patient compliance and the subsequent result of colorectal cancer screening.[2] Poor bowel preparation can result in missed colonic neoplasms, a difficult and time-consuming procedure, and an increased risk of complications. This meta-

analysis aimed to determine the effect of educational intervention on the quality of bowel preparation before colonoscopy.
A comprehensive literature review identified randomized controlled trials measuring the effect of educational intervention on the quality of bowel preparation. Two reviewers independently screened relevant articles, extracted data, and assessed the risk of bias. The primary outcome was the quality of each bowel preparation before colonoscopy using a particular assessment scale. The secondary outcomes were polyp detection rates during the procedure and the need for a repeat colonoscopy due to incomplete examination. The quality of all studies was assessed with the 5-point Jadad scale for assessing RCTs. Studies with 3 or more points were considered high quality.
Results: Nine randomized controlled trials were included in this meta-analysis. In all, 2885 patients were enrolled, with 1458 receiving education and 1427 assigned to the control group. Education before colonoscopy can lead adequate bowel preparation. A significant difference was observed in adequate bowel preparation between the education and control groups (OR = 1.97, 95% CI 1.63-2.38). However, no significant differences were identified in polyp detection rates (OR = 1.24, 95% CI 0.79-1.94) and the need for repeat colonoscopy (OR = 0.47, 95% CI 0.21-1.04) between both groups. The subgroup analyses in this meta-analysis based on education delivery methods, use of educational tools, and geographical differences in education delivery indicated that bowel preparation significantly improved after patient education.
Conclusion: Concerning the bowel preparation in all studies the intervention leads to better outcome, the consistency is an important indication to establish the causality. However, there is insufficient evidence to assess improvements in polyp detection rate and avoidance of a repeat colonoscopy.

P0809 CLINICAL OUTCOME OF ULCERATIVE COLITIS WITH MUCOSAL HEALING DEMONSTRATED BY WHITE LIGHT ENDOSCOPY BUT WITH SUBTLE ABNORMALITIES DETECTED BY HIGH DEFINITION ISCAN ENDOSCOPY

M. Fort Gasia[1], X. Gui[2], R. Panaccione[1], G. G. Kaplan[1], S. Ghosh[3], M. Iacucci[1]
[1]*IBD unit, University of Calgary, Calgary, AB,* [2]*Department of pathology,* [3]*Department of Medicine, University of Calgary, Calgary, AB, Canada*

Contact E-mail Address: iacuccim@yahoo.it
Introduction: Current practice is to assess mucosal inflammation in patients with ulcerative colitis (UC) with white light endoscopy (WLE). However, high definition (HD) iSCAN endoscopy can characterize in details the mucosal and vascular pattern to assess mucosal healing (MH) and inflammation. Subtle endoscopic and histologic abnormalities can still be detected in the apparently healed mucosa and the clinical significance of this is still uncertain
Aims & Methods: We aimed to monitor the clinical outcome of patients with Mayo subscore of 0 and to determine if abnormal mucosal and vascular pattern detected on HD iSCAN endoscopy are associated with worse prognosis of the disease.
79 patients (34 female, median age 48, range 19-72) with quiescent UC Mayo subscore of 0 were followed for a median period of 19 months. All of these patients were previously endoscopically assessed by WLE and HD iSCAN (Pentax EPKi processor (EC-3490Fi; Pentax Tokyo) and Mayo endoscopic subscore was assigned to patients according to WLE findings. Mucosal pattern on iSCAN was graded as 1 = normal, 2 = mosaic pattern, 3 = tubular-gyrus, 4 = nodular rosette. The vascular pattern was graded as 1 = normal, 2 = spiral isolated vessels, 3 = crowded tortuous vessels, 4 = irregular vessels. The histologic grading system New York Mount Sinai score was used to assess the grading of inflammation on histology. The clinical outcome was assessed by monitoring Mayo clinical score, CRP levels, further endoscopic evaluation, changes in treatment, use of steroids, introduction of new medication, admission to hospital and colectomy rate. Statistical analysis was performed with Chi Square test and compared the endoscopic findings between patients that flared and patients that remained stable.
Results: Eleven patients (13.9%) out of 79 developed a relapse of UC. The initial endoscopic assessment of these eleven patients showed an abnormal mucosal pattern in 2 patients (18.2%) and an abnormal vascular pattern in 7 patients (63.6%). Amongst the 68 patients that remained stable, 35 (51.5%) presented an abnormal vascular pattern and 10 (14.7%) had an abnormal mucosal pattern on HD iSCAN colonoscopy. Histologic assessment showed quiescent colitis in all patients. There was no statistical significance between patients that relapsed and those that remained stable when comparing the distribution of normal and abnormal iSCAN scoring.
Conclusion: A high proportion of patients with mucosal healing presented subtle residual changes detected by HD iSCAN endoscopy. However, this was not associated with increased frequency of relapse or worse outcome of the disease. A more precise endoscopic score is needed to better describe the endoscopic features of mucosal healing in those patients that relapse after initial Mayo endoscopic score of 0.

Contact E-mail Address: mirjanakalauz1@gmail.com
Introduction: The Croatian National Colorectal Cancer Screening Program was established by the Ministry of Health, and started at September 2007.
Aims & Methods: The Croatian National Colorectal Cancer Screening Program was established by the Ministry of Health, and started at September 2007. The aim of this study is to assess the quality of screening colonoscopy based on the fecal occult blood test (FOBT- guaiac Hemognost card-test).From 1.419.639 individuals invited to CRC screening till the end of first cicle, 288.935 (21%) persons returned correctly applied stool specimen on FOBT cards, and among them there were 15.578 (6.3%) positive. Colonoscopies were performed in 10.428 cases (67%), by 62 endoscopists in 24 centers. The quality of colonoscopies were analyzed for sample of 1003 colonoscopies, using caecal intubation rate (CIR), the adenoma and carcinoma detection rate (ADR, CDR), percentage of polypectomy during the first colonoscopy, and quality of colon cleaning. All parameters were assessed for the whole population, and the individual centers.
Results: In this sample, CIR for whole population was 82%, for individual centres 18–100%. We found 1028 polyps in 391 colonoscopied persons (ADR-39%, for centres 0–51%), and 47 cancers (CDR–4,7%). 428 (42%) polyps were immediate removed during the screening colonoscopy (for centres 0–92%). Remaining polyps, mostly larger than 1.5 cm, were scheduled for second colonoscopy. Colon cleaning was satisfactory for good and complete examination in 690 (68%), inadequate in 248 (25%), and very bad in 65 (7%) persons.
Conclusion: Caecal intubation rate was generally satisfactory in most of endoscopic centres. Numbers of polyps and cancers were very high, but proportion of polypectomies during the first screening colonoscopies was rather low. The poor colon preparation and cleansing was the main reason for inadequate examination and should be improved. On the other hand, it is very important to achieve standardized skills of endoscopists, or even, if needed, temporary exclude inadequatelly trained endoscopists from program. It is also required to assure satisfying endoscopic equipment or exclude centres where it is uncomplete or inadequate.

P0811 IMPACT OF NEW-GENERATION ENDOSCOPES ON COLONOSCOPY RESULTS

M. Szura[1], A. Pasternak[1], R. Solecki[1], A. Matyja[1], on behalf of Jagiellonian University, Ist. Dept of General, Oncological, G. I. Surgery
[1]*Ist Dept of General, Oncological and GI Surgery, Jagiellonian University, Krakow, Poland*

Contact E-mail Address: msszura@gmail.com
Introduction: Colonoscopy remains the most accurate method for detecting pathologic lesions within large intestine. It can reveal colorectal neoplasm at asymptomatic preinvasive stage allowing for its simultaneous treatment. In recent years the amount and quality of endoscopic examinations have systematically risen. Examination technique and endoscopic equipment have evolved. Electronic video endoscopes offer now a wide field of view with high resolution imaging and electronic colorization of mucosa. Mechanical construction of the endoscope has been redesigned to improve coecal intubation.
Aims & Methods: The aim of this study was to compare colonoscopy results of asymptomatic patients from the same endoscopic center across two date ranges separated by 12 year interval. Retrospective analysis enrolled 3905 colonoscopies performed in one endoscopic center in 2000 – 2001 and 2013 respectively. All examinations were financed by the Ministry of Health as a national screening program for early colorectal cancer detection. Patients aged 40-65 without symptoms suggesting colorectal cancer were included. Analysis concerned frequency of pathological lesions detection, cecal intubation and adenoma detection rates.
Results: Patients were divided into two different groups according to the year in which the colonoscopy was performed. Group I involved 1505 patients examined in 2000-2001 and group II - 2400 examined in 2013. Incidence rate of pathological lesions was 18.4% in group I vs. 30.7% in group II regarding polyps, 20% vs. 24% regarding diverticula, 1% vs. 1.3% regarding hemangiomas and 8% vs. 2.2% for inflammatory lesions, respectively. Colorectal detection rate was 1.2% in both groups. Adenoma detection rate increased from 11.2% in group I to 18.12% in group II.
Conclusion: New-generation endoscopes and physicians who constantly improve their skills contributed to improvement of the detection rate of all polyps, adenomas and diverticula. However, colorectal cancer detection rate still remains the same. The inflammatory lesions incidence was less frequently observed in group II, what undoubtedly results from more restrictive qualification of individuals for screening endoscopy.

P0812 COMPARISON AMONG CONVENTIONAL 4L POLYETHYLENE GLYCOL, SODIUM PICOSULFATE AND MAGNESIUM CITRATE, AND LOW-VOLUME PEG PLUS ASCORBIC ACID AS BOWEL PREPARATIONS FOR COLONOSCOPY: A PROSPECTIVE SINGLE-BLINDED RANDOMIZED CONTROLLED TRIAL

M. S. Park[1], B. S. Kim[1], W. K. Lee[1], M. A. Yang[1], J. U. Lee[1], S. H. Yun[1], S. H. Han[1], W. G. Oh[1], Y. J. Lee[1], G. M. Jung[1], Y. K. Cho[1], J. W. Cho[1], J. W. Kim[1]
[1]*Division of Gastroenterology, Department of Internal Medicine, Presbyterian Medical Center, Jeonju, Republic of Korea*

Contact E-mail Address: stromas@hanmail.net
Introduction: There are few data that compare among the three widely used bowel preparations: conventional 4L polyethylene glycol (4L PEG); sodium picosulfate and magnesium citrate(SPMC); and low-volume PEG plus Ascorbic acid(2L PEG + Asc).
Aims & Methods: The aim of this study is to compare among the three bowel preparations in the efficacy, tolerability, and safety.
228 patients undergoing outpatient elective colonoscopy were randomly assigned to one of the three bowel preparations by computerized randomization in a single-blinded prospective study. The three bowel preparations were as follows: Group A (n = 78), 4L PEG solution; Group B (n = 74), 3 sachets of SPMC as a split dose; or Group C (n = 76), 2L PEG + Asc as a split dose. Additional stimulant laxative (Bisacodyl 10mg) was taken at the night before colonoscopy in all groups. All colonoscopy images were recorded into computed video files. One endoscopist blinded to the type of preparation gave a bowel cleansing score using recorded video files according to the Aronchick bowel preparation scale and Boston bowel preparation scale. And tolerability and safety were evaluated by a questionnaire immediately before the procedure.
Results: Age, gender distribution, history of DM, previous abdominal surgery, constipation in the three groups were not different significantly from each other. Data analysis showed that efficacy by Aronchick bowel preparation scale and Boston bowel preparation scale was not different significantly among three groups. There were no significant differences among the three groups in tolerability such as overall satisfaction by visual analogue score, consumed volume, willingness to repeat the same preparation. But, taste in SPMC group was significantly better than that in other two groups. The factors associated with safety such as abdominal distension, nausea, vomiting, general weakness were not significantly different among the three groups.
Conclusion: There were no significant differences among three bowel preparations in colonic cleansing efficacy. But, taste in SPMC group was significantly better than that in other two groups.

P0813 EVALUATION OF THE USEFULNESS OF BALLOON-ASSISTED ENDOSCOPY IN ERCP-RELATED PROCEDURES FOR PATIENTS WITH SURGICALLY ALTERED GASTROINTESTINAL ANATOMY

K. Kuraoka[1], Y. Okabe[1], T. Ushijima[1], Y. Ishida[1], Y. Sasaki[1], G. Sugiyama[1], R. Kaji[1], M. Fukahori[1], M. Yasumoto[1], O. Tsuruta[1], T. Torimura[1]
[1]*Gastroenterology, Kurume University School of Medicine, Kurume, Japan*

Contact E-mail Address: kuraoka_kei@kurume-u.ac.jp
Introduction: The endoscopic approach to pancreatobiliary disease with surgically altered gastrointestinal anatomy has conventionally involved very difficult procedures, but balloon-assisted endoscopy(BAE) has made them practical. In this study, we divided endoscopic retrograde cholangiopancreatography (ERCP)-related procedures performed in our hospital for patients with postoperative gastrointestinal reconstruction into 2 groups, a group using BAE and a group without BAE to retrospectively investigate the usefulness of BAE.
Aims & Methods: The study involved 198 cases (125 patients, including 101 males and 23 females) who underwent ERCP-related procedures performed in our hospital for patients with postoperative gastrointestinal reconstruction (excluding Billroth I reconstruction) between February 2002 and December 2014. Reconstructive procedures included 137 cases of Billroth II (B2), 39 cases of Roux-en-Y (R-Y), and 22 cases of post-pancreatoduodenectomy (or post-choledochojejunostomy). 64 patients had bile duct stones, 22 had malignant biliary strictures, 11 had bilioenteric anastomotic strictures, and 27 had other diseases (such as those who underwent detailed examination for pancreatic tumor). The cases were divided into group A, consisting of 149 cases of normal endoscopy (conventional direct-view endoscopy, colonoscopy, forward oblique viewing endoscopy, and backward oblique-viewing endoscopy), and group B, consisting of 49 cases of balloon endoscopy (single and double balloon endoscopy), to compare the rate of reaching the blind end, cannulation success rate, procedure completion rate, and complications between the groups.
Results: The rates of reaching the blind end were 85.2% (127/149) and 98.0% (48/49) in groups A and B. The cannulation success rates were 92.9% (118/127) and 75.0% (36/48) in groups A and B. The procedure completion rates were 76.5% (114/149) and 65.3% (32/49) in groups A and B. The rate of reaching the blind end was significantly higher in group B ($P = 0.0159$), whereas the cannulation success rate was significantly higher in group A ($P = 0.0011$). There was no difference in the procedure completion rate between the two groups. Complications included 4 cases of mild acute pancreatitis (3 cases in group A and one in group B), two cases of hyperamylasemia (both in group A), and 3 cases of intestinal perforation (two cases in group A and one in group B) (including two cases of emergency laparotomy [one case in group A and one in group B]).
Conclusion: The use of balloon endoscopy improved the rate of reaching the blind end in ERCP-related procedures for patients with postoperative gastrointestinal reconstruction. On the other hand, it is desired to develop not only the technology but also the devices for balloon-assisted ERCP to improve the cannulation success rate and procedure completion rate.

Contact E-mail Address: k.iwahashi@gh.med.osaka-u.ac.jp
Introduction: Endoscopic retrograde cholangiopancreatography (ERCP) is an important procedure for diagnosis and management of pancreato-biliary disease. However, occurrence of complications, especially post-ERCP pancreatitis (PEP) is a huge problem. Rectal administration of 100 mg dose of non-steroidal anti-inflammatory drugs (NSAIDs) was reported to prevent PEP. However, only 25 or 50 mg of NSAIDs can be available and usable in Japan.
Aims & Methods: The aim of this study was to investigate the rate and risk factors of PEP and to assess effectiveness of prophylaxis in Japan. This was a prospective multicenter observational study. We created a common database of ERCP and each endoscopist entered data prospectively. Nineteen centers of Osaka Pancreas Forum joined this study. Study period was from October 2012 to February 2014. This protocol was approved by ethics committee at all participating centers. The definition of PEP was based on consensus criteria.
Results: A total of 2681 patients received ERCP during the study period. Patients who had undergone gastric or biliary surgery (166 patients) and who were unable to reach papilla because of perforation (3 patients), stenosis (6 patients), complications during ERCP (1 patient), or unable to attempt cannulation because of tumor invasion (2 patients) were excluded from analysis. In 2503 patients, the rate of PEP was 6.4%. Multivariate analysis revealed native papilla (odds ratio [OR] 2.96), female (OR 1.78), younger age (35-70) (OR 1.50 compared to age over 70), longer procedure time (more than 60 minutes) (OR 1.96 compared to time less than 30 minutes), pancreatogram (OR 2.57), double-guidewire cannulation (OR 1.87), endoscopic papillary balloon dilation (EPBD) (OR 2.91), biopsy or brush cytology on common bile duct (OR 1.74), transpapillary self-expandable metallic stent insertion (OR 4.71), bleeding after ERCP (OR 4.59), 25 mg administration of rectal diclofenac (OR 2.85 compared to no administration) were the significant risk factors of PEP, and history of acute pancreatitis (OR 0.33), pancreatic cancer (OR 0.53) were the significant protective factor of PEP.
Although 25 mg administration of rectal diclofenac was a significant risk factor, 50 mg administration of that was not a significant risk factor. Taking into account the bias that rectal diclofenac was selectively administered to patients who were considered vulnerable to PEP, 50 mg administration of rectal diclofenac was presumably effective to prevent PEP.
The frequency of PEP in the patients with pancreatic stent placement was significantly decreased compared to those without stent, when they were administered pancreatogram, EPBD, double-guidewire cannulation or biopsy or brush cytology on common bile duct.
Conclusion: We reported the rate and risk factors of PEP in Japan. Pancreatic stent may be effective to prevent PEP in patients with pancreatogram or procedures traumatic for papilla. Twenty-five mg rectal administration of NSAIDs may insufficient to prevent PEP. We need further investigation about administration dose of NSAIDs and its safety.

Contact E-mail Address: hiro1017@yokohama-cu.ac.jp
Introduction: Endoscopic retrograde cholangiopancreatography (ERCP) in patients with surgically altered anatomy is still challenging. In order to attain competence in performing this procedure, intensive training is necessary.
Aims & Methods: The study aim was to express development in ERCP in patients with surgically altered anatomy as a learning curve. We evaluate ERCP procedures by using single-balloon enteroscopy (SBE) at Yokohama City University Hospital (YCUH) in Japan between 2011 and 2014. In our facility, the same endoscopist performed the insertion into the target site, and ERCP procedures.
Results: 4 endoscopists were included in this study who have experienced more than 400 cases of the ERCP in normal anatomy. A total of 211 ERCP procedures were carried out in patients with surgically altered anatomy. The breakdown of surgical procedures was as follows: Roux-en-Y (R-Y) reconstruction (n = 55 [26.1%]), pancreaticoduodenectomy (PD) (n = 46 [21.8%]), hepaticojejunostomy (n = 80 [37.9%]), and Billroth II reconstruction (n = 30 [14.2%]). The overall success rate of reaching the target site was 94.3% (199 of 211 ERCP procedures). The overall mean time required to reach the target site was 22.8 min. The overall ERCP procedural success rate was 88.1% (186 of 211 ERCP

procedures). When the data for all the individual endoscopist assessment periods were combined, the overall insertion rate and ERCP procedural success rate were seen to gradually increase with the total of ERCPs performed in patients with surgically altered anatomy. According to learning curve per block of 10 ERCPs, in the ERCP number of less than 20, insertion rate was 82.0%, ERCP success rate was 75.4%, in 20-30 ERCPs, insertion rate was 93.3%, ERCP success rate was 83.3%, in more than 30 ERCPs, insertion rate was 96.9%, ERCP success rate was 94.0%.

Conclusion: Our findings suggest that more than 30 cases were required for competence development in ERCP with surgically altered anatomy.

Introduction: The role of endoscopic retrograde cholangiopancreatography (ERCP) in the setting of acute billiary pancreatitis (ABP) is still a matter of debate.

Aims & Methods: To evaluate the safety and efficacy of ERCP in ABP and its impact on the outcome. We conducted a retrospective evaluation of ERCP performed in the setting of ABP, over a period of 11 years. Data from ERCP reports and clinical files was analyzed.

Results: Ninety-four cases were observed [Male sex 40 (42.6%); medium age 74.6+/- 12.8 years]. Seventy-three patients (77.7%) presented with severe ABP and 10 patients (10.6%) had associated cholangitis. ERCP was performed in a median of 3 days after ABP onset (range: 0-93), with 58 patients (61.7%) being submitted to early ERCP (<72 hours). Successful canullation was obtained in 92.6% of the cases. Coledocolithiasis was confirmed in 37 cases (39.4%). Spinctherotomy was performed in 83 patitens (91.5%). There were complications related to the procedure in 10 patients (10.6%): 8 post-sphincterotomy bleeding (controlled with endoscopic treatment) and 2 sedation related complications (reverted). Medium in-patient time was 11 days (range: 1-79). Early ERCP did not affect in-patient time. Thirty days mortality was 9.6%. Patients submitted to early ERCP didn't have a significant lower mortality rate. Local complications (pancreatic necrosis, collections, pseudocysts and gastrointestinal bleegind) were seen in 44.7% of cases. There was no significant association between early ERCP and the development of local complications.

Conclusion: ERCP is safe in the setting of ABP. Performance of early ERCP did not affect in-patient time, mortality or the development of local complications.

P0818 ENDOSCOPIC PAPILLARY BALLOON DILATION WITH BILIARY SPHINCTEROTOMY : THE IDEAL TECHNIQUE FOR LARGE COMMON BILE DUCT STONES?

L. C. Lourenço[1], A. M. Oliveira[1], J. C. Branco[1], D. Horta[1], J. T. Canena[1], J. Reis[1]
[1]*Serviço de Gastrenterologia, Hospital Prof. Dr. Fernando Fonseca, Amadora, Portugal*

Contact E-mail Address: luisclourenco@gmail.com

Introduction: Endoscopic papillary balloon dilation (EPBD) with biliary sphincterotomy (BS) has been widely adopted when performing endoscopic retrograde cholangio-pancreatography (ERCP) for removing common bile duct stones larger than 10 mm.

Aims & Methods: The aim of this study was to compare results from EPBD with BS and BS alone (control group, CG) when treating large common bile duct stones.

We performed a rectrospective cohort study involving all cases of large common bile duct stones treated endoscopically in a single institution. The inclusion period was from 2011-2014 (4 years). EPBD was performed using a hydrostatic balloon ranging from 10 to 15 mm. We analysed efficacy (complete extraction, number of sessions needed, need for biliary stenting and lithotripsy), safety (complication rate) and recurrence.

Results: 110 patients were included. EPBD with EST was performed in 73 (66.3%), 61.6% were female and median age was 76 ± 9.4 years. GC comprised 37 patients (33.7%) 54.1% were female and median age was 77 ± 8.2 (p = ns). In EPBD with EST group, 70.6% presented multiple common bile duct stones versus 48.9% in CG ($p < 0.01$). Mean diameter of the largest stone was 15.3 ± 4.2 mm (10-30 mm) versus 16.1 ± 6.3 mm (10-35 mm) in CG (p = ns). The stones were totally removed in a single session in 73.9% versus 40.5% ic CG ($p < 0,01$). Complication (8.2% vs 8.1%, p = ns) and recurrence (5.4% vs 5.4%) rates were comparable between the two groups.

Conclusion: EPBD with BS was safe and effective in removing large common bile duct stones. When compared with BS alone, this method allowed to remove all stones more frequently in a single session, with less need for biliary stenting and no increase in complications.

P0819 ENDOSCOPIC PAPILLARY LARGE BALLOON DILATION FOR TREATMENT OF LARGE BILE DUCT STONES ASSOCIATED WITH POST-PROCEDURE PANCREATITIS – MYTH OR REALITY?

L. C. Lourenço[1], A. Oliveira[1], J. C. Branco[1], D. Horta[1], J. T. Canena[1], J. Reis[1]
[1]*Serviço de Gastrenterologia, Hospital Prof. Dr. Fernando Fonseca, Amadora, Portugal*

Contact E-mail Address: luisclourenco@gmail.com

Introduction: Endoscopic papillary large balloon dilation (EPLBD) is a well-known procedure for the treatment of common duct stones larger than 10 mm. However, it is classified as an independent risk factor for post-procedure pancreatitits (PPP) and is still not recommended as an alternative to sphincterotomy in routine ERCP.[1]

Aims & Methods: The aim of this study was to acess cases of PPP associated with EPLBD in our institution and correlate them patient and procedure related risks factors.

A rectrospective single-center cohort study was performed, including all cases of large common bile ducts (diameter more than 10 mm) treated using EPLBD with biliary sphincterotomy. Inclusion period was four years (2011-2014). To perform EPLBD, a hydrostatic baloon was used (10-15mm) during at least one minute. We defined PPP as a clinical syndrome consistent with acute pancreatitis with hyperamylasemia (level of amylase > 3 times the upper limit of normal) and increased epigastric pain persisting for ≥24 hours after the procedure. We analysed the risk factors for PPP (patient and procedure-related). Incidence and severity of PPP were studied.

Results: 73 patients were included in this study. 61.6% were female. Mean age was 76 ± 9.4 years; 5.4%(n = 4) were younger than 50 years. 4.1%(n = 3) had a previous acute pancreatitis episode. None of the patients had normal bilirrubin levels or was suspected to have of Oddi sphincter disfunction. As for procedure-related risks factors, infundibulotomy was performed in 3 cases; pancreatography and pancreatic sphincterotomy were not performed. PPP prophylaxis was performed in a total of 3 patients (with administration of rectal indometacine in two and pancreatic stent in one). There was not a single case of PPP.

Conclusion: EPLBD with biliary sphincterotomy did not increase the incidence of PPP in patients with large bile duct stones. Its role as an independent risk factor probably deserves a more detailed analysis.

P0820 ERCP-GUIDED CHOLANGIO-PANCREATICOSCOPY USING A SINGLE-OPERATOR SYSTEM. AN APPRAISAL OF ITS CLINICAL VALUE BASED ON A UNIQUE EXPERIENCE

M. Reuterwall[1], L. Enochsson[1], L. Lundell[1], M. Konradsson[1], F. Swahn[1], M. Löhr[1], U. Arnelo[1]
[1]*Center for Digestive Diseases, Karolinska University Hospital, Stockholm, Sweden*

Contact E-mail Address: marcus.reuterwall@gmail.com

Introduction: The single-operator peroral cholangio-pancreaticoscopy enables direct visualization of duct lesions, biopsy, and therapeutic interventions in the biliary and pancreatic ductal systems. This device was introduced into clinical practice in 2007 under the trade name Spyglass (Spyglass direct visualization system, Boston Corp.). Ever since, it has been met with divergent reactions from being a valuable tool for use in diagnosis and therapy to basically offering no relevant information for the ensuing management of the patient. At Karolinska University Hospital the Spyglass technology was introduced early and has since then frequently been utilized according to a standardized protocol. Accordingly we have collected a unique experience and hereby we have critically analyzed the clinical usefulness of the technology in the diagnosis and treatment of biliary-pancreatic diseases.

Aims & Methods: All Spyglass procedures performed between March 1, 2007, and December 31, 2014, were retrospectively reviewed. Each procedure's diagnostic yield and therapeutic value was evaluated using a 4 grade scale; where 1 = No diagnostic or therapeutic value. 2 = Information gained but did not affect clinical decision-making, if a therapeutic intervention was performed it did not alter the clinical course of the patient. 3 = Information gained which had an impact on the clinical decision-making. Therapeutic intervention completed which had a subsequent impact on the course of the disease management. 4 = Essential and critically important information was gained for the clinical decision-making. Therapy performed which solved the clinical problem leading to no further requirements for diagnostic or therapeutic modalities.

Results: Over approximately 8 years, 365 Spyglass procedures were performed. The overall post-procedural morbidity was 13%, where one case of severe pancreatitis was seen. The main indications for the procedure were; indeterminate stricture (28%), primary sclerosing cholangitis (20%), IPMN (17%), complex cholelithiasis (19%), chronic pancreatitis- including lithotripsy (8%) and miscellaneous in 7% of the cases. In 70% of our patients, the bile ducts were the main target whereas the pancreatic duct was aimed for in 22%. When the clinical usefulness was assessed according to the 4 grade scale, we found the Spyglass procedure of pivotal importance in 20% of the cases and grade 3 was scored in

36%. Information gained from, or therapy performed during the procedures did not affect clinical decision-making in 44% (grade 1+2).
Conclusion: The single-operator peroral cholangio-pancreaticoscopy technique is an advanced technique for intraluminal visual inspection, and for therapeutic intervention of the biliary and pancreatic ducts associated with an increased risk of intra- and post-procedural adverse events, which shall be balanced against the information and options offered by the technique. We scored the value of the procedure as clinically significant in 56% of the cases, which signifies an important clinical role, mandating further investigation.

P0821 EVALUATION OF THE SHORT TYPE SINGLE- AND DOUBLE-BALLOON ENDOSCOPY ASSISTED ERCP IN PATIENTS WITH ALTERED GASTROINTESTINAL ANATOMY

M. Shimatani[1], M. Takaoka[1], M. Tokuhara[1], K. Kato[1], S. Miyamoto[1], H. Miyoshi[1], T. Ikeura[1], K. Okazaki[1]
[1]*The Third Department of Internal Medicine, Kansai Medical University, Hirakata, Japan*

Contact E-mail Address: shimatam@hirakata.kmu.ac.jp
Introduction: Background: The pancreatobiliary disease in patients with altered GI anatomy is difficult to be intervened by endoscopic diagnosis and therapies. The development of the balloon assisted endoscope (BAE) radically made the endoscopic approaches feasible. The BAE enabled the deep insertion to the blind end, and the short type BAE made ERCP-related interventions easier to accomplish due to its applicability to almost all the devices that are used for conventional ERCP.
Aims & Methods: Objective: We evaluated utility of ERCP using short DBE (DB-ERCP) and SBE (SB-ERCP).
Patients and Methods: Between February 2006 and February 2015, we performed DB-ERCP in total of 734 patients with surgical anatomic variations (734 procedures (pro.); 400 pro. (220 patients (pts.)) for Roux-en-Y reconstruction (R&Y), 112 pro. (79 pts.) for Billroth II gastrectomy (BII), 110 pro. (44 pts.) for pancreatoduoderectomy (PD), 79 pro (39 pts.) for pylorus preserving pancreaticoduodenectomy (PpPD), and 33 pro. (21 pts.) for others) and SB-ERCP in 26 patients with surgical anatomic variations (26 pro.; 12 pro. (12 pts.) for R&Y, 3 pro. (3 pts.) for BII, 4 pro. (4 pts.) for PD, 5 pro. (5 patients) for PpPD, and 2 pro. (2 pts.) for others). We retrospectively evaluated the success rate of reaching the blind end, the therapeutic success rate, and occurrence of complications.
Results: Result: Deep insertion of the short DBE to the blind end was successful in 665 of the 677 procedures (98.2%). The success rates by type of surgical anatomic variations were; 98.3%for R&Y, 99.1% for BII, 98.2% for PD, 97.5% for PpPD, and 100% for others. Whereas, deep insertion of the short SBE to the blind end was successful in 24 of the 26 procedures (92.3%). The success rate by type of surgical anatomic variations were; 98.1% for R&Y, 100% for BII, 100% for PD, 100% for PpPD, and 100% for others. As for 2 patients in whom short type SBE failed to reach the blind end, the procedure was successfully accomplished after switching the scope to short type DBE. Deep biliary cannulation in DB-ERCP was successful in 702 of the 772 procedures (97.2%). The success rates by type of surgical anatomic variations were; 98.0% for R&Y, 94.6% for BII, 99.1% for PD, 96.1% for PpPD and 93.5% for others. Therapeutic intervention was achieved in all of the 772 procedures in which deep cannulation was successful (100%). Whereas, deep biliary cannulation in SB-ERCP was successful in 22 of the 24 procedures (91.7%). The success rates by type of surgical anatomic variations were; 90.0% for R&Y, 100% for BII, 100% for PD, 100% for PpPD and 50% for others. The therapeutic success rate was 100%. Complications for all the DBE-applied procedures were observed in 40 of the 734 procedures (5.4%). The rates of occurrence by type of surgical anatomic variations were; 5.5% for R&Y, 11.6% for BII, 2.7% for PD, 2.5% for PpPD and 0% for others. For all the SBE-applied procedures, only 1 case of laceration was observed in patients with R&Y (3.8%).
Conclusion: Conclusions: ERCP by BAE is highly effective and safe for pancreatobiliary disease in patients with altered GI anatomy. Especially the short type BAE has proved its high performance, however further improvement is yet to be expected.

P0822 THE PRECUT RATE: IS THERE A CORRELATION WITH INCREASED COMPLICATION RISK? RESULTS-FROM THE GERMAN SPHINCTEROTOMY REGISTRY

M. Bechtler[1,*], A. Bachor[2], K. Westerhausen[3], J. Labenz[4] on behalf of ALGK Study Group, M. Maier[5], R. Jakobs[1]
[1]*Medizinische Klinik C, Klinikum Ludwigshafen, Ludwigshafen,* [2]*BMI Heidelberg, Heidelberg,* [3]*Hegau-Bodensee-Klinikum Singen, Singen,* [4]*Jung-Stilling-Krankenhaus, Siegen,* [5]*Knappschaftsklinikum Saar, Püttlingen, Germany*

Contact E-mail Address: bechtlem@klilu.de
Introduction: Precut sphincterotomy seems to be associated with an increased complication rate. Whether this increased risk is caused by the procedure itself or by unfavourable circumstances under which it is used, is not yet clear. Early application of precut techniques might even reduce complications. Nevertheless, in 2006, the ASGE proposed a target precut rate below 15% as a possible quality indicator for ERCP. Data that show a clear correlation between precut rate and complication risk are missing, especially in a community setting. Here, we report results obtained by the German Sphincterotomy Registry.
Aims & Methods: Data obtained by the German Sphincterotomy Registry were analysed. 44 hospitals in Germany reported all patients that had undergone sphincterotomy during a one-year time frame between 2004 and 2007. Procedural variables concerning sphincterotomy setting and technique were collected prospectively and complication rates assessed before hospital discharge.
Results: 812 precut sphincterotomies and 4529 bile-duct sphincterotomies were included in the analysis. Participating hospitals reported between 26 and 247 sphincterotomies and 0 to 80 precut sphincterotomies during a given one-year period. The median precut rate between hospitals was 15.7% and ranged from 0.0 to 43.5%. Precut sphincterotomy was associated with a significantly increased complication rate of 17.6% vs. 9,0% of patients undergoing standard bile-duct sphincterotomy. An increased complication rate was observed for all subgroups of complications. However, a higher institutional precut rate was not associated with an increased complication risk (Spearman's rank correlation coefficient: 0.04, $p = 0.8$)
Conclusion: In our Registry, which largely represents the common sphincterotomy practice in Germany in community settings, the institutional precut rates varied widely. This seems to reflect differences in the timing and indication for precuts. Although precuts are associated with a higher complication rate, there is no correlation between high institutional precut rate and the higher number of complications, which indicates that a precut itself is no risk factor. We therefore conclude that the precut rate should not be used as a quality indicator for the quality of intraprocedural ERCP.

Contact E-mail Address: bulajic.milutin@gmail.com
Introduction: Fifteen percent of patients with suspected pancreatobiliary malignancy that undergo surgery without a cytological assessment have a benign lesion. Cytological or histological diagnosis of pancreatobiliary malignancies before surgery is desirable in order to avoid unnecessary interventions.
Aims & Methods: We conducted a study in order to assess whether the combined use of biliary brushing and endoscopic ultrasound-guided fine needle aspiration (EUS-FNA) has greater accuracy than the individual procedures in diagnosing pancreatobiliary malignancies before surgery. We recruited 25 patients with probable pancreatobiliary malignancy who underwent both biliary brushing and EUS-FNA at the Gastroenterology Unit of Azienda Ospedaliero-Universitaria Santa Maria della Misercordia, Udine (Italy). After brushing procedure, both collected material and cytology brush were sent for cytological analysis. The results of cytology were compared to the results of histology from surgical specimen, in order to evaluate the diagnostic accuracy of the two procedures.
Results: Histology of surgical specimen confirmed the diagnosis of pancreatobiliary malignancy in 24 of 25 patients, benign lesion caused by chronic pancreatitis was identified in one patient. Cytology from biliary brushing provided a correct diagnosis in 9 patients, with diagnostic accuracy of 36%, including the patient with a benign lesion. For the remaining 16 patients (54%), cytological diagnoses were as follows: indeterminate because of poor quantity or quality of the specimen in 15 patients, negative in one case (1 false negative). EUS-FNA provided a correct diagnosis in 18 patients with diagnostic accuracy of 72%, including the patient with a benign lesion. In 7 patients (28%) EUS-FNA didn't provide any result because of the poor quality of the specimen. The combined diagnostic accuracy of both methods was 80% as they together provided a correct diagnosis in 20 patients. The additional diagnostic gain derived from the joint use of biliary brushing and EUS-FNA was 11 cases, compared to biliary brushing alone (+44%) and 2 cases compared to EUS-FNA alone (+8%).
Conclusion: The combined use of the EUS-FNA and biliary brushing results in increased accuracy of cytological diagnosing in pancreatobiliary malignancies. The biliary brushing as an addition to EUS-FNA should be considered in patients undergoing the endoscopic retrograde cholangiopancreatography (ERCP) in therapeutic purposes.

P0824 A NEW PROTOTYPE OF SHORT SBE FOR ERCP IN PATIENTS WITH SURGICALLY ALTERED ANATOMY

M. Kida[1], H. Yamauchi[2], K. Okuwaki[2], S. Miyazawa[2], T. Iwai[2], H. Kikuchi[2], M. Watanabe[2], H. Imaizumi[2], W. Koizumi[2]
[1]*Endoscopy Center,* [2]*Gastroenterology, Kitasato University Hospital, Sagamihara, Japan*

Contact E-mail Address: m-kida@kitasato-u.ac.jp
Introduction: The recent advent of balloon enteroscopy has achieved to perform ERCP in patients with surgically altered anatomy. However we have to use special long devices because of the long length of endoscope and can't use wire-guided devices because of smaller channel. Then we have designed newly developed short-type prototype of single balloon enteroscope (SBE) and investigated its usefulness.
Aims & Methods: Then we have designed newly developed short-type prototype of single balloon enteroscope (SBE) and investigated its usefulness. From 2009 up to now, we have performed 233 ERCP in 160 patients (R-Y: 110, B- II: 50) with a new prototype of short enteroscope, which is 152 cm in length, 9.2 mm in diameter, and with 3.2 mm working channel. And we historically compared with a standard enteroscope which is used in 26 patients (R-Y: 18, B- II: 8) from 2007 to 2009, 200 cm, 9.2 mm, and with 2.8 mm working channel.
Results: Among the all sessions of ERCP, the rate of prototype and standard one of reaching the blind end was 88% (136/155), 84% (16/19) in R-Y, and 95 % (74/78), 100% (9/9) in B-II. The diagnostic success rates were 81%(80/99), 68% (11/16) in R-Y, and 84% (27/31), 89% (8/9) in B- II. The therapeutic success rates were 94% (75/80), 90% (9/10) in R-Y, and 96% (64/67), 100% (8/8) in B-II. The mean procedure time were 44.0 min., 50.6 min. in R-Y and 41.0 min., 38.4 min. in B-II. Because of the short length of endoscope, most conventional devices of ERCP could be used. And because the channel diameter was 3.2 mm, we could perform with wire guided devices. Hyperamylasemia and post-ERCP pancreatitis occurred 15.5% (24/155), 18.8% (3/16) and 5.2% (8/155), 12.5% (2/16) in R-Y, and 7.7% (6/78), 11.1% (1/9) and 0% (0/78), 0% (0/9) in B- II. Perforation occurred 2.6% (4/155), 0% (0/18) in R-Y, and 1.3% (1/78), 0% (0/9) in B- II.
Conclusion: Short-type SBE is effective for ERCP in patients with surgically altered anatomy and allows most conventional ERCP devices to be used.

P0825 USEFULNESS OF CONTRAST-ENHANCED EUS FOR INTRADUCTAL PAPILLARY MUCINOUS NEOPLASM (IPMN) PATIENTS WITH MURAL NODULES

M. Fujita[1], T. Itoi[1], A. Sofuni[1], T. Tsuchiya[1], S. Tsuji[1], K. Kamada[1], R. Tanaka[1], R. Tonozuka[1], M. Honjo[1], S. Mukai[1], K. Yamamoto[1]
[1]*Gastroenterology and Hepatology, Tokyo Medical University, Tokyo, Japan*

Contact E-mail Address: fujita.com.com@gmail.com
Introduction: Endoscopic ultrasonography (EUS) is a modality with high resolution. Recently, EUS has made it possible to use new diagnostic imaging techniques, such as contrast-enhanced EUS (CE-EUS). Furthermore, CE-EUS has been reported to be useful in evaluating for Intraductal papillary mucinous neoplasm (IPMN) with mural nodules.
Aims & Methods: The aim of this study is to evaluate the usefulness of CE-EUS relative to other imaging methods for diagnosing mural nodules of IPMN. 17 patients of IPMN who underwent CE-EUS were enrolled. EUS device system was HI VISION900 or HI VISION Avius (Hitachi Aloka Medical, Inc.) and, EG3870UTK endoscope (Pentax Co., Ltd.), or using ProSound SSDα-10 (Hitachi Aloka Medical, Inc.) and GF-UE260-AL5 endoscope (Olympus medical systems).The contrast agent used was Sonazoid® (DAIICHI SANKYO COMPANY). CE-EUS was performed after the B-mode EUS observation.
Results: The male/female ratio was 11:6, mean age was 61.8(38-78) years old, and mean cyst diameter was 20.5(8.2-50) mm, and mean diameter mural nodule was 7.3(2-16)mm . The modality by which mural nodules were detected was EUS for 5 patients, US for 5, CT for 4 and MRI for 3. Of the 17 patients, mural nodules were detected by EUS B-mode in 12 patients. B-mode imaging showed slightly high echo in 3, and low echo in 9 patients. The mural nodules in 5 of 12 patients was enhanced by CE-EUS. Seven mural nodules was not enhanced to diagnose as mucus lump or debris. Three of 7 patients with enhanced mural nodules were operated. The pathological diagnosis was Intraductal papillary mucinous carcinoma (IPMC) in 1 and Intraductal papillary mucinous adenoma(IPMA) in 2 patients.
Conclusion: CE-EUS is useful in evaluating whether mural nodule of IPMN or tumor.

Contact E-mail Address: soukaina.ra@gmail.com
Introduction: In developing countries, access to medical care for populations outside the large urban centers is often difficult. Endoscopic retrograde cholangiopancreatography (ERCP) is a gold standard in the management of pancreatobiliary diseases. It is often reserved for tertiary referral hospitals and until now, it is only available in a few centers in Morocco. The aims are to study the benefits of these humanitarian actions and to determine the challenges to achieve this kind of procedure in remote areas.
Aims & Methods: This is a prospective study carried out from April 2014 to April 2015, including all the medical campaign organized by "Action Urgence" Association (AU), in partnership with the Ministry of Health, local autorithies and other various partners, in public or private hospitals in the secluded areas of Morocco. We included all the patients who underwent ERCP. The characteristics collected were: age, gender, indication, outcome, complications and the main difficulties in realizing such procedures.
Results: During our study, AU organized 11 medical campaigns on a 12-month period all over Morocco, through mobile clinics involving many specialities such general surgery, pediatric surgery, ophthalmology and general medicine. Every event lasted an average of 3 days. 44 patients underwent ERCP: 30 women (68.1%) and 14 men (31.8%). The mean age was 48 years (11-80 years). The procedure was performed for treatment of choledocholithiasis in 36 cases (81.8%) (including 8 cholangitis and 5 pancreatitis), for a traumatic stenosis of the commun biliary duct (CBD) in 3 cases (6.8%), for a tumor stenosis requiring the placement of stents in 2 cases (4.5%), for a hydatid cyst fistulizing in the CBD in 2 cases (4.5%), and for 1 suspected sphincter oddities (2.27%). 5 patients (11.3%) underwent combined treatment (cholecystectomy under coelioscopy followed by endoscopic treatment) in the same procedure. The average length of hospital stay was 24 hours. We realized 35 sphincterotomies (79.5%), 6 infundibulotomies (13,6%) and 1 sphincteroclasy (2.27%). The biggest stone extracted measured 5/3 cm. treatment success was obtained from the first session in 38 patients (86.3%): 3 patients required performing a second procedure. Treatment by ERCP failed in 3 cases (6.8%). Complications were represented by 1 case of acute pancreatitis (2.27%). 1 death (2.27%) occurred as a result of severe cholangitis. The main difficulties met in these campaigns were: availability of the X-ray image intensifier, selection of patients and the difficulty of follow-up.
Conclusion: Performing ERCP in mobile hospitals provides access to tertiary centers care for population of remote areas. Our study demonstrates the feasibility of this procedure showing a good results and an acceptable complication rate. However, the organization of this kind of mobile unit requires an experimented multidisciplinary team and a significant investment.

Contact E-mail Address: osam@belle.shiga-med.ac.jp
Introduction: Endoscopic retrograde cholangiopancreatography (ERCP) often requires deep sedation because it is an invasive procedure. Although propofol has been widely used and accepted for ERCP, these agents occasionally cause respiratory depression. Dexmedetomidine (DEX), a highly selective α2-adrenoreceptor agonist with sedative effects and minimal respiratory effects, has recently been widely used for patients in the intensive care unit. However, its usefulness in endoscopic procedures remains unclear, particularly for elderly patients because of its effects on cardiac depression. In this study, we retrospectively investigated the safety and efficacy of DEX sedation during ERCP.
Aims & Methods: Among the patients who underwent ERCP from January 2013, 126 patients were sedated using DEX (intravenous infusion of 3.0 μg/kg/hr over 10 min followed by continuous infusion at 0.4 μg/kg/hr) with the addition of midazolam and pentazocine. Thirty elderly patients (> 81 years) were included in the study group. Additionally, pentazocine, midazolam, and propofol were administered as required to maintain a Ramsay sedation scale level of 4. For the control group, we collected information from patients who had undergone ERCP before January 2013 and who had been sedated with midazolam and pentazocine without DEX. The outcome measures were the amounts of midazolam and pentazocine administered, any adverse events associated with sedation, and patients hemodynamics.
Results: The incidence rate of decreased SpO_2 levels (3.5% vs. 11.6%, $p = 0.04$) and the median dose of additional midazolam and pentazocine were significantly lower in the DEX group than in the control group (5.2 mg vs. 12.5 mg and 7.5 mg vs. 11.4 mg, respectively; both at $p < 0.001$). There were no cases in whom propofol was required or the procedure had to be discontinued because of respiratory depression in the DEX group. The blood pressures and pulse rates were significantly lower in the DEX group than in the control group. The lower pressures and pulse rates were more common in the elderly patients in the DEX group. However, no patients required a vasopressor or suffered cardiac failure in the study group.
Conclusion: DEX reduced the incidence of respiratory complications and the total doses of other sedative agents that are concurrently administered. DEX can be used as an alternative to conventional methods for adequate sedation during ERCP even in elderly patients.

P0828 FULLY COVERED METAL STENTS VS MULTIPLE PLASTIC STENTING IN THE TREATMENT OF BILIARY STRICTURE AFTER LIVER TRANSPLANTATION: COST-EFFECTIVENESS ANALYSIS

P. Cantù[1], I. Parzanese[1], R. Rosa[1], A. Tenca[1], D. Conte[1], R. Penagini[1]
[1]*Department of Pathophysiology and Transplantation, Gastroenterology and Endoscopy Unit, Fondazione IRCCS Cà Granda, Ospedale Maggiore Policlinico, Università degli Studi di Milano, Milan, Italy, Milan, Italy*

Contact E-mail Address: paolo.cantu@policlinico.mi.it

Introduction: Multiple plastic stenting (MPS) is the traditional first-line endotherapy for anastomotic biliary stricture (ABS) after orthotopic liver transplantation (OLT). However, MPS requires multiple procedures to progressively maximize dilation of ABS, thus accounting for the high costs related to the procedures and hospital stay.

Aims & Methods: Aim was to compare, in patient with ABS, fully covered self expandable metal stent (FCSEMS) with MPS as concerns respective effectiveness, complications and costs. 25 OLT patients with clinically relevant ABS were retrospectively reviewed (#12) or prospectively collected (#13). FCSEMS and MPS groups were balanced for sex, age, etiology of cirrhosis and time from OLT. Eight or 10 mm large FCSEMS were used according to biliary duct diameter and removed after 4-6 months. Number of 10 Fr plastic stents was increased at 3 months interval up to maximal dilation. At stent removal, technical success was assessed by the easy passage of a balloon catheter through the anastomosis. During follow-up patients underwent clinical, laboratory and ultrasound abdominal examinations according to a standardized protocol. In case of technical failure or ABS recurrence, the patient was crossed-over to the other endoscopic procedure, whereas surgery was carried out when facing with endotherapy failure after cross-over. Overall costs included both procedures, stents and hospitalization.

Results:

	FCSEMSn = 10	MPSn = 15	p
ERCP, #pt (range)	2 (2-3)	4 (3-9)	**<0.01**
Technical success, n (%)	9 (90%)	14 (93%)	ns
Clinical success, n (%)	8 (80%)	14 (93%)	ns
Endoscopy costs (€) / pt,	4.432	6.509	**<0.01**
Hospitali stay costs (€) / pt,	2.400	6.720	**<0.01**
Treatment costs (€) / pt,	6.352	13.452	**<0.01**

Complications occurred in 2 (8.6%) cases after FCSEMS and in 3 (4.4%) cases after MPS (p = ns). Endotherapy duration was 4 (3-18) and 8 (4-55) months in the FCSEMS and MPS groups (p = 0.001). After cross-over, endotherapy achieved clinical success in 24/25 (94%) pts at 19 (3-84) months.

Conclusion: Technical and clinical success and complication rate of FCSEMS and MPS were comparable, but FCSEMS achieved a significant reduction in costs, because of a lower number of procedures and a shorter length of hospital stay. These preliminary data suggested the role of FCSEMS as first-line endotherapy in ABS. A larger controlled randomized trial is currently ongoing to confirm the above findings.

Disclosure of Interest: None declared

P0829 TOLERABILITY OF COVERED METAL STENTS VS MULTIPLE PLASTIC STENTS FOR TREATMENT OF ANASTOMOTIC BILIARY STRICTURE AFTER LIVER TRANSPLANTATION. INTERIM ANALYSIS OF A RANDOMIZED STUDY

I. Parzanese[1], R. Rosa[1], A. Tenca[1], L. Kylänpää[2], M. Udd[2], O. Lindström[2], D. Conte[1], R. Penagini[1], **P. Cantù**[1]
[1]*Department of Pathophysiology and Transplantation, Gastroenterology and Endoscopy Unit, Fondazione IRCCS Cà Granda, Ospedale Maggiore Policlinico, Università degli Studi di Milano, Milan, Italy, Milan, Italy,* [2]*Department of Gastrointestinal Surgery, Helsinki University Central Hospital, Abdominal Center, Helsinki, Finland*

Contact E-mail Address: paolo.cantu@policlinico.mi.it

Introduction: First-line endoscopic treatment of the anastomotic biliary stricture (ABS) is under debate. After orthotopic liver transplantation (OLT), high rate of technical and clinical success may be achieved by both multiple plastic stents (MPS) or covered self-expanding metal stent (CSEMS). However tolerability of these two endotherapies has never been evaluated, deserving integration in the ongoing randomized studies on effectiveness.

Aims & Methods: This prospective series was aimed at evaluating *tolerability and effectiveness* of CSEMS vs MPS in ABS management. From June 2013, 23 OLT pts with ABS were randomized to MPS or CSEMS in two Academic Centres. Age, sex, etiology of cirrhosis, time from OLT and severity of ABS were balanced between study groups. *Tolerability* was evaluated on: intensity of abdominal pain (Numerical Rating Scale, NRS), use of analgesics, need of pethidine, length of hospital stay (LOS ≥ 1 day) and early removal of stent for persistent pain. NRS was administered 1 day before ERCP (basal value) and daily after procedure with a thirty-day diary. To overcome intrapatient variability, for each value reported after maximal MPS or CSEMS, ΔNRS(daily value – basal) was evaluated. An easy transanastomotic passage of a balloon inflated at the diameter of native bile duct was considered as technical success, whereas absence of symptoms, cholestasis and bile duct dilation at US tested for clinical success. Tolerability data were correlated with severity of ABS, maximal diameter of stenting and type of endotherapy. ΔNRS > 4 was considered as relevant abdominal pain. Data were expressed as median ± IQ range. Mann-Whitney and Chi-squared (χ^2) tests were used.

Results: Tolerability data are summarized in the Table.

Parameter		MPS(n = 10)[1]	CSEMS(n = 12)	p
Pain	Pt # (%)	2 (20)	8 (67)	**<0.05**
ΔNRS (range)	0 (-2:9)	3 (-1:8)	ns	
ΔNRS > 4	Pt # (%)	2 (20)	5 (42)	ns
Need for:				
- drugs	Pt# (%)	2 (20)	8 (67)	**<0.05**
- pethidine	Pt # (%)	0 (0)	4 (33)	**<0.05**
Prolongation of LOS	Pt # (%)	1 (10)	6 (50)	**<0.05**

[1]*One patient was excluded because of mild post-ERCP pancreatitis*

Intensity of pain and use of drugs did not differ for other scheduled recordings. No patient underwent early stent removal for persistent pain and treatment is still ongoing in two MPS and three CSEMS pts. Technical success was achieved in 7 of 8 MPS pts (87%) and in 8 of 9 CSEMS ones (89%, p = ns). In one case, MPS failed due to bleeding and cross-over to CSEMS was needed for ABS treatment and hemostasis as well; in one case CSEMS failed for early migration and cross-over to MPS was needed due to cholangitis. Clinical success was achieved in 5 of 8 MPS patients (62%) at 7 mos (3-8) and in 7 of 9 (77%) CSEMS patients at 2 mos (1-16). ABS recurred in two MPS cases at 3 and 5 mos; the first was retreated with CSEMS and the other with maximal MPS. Technical and clinical success rates were not related to characteristics of population. Use of pethidine was associated with a more severe grade of ABS (>90%) (p = 0.04) and use of CSEMS but was not correlated with maximal diameter of stenting.

Conclusion: Due to its more rapid expansion, the need for analgesics was higher with CSEMS leading to a longer hospital stay. Noteworthy, the occurrence of abdominal pain did not impact on the success rate of endotherapies.

P0830 BALLOON ASSISTED ERC - AN ALTERNATIVE IN BILE DUCT DISORDERS IN PATIENTS WITH SURGICALLY ALTERED ANATOMY

P.-O. Stotzer[1]
[1]*Internal Medicine, Sahlgrenska University Hospital, Göteborg, Sweden*

Contact E-mail Address: per-ove.stotzer@vgregion.se

Introduction: Bile duct disorders in patients with surgically altered anatomy are a growing problem. ERC performed with a ballon assisted enteroscope has been reported as a way to handle these problems.

Aims & Methods: To evaluate double-ballon assisted ERC in postsurgical patients. ERC were performed with a double-balloon enteroscope with a working channel of 2.8 mm. All examinations were performed by a single investigator.

Results: Thirty-six investigations were performed in 29 patients, 15 women and 14 men. Mean age was 53 year, range 17 – 73. Surgery altering the anatomy was: Liver transplantation (n = 13), Whipple-procedure (n = 5), gastric by-pass (n = 5), Billroth II (n = 4) and Bile duct reconstruction after iatrogenic damage (n = 3). Seventeen had a biliodigestive anastomosis and 12 had an intact papilla. Mean procedure time were 86 min. 23/36 procedures were performed in full anesthesia. Overall success rate per procedure were 24/36 (67 %) and per patient 22/29 (76 %). Following procedures were successfully performed: Brush- cytology (n = 4), papillotomy + dilatation of the papilla + stone-extraction (n = 3), papillotomy + stone-extraction (n = 2), stone-extraction (n = 2), dilatation of the hepaticojejunostomy + stone-extraction (n = 2), stent-removal (n = 2), stent-insertion (n = 1). Five subjects had bile ducts without pathology, of whom two had an inconclusive MRCP and 3 had a false positive MRCP. Three patients had complications: one had a bowel perforation, one mild pancreatitis and one subject had post-procedural abdominal pain.

Conclusion: Balloon assisted enteroscopy is a feasible way to gain access to bile ducts in patients with altered anatomy. However, it is cumbersome and should probably be used in selected cases.

Disclosure of Interest: None declared

P0831 THE POLYMORPHISMS AT PRSS1-PRSS2 AND MORC4 LOCI AND THE RISK OF POST-ERCP PANCREATITIS

P. Angsuwatcharakon[1], P. Sodsai[1], R. Rerknimitr[1], N. Hirankarn[1]
[1]*Medicine, Chulalongkorn University, Bangkok, Thailand*

Contact E-mail Address: borndeb@yahoo.com

Introduction: The risks of post-ERCP pancreatitis (PEP) are identified as patient- and procedure-related factors. Recent data show that the polymorphisms of *PRSS1-PRSS2 (rs10273639)* and MORC4 *(rs12688220)* are associated with recurrent acute pancreatitis and chronic pancreatitis. However, the genetic contribution for PEP is still unclear.

Aims & Methods: We aim to evaluate the association between these polymorphisms and post-ERCP pancreatitis in order to improve better prognosis and better care for these patients. This is a retrospective, case-control study includes 49 cases and 101 controls that had age-, procedure-, and risk of PEP-matched with the cases in 1:2 fashion. The PEP was diagnosed and graded for severity according to the standard consensus, and the risk factors of PEP were identified according to ESGE guideline. Polymorphisms at *rs10273639* and *rs12688220* were evaluated by TaqMan technique and were identified in 133 (40 cases & 93 controls) and 150 patients repectively.

Results: The demographic data between 2 groups are not significantly different. The genotype frequencies of *PRSS1-PRSS2* (TT, TC, CC) are 26, 13, and 1 vs 67, 25, and 1 in cases and controls, respectively (p = 0.642). The genotype frequencies of *MORC4* in female (TT, TC, CC) are 8, 23, and 5 vs 12, 27, and 21 in cases and controls, respectively (p = 0.071). The genotype frequencies of *MORC4* in male (T, and C) are 5, and 8 vs 21, and 17 in cases and controls, respectively (p = 0.468). The allelic frequency of MORC4 in combination of both genders (T, C) are 44, and 41 vs 72, and 86 in cases and control, respectively (p = 0.431). In PEP cases, the allelic frequencies of PRSS1-PRSS2 (T, and C) are 59, and 13 vs 6, and 2 in mild and moderate/severe cases, respectively (p = 0.633). The allelic frequencies of MORC4 (T, and C) are 38, and 39 vs 4, and 4 in mild and moderate/severe cases, respectively (p = 0.972).

Table 1: Baseline characteristic and results of polymorphisms of PRSS1-PRSS2 and MORC4

	Case (n = 49)	Control (n = 101)	P-value
Age, mean (SD) (years)	60.3 (14.1)	60.0 (15.4)	0.901
Gender (%female)	72%	61%	0.145
Risk group (%high risk)	67%	63%	0.632
PRSS1-PRSS2 genotype frequency* TT TC CC	26131	67251	0.642
MORC4 genotype frequency TT (female)/ T (male) TC (female) CC (female)/ C (male)	8/5235/8	12/212721/17	0.071 (female)/ 0.468 (male)
PRSS1-PRSS2 allelic frequency* T C	6515	15927	0.493RR (95%CI) = 0.81(0.52-1.28)
MORC4 allelic frequency T C	4441	7286	0.431RR (95%CI) = 1.17(0.83-1.66)

* n = 113 (40 cases and 93 controls)

Conclusion: Polymorphisms at *PRSS1-PRSS2* and *MORC4* are not associated with the risk or severity of post-ERCP pancreatitis.

Disclosure of Interest: None declared

P0832 A RANDOMIZED ASSESSMENT OF A SEMI-DISPOSABLE, FIBEROPTIC SINGLE-OPERATOR CHOLANGIOSCOPE WITH A FULLY-DISPOSABLE, DIGITAL SINGLE-OPERATOR CHOLANGIOSCOPE IN A BILIARY TRACT BENCH MODEL

R. J. Shah[1], H. Neuhaus[2], M. Parsi[3], D. Reddy[4], D. K. Pleskow[5]

[2]*Gastroenterology, Evangelisches Krankenhaus Dusseldorf, Dusseldorf, Germany,*
[3]*Gastroenterology, Cleveland Clinic Foundation, Cleveland, United States,*
[4]*Gastroenterology, Asian Institute of Gastroenterology, Hyderabad, India,*
[5]*Gastroenterology, Beth Israel Deaconess Medical Center, Boston, United States*

Contact E-mail Address: raj.shah@ucdenver.edu
Introduction: A new four-way tip deflection digital single-operator cholangioscope (DSOC); (SpyGlass DS ™ Boston Scientific, MA) has a complementary metal-oxide semiconductor (CMOS) chip for higher resolution, magnification, and field of view; it has a thin copper cable for digital transmission and lacks a separate fiber optic probe which may improve catheter tip articulation. The processor is portable for simplified setup.
Aims & Methods: The aim was to compare maneuverability between the fiber optic SOC (FSOC) and DSOC. A biliary tract model devised after input from the authors (PULSE R&D, Southampton, PA) contained three fixed "left intrahepatic" (LIHD) tracts at varying angles with colored terminal targets and a variable "common bile duct" (CBD) and "right intrahepatic" (RIHD) tracts each with two ~4mm colored targets, respectively, and multiple configurations. Seven targets were placed on the circumference. Investigators were blinded to target locations. Runs were randomized and timed with a goal to target each colored area using forceps (Spybite™). Definitions: Visual Success – identifying targets; Targeting Success – touching a target with a forceps; Complete Run – touching all targets with a surrogate metric for futility of 20 minutes. Image quality and ease of use was recorded on a visual analog scale (VAS) of 0 to 10. Time to completion was analyzed using a t-test and a negative binomial model was used to test visual and targeting success between the groups (SAS 9.4).
Results: A total of 39 runs were completed by five expert investigators; 2 were excluded due to inadequate randomization and 37 (20 DSOC, 17 FSOC) were analyzed. DSOC was superior to FSOC in terms of Visual (96% vs. 66%, p < .001) and Targeting Success (6.6 vs. 4.5, p = .007) and Complete Runs (13/20 vs. 0/17, p < .001). Five FSOC trials terminated due to futility. For fixed LIHD, DSOC achieved higher targeting success compared to FSOC (2.6 vs. 1.1, p < .001); no difference was seen with RIHD and CBD targets (4.0 vs. 3.4, p = 0.39). DSOC run completion time (minutes) was faster than FSOC (mean 10.1 vs. 15.4, p < 0.001). By VAS (0-10), investigators reported superior image quality and ease of use with the DSOC.

TABLE 1: Comparison of Fiberoptic Single-Operator Cholangioscopy with Digital Single-Operator Cholangioscopy

	Fiberoptic SOC (n = 17)	Digital SOC (n = 20)	P-value
Percentage of Targets Visualized (n)	66% (79/119)	96% (134/140)	<0.001
Variable (n)	90% (61/68)	100% (80/80)	<0.001
Fixed (n)	35% (18/51)	90% (54/60)	<0.001
Successful Targeting per Run	4.47+/-0.72	6.55+/-0.69	0.007
Variable Targets	3.41+/-0.71	3.95+/-0.22	0.394
Fixed Targets	1.06+/-0.24	2.60+/-0.68	<0.001
Time of Run	15.35+/-4.00	10.05+/-3.72	<0.001
VASImage Quality	4.25+/-0.96	8.25+/-0.50	<0.001
VASEase of Use	4.75+/-0.96	8.50+/-0.58	<0.001

Conclusion: 1) In this benchtop biliary tract model that simulated CBD and intrahepatic ducts with variable and fixed colored targets, respectively, DSOC performed superiorly to FSOC with respect to image quality and maneuverability based on the metrics of visualization, targeting, and complete runs. 2) Whether these advantages will translate to higher clinical success or be appreciated by non-experts requires further investigation.

P0833 EUS-GUIDED GALLBLADDER DRAINAGE : AN ALTERNATIVE TREATMENT FOR ACUTE CHOLECYSTITIS

J. Privat[1], H. Demmak[1], I. Patrascan[1], L. Bianchi[1]
[1]*Gastroenterology, Centre Hospitalier de Vichy, Vichy, France*

Contact E-mail Address: jocelyn.privat@ch-vichy.fr
Introduction: Therapeutic EUS has greatly improved since the past years. Endoscopic ultrasound-guided gallbladder drainage (EUS-GBD is one of the next challenges in the field of therapeutic EUS and may become an alternative to the conventional percutaneous transhepatic gallbladder drainage for acute cholecystitis in non-surgical candidates.
Aims & Methods: This is a single center case-study of 10 EUS-GBD. All cases were reviewed retrospectively from June 2014 to March 2015. Surgery was contraindicated for all patients, most being in a palliative situation. Primary outcomes measured were technical and clinical success. Secondary outcomes were adverse events and recurence of cholecystitis.
Results: 10 patients underwent EUS-GBD with a mean age of 79 (62-92, 3M/7F). The mean follow up time was five months (3 days - 8 months). 7 cases were performed for malignant disease (pancreatic and biliary cancers). Transmural acces was prefered, offering better stability, from duodenal bulb in 8 cases and from gastric antrum in 2 cases. EUS-GBD was achieved by placement of combined metallic and plastic stents with stent in stent technique (Boston Scientific WallFlex™ biliary fully covered metallic stent 10mm x 4cm with double pigtail plastic stent 7Fr x 5cm). Technical and clinical success occured in all cases with no early adverse event. A delayed stent migration occured in one case at 3 week and was discovered by recurrence of cholecystitis, managed conservatively.
Conclusion: EUS-GBD appears to be a feasible, effective and safe technique for the treatment of acute cholecystitis in high risk patients. Further studies are needed to confirm theses results and establish safety of this procedure. Device and technical options needs also to be specified.

Introduction: Endoscopic ultrasound (EUS)-guided fine needle aspiration (FNA) is an accurate technique for sampling intraintestinal and extraintestinal lesions. However, cytology possesses certain limitations, which may be overcome if histological specimens are provided to the pathologist.
Aims & Methods: The aim of the study was to evaluate the feasibility and accuracy of a newly developed 20-gauge histology needle. METHODS: Retrospective

analysis of a prospectively collected data base including patients who underwent EUS-guided biopsy with the 20-gauge ProCoreTM histology needle with reverse bevel (3-HD-20) for the evaluation of intraintestinal or extraintestinal lesions. EUS procedures were performed under sedation with linear echoendoscopes (Olympus and Pentax).
Samples recovered into cytological solution or formalin and processed for histological evaluation. Results were compared to the gold standard of surgical histopathology, or global pathological, clinical and radiological assessment, and follow-up in non-operated cases. Feasibility of the procedure and different technical aspects were recorded. Percentage of samples suitable for histological evaluation and the overall diagnostic accuracy were evaluated. Results are shown as mean and standard deviation or 95% confidence interval.
Results: 51 patients (mean age 62.2 years, range 36-83 years, 26 male) were included. A total of 52 lesions were attempted to be sampled (mean size 31.88 ± 12.4mm). Indications were pancreatic mass (n = 30), intraabdominal lymph nodes (LN) (n = 6), subepithelial lesions (n = 6), liver mass (n = 3) and 1 cases of mediastinal LN, lung cancer, rectal mass, esophageal lesion, hiliar mass, intraabdominal mass and a left suprarenal gland mass. Lesions were accessed from esophagus in 3 cases, stomach in 27 cases, bulbous in 15 cases, second part of the duodenum in 6 cases and from the rectum in 1 case.
EUS-guided biopsy was feasible in 50 cases (96.1%), with a mean of 1.7 passes (range 1-4). From 50 cases completed, sample quality was adequate for histological assessment in 46 lesions (92.0%). In the intention to treat analysis, diagnostic yield was 84.6% (95%CI: 72.5-91.9) and in per protocol analysis, diagnostic yield was 88.0% (95%CI 76.2-94.4). There were 2 (3.9%) mild complications (intraparietal hematomas at the place of FNB).
Conclusion: The EUS-guided biopsy with the 20-gauge ProcoreTM histology needle provides with a very good core sample for histological evaluation allowing a high histopathological diagnostic accuracy.

P0835 OBSERVATIONAL, PROSPECTIVE, SINGLE-CENTER COMPARATIVE STUDY BETWEEN STRAIN HISTOGRAM AND STRAIN RATIO FOR THE QUANTIFICATION OF ENDOSCOPIC ULTRASOUND (EUS)-GUIDED ELASTOGRAPHY OF SOLID PANCREATIC LESIONS

J. Iglesias-Garcia[1,2], J. Lariño-Noia[1,2], I. Abdulkader[1], J. E. Domínguez-Munoz[1,2]
[1]*University Hospital of Santiago de Compostela,* [2]*Foundation For Research in Digestive Diseases, Santiago de Compostela, Spain*

Introduction: Quantitative EUS-elastography allows quantifying tissue stiffness during a standard EUS examination. Elastography is a very accurate technique supporting the diagnosis of malignancy in solid pancreatic lesions. Elastography result may be analyzed either by strain ratio (SR) or strain histogram (SH).
Aims & Methods: Aim of the study was to evaluate the accuracy of SR and SH for the differential diagnosis of solid pancreatic masses. METHODS: A prospective, observational, comparative study was designed. 162 consecutive patients (mean age 63 years, range 17-89, 98 male), with a solid pancreatic mass at EUS were prospectively included. Elastography was performed with linear Pentax-EUS and Hitachi-Preirus. For SH, the tumor area was selected and analyzed. The mass (area A) and a peripancreatic soft reference area (B) were selected for SR analysis (quotient B/A). Final diagnosis was based on surgical histopathology, or EUS-FNA/FNB and global clinical and radiological assessment at follow-up in non-operated cases. Data are shown as mean (95%CI) and analyzed by ANOVA. Diagnostic accuracy was calculated by drawing the corresponding ROC curves.
Results: Size of masses was 35.0 ± 17.8mm. Tumors were located in the head (n = 107), body (n = 45) and tail (n = 10) of the pancreas. Final diagnosis was pancreatic adenocarcinoma (n = 106), malignant neuroendocrine tumor (NET) (n = 9), benign NET (n = 4), pancreatic metastasis (n = 9), and inflammatory masses (n = 34). Results of SH were 84.42 (76.4-92.45) in benign masses and 26.33 (24.7-28.0) in malignant tumors ($p < 0.001$). SR was 8.73 (5.21-12.2) in benign masses and 43.90 (37.8-50.0) in malignant tumors ($p < 0.001$). Sensitivity and specificity of SR for diagnosing malignancy were 100% and 92.1% (cut-off 9.74) (AUC = 0.942; 95%CI 0.88-1), and of SH 92.1% and 100%, respectively (cut-off 62.0) (AUC = 0.961; 95%CI 0.91-1). There were no differences in terms of diagnostic yield between both methods.
Conclusion: Elastography is a very useful tool for the diagnosis of malignancy in solid pancreatic masses. SR and SH are equivalent in this setting.

P0836 A COMPARATIVE STUDY OF ENDOSCOPIC ULTRASOUND-GUIDED CHOLEDOCHODUODENOSTOMY AND TRANSPAPILLARY STENT PLACEMENT IN PATIENTS WITH MALIGNANT BILIARY OBSTRUCTION AS THE FIRST-LINE TREATMENT

K. Kawakubo[1], H. Kawakami[1], M. Kuwatani[1], S. Haba[1], Y. Abe[1], S. Kawahata[1], Y. Kubota[1], K. Kubo[1], N. Sakamoto[1]

Contact E-mail Address: kkawakubo-gi@umin.ac.jp
Introduction: Endoscopic ultrasound-guided choledochoduodenostomy (EUS-CDS) has gained popularity as an alternative to percutaneous biliary drainage in patients with failed ERCP. There was no comparative study as the first-line treatment for distal malignant obstruction between EUS-CDS and endoscopic trasnpapillary stenting (ETS).
Aims & Methods: The aim of this study was to compare the clinical efficacy and safety of EUS-CDS and ETS in patients with distal malignant biliary obstruction as the first-line treatment. Before May 2012, 56 patients underwent ETS, after that, 26 patients underwent EUS-CDS as the first-line treatment for the management of distal malignant biliary obstruction. We retrospectively compared the clinical success rate, adverse event rate and reintervention rate.
Results: Clinical success rate was equivalent in both groups (EUS-CDS; 96.2, ETS; 98.2%, p = 0.54). Procedure time was significantly shorter in EUS-CDS than in ETS (19.7 vs 30.2 min, $p < 0.01$). The rate of overall adverse events was not significantly different between groups (EUS-CDS; 27%, ETS; 36%, p = 0.46). Post-procedure pancreatitis was only observed in ETS group (0% vs 16%. P = 0.03). Reintervention rate at one year was 16.6 and 13.6% in EUS-CDS and ETS, respectively (p = 0.50).
Conclusion: EUS-CDS could be considered the first-line treatment of patients with distal malignant biliary obstruction due to the short procedure time and no risk of pancreatitis.

Contact E-mail Address: lpoincloux@chu-clermontferrand.fr
Introduction: Interventional EUS is a promising novel approach in intravascular interventions. The aim of this study was to assess the feasibility and the safety of EUS-Guided Intrahepatic Portosystemic Shunt (EGIPS) in a live porcine model.
Aims & Methods: The Left Hepatic Vein (LHV) or the Inferior Vena Cava (IVC) was punctured with a needle which was advanced into the Portal Vein (PV). A guide-wire was inserted into the PV and an intrahepatic fistula between LHV and PV was created with a needle-knife. A portal pressure was recorded. The intrahepatic fistula was dilated with a balloon and an expandable biliary metal stent was deployed between LHV and PV under sonographic and fluoroscopic observation. A final portocavography validated the permeability of the stent. Euthanasia allowed necropsies.
Results: A portosystemic stenting was technically achieved in 19/21 cases. Final portocavography confirmed the stent permeability between the PV and the LHV or the IVC in 17 cases (efficacy of 81%): 4 stents were dysfunctionning because 2 were thrombosed and 2 too proximal. Portal pressure before and after shunt was achieved in 20/21 cases. Necropsies revealed that 19/21 procedures were transesophageal, and 2 were transgastric. We observed 1 hemoperitoneum and 1 pneumothorax in pig 5, 1 hemothorax in pigs 6 and 20. The morbidity was 14.2% (3/21 animals).
Conclusion: EGIPS in a live porcine model was technically feasible in 91%, functional in 81% and with a morbidity of 14.2%. EGIPS should be assessed in portal hypertension pig models and could become an option to TIPS failure.

Introduction: Needle-based Confocal Laser Endomicroscopy (nCLE) is an imaging technique, which enables microscopic observation of solid organs, *in vivo* and in real-time, during an EUSFNA procedure. The CONTACT study

Abstract number: P0838

Final diagnosis	n	Sensitivity		Specificity		PPV		NPV		Accuracy	
		Group 1	Group 2	Group 1	Group 2	Group 1	Group 2	Group 1	Group 2	Group 1	Group 2
Adenocarcinoma	23	86%	78%	100%	100%	100%	100%	79%	67%	91%	85%
Neuroendocine neoplasm	3	100%	100%	93%	97%	60%	75%	100%	100%	94%	97%
Chronic Calcifying Pancreatitis	5	67%	40%	100%	100%	100%	100%	93%	90%	94%	91%

(Clinical evaluation Of NCLE in The lymph nodes Along with masses and Cystic Tumors of the pancreas) aims at building an image atlas, define interpretation criteria for nCLE images in the pancreatic masses and propose a first validation of these criteria.

Aims & Methods: 3 centres in France (7 investigators) took part in this prospective study. Any pancreatic mass studied by EUSFNA could be imaged by nCLE, but if a patient had multiple masses, only one of them could be imaged.

40 patients with a pancreatic mass were included prospectively during the study (June 2012 to March 2014).Out of these 40 patients, 33 were evaluable : 23 adenocarcinomas, 3 neuroendocrine neoplasms, 1 pseudopapillary tumor and 5 chronic pancreatitis.

Based on the previously described criteria (1), two validations of these criteria have been performed : one by the physicians who described the criteria (M.G, F.C, F.P, G.M), the second one by three gastroenterologists and one pathologist (B.N, B.P, L.P, A.I.L) external to the definition of the criteria.

For this evaluation, physicians were completely blinded to the clinical history of the patient, and the EUS examination. They only had the nCLE recorded sequence.

For each of the 33 patients, they were asked to give a diagnosis based on the existing criteria (1). When agreement between investigators was not complete, a consensus was reached.

Results: For the first validation (by investigators who established the classification- Group 1): IOA was perfect (k = 1) – agreement between the observers was complete in 70 % of the cases. A consensus was obtained for the other 30 %.

For the second validation (by external investigators- Group 2) : IOA was moderate (k = 0.55) – Agreement between the observers was complete in 40 % of the cases. A final consensus was obtained for the other 60 %.

Diagnostic performances of nCLE for the characterization of pancreatic masses are presented in Table 1.

Conclusion: These two validations, even preliminary due to the small number of inclusions, show a really slight difference between experts and less trained physicians: the learning curve seems to be short.

Although the sensitivity still needs to be improved (by an additional work on the criteria), the excellent specificity of nCLE for the characterization of pancreatic masses could be very usefull tu rull out malignancy and avoid repeated diagnosis procedures.

Introduction: Accurate preoperative staging for ampullary neoplasm is mandatory for making therapeutic decisions. Endoscopic Ultrasound (EUS) has been suggested as the modality of choice in the locoregional staging of the ampullary lesions, because the high frequency ultrasound transducer probe can be placed in close proximity to the ampullary region. To date, almost all information available on staging of ampullary tumors has been obtained with radial echoendoscope, that is considered the gold standard.

Aims & Methods: Aim of the study was to compare the accuracy of linear array echoendoscope in locoregional staging of ampullary lesions, with histology and surgical pathology as gold standard. The Endoscopy Database of a tertiary referral center was reviewed, searching for patients referred for an evaluation in known or suspected ampullary lesion between January 2010 and January 2015. Patients demographic and clinical data were collected, including the lesion size and local tissue invasion. Histology from endoscopic and surgical specimens was assumed as reference standard. All EUS were performed by 3 experienced endosonographers by using linear array echoendoscopes (Pentax EG3870UTK). Data were analyzed using descriptive statistics.

Results: We identified 89 patients who underwent EUS for ampullary lesions. Among them, 48 pts were excluded (41/48 underwent EUS, without any treatment and in 7/48 histology did not confirm the suspected diagnosis). 41 pts (22 M; mean age 70.7 years± 12.1) were included in the study (5 pts previously treated with biliary stent). The mean size of the lesions was 15.9 ±7.5 mm. 23 patients (56%) were treated with whipple resection, 15 patients (37%) underwent endoscopic papillectomy, and 3 (7%) surgical papillectomy. Pathologic type of the tumors were adenoma in 18 pts (44%), adenocarcinoma in 23 pts (56%). In those undergoing endoscopic/surgical papillectomy, 16 had adenoma (89%), and 2 had adenocarcinoma (11%). Of the patients who underwent whipple resection 2 had adenoma (9%), 21 had adenocarcinoma (91%). For the assessment of local tissue invasion, the overall accuracy of EUS was 75.6% by using histology as the reference standard. Excluding pts with biliary stent, accuracy raised up to 81.1%. The diagnostic accuracy of EUS was 85.7%, 55.6%, and 80% in identifying patients with T1, T2, T3-4 stages, respectively. Overstaging by EUS occurred in 5 patients (12%), 3 of them had biliary stent. Understaging occurred in 2 patients (5%).

Conclusion: Linear EUS accurately predicts the depth of invasion in the preoperative evaluation of ampullary lesions, providing useful information for making therapeutic decisions, especially in selection of eligible patients for endoscopic treatment.

Contact E-mail Address: Wallace.Michael@mayo.edu
Introduction: Endoscopic ultrasound fine needle aspiration (EUS-FNA) is the reference standard for pancreatic cystic lesions (PCLs) diagnosis. Limited fluid aspirate can restrict analysis. A new nitinol 19G flexible (19G Flex) needle may improve access and aspiration, especially for viscous and/ or difficult to reach PCLs.
Aims & Methods: Document impact of needle gauge and flexibility on success of PCL aspiration and sufficient yield for cytology and CEA. Prospective multinational trial of 250 patients (pts) with PCLs $\geq$ 13mm at largest axis. Interim report on ITT basis for 125 pts with 30 day follow up. Pts randomized in 2:1:1 ratio to 19G Flex:19G:22G needles. Salvage with another needle if no access or incomplete aspiration. Primary endpoint: percent (%) total cyst volume aspirated based on pre- and post-aspiration PCL measurements. Other endpoints: successful EUS-FNA (complete aspiration/ fluid sufficient for testing), salvage rate, 30 day adverse events.
Results: 125 pts (mean age 67, 43% male, 30% symptomatic) treated with 19G Flex(62), 19G(32), or 22G(31) needles. PCLs: mean largest diameter: 22.6 $\pm$ 13.1mm; head 43%, body 22%, tail 31%; unilocular: 61% (76). Mean # passes all procedures including salvage: 1.1 $\pm$ 0.5. Mean % aspirated volume: 78 $\pm$ 38% (124). Successful EUS-FNA: 93.5% (116/124); performance of all needles was equivalent. Primary endpoint for 76 pts with unilocular PCLs by location and viscosity (Table 1) illustrates % aspirated volume for viscous PCLs in head of pancreas of 85% (19G Flex), 63% (19G std) and 66% (22G std) with enrollment ongoing. Salvage required in 13.6% (17/125) pts including 14 (82.4%) in head or very viscous PCLs. 19G Flex required fewer rescues compared to other needles: 9.7% (6/62)-19G Flex, 18.8% (6/32)-19G, and 16.1% (5/31)-22G needles. Complications in 7pts (6%): 1 bleeding PCL that refilled with blood (22G), 1 abdominal pain (19G), 3 acute pancreatitis (2-19G Flex, 1-22G), 2 unrelated deaths from metastatic endometrial (19G Flex) and neuroendocrine (22G) cancer.
Conclusion: Results suggest that nitinol 19G flexible FNA needles may require fewer salvage procedures and show a trend of higher fractional cyst aspiration compared to standard needles for very viscous PCLs. Further data are forthcoming.

P0841 VARIATIONS IN DIAGNOSTIC ACCURACY OF RADIAL AND LINEAR ENDOSCOPIC ULTRASOUND (EUS) FOR SUSPECTED CHOLEDOCHOLITHIASIS ARE RELATED TO CLINICAL PRESENTATION AND NOT TO TIME TO ERCP OR CHOLEDOCHOLITHIASIS RISK LEVEL

N. Barsic[1], T. Pavic[1], D. Hrabar[1], I. Budimir[1], M. Nikolic[1], N. Ljubicic[1]
[1]*Sestre Milosrdnice University Hospital Center, Zagreb School of Medicine, Zagreb, Croatia*

Contact E-mail Address: neven.barsic@gmail.com
Introduction: EUS is considered a reliable method in assessment of choledocholithiasis, but reported diagnostic accuracy rates vary, and patient numbers are not very large in the majority of reports. Given the high occurrence of suspected choledocholithiasis seen in daily practice and use of an invasive method (ERCP) in those with positive EUS findings, implications of inaccurate diagnosis are medically, financially and organizationally significant.
Aims & Methods: Our aim was to evaluate diagnostic accuracy of EUS in our setting with a large emergency department and very frequent cases of biliary lithiasis complications, and to compare the accuracy across different clinical scenarios and ASGE choledocholithiasis risk levels, as well as its dependence on time elapsed between EUS and ERCP and type of EUS probe used (radial vs. linear).
We retrospectively included 194 consecutive patients who underwent EUS for suspected choledocholithiasis in the period of two years (2011 and 2012). Mechanical radial (n = 149) and linear (n = 45) Olympus probes were used for EUS examination in all patients.
We compared the positive EUS findings with subsequently performed ERCP, and in patients with negative EUS we confirmed the lack of later biliary events at a 6-month follow-up visit and through electronic medical records revision. Comparison of accuracy was made between different clinical presentations, ASGE choledocholithiasis risk levels, time elapsed between EUS and ERCP and probe type.
Results: 106/194 (54.6%) of patients had a positive EUS finding of choledocholithiasis, and positive predictive value when compared to ERCP was 88.5% (85/96). There were no differences in accuracy with ASGE choledocholithiasis risk levels (6/11 pts with a false positive finding were ASGE high risk level) or type of EUS probe used (PPV with linear 92% vs. radial 87.3%). Time elapsed to ERCP was only slightly longer in pts with a false positive finding (mean 3.87 vs. 2.71 days).
However, significant difference was observed when comparing PPV in pts presenting with biliary colic or pancreatitis (PPV 72.0 %, n = 18/25) and pts presenting with either cholangitis, obstructive jaundice or asympthomatic biliary dilatation or elevated liver enzymes (PPV 97.1 %, n = 67/69, P = 0.0011).
In 88 patients with negative EUS findings, there were only 3 cases of biliary complications during follow-up, and neither of them underwent recommended cholecystectomy after the initial event, so negative predictive value of EUS would at worst be 96.6%.
Conclusion: Although generally high, different levels of diagnostic accuracy of EUS for choledocholithiasis reported in various studies could well be influenced by a difference in distribution of clinical presentations of patients studied. This is probably the result of a transitory nature of biliary obstruction (due to a spontaneous propulsion of the stone), which is very frequent in settings of biliary colic and biliary pancreatitis, whereas obstructive jaundice and cholangitis are related to a more persistent CBD obstruction.

P0842 NATURAL HISTORY OF ASYMPTOMATIC UNIQUE PANCREATIC CYSTIC TUMORS CONSIDERED OF BENIGN POTENTIAL IN ENDOSCOPIC ULTRASOUND LONG-TERM SURVEILLANCE OF 144 PATIENTS

O. Luna[1],*, I. Oria[1], R. Gincul[2], C. Lefort[1], B. Pujol[1], J.-Y. Scoazec[3], J.-C. Souquet[4], J. A. Chayvialle[2], B. Napoleon[1]

Contact E-mail Address: oliluna@terra.com.br
Introduction: A follow up (FU) can be proposed for asymptomatic pancreatic cystic tumors with benignpotential (BCT) such as serous cystadenomas (SC) or congenital cysts. However, it is often difficult to confirm the diagnosis of BCT.In 1991,we proposed the criterias of BCT in endoscopic ultrasound (EUS).
Aims & Methods
Aim: Evaluatethe natural history of asymptomatic pancreatic cystic tumors considered as BCT by EUS. Between June 1992 and November 1996, 144 asymptomatic patients with suspected single BCT by the EUS were included. The exclusion criteria: acute or chronic pancreatitis; criteria for malignant potential in the EUS (wall thickening,echogenic fluid,mass syndrome,duct communication,unilocular cyst > 3 cm); multiple cysts. 111 women with a mean age of 60 years.EUS found in 101 cases a cyst multilocular(probable SC). In 43 cases,one cyst unilocular $\leq$ 3 cm. Cysts had an average diameter of 21 mm, a localization body-tail in 49. Clinical and radiological FU was recommended. Patients and physicians were recontacted every 5 years. Thelast assessment has been in September 2014.
Results: 4 patients (3%)were lost to FU. 21 patients (15%) underwent surgery,7 immediately (5 SC,1 Brunerienne,1 inconclusive) and 14 in FU due to the appearance of symptoms (1 SC),an increase in size or appearance of suspicious signs (8 SC,5 mucinouscystadenoma with one degenerated).47 patients (33%) died during the FU (mean 7 years).2 patients died of pancreatic pathology (1 neuroendocrine tumor,1 cystadenocarcinoma),42 died for a cause independent of the pancreas,3 died of unknown cause.4 patients had other cysts appearing (IPMN probably).54 patients are alive in October 2014 asymptomatic (mean 20 years).18 were a partial FU (mean 10 years). For these 72 patients (50%) the diagnosis of IPMN was mentioned 12 times before.4 cases the signs for a MC have occurred in older patients for surgery too.The mucinous lesions accounted for 18% of patients and were distributed between lesion initially unilocular (n = 9/43:21%) or with microcysts (n = 17/101:17%).
Conclusion: In this follow-up study in the very long term (20 years) EUS criteria had an accuracy of 82% for the diagnosis of BCT.One death related to pancreatic tumour was noted.18% of patients ultimately had mucinous cysts with malignant potential to justify the creation of more specific tests for BCT diagnosis.

P0843 IS ASCITES A CONTRA-INDICATION TO AN ENDOSCOPIC ULTRASOUND-GUIDED BILIARY DRAINAGE IN CASE OF UNSUCCESSFUL CATHETERIZATION?: RESULTS OF A PILOT STUDY

O. Luna[1], I. Oria[1], F. Fumex[1], J. Marsot[1], C. Lefort[1], V. Lépilliez[1], J. Balique[1], R. Bourdariat[1], S. Gaetan[1], B. Napoleon[1]
[1]*Hopital Prive Jean Mermoz, Lyon, France*

Contact E-mail Address: oliluna@terra.com.br
Introduction: In case of malignant obstruction of the bile duct with failure of endoscopic retrogradecholangiography (ERCP), a percutaneous trans-hepatic biliary drainage (PTBD) is usually done.One contra-indication of this procedure is the presence of ascites.Endoscopic ultrasound-guided biliary drainage (EUS-BD) could be a solution but it has never been evaluated in this situation.The objective of this single-center study is to determinewhether ascites is a contra-indication for EUS-BD.
Aims & Methods: Between July 2010 and July 2014 patients with choledocoduodenostomy (CD) or hepaticogastrostomy (HG) for an ERCP failure were included. Systematic bile samples for bateriology were performed at the time of puncture.October 2014 a retrospective analysis was performed comparing those with ascites (group 1) to those without ascites (group 2). The technical and clinical success, complications andfollow-up until death were compared between the two groups.
Results: 31 patients included.Group 1(5CD, 6HG) technical success in 10/11 cases.One complication (migration of the stent). Clinical success in 7/10 patients.4 patients died in the first month. One death related to the procedure. Bacteriology of the biliary fluid positive twice (22%). All patients died of disease progression (mean survival 78 days). Group 2 (8CD,12HG) technical

success in 17/20 cases. Three complications (1 perforation, 1 bile peritonitis, 1 bleeding). Clinical success in 16/17 cases. Bacteriology of the biliary fluid positive in four cases. One patient had cholangitis. 14 patients died of disease (mean 115 days, 6 alive (mean 300 days).
Conclusion: This study showsthat we can achieve a EUS-BD with good technical efficacy in patients with ascites.The risk of infection remains limited (22% of patients) and comparable to patients without ascites.These results suggest aprospective multicenter study.

P0844 AN ALTERNATIVE METHOD OF DRAINAGE OF PSEUDOCYSTS IN PRESENCE OF BIG VARICES IN THE FUNDUS

P. N. Desai[1]
[1]*Endoscopy, Surat Institute Of Digestive Sciences, Surat, India*

Contact E-mail Address: drp_desai@hotmail.com
Introduction: An alternative method of drainage of Pseudocysts in presence of big varices in the fundus.
Aims & Methods
Aims: A study 18 cases of draining pseudocysts complicated by portal hypertension and gastric varices with EUS guided locating the site of puncture distally on the bulge.
Methods: 18 cases from all that were referred to us from 1st January 2011 to May 30, 2014 with pseudocysts were found to be complicated with fundic and esophageal varcies secondary to splenic vein. UES revealed big varices around the GE junction and the proximal body and no window was found for EUS guided cyst drainage in the conventional manner. The bulge of the cyst was followed distally with an EUS scope and an area devoid of varices was found distally. Here the tip of the EUS scope was fully up and it was impossible to get a 19G needle out for puncture and further steps of conventional cyst drainage. Ttherefore we marked the area with biopsy forcpes taking a pinch of tissue for identification on passage of the side viewing scope subsequently. A conventional ERCP 4.2mm channel scope from Olympus was then passed, positioned in front of the marked area and the cyst punctured around the mark with a needle knife papillotome from Boston and guide wire placed under fluoroscopic control. The tract was then dilated with a 6.5Fr cystotome from Endoflex and dilated with a CRE balloon upto 12mm only to avoid bleeding. Two 10 Fr Double pig tail stents were kept. In cases with necrosis and additional naso cystic catheter was placed for lavage which was removed after 48 to 72 hours exchanging it for an additional 10Fr DPT stent. ERCP done if a leak was suspected at the time of removal of naso cystic drain and stent placed. Stents were removed after six weeks to three months and the PD stent removed or changed as needed.
Results:

Bulge Present	**18**	**100.%**
Puncture Possible around marked site	**17**	**94.4%**
Bleeding (Minor)	**3**	**16.7%**
Necrosis Present	**5**	**27.7%**
Infected Fluid	**4**	**22.2%**
Naso Cystic Drain kept	**9**	**50%**
Perforation	**0**	**0**
Sepsis	**4**	**22.2%**
ERCP Performed	**6**	**33.3%**
Cysto gastrostomy stents Removed	**12**	**63.1%**
Stents still present	**4**	**22.2%**
Lost to Follow up	**2**	**11.1%**
Procedure Related Mortality	**0**	**0**

The bleeding was minor from the wall and was treated with injection of adrenaline and balloon tamponade.
The sepsis was treated with antibiotics for 5 to 7 days and was seen in patients with necrosis and infected fluid.
4 patients had a disrupted duct and hence the stents have not been removed.
Conclusion: In difficult situations of pseudocysts complicated with varices, puncturing distally on the bulge at a site marked by EUS scope is a feasible alternative. EUS guide drainage is difficult in these situations as the scope is angled acutely and this makes the procedure very difficult. The complications rates are also reasonable.

P0845 GLOBAL ASSESSMENT OF EUS PERFORMANCE SKILLS (GEUSP) - A NEW TOOL AND APPROACH TO OBJECTIFY AND MEASURE THE LEARNING CURVE AND TECHNICAL SKILLS OF ENDOSONOGRAPHISTS

P. Hedenström[1], B. Lindkvist[1], **R. Sadik**[1]
[1]*Departement of Internal Medicine, Division of gastroenterology, Göteborg, Sweden*

Contact E-mail Address: per.hedenstrom@vgregion.se
Introduction: The overall learning curve of endoscopic ultrasound (EUS) is regarded long, but until now it is not very well characterized in the literature. There is also a lack of easy to use tools to assess the practical skills of endosonographists in training.
Aims & Methods: The aim of this study was to elaborate and validate a new tool for the assessment of endosonographists in training and by this elucidate the learning curve of EUS.
The study was conducted at a tertiary university endoscopy center in West Sweden. Patients undergoing EUS for clinical reasons were enrolled and examined first by an endosonographist in training (performer) and secondly by an experienced endosonographist (observer). Both doctors performed EUS-guided puncture if this procedure was indicated. The observer assessed and scored 5 different parameters of the performer's EUS-procedure, each on a 5-graded scale. A study specific assessment sheet, GEUSP, was designed for this purpose. The performer also scored him- or herself regarding the same 5 parameters including an aspect on confidence in own performance. Previous endoscopy experience including EUS and annual endoscopy volumes of the performer were registered. The overall GEUSP score was calculated regarding each case to assess the performeŕs development over time. The influence of different variables on the GEUSP score was analyzed using non-parametric tests.
Results: During May 2014 – February 2015 a total of 60 patients (38 males and 22 females) were examined and four performers were assessed according to GEUSP. Two performers performed the majority of examinations (P1 = 48, P2 = 10, P3 = 1, P2 = 1) all were assessed by one single observer. EUS-FNA/FNB was performed by the performer in 22 cases. Target organs were as followed: Pancreas (29), Submucosal lesions (22), Paraintestinal lesions (11). There was a good correlation between the overall mean GEUSP-score of the observer and that of the performer ($r = 0.68$, $p < 0.001$) supporting the robustness of the assessment sheet. Analyzing comparable lesions there was a correlation between the overall mean GEUSP-score and the previous overall EUS experience of four performers assessed so far ($r = 0.9$, $p = 0.06$). The observeŕs mean overall GEUSP Score of Performer 1 was significantly higher after initial first 25 examinations, (3.7 vs 3.1, $p < 0.01$). There was no significant difference in the overall GEUSP score comparing different target organs nor comapring solid and cystic lesions. The assessment sheet was easy to use and the registration engaged few minutes. We did not notice any negative influence on the everyday endoscopy program due to the use of GEUSP. Two patients reported brief abdominal symptoms the day after EUS, but no certain complications related to EUS were verified during follow-up.
Conclusion: A new tool for the assessment of endosonographists in training (GEUSP) has been proven feasible and simple to use in clinical practice. Further evaluation of a larger cohort of endosonographists is ongoing. We invite other centers to participate in this study.

P0846 DIAGNOSTIC EFFICACY OF ENDOSCOPIC ULTRASOUND-GUIDED NEEDLE SAMPLING FOR UPPER GASTROINTESTINAL SUBEPITHELIAL LESIONS: A META-ANALYSIS

Q.-L. Li[1], **P.-H. Zhou**[1]
[1]*Endoscopy Center and Endoscopy Research Institute, Zhongshan Hospital, Fudan University, Shanghai, China*

Contact E-mail Address: zhou.pinghong@zs-hospital.sh.cn
Introduction: An increasing number of studies have been conducted on the use of endoscopic ultrasound (EUS)-guided needle sampling, including fine needle aspiration, fine needle biopsy, and trucut needle biopsy, for upper gastrointestinal (GI) subepithelial lesions (SEL). However, reported diagnostic efficacy varies greatly.
Aims & Methods: We did a meta-analysis to summarize up current evidences on diagnostic efficacy of EUS-guided needle sampling for upper GI SEL. A reproducible strategy was used to search four databases. 17 studies, including a total of 978 sampling attempts, were included in the final analysis. The primary outcome was the pooled efficacy of EUS guided needle sampling in upper GI SEL. Secondary outcomes were procedure-related complications, diagnostic errors, and independent factors related to a higher success rate.
Results: The pooled diagnostic rate of EUS-guided needle sampling was 59.9%, with a heterogeneity I^2 of 55.2%. Subgroup analysis and meta-regression suggested that the cell block method might be correlated with a higher diagnostic rate. Few severe complications were reported. Diagnosis errors were rare.
Conclusion: EUS guided needle sampling is a safe, but only moderately effective method for pathological diagnosis of upper GI SEL. However, the results have inherent limitations, especially in view of the limited sample size and heterogeneity of the original studies.

Contact E-mail Address: ana.ilponte@gmail.com
Introduction: In western countries, small-bowel vascular lesions (SBVL) represent the most frequent small bowel finding in patients with obscure gastrointestinal bleeding (OGIB).[1] Recent systematic reviews raise some doubts concerning the therapeutic efficacy of Balloon-Assisted Enteroscopy (BAE) of SBVL after 2y of follow-up and there is limited data regarding the long-term outcome of these

patients.[2,3] Objective: Evaluate the short- and long-term rebleeding risk after BAE therapy of SBVL detected in capsule enteroscopy.
Aims & Methods: Between July 2007 and February 2015, all patients with SBVL who underwent BAE therapy were included. The endpoint was rebleeding, defined as the presence of overt OGIB, the need for red blood cells transfusions or a decrease in haemoglobin ≥2g/dL. Factors predictive of rebleeding were also analysed. Statistical analysis: Kaplan-Meier survival curves, Log-rank test, t-student test, X^2. Significance: $p < 0.05$.
Results: 35 patients with SBVL underwent BAE therapy, 57.1% were men with a mean age of 67.8+/-13.7 years. Findings included angioectasias in 97.1% (n = 34), classified in types 1a in 14.3% (n = 5) and 1b in 82.9% (n = 29), and Dieulafoy's lesion in 2.9% (n = 1) classified as type 2a.[4] Types 1a/1b were approached exclusively with argon plasma coagulation in 88.6% (n = 31) or combined with other technique in 11.4% (n = 3); and the type 2a lesion was treated with adrenaline and clips. Globally, rebleeding occurred in 40% (n = 14) of cases, manifested as overt OGIB in 35.7% (n = 5), need of blood transfusion in 42.9% (n = 6) and haemoglobin drop ≥2g/dL in 21.4% (n = 3). Rebleeding at 1y/2y/3y/4y/5y after BAE therapy occurred in 32.7%/38.3%/46.0%/53.7%/63.0%, respectively. Patients with aortic stenosis/chronic renal failure/cirrhosis/Osler-Weber-Rendu syndrome had a rebleeding risk at 2y/3y after BAE therapy of 51.3/67.6%, superior to those without these comorbidities (22.2/22.2%), p = 0.006.
Conclusion: Rebleeding at 2y after BAE therapy of SBVL occurred in 38.2%, consistent with two recent systematic reviews which revealed a rebleeding rate of 45% at 26 months and 42.7% at 1.5-2y.[2,3] Long-term risk of rebleeding progressively increases, reaching 63% at 5y after BAE therapy. The presence of comorbidities increases the rebleeding risk.

Introduction: Surveillance of the small-bowel with polypectomy of significant polyps (SP, defined as polyps ≥15mm in diameter) prevents polyp-related complications in Peutz-Jeghers syndrome (PJS). However, evidence for the optimal imaging technique for these patients is lacking. Therefore, we aimed to compare the diagnostic yield and patient preference of Magnetic Resonance Enteroclysis (MRE) and Double Balloon Enteroscopy (DBE) in PJS.
Aims & Methods: Adult PJS patients recruited from two academic centers underwent MRE followed by a proximal DBE with polypectomy of SP within 20 weeks. The endoscopists were blinded for the MRE results. DBE was performed under conscious sedation with midazolam and fentanyl intravenously or under general anaesthesia with propofol. We compared the number of SP and total number of polyps detected by MRE and DBE. Patients' perception regarding shame, pain, burden and duration of both procedures were assessed through questionnaires, as well as their preference for future surveillance.
Results: Fifteen PJS patients, 67% males with a median age of 47 (IQR 39-53) years underwent both MRE and DBE. The median maximal insertion depth for DBE was 270cm (IQR 160-340cm). SP were identified by MRE and/or DBE in 12/15 (80%) patients. Agreement between MRE and DBE on the presence of SP was 87% (13/15) and both methods identified 11 patients with SP. Significantly more polyps were detected by DBE than with MRE (148 vs. 93, p = 0.03), however there was no significant difference in the detection of SP (47 by DBE vs. 38 by MRE, p = 0.37). Patients' perception regarding shame and burden at preparation and during both procedures did not differ significantly between MRE and DBE. However, patients reported significantly more pain during the preparation for MRE than for DBE (moderate vs. no pain, p = 0.02). Perception of pain during the procedures was comparable (both mild, p = 0.89). Significantly more patients perceived a longer procedure time for MRE than for DBE (38.5% vs. 8.5%, p = 0.05). For future small-bowel surveillance 10/13 (77%) patients preferred DBE over MRE (p = 0.09).
Conclusion: Our results suggest that MRE and DBE have comparable diagnostic yield of clinically relevant polyps ≥15mm in diameter. Although DBE resulted in incomplete small-bowel visualization in all patients, it allows for direct intervention and was preferred over MRE by patients in this series. Based on the MRE results, 11/15 (73%) patients had an indication for DBE with polypectomy. Larger cohorts of PJS patients are needed to fully evaluate the diagnostic yield of DBE compared with other diagnostic modalities.

P0849 THE ROLE OF DOUBLE-BALLOON ENTEROSCOPY IN MALIGNANT SMALL BOWEL TUMORS MAY BE DECISIVE

E. Pérez-Cuadrado Robles[1], P. Esteban Delgado[1], B. Martinez Andrés[1], P. Bebia Conesa[1], J. L. Rodrigo Agudo[1], S. Chacón Martinez[1], E. Torrella[1], A. Lopez Higueras[1], J. Shanabo[1], E. Perez-Cuadrado Martinez[1]
[1]*Gastroenterology, Morales Meseguer Hospital, Murcia, Spain*

Contact E-mail Address: kikemurcia@gmail.com

Introduction: Malignant small bowel tumors (MSBT) are a heterogeneous and relatively rare group of neoplasms. Double balloon enteroscopy (DBE) role in these lesions remains controversial.
Aims & Methods: The aim of this study was to assess the DBE role in MSBT. The present retrospective study included all consecutive patients who underwent a DBE with final diagnosis of a malignant neoplasm from 2004 to 2014 in our referral center. Patient demographic and clinical pathological characteristics were reviewed. MSBT diagnosis was achieved either by DBE directed biopsy, endoscopic findings or histological analysis of surgical specimen. We have analyzed DBE impact in the outcome and clinical course of these patients.
Results: Of 627 patients, 28 (4.5%) (mean age: 60 ± 17.3 years) underwent 30 procedures (25 anterograde, 5 retrograde) and were diagnosed of a malignant tumor. Patients presented with obscure gastrointestinal bleeding (n = 19, 67.9%), occlusion syndrome (n = 7, 25%) and diarrhea (n = 1, 3.6%). They were diagnosed by DBE biopsy (n = 18, 64.3%), histological analysis of surgical specimen (n = 7, 25%) and unequivocal endoscopic findings (n = 2, 7.1%). Gastrointestinal stromal tumor (n = 8, 28.6%), adenocarcinoma (n = 7, 25%), lymphoma (n = 4, 14.3%), neuroendocrine tumor (n = 4, 14.3%), metastatic (n = 3, 10.7%) and Kaposi sarcoma (n = 1, 3.6%) were identified. In summary, DBE modified outcome in 7 cases (25%), delaying or avoiding emergency surgery (n = 3), modifying surgery approach (n = 2) and indicating emergency SB partial resection instead of elective approach (n = 2).
Conclusion: DBE may be critical in the management of MSBT providing additional information that may be decisive in the clinical course of these patients.

P0850 A PROSPECTIVE COMPARISON OF SAFETY AND TOLERABILITY OF PROPOFOL VERSUS STANDARD SEDATION FOR DOUBLE BALLOON ENTEROSCOPY - TIME FOR A PUSH FORWARD?

F. Branchi[1], D. Sanders[2], D. Turnbull[3], G. Eapen[3], S. Jankowski[3], R. Sidhu[2]
[1]*Department of Pathophysiology and Transplantation, Università degli Studi di Milano, Milano, Italy,* [2]*Academic Department of Gastroenterology,* [3]*Department of Anesthesiology, Royal Hallamshire Hospital, Sheffield, United Kingdom*

Contact E-mail Address: federica.branchi@gmail.com

Introduction: Double balloon enteroscopy (DBE) is routinely performed with moderate sedation in the UK. However, in comparison to standard endoscopy, DBE is complex and takes longer, therefore deep sedation with propofol could improve tolerability and feasibility of the test.
Aims & Methods: All patients undergoing DBE between March13 and October14 were prospectively enrolled. DBE was performed either with administration of sedation with fentanyl and midazolam or with anesthetist-assisted deep sedation with propofol, the decision being made on the basis of patients' clinical history and expected length of the test. Data from patients receiving propofol were compared to those from patients receiving standard sedation during the same period. Patients were asked to fill in a questionnaire regarding their expectations before the test and their satisfaction afterwards. Anxiety, pain and discomfort were assessed by means of validated numeric rating scales (NRS, range 0-10). Data on comorbidities, previous surgery and hospital anxiety and depression scores (HADS) were also collected. The procedural characteristics of DBE were assessed.
Results: Twenty-one DBE (18 oral, 3 anal, 33% male) were performed with the aid of propofol infusion and 67 (54 oral, 13 anal, 51% male) with standard sedation. Mean age was 48 ± 14.3 in the propofol group and 58.6 ± 15.9 in the sedation group (p = 0.012). There were no other differences in demographics, comorbidities or HADS scores between the groups. The indications for DBE included obscure gastrointestinal bleeding (n = 45), Peutz-Jeghers syndrome (9) and suspected Crohn's disease (20), small bowel tumor (10) or celiac complication (2). The mean dose of propofol administered was 1123 ± 483 mg. The mean doses of midazolam and fentanyl were 6 ± 3 mg and 118 ± 54 mcg respectively. No differences were observed in terms of diagnostic yield (52% vs 57%, p = ns) and therapeutic yield (33% both groups). Patients in the propofol group reported lower scores of pain (median score 0, IQR 0-0.5 vs 3, IQR 0-6, p < 0.0001), discomfort (median 0, IQR 0-0.5 vs 3, IQR 1-7, p < 0.0001) and distress (median 0, IQR 0-0 vs 1, IQR 0-5, p = 0.001) during the procedure. Whilst there were no complications in the propofol group, there was one episode of oxygen desaturation in the control group.
Conclusion: The use of propofol for DBE has a good safety profile and better patient tolerability and satisfaction in comparison with moderate sedation. It is associated with a high diagnostic and therapeutic yield. Its use should be

recommended when the procedure is expected to be longer and technically challenging.

P0851 DOUBLE-BALLOON ENTEROSCOPY IN PATIENTS WITH CARDIOVASCULAR COMORBIDITIES - IS IT WORTH THE 'CORONARY'?

F. Branchi[1], D. Sanders[2], R. Sidhu[2]
[1]*Department of Pathophysiology and Transplantation, Università degli Studi di Milano, Milano, Italy,* [2]*Academic Department of Gastroenterology, Royal Hallamshire Hospital, Sheffield, United Kingdom*

Contact E-mail Address: federica.branchi@gmail.com
Introduction: Double balloon enteroscopy (DBE) is an advanced endoscopic technique for the diagnosis and treatment of small bowel diseases. It is a relatively invasive and long procedure therefore its use in patients with comorbidity can be risky.
Aims & Methods: The aim of our study was to assess the safety and feasibility of DBE in patients with cardiovascular comorbidities.
All consecutive patients referred for DBE in our trust were prospectively reviewed. Clinical and demographic data were collected and patients with cardiovascular comorbidities were included in the analysis. Patients were divided into 2 groups- elderly (Group 1: age > 70 years) and the young (Group 2: age < 70 years) Diagnostic and therapeutic yields, dose of sedation and complications rates were collected.
Results: Out of a total of 404 DBE procedures, 97 were performed in patients with one or more cardiovascular (CV) comorbidities (Group 1 = 52, group 2 = 45), including ischaemic heart disease (n = 61), valvular replacement (n = 24), atrial fibrillation (AF, n = 19), chronic cardiac failure (CCF, n = 16), arrhythmias with pacemaker implantation (n = 5), previous cerebrovascular event (n = 8). AF and CCF were commoner in the elderly compared to the young (p = 0.035 and p = 0.026 respectively). There were no significant differences in warfarin or NSAIDS use in the two groups. The indications for DBE were obscure gastrointestinal bleeding (occult, 59%, and overt, 27%), suspected Crohn's disease (7%), small bowel stricture at radiology (4%) and suspected celiac complication/malabsorption (3%). Transfusion was required in 67% patients in the elderly group and 60% in the younger group (p = ns). There were no differences in terms of procedure time between the elderly and the young (median time 70 minutes, range 35-125, vs 65, range 25-140, p = ns). Elderly patients were administered significantly lower doses of midazolam (median dose 4 mg, range 1.5-10 vs 6 mg, range 2-10, $p < 0.0001$) and fentanyl (median dose 50 mcg, range 12.5-100 vs 75, range 12.5-200, $p < 0.0001$).
DBE had high diagnostic (65% and 58%, p = ns) and therapeutic yield (54% vs 33%, p = ns) in both groups. The most common finding was angiodysplasia in both groups (48% vs 29%, p = 0.06), other findings included ulcers (6% vs 9%), small bowel polyps (0% vs 7%) or tumors (0% vs 4%), diverticula (4% vs 0%), changes of celiac disease and intestinal lymphangectasia (0% vs 6%). The complication rate was 3% overall with one non STEMI in the elderly group and one episode of cardiac failure and a respiratory arrest in the younger group.
We also made comparisons between patients with CV comorbidity compared to all others without CV comorbidity undergoing DBE in the same period. The overall diagnostic yield was higher in patients with CV, irrespective of age, as compared to all other patients without CV comorbidity (62% vs 46%, p = 0.005). Similarly, the therapeutic yield was also higher (44% vs 18%, $p < 0.0001$) in relation to the high number of vascular lesions treated in patients with CV comorbidity. The difference in complication rate between patients with and without CV comorbidities did not reach statistical significance (3% vs 1%, p = 0.15).
Conclusion: We are the first to demonstrate that DBE in patients with CV comorbidity is relatively safe and with a good diagnostic and therapeutic yield. Careful patient selection is imperative to prevent serious complications.

P0852 THE OVER-THE-SCOPE-CLIP (OTSC) AS A THERAPEUTIC OPTION FOR IATROGENIC PERFORATION (IP), ANASTOMOTIC LEAKAGE (AL) AND CHRONIC FISTULA (CF) IN THE GASTROINTESTINAL TRACT

J. Stückle[1], J. Brueckner[1], A. Probst[1], M. Bittinger[1], A. Ebigbo[1], H. Messmann[1], S. Goelder[1]
[1]*Department of Internal Medicine III, Klinkum Augsburg, Augsburg, Germany*

Contact E-mail Address: johannes.stueckle@klinikum-augsburg.de
Introduction: Patients with iatrogenic perforation during endoscopy, anastomotic leakage and chronic fistula used to be transferred to the surgeon for further therapy. Since the recent development of the Over-The-Scope-Clip (OTSC), an increasing number of such lesions can be treated endoscopically which makes the closing procedure to a fast and safe method.
Aims & Methods: All applications of OTSC in our department between 12/2009 and 02/2015 were assessed prospectively and classified into three groups: 1. iatrogenic perforation (IP) during endoscopy, 2. anastomotic leakage (AL) after upper, middle or lower gastrointestinal surgery and 3. chronic gastrointestinal fistula (CF). Technical success was determined by the endoscopist subsequently to the procedure. As a second end point, we assessed the clinical success. Additionally, we added all cases of further interventional or surgical treatment All additionally required interventions (e.g. interventional radiology or surgery) were documented.
Results: n = 34 patients (m = 20, f = 14; mean age 70 years, range 30-89) underwent OTSC-treatment and were classified by indication:
1. IP (n = 10): The perforations were caused by piece-meal resection of an duodenal (4) or antral (1) adenoma, endoscopic retrograde cholangiopancreatography (2), diagnostic colonoscopy (2) and accidental perforation of an endosonographic fine-needle biopsy (1).
None of the patients needed to be transferred for surgical treatment. One patient (10 %) showed an insufficient closure but could be treated conservatively by means of a drainage of a retroperitoneal abscess. All patients survived with an excellent outcome.
2. AL (n = 15): OTSC clipping was performed due to anastomotic leakage in different surgery sides of the upper, middle and lower gastrointestinal tract: Gastric anastomosic leakage in bariatric surgery (2), duodenal leakage after pancreas- or aorta-surgery and cholecystectomy (3), leakage after esophageal (5) and colonic surgery (5). Technical success was achieved in 100% of these interventions. However, 6 patients (40 %) did not experience sufficient clinical amerlioration. The reason for these failure were additional developed leakage and persisting leakage. Further interventional and surgical treatment was needed.
3. CF (n = 9): Persisting leakage after removal of an infected percutanous endoscopic gastrostomy (1), intestinale fistulae due to acute-necrotising panceatitis (2), chronic enterocutanous fistula (1), rectovaginal fistula after radiation therapy (1), perforating nasojejunal tube (1), spontaneously perforated gastric ulcer (1) and colonic perforation of unknown reason (2). All 9 patients could be successfully treated by endoscopic closing with the OTSC primarily. However, 7 patients (77.8%) developed a relapse of fistula or new fistula were arisen. Endoscopic treatment failed in these cases.
Conclusion: All iatrogenic perforations were sufficiently closed by OTSC and showed an excellent technical and clinical outcome without any further surgical treatment required. However, anastomotic leakage and chronic fistula that are endoscopically closed by OTSC, often require additional interventional or surgical procedures.

P0853 HYPERAMYLASAEMIA AND ACUTE PANCREATITIS AFTER DOUBLE BALLOON ENTEROSCOPY: A PROSPECTIVE STUDY

M. F. Hale[1], D. Sanders[1], R. Sidhu[1]
[1]*Academic Unit of Gastroenterology, Royal Hallamshire Hospital, Sheffield, United Kingdom*

Contact E-mail Address: melissa.hale@sth.nhs.uk
Introduction: Hyperamylasaemia and acute pancreatitis are potential complications following a double balloon enteroscopy (DBE) procedure. The mechanism of these complications is not fully understood. We present a prospective analysis of all patients undergoing DBE at a tertiary centre.
Aims & Methods: Single centre, prospective study involving all consecutive patients attending for DBE by either route, between 23rd Aug 2012 and 3rd October 2014. Serum amylase levels were obtained before and three hours after the procedure. Clinical evaluation for signs and symptoms of pancreatitis was performed three hours after the procedure. A record of the procedure duration, insertion depth and number of passes was also documented. Hyperamylasaemia was defined as an elevation of the serum amylase level to greater than the upper limit of normal.
Results: 115 procedures were performed on 89 patients, mean age 57.4 years (21-83 years), 46 male (51.7%). Indication for procedure is presented in Table 1. 91 procedures were performed per orally and 24 via the anal route. 88 procedures were performed on the basis of a positive small bowel capsule endoscopy (SBCE), 9 patients did not have prior SBCE due to failure to excrete the patency capsule. Indication for DBE is presented in Table 1. Overall 47 patients (61%) had an elevated serum amylase post procedure. Hyperamylasaemia post-procedure was observed in significantly more patients following per-oral DBE compared to DBE via the anal route (p = 0.03). Hyperamylasaemia in the per-oral group was associated with procedure depth (mean 147cm vs 187cm $p < 0.0009$) and number of passes (mean 10 vs 18 $p < 0.0007$), but not procedure duration (mean 64 vs 70 mins p = 0.2) or dose of fentanyl administered (mean 108mcg vs 118mcg p = 0.6). No patients developed signs or symptoms of pancreatitis post-procedure.

Table 1

INDICATION	No. of PATIENTS
Iron deficiency anaemia	46
Obscure gastrointestinal bleeding	19
Suspected Crohn's	15
Peutz Jegher's syndrome	11
Abnormal radiology	6
Small bowel stricture	6
Abdominal pain	4
Coeliac complications	3
Other	4

Conclusion: Hyperamylasaemia is common following DBE per-orally and is associated with procedure depth and number of passes. However, in the majority of cases this is of limited clinical significance and no patients in our series went on to develop pancreatitis.

P0854 MAGNIFYING NARROW-BAND IMAGING BY USING NEWLY DEVELOPED MAGNIFYING ENTEROSCOPY CAN BE USEFUL FOR EVALUATION OF INFLAMMATORY ACTIVITY IN SMALL INTESTINAL CROHN'S DISEASE: A PILOT STUDY

N. Ogata[1], K. Ohtsuka[2], S. Hayashi[1], M. Misawa[1], F. Ishida[1], S.-E. Kudo[1]
[1]*Digestive Disease Center, Showa University Northern Yokohama Hospital, Yokohama,* [2]*Enodoscopy unit, Tokyo Medical and Dental University Hospital, Tokyo, Japan*

Contact E-mail Address: n.ogata@hotmail.co.jp
Introduction: The development of balloon endoscopy and capsule endoscopy has made observation of the small intestine possible in clinical practice. The usefulness of magnifying endoscopy has already been reported in observing the pharynx, esophagus, stomach and colon. The prototype of a single-balloon enteroscopy (SBE) with 80x magnification has been recently developed.
Aims & Methods: The aim of this pilot study was to assess the efficacy of narrow-band imaging (NBI) magnifying findings for evaluating the severity of inflammation in small intestinal crohn's disease (CD). The study was conducted in Showa University Northern Yokohama Hospital. We included CD patients who underwent enteroscopy with magnification from September 2013 to December 2014. NBI images and a biopsy specimen were obtained from small intestinal mucosa for CD patients with use of SBE (Y-0007, Olympus, Tokyo). Magnifying NBI was performed, and the images were evaluated by assessing visibility, increased vascularization, and the increased caliber of capillaries into three grades as follows: Normal, Visible and Irregular. Normal was indicative of inactive disease, while Visible and Irregular were indicative of acute inflammation in our study. The outcome measures included the diagnostic ability of magnifying NBI findings to distinguish active CD from inactive CD on the basis of histological activity.
Results: Twenty-two patients were enrolled. There was a correlation between magnifying NBI findings and the histological assessment (Spearman's $|r| = 0.667$).The sensitivity, specificity, positive predictive value, negative predictive value, and accuracy of magnifying NBI findings for diagnosing acute inflammation were 71.4%, 95.2%, 83.3%, 90.9%, and 89.3%, respectively.
Conclusion: The NBI magnifying findings in the small intestinal mucosa had a correlation with histological inflammation and could help in distinguishing between active and inactive in CD.

P0855 MULTICENTRE EXPERIENCE USING A NOVEL DEEP ENTEROSCOPY PLATFORM IN SURGICALLY ALTERED GASTROINTESTINAL ANATOMY

J. X. Cai[1], D. L. Diehl[2], A. Hoffman[3], A. C. Storm[1], A. H. Tieu[1], M. H. El Zein[1], M. A. Khashab[1], R. Kiesslich[3], P. I. Okolo III[1], **V. Kumbhari**[1]
[1]*Division of Medicine, Department of Gastroenterology and Hepatology, Johns Hopkins Medical Institutions, Baltimore,* [2]*Department of Gastroenterology and Nutrition, Geisinger Medical Center, Danville, United States,* [3]*Department of Internal Medicine II, HSK Hospital, Wiesbaden, Germany*

Contact E-mail Address: vkumbhari@gmail.com
Introduction: Conventional deep enteroscopy platforms achieve technical success rates between 61-98% in patients with surgucally altered anatomy. However, they lack widespread availability and have limited therapeutic potential due to a smaller working channel. Through-the-scope balloon-assisted enteroscopy (TTS-BAE) marketed as NaviAid AB (Smart Medical Systems Ltd., Ra'anana, Israel) is a novel technique using a standard adult colonoscope allowing for a broader range of interventions through the larger working channel but may be hampered by a shorter depth of maximal insertion.
Aims & Methods
Aims: to determine the efficacy and safety of TTS-BAE in patients with surgically altered anatomy.
Methods: A retrospective multicentre (2 in U.S., 1 in Germany) study of consecutive patients with sugrically altered anatomy who underwent TTS-BAE between 2012 to 2014 were included. Target success was defined as ability to access the intended target. Technical success was defined as completion of the procedure as intended. Clinical success was defined as >50% reduction in abdominal pain or hepatic enzyme levels and resolution of jaundice or bleeding. Adverse events were graded according to the ASGE lexicon's severity grading system.
Results: A total of 42 patients (mean age 53yr, 18 female) underwent anterograde enteroscopies with a median procedure time of 42.5 minutes (25-250) (**Table 1**). Overall, the intended target was reached in 57.14% (n=24), of which 95.83% (n=23) were technically successful and 91.67% (n=22) were clinically successful. The biliopancreatic limb and deep small bowel had the highest rates of target and technical success (**Table 1**). Success rates did not differ between patients with RY vs not RY anatomy (P=0.78). A total of 7 metal stents and one 10Fr plastic stent were successfully deployed (5 biliary, 2 jejunal); this would not have been possible using other platforms. Adverse events occurred in 3 (7.14%) cases: aspiration pneumonia (mild), cholangitis (mild) and perforation (severe) distal to the HJ requiring surgical closure.

Continued

	N (%)	Target success (%)	Technical success (%)	Clinical success (%)
Type of anatomy				
RYGB	8 (19.05)	62.5	62.5	62.5
Transplant RYHJ	7 (16.67)	57.14	57.14	57.14
Non-transplant RYHJ	12 (28.57)	50	41.67	41.67
Whipple	10 (23.81)	60	60	60
Other	5 (11.90)	60	60	40
Indication for TTS-BAE				
ERCP	33 (78.57)	57.58	54.55	54.55
Small bowel stricture	5 (11.9)	80	80	60
GI bleeding	4 (9.52)	75	75	75
Target of TTS-BAE				
Hepaticojejunostomy/ Jejunojejunostomy	32 (76.19)	56.25	56.25	56.25
Deep bowel	5 (11.9)	75	75	50
Biliopancreatic limb	4 (9.52)	50	25	25
Excluded stomach	1 (2.38)	0	0	0

Conclusion: TTS-BAE does not reach the therapeutic target as often as conventional platforms possibly due to its shorter depth of insertion and the less flexible adult colonoscope. However, we demonstrate very high technical and clinical success rates once an intended target is reached, which can be particularly useful for metal stent deployment.

P0856 THE SMALL BOWEL VIDEOCAPSULE ENDOSCOPY: MAY WE DELEGATE IT TO NURSES ?

J. Dreanic[1], M. Gaudric[1], M. Dhooge[1], R. Coriat[1], S. Leblanc[1], F. Prat[1], V. Abitbol[1], E. Sion[1], V. Goncalves[1], C. Michel[1], D. Lalo[1], S. Chaussade[1]
[1]*Gastroenterology and endoscopy unit, Hopital Cochin - APHP, Paris, France*

Contact E-mail Address: johann.dreanic@cch.aphp.fr
Introduction: Small bowel videocapsule endoscopy (VCE) is a non-invasive and validated technique allowing the visualization of the small intestine mucosa. It generates more than 40,000 images per examination and induces a long median time of medical reading that may exceed one hour. In a transfer of skills' program, Nurses (N) might be involved in the VCE reading. We herein present a feasibility study that evaluated two strategies of transfer skills of the VCE to N through either the pre-selection of abnormalities or the complete analysis.
Aims & Methods: Twenty VCE were selected and interpreted by two medical experts (group A). Two N with endoscopic experience were trained for the small bowel VCE reading. Pre-selection of VCEs' pathological images were performed by N. Other experts in VCE readings established the definitive VCE's report from pre-selected images (group B). Meanwhile, N produced a report of the VCE (group C). The stomach and small intestine transit times and the reading time were recorded. The accuracy of the whole VCE interpretation was compared (group A vs. B; A vs. C). Experts reviewed all discordant interpretations.
Results: The extent of transit time in the stomach and the small intestine, and the identification of a normal endoscopic examination were not statistically different between group A and group B. The accuracy of reports from group A and B was 95% (19/20). In one case, N has not selected the pathological image, corresponding to a duodenal ulcer. The VCE average reading time by the expert in the group B was significantly shorter than in the group A (9.2min +/- 0.5 vs. 34 +/- 9.9min; $p<0.01$). Time analysis was not statistically different between the groups A vs. C (34min +/- 9.9 vs. 4.1 +/- 34.1min; $p=0.53$). The accuracy of reports from group A and C was 80% (16/20). In 4 cases, proofreading revealed a discordant interpretation. The discrepancy was due to a lack of pathological images' selection of the selected pictures for the final report (n = 2) and a lack of interpretation (n = 2) in group B.
Conclusion: In small bowel VCE interpretation, a pre-selection of pathological images by a trained N could be integrated in a transfer of skills' program and appeared feasible. The average gain of time for the gastroenterologists is significant and up to 25 minutes per examination. Interestingly, an overall delegation of small bowel VCE interpretation from physicians to N remained not sufficient enough and deserved to be improved. Considering the medical time constrains, our study justifies evaluating in a larger study the delegation of the pre-selection images by N in a transfer of skills' program.

P0857 HISTORICAL ANALYSIS OF SMALL BOWEL CAPSULE ENDOSCOPY PERFORMANCE IN A SPANISH TERTIARY HOSPITAL

J. Egea-Valenzuela[1], P. Tomas-Pujante[1], E. Iglesias-Jorquera[1], G. Carrilero-Zaragoza[1], F. J. Alvarez-Higueras[1], A. Pereñiguez-Lopez[1], E. Sanchez-Velasco[1], F. Alberca-de-las-Parras[1], F. Carballo-Alvarez[1]

[1]Digestive Diseases, Hospital Clinico Universitario Virgen de la Arrixaca, Murcia, Spain

Introduction: Capsule endoscopy (CE) is a widely extended technique for the diagnosis of small bowel pathology. In our hospital it has been available since 2004 with an increasing number of procedures along the time. At the beginning no more than some tens of studies were performed while up to 150 patients per year have come for CE in the last years.
Aims & Methods: Our aim is to analyze the data from our historical database of small bowel CE starting in year 2004.
We have retrospectively analyzed the data from the patients under small bowel CE in our hospital from October 2004 to April 2015, including demographic data, indications, findings and complications. Indications have been divided in: obscure occult gastrointestinal bleeding (OOcGIB), obscure overt gastrointestinal bleeding (OOvGIB), inflammatory bowel disease (IBD), and other indications (including polyposis, celiac disease, abnormal previous radiologic test, etc.). Findings in CE studies have been defined as: vascular ectasia (VE); ulcerative lesions (UL), including drug-induced lesions and Crohn's disease; other lesions, such as polyps, submucosal tumors, atrophy, etc.; normal (no findings); and inconclusive studies due to gastric o enteric retentions, technical problems, poor bowel cleansing, etc.
Results: We have included 1027 CE studies, after exclusion of those with incomplete or indefinite information. The average age of the patients is 56.45 years old (4 - 91 y-o), including 471 men (57.55 y-o) and 556 women (55.54 y-o). The most frequent indication was OOcGIB (n = 471, 214 men/257 women), followed by OOvGIB (n = 240, 126 men/114 women), IBD (n = 224, 94 men/130 women) and other indications (n = 92). In *TABLE 1* we show the distribution of the different indications according to sex and age.
The most frequent finding was VE (n = 583), alone or with secondary findings. UL were observed in 329 cases, alone or with other lesions. Other kind of lesions as polyps or small bowel submucosal tumors were observed in 159 cases, in most of them as secondary or incidental findings.
It is remarkable that the greatest rate of normal studies occur in the group of IBD, probably related to the lack of evidence referring to factors associated to the diagnostic yield of CE in these cases and over-indication of the technique. On the other hand it is also striking the number of UL seen in patients presenting with OOvGIB, probably because many of them were under nonsteroidal anti-inflammatory drugs or antiplatelets.
No major complications have been observed in our database. 3 cases of gastric and 5 small bowel retentions of the capsule have been reported. All of them were managed conservatively, with no need for urgent surgery.

	OOcGIB	OOvGIB	IBD	Other indications
MEN	n = 214	n = 126	n = 94	n = 41
	Age: 65.2	Age: 62.2	Age: 35.4	Age: 52
WOMEN	n = 257	n = 114	n = 130	n = 51
	Age: 63	Age: 62	Age: 37.8	Age: 49.3
OVERALL	n = 471	n = 240	n = 224	n = 92
	Age: 64	Age: 62	Age: 36.8	Age: 50

Conclusion: Our experience shows that CE is a safe and useful tool for the diagnosis of small bowel pathology. We have observed an increasing number of studies along the years, with a high diagnostic yield specially in cases of obscure bleeding.

P0858 "SUSPECTED BLOOD INDICATOR" AND "QUICK VIEW" IN SMALL BOWEL CAPSULE ENDOSCOPY FOR OBSCURE GASTROINTESTINAL BLEEDING: A COMPARATIVE STUDY

M. Barbosa[1], P. Carvalho[1], T. Goncalves[1], B. Rosa[1], M. J. Moreira[1], J. Cotter[1]
[1]*Gastroenterology, Centro Hospitalar do Alto Ave, Guimaraes, Portugal*

Contact E-mail Address: maraisabelbarbosa@net.sapo.pt
Introduction: Small bowel capsule endoscopy (SBCE) is indicated to evaluate for obscure gastrointestinal bleeding (OGIB). As Standard view (SV) reading is time-consuming, Suspected Blood Indicator (SBI) and Quick View (QV) readings can be useful in the initial evaluation of the VCE study, as they allow for a more rapid reading.
Aims & Methods: To compare the diagnostic accuracy of SBI reading and QV reading *versus* SV reading in OGIB.
Unicentric retrospective study which included patients who underwent SBCE studies for evaluation of OGIB in a 7-year period. Exclusion criteria: incomplete SBCE and technical recording errors. SBI and QV readings were performed by two independent investigators. The presence of small bowel active bleeding, P2 lesions and QV reading time were recorded. Goldstandard: SV reading.
Results: Three-hundred patients were included: 63.3% female, mean age 62 years, 16.7% with overt OGIB. In SV, active small bowel bleeding was visualized in 31 cases (10.3%) and the bleeding origin was identified in 13 (41.9%). For SBI, the sensitivity was 93.5%, with a negative predictive value (NPV) of 99.3%; for QV, the sensitivity was 100%, with a NPV of 100%. SBI revealed the bleeding origin in 34.5% of the cases and QV in 38.7% of them. In SV, small bowel P2 lesions were visualized in 29.3% of the SBCE. The sensitivity for P2 lesions was 42.0% for SBI and 79.5% for QV, with a NPV of 80.6% and 92.2%, respectively. The mean diagnostic reading time in QV was 2min22s.
Conclusion: Although both modalities are extremely sensitive at identifying active bleeding, Quick View reading detects a higher number of P2 lesions than the Suspected Blood Indicator. In comparison to SBI reading, QV reading is a more accurate diagnostic tool at evaluating patients with OGIB, and it may prove useful as an initial screening in urgent cases.

P0859 ENABLING TANDEM PROCEDURE OF COLONOSCOPY FOLLOWING COLON CAPSULE ENDOSCOPY IN COLORECTAL CANCER SCREENING

M. Khoury[1], L. Bredow[2], F. Khoury[1], A. Sollacher[2], S. Froschauer-Haefele[3], G. Dahlhoff[4], A. Munte[2]
[1]*Gastroenterological Center, Hof,* [2]*Libertamed, Munich,* [3]*Libertamed, Hof,* [4]*AOK Bayern, Munich, Germany*

Contact E-mail Address: mkhoury@t-online.de
Introduction: Importance of prevention of colorectal carcinoma (CRC) is rising due to increased incidence; yet, acceptance of screening by colonoscopy remains low in Germany. Major reasons are the invasive and intimate character of the colonoscopy itself and the bowel preparation. To overcome these barriers a pilot project by AOK Bayern health insurance in north-eastern Bavaria offers patients aged 45 to 75 to choose between a colon capsule endoscopy (CCE) and screening colonoscopy. If significant findings are discovered during CCE (polyps ≥ 6mm, or ≥ 3 polyps) a so-called tandem procedure is offered: a therapeutic colonoscopy follow-up on the same day with the same bowel preparation, therefore avoiding a second appointment. Feasibility of such a tandem procedure in a non-clinical trial setting has not yet been proven.
Aims & Methods: To allow a tandem procedure, capsule excretion has to be achieved before 3 pm (about 7 hours after capsule ingestion). Following the protocol all patients receive a series of boosts of sodium phosphate to propel the capsule through small and large bowel. To avoid too fast colonic transit, a reduced first boost of 15 ml instead of 30 ml sodium phosphate was given after capsule entry into the duodenum. If CCE was not excreted after 2.5 hours, a second and eventually a third boost after further 2 hours were administered while not exceeding 55 ml of total concentration of sodium phosphate, as recommended in Spada et al. (2012). Percentages were performed to demonstrate that tandem procedure is feasible in clinical practice. Total capsule transit time not exceeding 7 hours was used as outcome criteria.
Results: In total, 260 patients received a CCE from January 2014 – March 2015. In our setting 78% (n = 203) of the CCE was below 7 hours, which allows a tandem procedure. 53 patients (20%) out of the 260 patients needed one boost to complete CCE. 207 patients (80%) received a second boost and out of them 46 (18%) even a third to achieve capsule excretion. 130 (81%) out of 161 patients who received only two boosts would have qualified for a tandem procedure. If a third boost was necessary 43% of the patients would have been able to receive a tandem procedure.
Conclusion: The analysis shows that a tandem procedure of CCE followed by a therapeutic colonoscopy within one day with only one bowel preparation is feasible in a real-world clinical setting. In most of the cases realizing a passage time under 7 hours while producing high-quality video recordings could be achieved with a first boost of 15 ml. However, the quite high percentage of a necessary third boost in our setting suggests that dosages of the first and second boost should be analysed further to potentially reduce the need of a 3rd one.

P0860 REALIZATION OF COLON CAPSULE ENDOSCOPY AND COLONOSCOPY FOLLOW-UP IN TANDEM ON THE SAME DAY IN A REAL-WORLD SETTING

M. Khoury[1], L. Bredow[2], A. Sollacher[2], S. Froschauer-Haefele[2], G. Dahlhoff[3], **A. Munte**[2]
[1]*Gastroenterological Center, Hof,* [2]*Libertamed,* [3]*AOK Bayern, Munich, Germany*

Contact E-mail Address: mkhoury@t-online.de
Introduction: To increase prevention of colorectal carcinoma (CRC) a pilot project by AOK Bayern health insurance in north-eastern Bavaria offers patients aged 45 to 75 both traditional colonoscopy and colon capsule endoscopy (CCE) as well as a so-called tandem procedure. It enables colonoscopy follow-up on the same day in case of significant findings during CCE, thereby avoiding a second bowel preparation. Aim of this abstract is a description of processes that allow for this tandem procedure.
Aims & Methods: To realize tandem procedure, several organizational and personal requirements need to be considered (see also Krause & Riemann, 2013). At least 3 days before CCE the medical staff needs to inform the patient comprehensively about advantages and disadvantages of traditional colonoscopy, CCE and tandem procedure. Like colonoscopy, CCE preparation involves bowel cleansing including high intake of fluids two days before, a liquid diet one day before and 1.5 l of peg 3350-electrolytes-vitamin C (PEG C) and 2 l water between 6-8 pm the night before CCE. The next morning the patient again has to drink 1 l of PEG C and 2 l of water until 6:30 am, since no fluids should be taken 90 min before swallowing the capsule to ensure quick stomach passage. During CCE the patient should not eat. Optimally, the CCE should start at 8 am in the doctor's practice to realize capsule excretion before 3 pm. During CCE patients may rest in a recreational room, which allows the medical staff to supervise capsule progress every 30 minutes and to give recommended boosts according to protocol to accelerate passage time. Further, average video analysis time (90 min) needs to be reduced, which can be warranted due to intelligent image recognition software and highly trained staff. If significant findings (polyps ≥ 6mm in size, or ≥ 3 polyps) are observed, the patient may receive a

follow-up colonoscopy the same evening without further intake of bowel cleansing. This however requires availability of spatial resources and medical staff until 7 pm.
Results: Following this procedure a colonoscopy on the same day after significant findings during CCE could have been realized in 78% of all screenings. In total, 348 patients opted for a CCE from September 2013 – March 2015.
Conclusion: The pilot project shows that a follow-up colonoscopy the same day than a CCE in case of significant findings can be realized in a real-world practice setting, which avoids a second bowl preparation in case of diagnostic findings. This method however, requires a well-timed and personnel good organized practice as well as a trained doctor. Advantages of a tandem procedure are a non-invasive procedure, only one bowl cleansing, and an intensive medical support. Disadvantages are long fasting times before and during the examination day, preparation early in the morning and spending a whole day in the medical practice.

Introduction: Capsule endoscopy (CE) is a well-tolerated, first-line small bowel (SB) investigative modality. A specifically adapted version is available to image the colon, thus providing an option for non-invasive, single visit imaging of the entire gastrointestinal tract. This study evaluates a novel panenteric protocol utilised to investigate patients with symptoms which could originate from the SB, large bowel or both sites.
Aims & Methods: Retrospective, single centre, involving consecutive patients attending for panenteric CE between July 2008 and December 2014. PillCam SB (Given Imaging, Israel) or MiroCam (Intromedic, Korea) and PillCam Colon 2 (Given Imaging) were used. All patients with known inflammatory bowel disease (IBD) successfully passed a PillCam Patency device prior. Patient demographics, procedural data, final diagnosis and outcomes were collected.
Results: 108 procedures were performed, mean age 41.5 years (range 16-95), 72 female, median follow up 27 months (range 2-79).
41 patients had known IBD (37 Crohn's, 4 ulcerative colitis (UC)) and were undergoing disease re-assessment after 12 months of anti-TNF therapy (12), or due to relapse in symptoms (29). The remaining 67 patients had suspected IBD with predominant symptoms of diarrhoea (33), abdominal pain (15), iron deficiency anaemia (8), weight loss (6) and gastrointestinal bleeding (5). 51 patients refused colonoscopy, 37 chose CE over colonoscopy, 17 had an incomplete colonoscopy and 3 were unfit for colonoscopy.
Panenteric capsule endoscopy completion rate (CECR) was 60.1% (65/108), SB CECR 86.1% (93/108) and colon CECR 71.3% (77/108). Colon CE bowel preparation was graded as good or excellent in 61.8%. 2 patients were excluded due to prolonged gastric retention of the colon capsule, 1 subsequently diagnosed with narcotic bowel syndrome. No complications were encountered.
In the IBD group, 25 patients (61.0%) had evidence of active disease, leading to medication alterations in 21, surgery in 1 and conservative management in 3. Of the 16 patients in whom mucosal healing had been achieved, medication regimens were downgraded in 10 patients.
In the suspected IBD group, this was identified in 13.4% (7 Crohn's, 2 UC). Clinically relevant alternative findings included colon polyps (16), diverticular disease (9 colonic, 1 SB), angioectasia (6 SB, 1 colonic) and a small bowel carcinoid (1).
The remaining 24 patients were diagnosed with functional bowel disorders and discharged.
Of all the 34 patients with IBD identified, 22 had ileitis alone, 5 had ileocolonic disease and 7 had colonic disease alone.
Conclusion: Panenteric capsule endoscopy is feasible and can be performed safely in patients known to have IBD. It can be used to guide management without resorting to conventional endoscopy and identifies pathology in all areas of the gastrointestinal tract.

P0862 COLON CAPSULE ENDOSCOPY: A USEFUL DIAGNOSTIC MODALITY THAT INFORMS PATIENT MANAGEMENT

M. F. Hale[1], K. Drew[1], E. Ejenavi[1], R. Sidhu[1], M. E. McAlindon[1]
[1]*Academic Unit of Gastroenterology, Royal Hallamshire Hospital, Sheffield, United Kingdom*

Introduction: Colon capsule endoscopy (CCE) has been demonstrated to be a feasible alternative to colonoscopy for the detection of polyps and neoplasia[1] and avoids intubation and sedation**.** This study evaluates the utility of CCE in routine clinical practice and its impact on patient outcomes.
Aims & Methods: Retrospective, single-centre, including symptomatic patients attending for CCE using PillCam Colon 2 (Given Imaging, Yoqneam, Israel). All patients with known inflammatory bowel disease (IBD) successfully passed a PillCam Patency device prior. Patient demographics, procedural data, final diagnosis and management outcomes were collected.
Results: 101 patients were included, mean age 43 years (range 16-95), 73 female, median follow-up 29 months (range 1-52). 48% refused colonoscopy, 29% had an incomplete colonoscopy, 17% chose CCE over colonoscopy and 6% were unfit for colonoscopy. Indication for the procedure: anaemia (24%), IBD assessment (16%) and suspected IBD (60%). The latter had predominant symptoms of diarrhoea (77%), abdominal pain (18%) or weight loss (5%). Procedure completion rate 69%, bowel preparation was adequate in 75%. There were no complications.
Results are summarised in Table 1.
In the anaemia group, CCE altered management in 15%: 3 further procedures (1 double balloon enteroscopy (DBE) and argon plasma coagulation, 1 catheter embolisation and 1 small bowel capsule endoscopy) and 1 altered medication. The remaining 20 were managed conservatively.
In the known IBD group, CCE altered further management in 69% (7 altered medication, 2 surgery, 2 further procedures (1 DBE, 1 colonoscopy), the remaining 5 patients were managed conservatively.
In those suspected as having IBD, this was identified in 7%. Other clinically significant diagnoses were made in 36%. The remaining 57% patients were thought to have functional bowel disorders and were discharged. 3 patients were excluded due to a non-diagnostic examination.

Abstract number: P0863

VC, virtual chromoendoscopy; *statistically significant; § stratified McNemar test; WLI, white light image; CI, confidence interval

Table 1

INDICATION	DIAGNOSIS							
		FRESH			SB			
NORMAL	POLYPS	BLOOD	AE	DD	ULCERATION	COLITIS	HAEMORRHOIDS	
ANAEMIA	10	3	3	2	2	3	1	0
KNOWN IBD	7	0	0	0	0	8	1	0
SUSPECTED IBD	33	16	0	0	4	3	1	1

Conclusion: CCE may be a useful alternative for detecting clinically relevant pathology in symptomatic patients and can help guide management. An incomplete examination (i.e. distal colon not visualised) was less relevant in the 29 patients who had already had an incomplete colonoscopy beforehand or the 24 patients whose incomplete CCE was sufficient to provide a diagnosis. Although marketed as a colonic imaging device, a third of pathology identified by CCE was in the SB, serving as a reminder that it may be difficult to distinguish symptoms arising from the small or large bowel, or both.

Introduction: Identification of subtle small bowel mucosal lesions by less experienced videocapsule endoscopy (VCE) readers can be challenging, as small differences in mucosal hue or pattern are difficult to detect. To improve lesions' characterization, chromoendoscopy virtual techniques based on narrowing the bandwidth of the conventional white light endoscopy image (WLI) were developed. However, data on the virtual chromoendoscopy (VC) application in VCE are limited.
Aims & Methods: This multicenter study involved 15 trainees or young endoscopists with good experience in GI endoscopy but no experience in VCE examination. In the first step, they evaluated a WLI selection of mixed de-identified images of 250 unequivocally confirmed difficult to interpret small bowel ulcerative lesions, and 100 artifacts mimicking ulcerative lesions. In the second step, they were randomized in clusters of 3 to evaluate the same images with the addition of one of the VC setting (FICE 1,2,3 and Blue Mode) or in WLI again, labeling them as real or faked. The comparison of accuracies in correctly categorizing the images was performed between the two readings (McNemar's test).
Results: The results were very heterogeneous. There was a small decrease in accuracy for the second evaluation of WLI pictures. By adding any of the chromoendoscopy settings resulted in an improvement in lesions' characterization; statistical significance was obtained only for Blue Mode (*see table*).
Conclusion: Virtual chromoendoscopy (especially Blue Mode) seems to help beginner VCE readers in correctly categorizing small bowel mucosal ulcerative lesions.

P0864 A NOVEL PREP-LESS X-RAY IMAGING CAPSULE FOR COLON CANCER SCREENING: SAFETY AND PRELIMINARY HUMAN TESTS

N. Gluck[1], **N. Arber**[1,2], M. Moshkowitz[1,2]
[1]*Department of Gastroenterology,* [2]*Integrated Cancer Prevention Center, Tel Aviv Sourasky Medical Center, Tel Aviv, Israel*

Contact E-mail Address: nadira@tlvmc.gov.il
Introduction: The demand for bowel cleansing hampers participation in screening colonoscopy, while poor preparation impairs adenoma detection. A screening method, which generates structure data of the colon, without any cleansing or diet restrictions, would offer an attractive modality for many of the non-compliant patients from the target population.
Aims & Methods
Aims: To evaluate feasibility, safety and outcomes of a novel prep-less X-ray imaging capsule for colon screening.
Device: The capsule is similar in dimensions to other approved capsules. Novel ultra-low dose X-ray based imaging technology (X-Ray radar) generate high-resolution 3-dimensional (3D) imagery of the colon without bowel cleansing. The radar is activated and scans the inner surface only when the capsule is propelled within the colon.
Methods: Capsules were swallowed by ~20 volunteers (aged 37-66) and tracked during the entire passage of the capsule through the alimentary tract using radio frequency telemetry and a Capsule localization system (CPS). The system performed scans upon detecting effective capsule motion in the colon and transmitted imaging data to an external recorder unit attached to the patients' lower back. Combined data from colon scans and the CPS system were used to reconstruct 3D colon segments in non-prepped colons. Total transit time and total X-ray exposure were calculated to assess the safety profile of the capsule in human subjects.
Results: All capsules were swallowed and eliminated naturally and uneventfully after an average transit time of 68 ± 31 hours. The volunteers were exposed to an ultra-low total radiation dose (average total exposure 0.03 ± 0.007 mSv). The generated traces from various participants present large variability of colon macro structure. Reconstruction of synthetic colon phantoms with and without polyps as well as data from a Bovine colon phantom with induced tissue-made polyps showed spatial resolution of 2–3 mm in colon diameter measurements.
Conclusion: A safety and preliminary efficacy study has been performed using a novel prep-less x-ray imaging capsule for colon cancer screening.
Quantitative ultra-low dose x-ray 3D imaging was achieved in the colon of human subjects. The efficacy of the tracking system and the colon 3D reconstruction will be validated in a multicenter study.

Introduction: Reading of tens of thousands of CE images is labor-intensive and time-consuming. Olympus Corp. has developed a new algorithm to minimize redundant images so that all the areas captured by CE can be displayed.
Aims & Methods: The co-primary endpoints in this study were (1) to demonstrate the non-inferiority of this new algorithm modality showing only selected images in reading major and minor lesions compared to the control (EC-10 normal mode modality) showing all the images in terms of the number of true positives (TP), and (2) to demonstrate the superiority of this modality to the control in reading time. Multicenter crossover study was performed at 8 hospitals in Japan. This study consisted of 7 readers and 3 adjudication committee members, 2 reading modalities, and 40 patients with various small-bowel pathology reviewed and documented by 3 judging members from 60 patients with suspected small-bowel diseases (10 patients from 6 hospitals). Each patient's images were read by randomly-allocated 2 readers, each of whom used each modality for each patient (i.e. Doctor A: the new modality followed by the control, Doctor B: the control followed by the new modality). The reading modalities were switched after a certain interval more than 2 weeks. Thereby, this amounted to a total of 4 readings per patient. The adjudication committee defined clinically relevant lesions as major lesions, and irrelevant subtle lesions as minor lesions. A priori non-inferiority margin of 0.9 was established.
Results: Estimated ratios of detection rates of total, major, and minor lesions with the new modality compared to the control were 0.87 (0.80-0.95), 0.93 (0.83-1.04), and 0.83 (0.74-0.94), respectively. Although non-inferiority was not demonstrated with the new modality, the detection rate of major lesions was not significantly different between the new modality and the control. The reading

time of the new modality and the control was 27.3 and 75.1 minutes, respectively, the difference of which was -47.7 minutes (-52.0,-43.4)($P < 0.001$).
Conclusion: The Olympus new algorithm-implemented reading software significantly shortened the reading time without declining detection rate of major lesions, although non-inferiority was not demonstrated in detecting all small-bowel lesions.

P0866 POLYETHYLENE GLYCOL SOLUTION PRIOR TO SMALL BOWEL CAPSULE ENDOSCOPY – DOES IT HELP?

O. S. Omer[1], **S. Salehi**[1], D. De Coster[1], M. Wong[1], L. Pee[1], A. McNair[1]
[1]*Gastroenterology, Queen Elizabeth Hospital, Woolwich, London, United Kingdom*

Contact E-mail Address: a.mcnair@nhs.net
Introduction: The diagnostic yield of capsule endoscopy (CE) relies heavily upon obtaining clear luminal views and is often hampered by biliary secretions, small intestinal fluid and bubbles. Studies assessing the efficacy of bowel preparation in CE have been inconsistent and a general consensus on this matter has not been reached. Our department has recently moved from a pre-procedure regimen of 24 hours of clear fluids only, to 24 hours of clear fluids and the addition of a single sachet of polyethylene glycol (PEG) solution the evening prior to CE. To investigate the effect of this change, we performed a retrospective review of CE findings in patients who received PEG solution vs. clear fluids.
Aims & Methods: Patients who underwent CE from August 2013 to March 2015 were indentified using Rapid® capsule endoscopy software. This provided an even distribution of patients receiving PEG solution vs. clear fluids only. Data were collected on patient demographics, indication for CE and clinical findings. Three independent assessors then reviewed image quality of capsule footage at 20 minute intervals to examine the bowel preparation. Overall adequacy was determined as 'adequate' or 'inadequate' (views of mucosa obscured by cloudy fluid or bubbles in a high proportion of images) by consensus opinion. Lesion detection rates were then calculated for patient groups. Comparisons between groups were performed using chi-square analysis.
Results: A total of 62 patients were identified: 31 (50%) received polyethylene glycol (PEG) solution and 31 (50%) received clear fluids only (CF) prior to CE. There were no significant differences in patient demographics between PEG and CF groups (mean age 50 vs. 52, and M:F 20:11 vs. 18:13, respectively). Indications for CE included obscure gastrointestinal (GI) bleeding (18 in PEG group vs. 22 in CF) and possible small bowel Crohn's disease (13 in PEG group vs. 9 in CF). There were no significant differences in lesion detection rate between the two groups when all lesions, including those deemed clinically insignificant (e.g. minor aphthous ulceration) were analysed (90.3% PEG group vs. 83.9% CF, $p = 0.45$). When these lesions were excluded, the detection rate for clinically significant lesions in the PEG group was significantly higher than that in the CF group (58.1% vs. 32.3%, $p < 0.05$). Moreover, a significantly higher proportion of patients had 'adequate' image quality following bowel preparation in the PEG group vs. CF group following independent assessment (74.2% vs. 48.4%, $p < 0.05$).
Conclusion: We conclude that moving to a regimen of clear fluids and a single sachet of PEG solution prior to CE has significantly improved our detection rate of clinically significant lesions. This may be explained by improved image quality and adequacy of bowel preparation associated with PEG solution. Larger prospective studies comparing different bowel cleansing regimens (including a 'full' bowel preparation as taken prior to colonoscopy) are needed to firmly establish the ideal preparation for capsule endoscopy.

P0867 STANDARTIZATION OF VIRTUAL NAVIGATOR WORK IN ABDOMINAL RADIOLOGY

I. Timashkov[1], A. Borsukov[1]
[1]*Problem Scientific Research Laboratory, SSMU, Smolensk, Russian Federation*

Contact E-mail Address: Ivan.Timashkov@gmail.com
Introduction: The essence of the virtual navigator is to synchronize the real-time data obtained by ultrasound and MSCT / MRT. There are 2 modes of synchronization: 1-manual alignment of the plane and point 2-technology automatically align with a magnetic sensor - Active Tracker. The scientific sources available to us is not given a standardized method of using the device Active Tracker, depending on the zone of interest.
Aims & Methods: In order to standardize the work of the virtual navigator LOGIQ E9 in abdominal radiology surveyed 11 people (6 male, 5 female) with different pathologies of the abdominal cavity during 2014. Algorithm examination consisted of 3 phases. The first phase was carried out ultrasound research of the abdomen, which determines the location of the pathological focus in the abdomen. The second stage was carried out MSCT of the abdomen (model Toshiba Aquilion) superimposed on the anterior abdominal wall unit Active Tracker. In the third phase image obtained by MSCT were loaded on the console LOGIQ E9, where the automatic synchronization of the image obtained by MSCT and ultrasound research in real time using the device Active Tracker. We have proposed a method of standardization Active Tracker device location on the anterior abdominal wall at pathological foci ranging in 1- the right lobe of the liver, 2 - the left lobe of the liver, 3- pancreas, 4- right kidney, 5-, left kidney. In the study of the pathological focus in the right lobe of the liver is necessary to have Active Tracker midline at a distance of 7-8 cm from the edge of the xiphoid process. In the study of the pathological focus in the left lobe of the liver is necessary to have Active Tracker midline at a distance of 10-11 cm from the edge of the xiphoid process. In the study of the pathological focus in the pancreas is necessary to have Active Tracker midline at a distance of 12-13 cm from the edge of the xiphoid process. In the study of the pathological focus in the right kidney is necessary to have Active Tracker on the right midclavicular line in the 7-8 intercostal space. In the study of the pathological focus in the left kidney is necessary to have Active Tracker on the left midclavicular line in the 7-8 intercostal space.
Results: The standardization work of the virtual navigator has led to a reduction in the time synchronization of images from 15-20 minutes to 3-7 minutes, increase the accuracy of coincidence of the two images (with 78% for the standard method to 92% with improved), reducing the number of operator errors when synchronizing images.
Conclusion: Thus, we developed a technique proved its efficiency and propose to use when working with virtual navigation.

P0868 ENDOSCOPIC ULTRASONOGRAPHY-GUIDED INTERSTITIAL BRACHYTHERAPY BASED ON SPECIAL TREATMENT-PLANNING SYSTEM FOR UNRESECTABLE PANCREATIC CANCER: A PILOT STUDY

Y. Liu[1], **M. Min**[1], Y. J. Wu[2]
[1]*Affiliated Hospital of Academy of Military Medical Sciences, Beijing,* [2]*Information Science and Engineering School, Fudan University, Shanghai, China*

Contact E-mail Address: minmin823@sina.com
Introduction: EUS-guided interstitial brachytherapy is promising in the treatment of unresectable malignant carcinoma adjacent to the digestive tract. The feasible treatment plan is not established.
Aims & Methods: To develop a novel treatment plan and evaluate the feasibility in patients with unresectable pancreatic cancer.14 patients with unresectable pancreatic cancer.A special treatment-planning system (TPS) for EUS was designed and evaluated by comparing with the traditional TPS. (IIIstage: 6; IVstage: 8) underwent EUS-guided interstitial brachytherapy based on the new software.
Results: In the test model, there was no obvious difference of irradiation doses calculated by the two softwares (EUS TPS vs. traditional TPS) ($P > 0.05$). Under the support of EUS TPS, a novel treatment plan for EUS-guided interstitial brachytherapy was successfully established, which contained seven principles. All patients tolerated the treatment well without any serious complications. In 5 patients (stage III) that the minimal peripheral dose was larger than 90Gy, the PD rate was 80%(4/5).Four patients (4/6) in stage III were alive for more than 12 months with a median peripheral dose of 107.5 Gy. The expected median survival time of the 14 patients was 9.0 months (95%CI, 7.6–10.4 months).
Conclusion: The results demonstrated that the new EUS TPS will play an important role in EUS-guided interstitial brachytherapy in patients with unresectable malignant carcinoma.

P0869 TYPE OF COMBINED ENDOSCOPIC BILIARY AND GASTRODUODENAL STENTING IS A SIGNIFICANT FACTOR FOR BILIARY ROUTE MAINTENANCE

T. Sato[1,2], K. Hara[2], N. Mizuno[2], S. Hijioka[2], H. Imaoka[2], A. Nakajima[1], K. Kubota[1], K. Yamao[2]
[1]*Department of Gastroenterology and Hepatology, Yokohama City University School of Medicine, Yokohama,* [2]*Department of Gastroenterology, Aichi Cancer Center Hospital, Nagoya, Japan*

Contact E-mail Address: tkmtsato@yokohama-cu.ac.jp
Introduction: Some patients with malignant gastric outlet obstruction require combined biliary and gastroduodenal stenting (double stenting)[1], but there is often difficulty performing biliary re-intervention for stent dysfunction, and the optimal biliary stenting for such cases remains controversial[2].
Aims & Methods: From the perspective of biliary re-intervention, 43 consecutive patients who successfully underwent endoscopic double stenting with metallic stents were reviewed, and features of double stenting and clinical outcomes were evaluated. The present study aimed to clarify what affects for long-term maintenance of the biliary drainage route.
Results: All patients with biliary stent dysfunction were studied, and univariate analysis showed that the separate type of double stenting (two stents placed not in a crossed position) was a unique predictive factor related to successful biliary re-intervention for stent dysfunction (odds ratio 73.67, $P = 0.001$). From the comparison of clinical features between the separate and cross (two stents placed in crossed position) types, cases with biliary stenting before gastroduodenal stenting ($P = 0.008$) and transpapillary biliary drainage ($P = 0.01$) tended to become the cross type. There were no significant differences in overall survival and the biliary stent dysfunction rate, but the Kaplan-Meier method showed that the separate type was superior for biliary stent patency after double stenting ($P = 0.04$). Moreover, the initial biliary route maintenance rate was significantly higher in the separate type, with an estimated hazard ratio of 0.25 (95% confidence interval, 0.061-0.99; $P < 0.001$).
Conclusion: The separate type of double stenting might contribute to successful biliary re-intervention and maintain the drainage route longer. Technical considerations of biliary drainage should be considered in order to perform the separate type of double stenting.

P0870 INDICATION FOR THE PLACEMENT AND THE REMOVAL OF PROPHYLACTIC DRAINS FOLLOWING HEPATECTOMY

A. Oshita[1,2], M. Sasaki[1], A. Nakamitsu[1]
[1]*Gastroenterological Surgery, JA Hiroshima General Hospital, Hatsuka-ichi,*
[2]*Gastroenterological Surgery, Hiroshima Prefectural Hospital, Hiroshima, Japan*

Contact E-mail Address: oshita-akihiko@umin.ac.jp
Introduction: Although abdominal prophylactic drains following hepatectomy is still controversial, they have been routinely placed in most of institutions for hepato-biliary-pancreatic surgery. The present study was aimed to establish the indication to place prophylactic drains after hepatectomy and the optimal time for their removal.
Aims & Methods: From June 2011 to December 2014, consecutive 77 cases underwent hepatectomy without biliary reconstruction for benign and malignant liver tumors in JA Hiroshima General Hospital. Of them, prophylactic drains were placed in 60 cases whose Glissonean pedicles of more than 2 mm in diameter were ligated or clipped and divided. Perioperative data were prospectively collected and analysed. Bilirubin levels in drain fluid were measured on postoperative day (POD) 3 after surgery. Drains were removed on POD 3 or 4 if the drain-fluid bilirubin level was less than three times as the serum level of bilirubin according to the International Study Group of Liver Surgery (ISGLS). As postoperative complications related with placement of prophylactic drains, biliary leakage was analysed and classified into two groups: one is early biliary leakage (EBL) when diagnosed within POD 10. The other is delayed biliary leakage (DBL) when diagnosed after POD 11.
Results: Biliary leakages of Grade A and B according to ISGLS were observed in 6 cases (7.8%). The drain-fluid bilirubin level more than three times as the serum level of bilirubin was observed only in one case, treated conservatively by repeated replacement of drainage (Grade A). In the rest of 59 cases, placed with prophylactic drains, they were removed on mean POD 3.5. Of them, five cases were treated with re-drainage on mean POD 19.0 (ranging from 11 to 30) and four cases were co-treated with endoscopic nasal biliary drainage (Grade B). On multivariate analysis, the exposure of Glissonean pedicles of more than 2 cm in the major axis was the strongest predictor of biliary leakage (odds ratio 14.210, 95 per cent confidence interval 1.289 to 156.717; $p = 0.03$).
Conclusion: Prophylactic drains might be essential in hepatectomy, exposing the Glissonean pedicle. The optimal time for their removal according to the ISGLS criteria of biliary leakage was thought to be appropriate for EBL. However, the careful observation is also needed after POD 11 for DBL.

P0871 POSTTRANSPLANT PEAK C-REACTIVE PROTEIN CORRELATES WITH ISCHEMIA-REPERFUSION INJURY AND RECURRENCE-FREE OUTCOME IN LIVER TRANSPLANT PATIENTS WITH HCC

A. Kornberg[1], U. Witt[2], J. Kornberg[3,4], H. Friess[1], K. Thrum[5]
[1]*Surgery,* [2]*TU Munich,* [3]*LMU, Munich, Germany,* [4]*Anesthesiology, LMU, Munich,* [5]*Pathology, Helios Klinikum, Berlin, Germany*

Contact E-mail Address: ArnoKornberg@aol.com
Introduction: Ischemia reperfusion (I/R) injury was shown to promote intra- and extrahepatic tumor outgrowth in liver transplant patients with hepatocellular carcinoma (HCC). C-reactive protein (CRP) is a parameter of inflammatory response to surgical trauma.
Aims & Methods: The aim of this study was to determine the correlation of posttransplant peak CRP-level with I/R-induced hepatocellular damage and recurrence-free outcome following liver transplantation (LT) for HCC. 103 liver transplant patients with HCC were included. Patients were classified as Milan In and Milan Out, based on explant histopathology data. By ROC-analysis, the most optimal cut-off post-LT peak CRP-level for overall and recurrence-free outcome was determined. Peak CRP values along with other established clinicopathologic variables were correlated with early hepatocellular damage (transaminases, hepatic artery resistive index) and tumor-specific outcome.
Results: ROC-analysis defined an optimal cut-off peak CRP-level of 3.5 mg/dl for overall and recurrence-free survival. In the high CRP-group (< 3.5 mg/dl), hepatocellular damage was higher and hepatic artery perfusion more compromised than in the low CRP-group (≤ 3.5 mg/dl; $P < 0.001$). Five patients in the low CRP-group (7.8%), but 19 patients of the high CRP-subset (48.7%) developed HCC relapse post-LT ($P < 0.001$). The 1- and 5-year disease-free survival rates were 95.3% and 91.7% in the low CRP-group, but 89.5% and 48.7% in high CRP-subset ($P < 0.001$). In multivariate analysis, presence of microvascular invasion (Hazard ratio [HR] 10.9), peak CRP > 3.5 mg/dl (HR 4), AFP-level > 400 IU/ml (HR 3) and total ischemia time > 450 min (HR 3.4) were identified as independent predictors of HCC relapse. In Milan In patients, CRP level had no predictive value. In contrast, peak CRP-value (HR 5.8) together with microvascular invasion (HR 8.3) were identified as the only independent predictors of recurrence-free survival in Milan Out recipients. The 1- and 5-year recurrence-free survival rates in this special subset were 94.4% and 88% the low (n = 36), but only 87.8% and 29.3% in the high CRP-patients (n = 25; $P < 0.001$).
Conclusion: Early posttransplant peak CRP correlates with I/R-induced hepatocellular injury and risk of HCC recurrence. In particular patients with HCC exceeding the Milan criteria might benefit from targeting inflammatory mechanisms.

P0872 POST CHOLECYSTECTOMY BILIARY INJURIES: ONE CENTER EXPERIENCE

G. Elebidy[1], O. Fathy[1], E. Atif[1], A. Abdelraof[1], A. Sultan[1]
[1]*General Surgery, Gastroenterology Surgical Center, Mansoura, Egypt*

Contact E-mail Address: dr.ehab.atif@gmail.com
Introduction: Laparoscopic cholecystectomy has lead to a rise in the incidence of BDIs from 0.1-0.2% in OC to 0.4-0.6% after LC.[1] The early and accurate diagnosis of postcholecystectomy BDIs is mandatory for surgeons and gastroenterologists, because unrecognized or badly managed BDIs lead to serious complications such as biliary cirrhosis, hepatic failure and even death.[2] The choice of the appropriate treatment for BDIs is very important, because it may avoid these serious complications and improve quality of life among these patients. Therefore, the question regarding the type of treatment for patients with BDIs is still a matter of debate. Initially, endoscopic treatment is recommended in patients with BDIs. When endoscopic techniques are not effective, surgical reconstruction is performed.[3] The management of BDIs is a surgical challenge that needs collaboration among surgeons, gastroenterologists and interventional radiologists at tertiary referral centers.[4,5]
Aims & Methods: Between 1995 and 2012, 330 patients with post-cholecystectomy bile duct injuries presented to Gastroenterology Surgical Center, Mansoura University, Egypt.
Results: Of the studied patients, 232 were females and 98 patients were males. Their mean age was 38 years $\pm$ 12. 63% of the patients were referred from private hospitals while 34.5% were referred from primary hospitals. 252 patients had open cholecystectomies while 78 patients had laparoscopic cholecystectomies. Regarding the type of injuries according to Strasberg-Bismuth classification, the most common was type E2 injury (31.2%) followed by type A injury (20.6%). According to the time of diagnosis, 10 patients were diagnosed intraoperatively, 236 patients were diagnosed early (within one month of the cholecystectomy) and 84 patients were lately diagnosed (more than one month after the cholecystectomy). Patients presented with generalized peritonitis, localized peritonitis with fistulae or with progressive jaundice.
229 patients were managed surgically where 217 patients underwent bilio-enteric reconstruction while 122 were managed by endoscopic dilatation and stent out of which 21 patients needed surgical reconstruction after failed repeated dilatations. 87.3% of patients who were managed surgically showed excellent outcomes according to Johns Hopkins criteria compared to 78.6 % for endoscopic management.
Conclusion: As a conclusion, early diagnosis of iatrogenic bile duct injuries together with management by experienced hepatobiliary surgeon greatly improves the patient outcomes.

P0873 APPLICATION OF HEPATOBILIARY SCINTIGRAPHY FOR THE IDENTIFICATION OF HIGH-RISK PATIENTS REQUIRING PREOPERATIVE PORTAL VEIN EMBOLIZATION

K. P. Cieslak[1], R. J. Bennink[2], W. de Graaf[3], M. G. Besselink[1], O. R. Busch[1], D. J. Gouma[1], T. M. van Gulik[1]

Contact E-mail Address: k.p.cieslak@amc.nl
Introduction: Patients with insufficient future remnant liver (FRL) are at risk of developing postoperative liver failure (LF) and are candidates for preoperative portal vein embolization (PVE). ^{99m}Tc-mebrofenin-hepatobiliary-scintigraphy (HBS) is a quantitative method enabling functional assessment of the FRL with a validated cut-off value for safe resection (2.7%/min/m^2). Other, mathematical methods of preoperative FRL-assessment, like FRL/body-weight ratio (FRL-BWR) and standardized (estimated) volumetry, claim to accurately assess the FRL.
Aims & Methods: The aim of this study was to evaluate the above mentioned methods in the identification of patients requiring preoperative PVE. From November 2006 to June 2014, preoperative HBS and CT-volumetry followed

by major liver resection (≥3 segments) were performed in 169 patients. Patients with FRL volume <25% and/or FRL function <2.7%/min/m2 were considered for preoperative PVE. We compared CT-volumetry in combination with HBS with FRL-BWR (cut-off value 0.5% patient's weight) and estimated volumetry (cut-off value 25% of estimated total liver volume). The endpoints were the differences in FRL-evaluation between the methods.
Results: 29/169 (17.2%) patients underwent preoperative PVE. The median FRL percentage of the total liver volume before PVE was 23.7% (IQR 18.7-27.8). The median FRL-function was 1.9%/min/m2 (IQR 1.50-2.36). In 8/29 (27.6%) of these patients, PVE was performed because FRL-function was below the cut-off value in spite of FRL-volume ≥25%. Median FRL-BWR was 0.52% (IQR 0.40-0.70) and median estimated FRL was 24.5% (IQR 18.34-29.43). According to BWR-FRL and estimated volumetry, 16/29 (55.2%) and 14/29 (48.3%) patients, respectively, had sufficient FRL and would not have undergone PVE if the decision was based on these methods. 1/29 (3.4%) patient developed LF resulting in death. This patient had insufficient FRL according to all the above mentioned methods.
Conclusion: Non-functional FRL-assessment may lead to overestimation of the FRL. HBS provides useful information for the identification of patients requiring preoperative portal vein embolization.
Disclosure of Interest: None declared

P0874 ASSESSMENT OF LIVER FUNCTION IN PATIENTS UNDERGOING MAJOR LIVER RESECTION USING HEPATOBILIARY SCINTIGRAPHY

K. P. Cieslak[1], R. J. Bennink[2], W. de Graaf[3], M. G. Besselink[1], O. R. Busch[1], D. J. Gouma[1], T. M. van Gulik[1]
[1]*Surgery,* [2]*Nuclear Medicine, Academic Medical Center, Amsterdam, The Netherlands, Amsterdam,* [3]*Gastroenterology & Hepatology, Erasmus Medical Center, Rotterdam, Netherlands*

Contact E-mail Address: k.p.cieslak@amc.nl
Introduction: ^{99m}Tc-mebrofenin-hepatobiliary-scintigraphy (HBS) is a quantitative method enabling functional assessment of the future remnant liver (FRL-function). In a previous validation study, we determined a single cut-off value of 2.7%/min/m^2 in patients with non-compromised and compromised liver parenchyma, for the prediction of postoperative liver failure (LF).
Aims & Methods: The aim of this study was to evaluate the value of HBS in the preoperative assessment of patients eligible for major liver resection. From November 2006 to June 2014, 169 patients, of which 71/169 (42.0%) with (peri)hilar cholangiocarcinoma, underwent major liver resection (≥3 segments) after preoperative HBS and CT-volumetry. Patients with FRL-volume <25% and/or FRL-function <2.69%/min/m^2 were considered for preoperative portal vein embolization (PVE). The study endpoints were postoperative LF and LF related mortality.
Results: 29/169 (17.2%) patients underwent preoperative PVE. Median FRL-volume prior to PVE was 23.7% (IQR 18.7-27.8) of total liver volume. Median FRL-function was 1.9%/min/m^2 (IQR 1.50-2.36). In 8/29 (27.6%) of these patients, PVE was performed because FRL-function was below the cut-off value in spite of FRL-volume ≥25%. Major hepatectomies comprised 72 (42.6%) right and 56 (33.1%) left hemihepatectomies, 30 (17.8%) extended right and 6 (3.6%) extended left hemihepatectomies, 2 (1.2%) central resections and 3 (1.8%) segmentectomies of ≥3 liver segments. Overall, clinically relevant complications (≥ Clavien-Dindo grade 3a) were seen in 66/169 (39.1%) patients. LF (overall 2.4%) was seen in 3/140 (2.1%) of the non-PVE patients and in 1/29 (3.4%) of the PVE patients while LF related mortality (overall 1.8%) occurred in 2/140 (1.4%) of non-PVE vs. 1/29 (3.4%) of the PVE patients. There were no significant differences in postoperative outcomes between PVE and non-PVE patients.
Conclusion: Preoperative HBS provides useful functional information on the FRL in patients requiring major liver surgery. Patients with sufficient FRL-volume but decreased FRL-function may benefit from preoperative portal vein embolization.

P0875 ARE "TAKE HOME" BOX TRAINERS AS GOOD AS HIGH FIDELITY, VIRTUAL REALITY (HFVR) SIMULATORS IN ACQUIRING LAPAROSCOPIC SURGICAL SKILLS?

M. Yiasemidou[1], J. de Siqueira[1], D. Glassman[2], J. Tomlinson[1], M. Gough[1]
[1]*School of Surgery, Health Education Yorkshire and the Humber, Leeds,* [2]*MidYorks Medical Education and Simulation Hub, Wakefield, United Kingdom*

Contact E-mail Address: marinayiasemidou@gmail.com
Introduction: High Fidelity Virtual Reality (HFVR) simulators have been proposed as providing optimum training for laparoscopic procedures such as cholecystectomy. However, purchase and maintenance costs have compromised widespread use of this type of equipment. Further, recent short-term studies have demonstrated equal or greater efficacy of supervised training programmes using simple box trainers (BT) compared to HFVR simulators.
Aims & Methods
Aim: This study explores the value of independent learning using a BT over a longer period of training, compared to the same duration of "free access" to HFVR simulators.
Methods: 16 surgical trainees who had performed fewer than 15 laparoscopic cholecystectomies were recruited to this study and randomised into two groups: the BT Group were to be provided their own BT whilst the HFVR Group were subsequently offered free access to a HFVR. Prior to commencing their allocated training programme all trainees performed laparoscopic cholecystectomy on a HFVR simulator from which the simulator-derived matrix scores were collected. Subsequently both groups were asked to practice 3 simple tasks (peg transfer, clip applying and precision cutting) for 6 weeks (20 repetitions of each) using their allotted training tool. Finally trainees performed a second laparoscopic cholecystectomy on the HFVR simulator from which the same matrix scores were determined. Change in performance from baseline to the second assessment was compared between the groups.
Results: The BT group improved significantly in respect of the number of movements (before median, (25th -75th percentile) 1419 (893.5-1689), after 466 (324-888.5), p = 0.021) performed and total path length (PL before mean 2951.58 (2037.6-4258.5) after 1610.57 (906.05-2211.85), p = 0.024). The time to perform cholecystectomy was not statistically reduced (before mean, 1373.22 sec (1057-1880) after 749.22 (294.5-1071.5), p = 0.051). In contrast, there was no statistically significant improvement in any of the matrices in the VR group (time before mean 923.71 sec (317-1238) after 820.29 (430-1264), p = 0.920; NOM before median 760 (430-1264) after 964 (608-1442), p = 0.446; PL after mean 1856.3 (981-2739.4) after 2393.9 (939.9-3056.3), p = 0.425). Inter-group comparison of these parameters showed no difference in the reduction in time to perform cholecystectomy (Time BT mean 624sec (-2-1422) HFVR: -33.24 (-968-639) sec p = 0.137). However the BT group performed significantly better in terms of NOM (BT median 447 (112-1416) HFVR -182 (-811-337), p = 0.031) and PL (BT mean 1341.01 (172.6-2800.7) HFVR -537.6 (-2210-1011.2), p = 0.03). These differences could be explained by the number of repetitions performed by each group (BT: median 20 (20-25) v HFVR: 10 (2-10), p = 0.008).
Conclusion: There are strong indications that longer-term practice on a "take-home" BT may be more effective for the acquisition of laparoscopic skills, compared to VR simulators. This may be explained by the greater opportunity for practice with the BT.

P0876 CLINICOPATHLOGICSTUDY OF MINIMUM INVASIVE SURGERY AND ENDOSCOPIC PAPILLECTOMY FOR TUMOR OF THE AMPULLA OF VATER

M. Hamano[1]
[1]*Surgery, Gastroenterology, Tokyo, Japan*

Contact E-mail Address: hamano.mie@tymc.ac.jp
Introduction: Ablative therapy is required for patients with pathological abnormalities at The Tumor of the Ampulla of Vater: in particular, carcinomas, adenomas and carcinoids. Adenomas are benign lesions, but because suspicions are raised about adenoma-carcinoma sequence during the process of developing adenoma, a treatment for premalignant lesions also needs to be considered. Local excision of the Ampulla of Vater and partial duodenectomy as Minimum Invasive Surgery for adenomas and early carcinomas have been performed at our hospital since 1989. For the case of adenomas, endoscopic Papillectomy has also been carried out. A decision regarding the adequacy of borderline lesions has been made by a discussion with gastroenterologists in our hospital. In the present study, the adequacy of borderline lesions and results of it were examined by attempting to compare between endoscopic Papillectomy and Local excision of Tumor of the Ampulla of Vater.
Aims & Methods: From 1989 ~ 2014, 18 patients underwent Local excision of the Ampulla of Vater, 2005 ~ 2013, 12 patients underwent endoscopic Papillectomyrespectively. We examined in terms of clinicopathlogical findings, complications?background, curability and the postoperative hospitalization days.
Results: 18 patients underwent Local excision of the Ampulla of Vater, and another 12 patients were given endoscopic Papillectomy. The patients who underwent Local excision were histopathologically diagnosed as follows: 9 patients with papilla cancer, 8 patients with adenoma, and 1 patient with carcinoid; meanwhile, the patients who underwent endoscopic Papillectomy were as follows: 2 patients with papilla cancer, 8 patients with adenoma, 1 patient with carcinoid, and 1 patient with polyp. The number of patients who received a diagnosis of adenoma before surgery but who were recognized as malignancy after surgery was 4 in Local excision of the Ampulla of Vater and 2 in endoscopic Papillectomy. Resection stumps in 3 patients who were given endoscopic Papillectomy were partially unclear, but there was 1 patient with positive surgical margins. The number of patients who suffered complications before surgery was 3 in Local excision, but none were in endoscopic Papillectomy. The average of a hospital stay after surgery was 18.5 days in Local excision of the Ampulla of Vater and 11.6 days in endoscopic Papillectomy. The number of patients who suffered complications after surgery in Local excision of the Ampulla of Vater was 1 patient with pancreatitis, and that in endoscopic Papillectomy was 5 patients with bleeding, 3 patients with inflammation of the gall bladder and the bile duct, and 2 patients with pancreatitis. 1 patient had a prognosis of stump recurrence (adenoma) in endoscopic Papillectomy, but others were alive without evidence of any cancer.
Conclusion: Patients had neither severe complication nor cancer recurrence in both Local excision of the Ampulla of Vater and Endoscopic papillectomy;

therefore, a decision regarding the adequacy of borderline lesions in our hospital was thought to be responsible.
Because patients had a good prognosis in both therapeutic procedures, each benefit was thought to be utilized by greatly considering the adequacy of borderline lesions and choosing surgical procedures, and appropriate medical care for patients was also thought to be provided by means of the lowest operative stress on borderline lesions.

P0877 IN SITU HYPOTHERMIC PERFUSION WITH RETROGRADE OUTFLOW DURING RIGHT HEMIHEPATECTOMY: FIRST CLINICAL EXPERIENCES

P. Olthof[1], M. Reiniers[1], R. van Golen[1], M. Heger[1], T. van Gulik[1]
[1]*Surgical Laboratory, Academic Medical Center, Amsterdam, Netherlands*

Contact E-mail Address: p.b.olthof@amc.nl
Introduction: A new technique of selective in situ hypothermic perfusion with retrograde outflow (IHP-R) was developed. The outcomes of IHP-R were assessed during right hemihepatectomy in a randomized controlled clinical trail.
Aims & Methods: After right liver mobilization, the right branch of the portal vein (RPV) and the right hepatic artery (RHA) were clamped and cut. Following RHA cannulation, the portal triad was clamped, the right hepatic vein was closed and cut, and the middle/left hepatic veins were clamped to exclude the liver from the circulation. The left hemiliver was perfused through the RHA using cold Ringer's lactate solution (target liver temperature of 28°C), allowing retrograde outflow via the cut end of the RPV until parenchymal transection was completed. Fourteen patients were randomized between IHP-R and the standard procedure. Outcomes included laboratory parameters (AST, ALT, total bilirubin), transfusion requirements, complications, ICU stay, functional liver regeneration (assessed preoperatively and at postoperative day (POD) 3 by hepatobiliary scintigraphy with SPECT), and hospital stay.
Results: There were no statistical differences regarding baseline demographic and clinical characteristics. The median/range IHP-R times were 45/43–55 min while the target temperature of 28°C was reached in 6 of 7 IHP-R patients. Ischemia time, resection type, transfusion requirements, ICU stay, complications, and hospital stay were not different between groups. Procedure duration was longer in the IHP-R group (454/371-494 versus 330/256-351 min, $p = 0.007$). Postoperative AST and bilirubin were not different between groups, however peak ALT levels were higher in the IHP-R group (512/399-667 versus 397/214-415 U/L, $p = 0.038$). There was significant functional liver regeneration within the IHP-R but not in the control group on POD-3 compared to preoperatively calculated values ($p = 0.018$), suggesting early and possibly improved functional liver regeneration following IHP-R.
Conclusion: IHP-R allows easy and safe cold liver perfusion. The higher peak in ALT levels following IHP-R might be due to the prolonged procedure duration. Nevertheless, IHP-R induces early, and possibly improved liver regeneration following major liver resection.

Introduction: Endoscopic biliary drainage (EBD) and percutaneous transhepatic biliary drainage (PTBD) are both used to resolve jaundice prior to surgery for perihilar cholangiocarcinoma (PHC). PTBD has been associated with seeding metastases.
Aims & Methods: The aim of this study was to compare overall survival (OS), and the incidence of initial seeding metastases that potentially influence survival, in patients with preoperative PTBD versus EBD. Between 1991 and 2012, 278 patients underwent preoperative biliary drainage and resection of PHC at two institutions (Netherlands and USA). Of these, 33 patients were excluded for postoperative mortality. Among the 245 included patients, 88 patients who underwent preoperative PTBD (with or without previous EBD) were compared with 157 patients who underwent EBD-only. Survival analysis was done with Kaplan-Meier and Cox regression with propensity score adjustment.
Results: Unadjusted median OS was comparable between the PTBD group (35 months) and EBD-only group (41 months; $P = 0.26$). After adjustment for propensity score, OS between the PTBD group and EBD-only group was similar (Hazard ratio, 1.05; 95% CI, 0.74-1.49; $P = 0.80$). Seeding metastases in the laparotomy scar occurred as initial recurrence in 7 patients, including 3 patients (3.4%) in the PTBD group and 4 patients (2.7%) in the EBD-only group ($P = 0.71$). No patient had an initial recurrence in percutaneous catheter tracts.
Conclusion: The present study found no effect of PTBD on survival when compared to patients with EBD, and no increase in seeding metastases that develop as initial recurrence. These data suggest that PTBD can safely be used in preoperative management of PHC.

P0879 EVALUATION OF THE PREDICTORS OF SURGICAL SITE INFECTION AFTER HEPATECTOMY: A SINGLE-CENTER EXPERIENCE

T. Takayashiki[1], H. Shimizu[1], M. Ohtsuka[1], A. Kato[1], H. Yoshitomi[1], K. Furukawa[1], S. Takano[1], S. Kuboki[1], D. Suzuki[1], N. Sakai[1], S. Kagawa[1], M. Miyazaki[1]
[1]*Department of General Surgery, Chiba university, Chiba, Japan*

Contact E-mail Address: takayashiki@hospital.chiba-u.jp
Introduction: Surgical site infection (SSI) is the most common infectious complication after hepatectomy for hepato-biliary malignancies or hepatic benign lesions, with leading to longer hospital stays and higher medical costs. To clarify the predictors associated with SSI after hepatectomy, we conducted a retrospective cohort study of the patients who underwent hepatectomy at a single institution.
Aims & Methods: Recent 4 years, from June 2010 to June 2014, 430 patients underwent hepatic resection at our institution. Patient demographics, laboratory parameters, surgical records, and postoperative morbidity were evaluated and the predictors were identified using multivariate analysis between SSI group and non-SSI group.
Results: Of these 430 patients, 66 (15.3%) had SSIs after hepatectomy. 38 were men and 28 were women whose mean age was 66.6 years (range, 27 to 82). The most commonly disease and surgical procedure were hilar cholangiocarcinoma ($n = 25$, 37.9%) and hemihepatectomy ($n = 32$, 48.5%), respectively. The following pathogens were isolated by bacterial culture of purulent fluid from the patients of SSI; Enterococcus sp. ($n = 31$), Staphylococcus sp. ($n = 17$), Enterobacter sp. ($n = 3$), and Klebsiella sp. ($n = 2$), with high concordance of the bacterial culture from bile juice (70%). Postoperative hospital stays of SSI group ($n = 66$) were significantly longer than that of non-SSI group ($n = 364$). In a multivariate analysis, biliary reconstruction (odds ratio 6.24, 95% confidence interval 3.10-12.91, $P < 0.001$) and duration of operation (odds ratio 1.01, 95% confidence interval 1.00-1.01, $P = 0.01$) were identified as independent predictors for SSI after hepatectomy.
Conclusion: Biliary reconstruction and duration of operation were independent predictors of SSI after hepatectomy. Bacterial infections of bile juice was one of the major source of SSI after hepatectomy.

P0880 LAPAROSCOPIC VERSUS OPEN REPAIR OF PERFORATED PEPTIC ULCER (PPU)

C. Lannerstad[1], S. Moradi[1], F. Frozanpor[1]
[1]*Karolinska institutet, Dept of clinical sciences, Dept of Surgery, Danderyd Hospital, Stockholm, Sweden*

Contact E-mail Address: carl.lannerstad@ds.se
Introduction: While open surgery for PPU has long been golden standard, laparoscopic repair is steadily increasing at Danderyd general hospital. Our hypothesis is, in this retrospective descriptive single-center study, that laparoscopic is superior to open repair.
Aims & Methods: All patients who underwent a primary surgical procedure for PPU from January 2011 to December 2014 were included. Our aim is to describe and compare the outcome of different surgical approaches regarding age, ASA, boey score, clavian-dindo and mortality.
Results: 67 patients were treated for PPU, 9 were excluded due to non-operative or endoscopic treatment. Repair was performed laparoscopically in 32 cases, open surgery in 26 among which 8 had been converted from initial laparoscopy. In 2 cases only a peritoneal lavage was performed and in another 2 cases lavage was performed and a duodenal stent was placed. Conversion from laparoscopy was due to adhesions, the size of the perforation or inability to locate it. No significant preoperative differences were found between the groups of patients who underwent open or laparoscopic repair concerning characteristics of patients or ulcer.
The mortality rate was highest among elderly and those with high ASA-scores. In the open repair group the Clavian-Dindo score, mortality and length of hospital stay were significantly higher.
Reoperation had to be performed in 6 cases, 4 for continued leakage, 1 for deep abscess and 1 for suture dehiscence.

	Laparoscopic N = 32	Open approach N = 26	p
Male (n)	16	14	n.s
Age, yrs	63.0 (±19.3)	69.9 (±18.2)	n.s
ASA ≥3 (n)	15	16	n.s
General peritonitis (n)	22	16	0.59
Duodenal ulcer (n)	22	15	0.42

(continued)

Continued

	Laparoscopic N = 32	Open approach N = 26	p
ICU-care (days, median)	2	8	0.016
In hospital (days)	5.5 ± 2.3	9.8 ± 8.0	0.04
Clavian-Dindo≥ 3a (n)	6	10	0.14
Abscess (n)	1	2	0.59
Reoperation (n)	4	2	0.40
Mortality (n)	2	7	0.05

Conclusion: The size and design of this study do not allow too strong conclusions despite the fact that significant differences were found for morbidity, mortality and length of hospital stay. Albeit not having found significant differences for preoperative status (ASA, boey score) several patients in the open repair group underwent open surgery because they were deemed unfit for laparoscopy. Either based on pulmonary disease or multi organ failure, it will bias the outcome between the groups to the advantage of the laparoscopic group. In conclusion, when feasable, laparoscopic repair for PPU seem to be beneficial for the postoperative care.

Introduction: This study aims at assessment of the outcome of laparoscopic cholecystectomy (LC) with intraoperative endoscopic sphincterotomy (IOES) as a single session management option for patients with cholecysto-choledocholithiasis (CCL).
Aims & Methods: This is a retrospective analysis of the records and collected data for patients with CCL who were submitted for LC with IOES. Patients were preoperatively diagnosed by clinical presentation, laboratory findings, abdominal ultrasound examination, and magnetic resonance cholangiopancreatography (MRCP). IOES was performed after completion of LC and closure of ports in most cases. ERCP procedure was done by the surgeon with the patient is in the left lateral position.
Results: In the period between June 2009 to June 2013, 140 patients having combined (LC) and (IOES) for CCL were analyzed. One hundred and fourteen patients were females (82%). The mean age was 35.1 years. Mean serum bilirubin level was 7.5 mg/dl. Mean CBD diameter at MRCP was 9.1 mm and the mean CBDS size was 5.1 mm. Mean operation time was 87 minutes. Complete CBD clearance was possible in 134 patients (95.7%). The mean hospital stay was 3.1 days. There was no procedure related mortality. Complications were reported in 15 patients and included bleeding sphincterotomy (n = 6; 4.3%), pancreatitis (n = 7; 5%), and minor bile leak (n = 2; %). All complications were treated by conservative means.
Conclusion: Combining IO-ERCP and sphinctrotomy with LC is a safe and effective single-session minimally invasive treatment strategy for patients with CCL that should be available in the hands of the experienced hepatobiliary surgeon.

P0882 SHORT-TERM OUTCOMES OF TOTALLY ROBOTIC ABDOMINOPERINEAL RESECTION FOR LOW RECTAL CANCER: A RETROSPECTIVE COMPARISON WITH LAPAROSCOPIC AND OPEN SURGERY

J. Xu[1], Y. Wei[1], L. Ren[1], Q. Feng[1], D. Zhu[1], J. Chen[1], W. Chang[1], Q. Lin[1]
[1]*General Surgery, Zhongshan Hospital, Fudan University, Shanghai, China*

Contact E-mail Address: xujmin@aliyun.com
Introduction: Currently, robotic surgery for rectal cancer using da Vinci System was common. However, few studies reported robotic approaches in abdominoperineal resections (APRs).
Aims & Methods: This study compared short-term outcomes of totally robotic, laparoscopic and open APRs for low rectal cancer. Between September 2013 and March 2015, a total of 231 consecutive patients received APRs were retrospectively engaged: 66 received totally robotic surgery as TRAP group, 89 received conventional laparoscopic surgery as LAP group, and 76 received open surgery as OS group. Short-term outcomes were analyzed, including length of recovery, quality of total mesorectal excision (TME), morbidity and mortality.
Results: The operating time of TRAP group (209.8 min) and LAP group (205.4 min) were almost the same (P = 0.864), both longer than OS group (166.6 min, P < 0.001). TRAP group had less intraoperative hemorrhage, compared to LAP group (99.2 vs. 129.1 ml, P < 0.001) and OS group (99.2 vs. 141.6 ml, P < 0.001). TRAP resulted in shorter days to first flatus than LAP (1.6 vs. 2.3 days, P < 0.001) and OS (1.6 vs. 2.5 days, P < 0.001). Also, TRAP showed advantage in reducing days of retention catheterization after operation (TRAP vs. LAP, 2.3 vs. 3.3 days, P < 0.001; TRAP vs. OS, 2.3 vs. 3.1 days, P < 0.001). There was no difference among the three groups in open conversion rate, length of hospital stay after surgery, lymph node harvested, positive rate of circumferential resection margin or postoperative mortality. The morbidity rates were 16.7%, 28.1%, and 27.6% in the TRAP, LAP and OS groups respectively, with no significant difference. However, TRAP resulted in potentially less urinary retention than LAP (3.0% vs. 11.2%, P = 0.059), and potentially less wound infection than OS (3.0% vs. 10.5%, P = 0.082).
Conclusion: Totally robotic APRs were safe, and reproduce the equivalent TME quality of conventional laparoscopic and open surgery. Also, it provided less injury and faster functional recovery.

P0883 ROBOT-ASSISTED SIMULTANEOUS RESECTION OF COLORECTAL CANCER WITH LIVER METASTASES: A FEASIBLE AND INNOVATIVE TECHNIQUE

J. Xu[1], Y. Wei[1], X. Wang[2], W. Chang[1], Y. Peng[2], L. Ren[1], D. Zhu[1]
[1]*General Surgery,* [2]*Department of liver surgery, Zhongshan Hospital, Fudan University, Shanghai, China*

Contact E-mail Address: xujmin@aliyun.com
Introduction: The Da Vinci Surgical System may help to overcome some of the difficulties of laparoscopy for complicated abdominal surgery. The aim of this study was to present an innovative technique that is robot-assisted, simultaneous radical resection of both colorectal cancer and liver metastasis (RSRCLM).
Aims & Methods: Between May 2013 and November 2014, we attempted to perform robot-assisted simultaneous resection of liver metastases in 24 patients with sigmoid colon cancer or rectal cancer. Procedure of this technique was described and clinic data of patients were collected and analyzed.
Results: We successfully completed the technique of RSRCLM in 24 patients with no conversions to an open procedure. The mean age was 55.1 ± 11.9 years and BMI (body mass index) was 22.9 ± 1.9 kg/m^2. The mean operation time was 293.3 ± 96.6 minutes and blood loss was 133.7 ± 105.4 ml. An R0 resection was achieved in all patientswith the minimal margin from 2mm to 35 mm. The aver age tumor size of colorectal cancer was4.7 ± 1.3 cm and that of metastatic liver tumor was 3.3 ± 1.9 cm. The aver age number of harvested lymph node was 20.7 ± 7.6. Patients were able to walk in first 2 days of surgery. The mean time get pass gas was 2.2 ± 0.5 days and flow eating start at 3.4 ± 0.9 days. The median duration for indwelling urine Foley catheter was 3.1 ± 1.2 days. The voiding function after removal of the urine Foley catheter was good (International Prostate Score Symptom (IPSS, 0–7) in 20 (83.3%) patients, fair (IPSS, 8–14) in three (12.5%), and poor (IPSS, 15–35) in one (4.2%).The mean postoperative hospital stay was 7.2 ± 2 days and hospital cost was 11325.5 ± 1337.6 US dollars. Overall morbidity and mortality was 8.3% and 0% respectively, within one month after surgery. At a median follow-up of 10 (range, 2-21) months, 23 (95.9%) patients remain disease-free.
Conclusion: This study shows that robot-assisted simultaneous resection is safe and technically feasible in selected patients with sigmoid colon cancer or rectal cancer liver metastases.

P0884 TRANSLATIONAL 3D-PRINTED ORGAN MANUFACTURING OF BIO-ELASTIC PATIENT-SPECIFIC ORGAN REPLICA FOR LAPAROSCOPIC SURGERY SIMULATION

M. Sugimoto[1]
[1]*Gastroenterology, Kobe University, KOBE HYOGO, Japan*

Contact E-mail Address: sgmt@med.kobe-u.ac.jp
Introduction: Professional 3D printers now incorporate photo-curable resins of various textures, transparency and flexibility. Before procedures, surgeons can now plan complex surgeries with MDCT scan data of a patient's bones, blood vessels or other organs, converted to a 3D-printable digital file (STL) that can be manipulated and studied. But these applications in the operating room are generally limited to a relatively small number of procedure types, though physicians can easily apply the lessons from one surgery to many others.
Aims & Methods: To overcome the limitation, we developed an anatomically accurate translational 3D-printed organ manufacturing system for surgical simulation. Our hybrid 3D imaging and 3D-printed injection molding technology allowed to manufacturing bio-elastic organ and abdominal wall replica.
Based on patient-specific DICOM data from MDCT, after generating its surface polygons using OsiriX application, the multi-material inkjet 3D printer created life-size copies of the 3D organs, blood vessels, and abdominal cavity. The replicas were manufactured bio-elastic by simultaneous jetting of different types of materials and injection molding the polyvinyl alcohol (PVA), which is a water-soluble synthetic resin. Each organ's mold model was given an injection of a synthetic resin that helps make it feel wetter and more lifelike for the surgeon. We evaluated the feasibility of this system in 20 liver, pancreas, and kidney surgery simulations. We programed a printer to create clear models made from acrylic resins that allowed us to visualize and understand the hepatobiliary pancreatic complex internal structures and blood vessels or the exact tumor locations. We printed liver, pancreas, and kidney models compounding the polyvinyl alcohol (PVA) for tensile strength and elongation to break. It allowed these models realistic stand-in for ultrasonic diagnosis, hepatic intervention and surgical procedure such as cutting, suturing and ligation.
Results: The personalized bio-elastic wet organ replicas were useful for visible and tangible surgical simulation and navigation to plan and guide the successful liver, pancreas, and kidney surgeries. Such organ models can be soaked in water to look and feel closer to real organs. With the wet model, surgeons can

experience the softness of organs and see them bleed, to help us in practice on lifelike models before stepping into real surgery. Using abdominal cavity replica, there was a place for using synthetic models in realistic surgical situation including laparoscopic surgery. The use of these replicas reduced the length of the operation and provided better anatomical reference tools for tailor-made navigation surgery, consequently helping to improve training for the operating room staff, students, and trainees.
Conclusion: The translation from 3D imaging to 3D manufacturing provided realistic surgical simulation of specific values of bio-texture in liver, pancreas, and kidney. The PVA was compatible for wet tissue simulation in ultrasonography and intervention in liver, pancreas, and kidney surgeries. These could overcome the limitations of the conventional image-guided navigation. Its combines the advantages of conventional 3D modeling and precise virtual 3D planning in personalized surgical simulation and navigation.

P0885 A PROSPECTIVE, RANDOMISED MULTICENTER STUDY COMPARING MINILAPAROTOMY CHOLECYSTECTOMY VERSUS LAPAROSCOPIC CHOLECYSTECTOMY WITH ULTRASONIC DISSECTION IN BOTH GROUPS – POSTOPERATIVE RECOVERY AT 4 WEEKS AFTER SURGERY

M. Kinnunen[1], S. Aspinen[1], J. Harju[2], P. Juvonen[1], H. Kokki[3], M. Eskelinen[1]

Contact E-mail Address: maripk@student.uef.fi
Introduction: Cholecystectomy by minilaparotomy (MC) or by laparoscopy (LC) have been shown to have quite similar early recovery after surgery (Harju et al. 2013, 1). Monopolar electrosurgical energy is the most frequently used form of energy to achieve adequate dissection and haemostasis in the MC and in the LC. We assessed the MC with the ultrasonic dissection (UsD) versus the LC with the monopolar electrosurgical energy and our results suggested a shorter early recovery after surgery (Harju et al. 2013, 2). The outcome after the LC versus the MC with the UsD technique in both groups has not been compared in randomised trials. We therefore investigated the four weeks recovery after the LC and the MC with the UsD in 100 patients (ClinicalTrials.gov Identifier: NCT0172340).
Aims & Methods: Initially 100 patients with non-complicated symptomatic gallstone disease were randomized into the MC with the UsD (n = 50) or the LC with the UsD (n = 50) over a period of 2-years (2013-2015) and 95 of them (95%) were reached for a follow-up interview at four weeks after the surgery. Postoperative recovery at 4 weeks after surgery in the two study groups was assessed with a follow-up questionnaire to be filled and returned in a prepaid envelope, the non-responders were contacted by a phone. Analgesic efficacy was assessed with an 11-point numeric rating scale (NRS, 0 = no pain relief, 10 = total pain relief).
Results: Both groups were similar in terms of the demographic variables and surgical data. Postoperative data for the first four weeks after surgery were available for 95% of patients from both groups. The duration of postoperative pain (in days) was slightly shorter in the LC group, 8.5 (SD, 8.2) days, than in the MC group, 11.1 (SD, 10.8) days, ($p = 0.24$). The mean length of sick leave was five days shorter in the LC group, 14.4 (SD, 10.3) days, than in the MC group, 19.9 (SD, 12.4) days, ($p = 0.05$). The pain at normal activities after four weeks assessed with the NRS showed slightly lower scale values in the MC group, 0.3 (SD, 0.9) versus in the LC group, 0.6 (SD, 1.2), ($p = 0.23$). Total use of analgesics after discharge (in days) was slightly shorter in the LC group, 6.6 (SD, 8.0) versus in the MC group, 7.7 (SD, 10.8), ($p = 0.59$). The satisfaction with surgery was quite similar in the both study groups.
Conclusion: In conclusion, the cholecystectomy by minilaparotomy versus the cholecystectomy by laparoscopy with ultrasonic dissection in both study groups seems to have quite similar four weeks recovery after surgery. A new finding with the clinical relevance in the present work is the applicability of the UsD technique in the MC and the LC procedures.

P0886 MENTAL REHEARSAL WITH PATIENT SPECIFIC IMAGERY ENHANCES LAPAROSCOPIC SURGERY PERFORMANCE: A PILOT STUDY

M. Yiasemidou[1,2], D. Glassman[1], D. Miskovic[2]
[1]*Education and Simulation Hub, MidYorkshire Hospitals Trust, Wakefield,* [2]*LIBACS, University of Leeds, Leeds, United Kingdom*

Contact E-mail Address: marinayiasemidou@gmail.com
Introduction: Mental rehearsal of a task is known to improve performance in sports and music. Recent studies have shown some indications that it can do the same in surgery, with or without visual aids. Our study aims to assess the impact of mental rehearsal with interactive patient specific 3D imagery, on laparoscopic surgery performance.
Aims & Methods: 15 laparoscopic cholecystectomy novices were matched into two groups on 2:1 ratio. Group 1 (n = 10) performed a simulated laparoscopic cholecystectomy on a virtual reality (VR) simulator after watching a didactic video of a real procedure. Group 2 (n = 5) performed the same procedure after structured mental rehearsal with an interactive 3D visual aid. The optic tool was a 3D reconstruction of the relevant surgical anatomy (gallbladder, liver, cystic duct, cystic artery and peritoneal gathering), from an anonymised Computer Tomography. The anatomical features were modified to resemble the anatomy of the simulated model. Performance and safety variables were obtained from the VR simulator database after each procedure and compared between the two groups.
Results: Trainees who performed structured mental rehearsal using a 3D model prior to the operation had significantly less total number of movements (Group 2 median 553, Group 1 1391.5, $p = 0.005$) and total path length of instrument tip (Group 2 mean 1540.24, Group 1 mean 2837 $p = 0.007$). Furthermore, trainees in group 2 performed the procedure significantly faster than the trainees in Group 1 (Group 2 median 667s, Group 1 mean 1283, $p = 0.003$). There was no statistical difference in the safety metrics (number of perforations $p = 0.07$, non-cauterised bleeding $p = 0.114$, damage to vital structures $p = 0.529$).
Conclusion: From this pilot data there are strong indications that viewing a patient-specific 3D model of the relevant anatomy can enhance surgical performance.

P0887 LAPAROSCOPIC BASIC SKILLS TRAINING - BLACK BOX OR HIGH FIDELITY SIMULATORS ?

N. Oussi[1,2], C. Loukas[3], L. Henningsohn[2,4], A. Kjellin[2], E. Georgiou[3], L. Enochsson[1,2]
[1]*Division of Surgery, Department of Clinical Science, Intervention and Technology, Karolinska Institutet,* [2]*Center for Advanced Medical Simulation and Training, Karolinska University Hospital, Stockholm, Sweden,* [3]*Medical Physics Laboratory and Simulation Center, Medical School, University of Athens, Athens, Greece,* [4]*Division of Urology, Department of Clinical Science, Intervention and Technology, Karolinska Institutet, Stockholm, Sweden*

Contact E-mail Address: lars.enochsson@ki.se
Introduction: Training in laparoscopic high-fidelity simulators to proficiency levels has been shown to improve laparoscopic cholecystectomy skills (1-3). However, since high-fidelity laparoscopic simulators are expensive the availability is limited which could have a negative impact on the opportunity of laparoscopic training for residents. In countries with a strained economy other priorities within the health sector than buying expensive simulators are made. In countries with a somewhat better economy but with large distances to travel, residents working in or near large academic centers often have a much better access to simulator training. Whether laparoscopic basic skills training in black boxes can be an adequate alternative to corresponding basic skills training in high fidelity simulators for students and residents in this high-tech era is not known.
Aims & Methods
Aim: To analyze how basic skills training in a black box or a high fidelity simulator (LapMentor, Simbionix, USA) motivated medical students and if differences in surgical skills performance were noted when tested in a validated surgical simulator (MIST, Mentice, Sweden).
Methods: Medical students (n = 57) during their surgical semester volunteered to participate in the study. After signing informed consent the students completed a questionnaire regarding their expectations of the simulation training. Their visuospatial ability was also tested. They were then randomized into either basic skills training in a black box (n = 31) or in the LapMentor (n = 26). Following their skills training all the students did three tests in the validated MIST simulator (1) and then finally they completed a questionnaire of how they had experienced the simulator practice sessions regarding how they liked it, if it facilitated their MIST performance and if it had been difficult.
Results: Students training in both the BlackBox and the LapMentor found that the training exceeded their expectations regarding how well they thought that they would like it.
BlackBox estimations increased from an expectation level of 73.1% pre-training on the VAS scale to 80.0% post-training ($P = 0.0365$) and LapMentor from 75.8% pre-training to 82.2% post-training ($P = 0.0225$). There was a significant correlation in the BlackBox group between how difficult they experienced the simulation training was and their MIST-performance ($RSquare = 0.25$; $P = 0.0064$). There was also a positive trend towards how well they thought that the BlackBox training facilitated their MIST-performance ($RSquare = 0.10$; $P = 0.0953$). In the LapMentor group no such correlations existed ($RSquare = 0.02$; $P = 0.61$ "Was difficult" and $RSquare = 0.00$; $P = 0.92$ "Facilitated"). More students in the BlackBox group also completed the MIST excercises (28 vs. 19).
Conclusion: The perhaps more straightforward approach to basic skills training procedures in the low-tech BlackBoxes seems to correlate better with MIST performance. The results indicate a still important role for low-tech and low-cost BlackBoxes in laparoscopic basic skills training of students in an otherwise high-tech surrounding.

P0888 T4 COLON CANCER: AN ABSOLUTE CONTRAINDICATION TO LAPAROSCOPIC RESECTION?

S. Arolfo[1,*], M. E. Allaix[1], M. Mistrangelo[1], A. Arezzo[1], M. Morino[1]
[1]*Department of Surgical Sciences, University of Torino, Torino, Italy*

Contact E-mail Address: meallaix@gmail.com

Introduction: Some retrospective comparative studies have shown that laparoscopic resection (LR) of T4 colon cancer is feasible and oncologically adequate, but it is burdened by high conversion rates to open resection (OR). The selection criteria for the laparoscopic approach to T4 colon cancers are unclear.

Aims & Methods: The aim of this study was to identify possible tumor-related factors that should be considered as contraindication to LR in T4 colon cancer patients. The short-term and the long-term oncologic outcomes of LR or OR were also evaluated.

It is a retrospective analysis of a prospectively collected database. All patients undergoing elective LR or OR for non-metastatic T4 colon cancer were included. Statistical analyses were performed on an ''intention-to-treat'' basis and by actual treatment. Kaplan-Meier curves were compared to analyse overall survival (OS) and disease-free survival (DFS).

Results: OR and LR were performed for T4 colon cancer in 50 and 48 patients, respectively. A complete R0 resection was obtained in 49 (98%) OR and in 48 (100%) LR patients (P = 0.962). Conversion to open surgery occurred in 12 LR patients (25%), due to a tumor larger than 6 cm (75%) or the need for a multivisceral resection (25%). There was a trend towards a higher rate of 30-day morbidity after OR than LR (34% vs. 16.7%; P = 0.083). Thirty-day mortality rate was similar after OR and LR: 4% vs. 0% (P = 0.495). Median postoperative length of stay was longer after OR, than converted resection or LR: 12 (range, 7-60) vs. 9 (range, 6-14) vs. 7 (range, 5-51) days (P = 0.005). No significant differences were observed in the median number of lymph node harvested after OR or LR: 16 (range, 6-29) vs. 14 (range, 7-36), P = 0.455. Median follow-up was 46.5 (range, 3-140) months for OR patients and 37 (range, 6-139) months for LR patients (P = 0.274). Five-year OS and DFS did not differ significantly between OR and LR patients: 66.7% vs. 65.8% (P = 0.828), and 59.7% vs. 58.6% (P = 0.634). Conversion to OR did not affect OS and DFS.

Conclusion: LR is associated with a high conversion rate to OR. Patients with a tumor larger 6 cm and/or infiltrating adjacent organs should be treated by OR. In selected cased, LR for T4 colon cancer has better short-term outcomes and similar oncologic outcomes compared to OR.

Introduction: Benefits of minimally invasive pancreatic surgery, especially for cancer, are under debate since no randomized studies have been performed. It is unclear which proportion of pancreatic resections (pancreatoduodenectomy, distal pancreatectomy) is currently performed via a minimally invasive approach and whether these procedures are performed for cancer.

Aims & Methods: An online survey, consisting of 30 questions, was sent to the members of the European Pancreatic Club, the European-African Hepato-Pancreato-Biliary Association and to 5 national pancreatic societies in Europe between June and December 2014. Non-responders received two reminders. Fully completed responses were included. Because of overlapping, confidential membership lists, the number of invitees was unknown.

Results: In total, 237 pancreatic surgeons responded. After excluding 34 for incomplete responses, 203 responses from 27 European countries were analysed. 164 (81%) surgeons were employed at a university hospital, 184 (91%) performed advanced minimally invasive surgery, 148 (73%) performed minimally invasive distal pancreatectomy. Minimally invasive pancreatoduodenectomy was performed by 42 (21%) surgeons whereas only 9 surgeons had performed more than 10 of these procedures. Robot-assisted pancreatic surgery was performed by 28 (14%) surgeons. 63 (31%) surgeons expected minimally invasive distal pancreatectomy for cancer to be inferior to open distal pancreatectomy concerning oncological outcomes. 151 (74%) surgeons expected to benefit from training in laparoscopic distal pancreatectomy and 149 (73%) were willing to participate in a randomized trial on this topic.

Conclusion: Minimally invasive distal pancreatectomy has become a common surgical procedure, although its benefits for cancer are under debate. Minimally invasive pancreatoduodenectomy has not yet been implemented. Specific training in laparoscopic distal pancreatectomy is welcomed and a pan-European randomized controlled trial for pancreatic cancer (DIPLOMA) seems indicated.

Introduction: Superficial duodenal neoplasms (SDNs) are rare, but clinically important disease, whereas whose therapeutic strategies have not been established. Endoscopic resection is technically difficult, due to thin intestinal walls which can be easy to perforated and difficulty of maneuvering endoscope. On the other hand, surgical resection seemed considerably invasive. In addition, it is often difficult to recognize the extent of the lesion precisely during surgical approach. To overcome these problems, we developed a noble approach to treat SDNs which involves a combination of endoscopic and laparoscopic techniques; endoscopy-assisted laparoscopic full-thickness resection (EALFTR).

Aims & Methods: The aim of this study was to assess the clinical outcomes after EALFTR for SDN. Between January 2011 and March 2015, a total of 85 patients with 90 non-amupllary SDNs were enrolled in this study. Patients with familial polyposis syndrome were excluded. Clinocopathological characteristics (e.g. age, sex, tumor location and size) were collected at initial endoscopic examination. The primary outcome was en-bloc R0 resection rate. Secondary outcomes were procedure time, complications and length of hospital stay after EALFTR. Moreover, long-term outcomes of SDNs after EALFTR were also evaluated. EALFTR procedure was previously described in our report. In summary, subsequent to the laparoscopic duodenal mobilization, peripheral margin was marked around the tumor endoscopically and each marking was perforated intentionally using a needle knife in the coagulation mode.After laparoscopic full-thickness incision, closure of the defect in the duodenal wall was performed by a laparoscopic hand-suturing technique.

Results: Lesions were predominately located at the second portion (50/90, 56%), whereas others located at bulb (32/90, 35.6%) and third portion (8/90, 8.9%), respectively. The tumor size was 13.2 ±11.6 mm, and the resected specimen size was 26.0 ±10.5 mm. The mean procedure time was 146 ±43.2 minutes. The mean length of hospital stay after EALFTR was 11.6 ±6.7 days. Although two of 90 cases were converted to open surgery, en-bloc R0 resection was achieved in most of remaining cases (86/88, 98%). Regarding to complications, postoperative anastomotic leakage and stenosis occurred in three (3.5%) and five patients (5.9%), respectively, however all patients recovered conservatively. Histopathological examination confirmed 42 adenomas, 22 adenocarcinomas, 17 neuroendocrine tumors, and 9 others. Of 71 patients whose follow-up period longer than 1 year, no metastasis and/or local recurrence was detected during the median follow-up period of 27 months (range, 12 – 44).

Conclusion: We confirmed favorable clinical outcomes of EALFTR for SDNs. EALFTR enables successful en-bloc R0 resection, with minimally invasive manner. Our results indicated that EALFTR hardly concerns with tumor dissemination. We believe EALFTR can be a effective treatment option for SDNs, although great caution against complications is mandatory.

TUESDAY, OCTOBER 27, 2015 09:00–17:00
IBD II – HALL 7

sensation, acting through μ, κ and δ opioid receptors (MOR, KOR and DOR, respectively).
Aims & Methods: The aim of this study was to investigate the effect of the natural peptide inhibitor of NEP, sialorphin and Met- and Leu-enkephalins in mouse models of experimental colitis.
Methods: To assess the anti-inflammatory activity of tested compounds, we used acute and semi-chronic models of inflammation induced by intracolonic administration of TNBS as well as acute model of DSS-induced colitis. Body weight, macroscopic score, ulcer score, colon length, weight and thickness were recorded. Moreover, in all experiments the level of myeloperoxidase (MPO) activity was determined as an indicator of neutrophil infiltration in colonic tissue. In order to determine the mechanism of action of sialorphin, we used selective MOR, KOR and DOR antagonists; β-funaltrexamine (β-FNA), nor-binaltorphimine (norBNI) and naltrindole (NLTR), respectively.
Results: Met- and Leu-enkephalin and sialorphin administered intraperitoneally (i.p.) at the dose of 1 mg/kg twice daily significantly ameliorated colitis in the acute model, as indicated by reduced macroscopic and ulcer scores, as well as bowel length and thickness and MPO activity. In addition, the anti-inflammatory activity of sialorphin was dose-dependent at the dose range from 0.3 to 3 mg/kg (i.p., twice daily). The therapeutic effect of sialorphin (1 mg/kg, i.p. twice daily) in the acute model was blocked by selective MOR and KOR, but not DOR antagonists (all at a dose of 1 mg/kg i.p.). In the semi-chronic model of TNBS-induced colitis sialorphin (1 mg/kg, i.p.) partially improved macroscopic parameters of the disease but this effect was not statistically significant. Interestingly, treatment with sialorphin had no effect in the model of DSS-induced colitis.
Conclusion: We propose a novel anti-IBD therapeutic strategy, based on the treatment with inhibitors of enkephalin-degrading enzymes and the elevation of endogenous enkephalin levels.

P0892 IS INTESTINAL DYSBIOSIS A FACTOR LEADING TO COLONIC INFLAMMATION?

M. Aguilera[1], **J. Estévez**[1], V. Martinez[1]
[1]*Cell Biology, Physiology & Immunology, Universidad Autonoma de Barcelona, Bellaterra - Barcelona, Spain*

Contact E-mail Address: vicente.martinez@uab.es
Introduction: Dysbiotic states have been associated to intestinal inflammation. However, a causal relationship has not been established and it is not clear if dysbiosis should be regarded as a cause or a consequence of intestinal inflammation. To further understand the relationship disbiosis-inflammation we assessed immune activation and the appearance of colitis in mice subjected to antibiotics-induced dysbiosis.
Aims & Methods: A dysbiotic state was induced with a 1-wk or 2-wk duration oral treatment with non-absorbable, broad spectrum antibiotics (bacitracin and neomycin) in mice. At the end of the treatment, colonic luminal and wall adhered microbiota (fluorescent in situ hybridization and qPCR), inflammatory markers (RT-qPCR) and macroscopical and microscopinal signs of colonic inflammation were assessed.
Results: 1-wk or 2-wk antibiotic treatment resulted in a similar dysbiotic state; with an increase in the proportion of *Lactobacillus* spp, *Bifidobacterium* spp and coccoid forms of *Clostridium* cluster XIVa. However, total bacterial counts were reduced during a 1-wk treatment (by 50% vs. control conditions, $P < 0.05$), while there was a 2-fold increase during the 2-wk treatment ($P < 0.05$ vs. control). During a 1-wk treatment, bacterial adherence to the colonic epithelium was favored, while no changes were observed during the 2-wk treatment. A local immune activation, as seen by an increase in the luminal levels of secretory IgA (Table) and the up-regulation in the expression of antimicrobial peptides was observed. Although these changes, no macroscopical (except for an enlargement of the cecum) or microscopical signs of colonic inflammation were observed (see Table).**Table: Immune activation and macro and microscopic changes in the colon during antibiotic treatment (Data are mean ± sem, 6-16 animals per group; *: P < 0.05 vs. respective vehicle control.)**

	Secretory IgA (mg/ml)	Weight cecum (mg)	Colon relative weight (mg/cm)	Histopathological score (0-12)
Vehicle 1-wk	7.2 ± 1.4	318.4 ± 16.5	12.6 ± 0.7	1.6 ± 0.4
Antibiotics 1-wk	261.7 ± 6.5 *	661.9 ± 16.5 *	14.8 ± 0.9	1.8 ± 0.6
Vehicle 2-wk	36.7 ± 11.5	409.0 ± 20.2	23.3 ± 1.8	0.7 ± 0.2
Antibiotics 2-wk	362.5 ± 11.5 *	507.7 ± 18.4 *	23.9 ± 1.9	1.3 ± 0.2

Conclusion: Colonic dysbiosis might result in a state of ''low grade inflammation", characterized by a local immune activation in the absence of structural changes. Similar states (disbiosis and low-grade inflammation) are described in patients with functional gastrointestinal disorders, mainly irritable bowel syndrome. Dysbiosis seems to represent a contributing factor to immune colonic responses but, per se, does not result in an overt inflammatory reaction.

P0893 EXOSOME: A NEW MEDIATOR OF HOST RESPONSE TO CROHN'S DISEASE-ASSOCIATED ADHERENT-INVASIVE *ESCHERICHIA COLI*

J. Carriere[1], A. Bretin[1], N. Barnich[1], A. Darfeuille-Michaud[1], H. T. T. Nguyen[1]
[1]*M2iSH UMR 1071 Inserm/University of Auvergne, Clermont-Ferrand, France*

Contact E-mail Address: Jessica.CARRIERE@udamail.fr
Introduction: Crohn's disease (CD) is a chronic inflammatory bowel disease of which the etiology involves environmental, genetic and microbial factors. A high prevalence of invasive *Escherichia coli* strains, named AIEC (adherent-invasive *E. coli*), has been reported in the intestinal mucosa of CD patients. Exosomes are small endosomal-derived vesicles involved in cell to cell communication and have been implicated in various diseases including cancer and infectious disorders.
Aims & Methods: Here, we investigated the potential involvement of exosomes in host response to AIEC infection. Exosomes were extracted from human intestinal epithelial T84 cells and human monocyte-derived THP-1 macrophages uninfected or infected with the AIEC reference strain LF82 or the non-pathogenic K-12 C600 strain by using the ExoQuick exosome precipitation kit (System Biosciences). Epithelial permeability was assessed by measuring the TER and the translocation of FITC 4kDa. Intracellular number of AIEC was determined by using the gentamicine protection assay.
Results: Electron microscopy showed that infection with AIEC LF82 increased the release of exosome-like microvesicles of 30-100nm from T84 and THP-1 cells. Immunogold labelling and Western blot analyses confirm the presence of the well-known exosomal marker CD63 in these microvesicles. Characterization of exosomes released from LF82-infected cells showed that they did not affect either intestinal epithelial permeability, or adhesion and invasion capacity of AIEC LF82 in T84 cells, or expression of carcinoembryonic antigen-related cell adhesion molecule 6 (CEACAM6)-host epithelial receptor for AIEC. However, compared to exosomes released from non-pathogenic K12-infected host cells, those from LF82-infected cells induced in naïve recipient cells increased activation of NF-kappaB and MAPK pro-inflammatory signaling pathways and enhanced production of pro-inflammatory chemokines and cytokines IL-8, TNF-α and IL-6. In contrast, exosomes released from uninfected cells did not exhibit these pro-inflammatory activities. Mass spectrometry analysis revealed that exosomes released from LF82-infected T84 cells carried microbial antigens including the outer membrane protein C (OmpC), a known virulence factor of AIEC bacteria.
Conclusion: In conclusion, our study shows that in response to CD-associated AIEC infection, intestinal epithelial cells and macrophages release exosomes that can trigger pro-inflammatory responses in naïve macrophagic recipient cells.

Introduction: Mucosal repair is a key goal in Inflammatory Bowel Disease (IBD) treatment and the Wnt signalling pathway plays a crucial role in this process. Macrophages coordinate tissue repair and expression of canonical Wnt ligands has been associated with the M2 phenotype. Recent studies reported an impaired M2 polarization and delayed wound healing in STAT6-/- mice.
Aims & Methods: We aim to evaluate the role of STAT6 in Wnt ligands expression associated with M2 polarization *in vivo* and the relevance of these cells in wound healing in a murine model of colitis. Peritoneal macrophages were isolated from WT and STAT6-/- and polarized towards M1 and M2 phenotype. mRNA expression of canonical Wnt ligands was analyzed by qPCR (fold induction). Colitis was induced in STAT6-/- by an intrarectal injection of TNBS (3.5mg/20g mice) and 2 days later received an i.p. injection of macrophages ($2{\cdot}10^6$ million) obtained from WT and STAT6-/- treated with Il-4 (WT-M2a and STAT6-M2a, respectively). Mice were weighed daily (percentage of body weight at day 4 vs day 0). 4 days after TNBS were sacrificed, colon length was measured and mucosal histology was evaluated according to Wallace Score. Mucosal expression of iNOS, TNFα, IL-1β, c-myc and Lgr5 was analyzed by qPCR and protein levels of nuclear β-catenin by western blot. Data are expressed as Mean ± SEM ($n \geq 5$).
Results: In peritoneal macrophages from WT mice we detected the expression of Wnt2b, Wnt7b, Wnt10a and Wnt10b, while Wnt1, Wnt3a and Wnt6 were not detected. In macrophages obtained from WT mice, polarization towards the M2a phenotype induced a significant increase in the expression of Wnt2b (4.0 ± 1.1) and Wnt7b (2.8 ± 0.3) compared with that detected in non-polarized (1.1 ± 0.2 and 1.1 ± 0.2) and M1 macrophages (1.1 ± 0.4 and 0.8 ± 0.2). However, in macrophages obtained from STAT6-/- mice and polarized towards M2a phenotype the expression of Wnt2b (0.9 ± 0.2) and Wnt7b (0.9 ± 0.3) was not significantly different to that detected neither non-polarized (1.3 ± 0.2 and 0.9 ± 0.2, respectively) nor M1-macrophages (0.9 ± 0.4 and 1.1 ± 0.1, respectively). In STAT6-/- mice treated with TNBS, administration of WT-M2a macrophages accelerated the regain of body weight (98.1 ± 0.6%) compared with the administration of STAT6-M2a macrophages (92.9 ± 1.1%). These cells also enhanced the functional recovery of mice since colons from mice treated with WT-M2a macrophages were significantly longer and exhibited less histological damage score than those colons from mice with STAT6-M2a macrophages. The mRNA expression of pro-inflammatory markers such as iNOS, TNFa and IL-1b was significantly lower in the mucosa of mice treated with WT-M2a macrophages (0.7 ± 0.1, 0.5 ± 0.1 and 0.6 ± 0.2, respectively) than in that of mice treated with STAT6-M2a macrophages (1.0 ± 0.1, 1.1 ± 0.1 and 1.0 ± 0.1, respectively). A significant increase in nuclear b-catenin (1.6 ± 0.1) and mRNA expression of two Wnt target genes, c-myc (1.6 ± 0.2) and Lgr5 (2.1 ± 0.4) was detected in the mucosa of mice treated with WT-M2a macrophages compared whith that of mice with STAT6-M2a macrophages (1.0 ± 0.1, 1.1 ± 0.1 and 1.1 ± 0.1, respectively).
Conclusion: STAT6 mediates the expression of canonical Wnt ligands associated with the M2a macrophage phenotype. Activation of Wnt signalling by a STAT6-dependent macrophage phenotype promotes mucosal repair in murine IBD.

P0895 ACTIVATION OF COLONIC AUTOPHAGY WITH TREHALOSE IMPROVES WOUND HEALING IN MURINE COLITIS

J. Cosin-Roger[1], D. Ortiz-Masia[1], D. C. Macias-Ceja[1], P. Salvador[1], S. Calatayud[1], C. Hernández[1], M. D. Barrachina[1]
[1]*Pharmacology, Faculty of Medicine, University of Valencia, Valencia, Spain*

Introduction: Autophagy plays a homeostatic role in intestinal epithelial cells by engulfing intracellular organelles and endogenous pathogens leading to the degradation of their contents. Several polymorphisms in gene loci containing autophagy-related proteins such as ATG16L1, IRGM, and NOD2 have been associated with an increased risk of Crohn's disease and it has been suggested that a defective autophagy may have a role in its pathogenesis.

Aims & Methods: We aim to analyze the expression of autophagic protein markers in a murine model of colitis induced by TNBS and the resultant effects of activating mucosal autophagy on the course of the disease. Mice received an intrarectal injection of TNBS (3.5mg/20g) in order to induce colitis and control animals received an intrarectal injection of TNBS-vehicle (EtOH 40%) (day 0). Some mice received trehalose in the drinking water (3%) during three weeks before TNBS administration. After colitis induction, changes in body weight were determined daily (results are expressed as percentage vs the weigth at day 0) and mice were sacrificed 2 and 4 days after TNBS administration. Mucosal histology was evaluated after an hematoxylin staining according to Wallace Score (1-10). Colons were frozen for protein extraction and Western blot experiments of p62, LC3 and b-actin were performed. Data are expressed as Mean ± SEM ($n \geq 5$).

Results: Treatment of mice with TNBS induced a loss of body weight that peaked 2 days after treatment. Subsequently, mice began to recover and, four days after treatment, body weight reached similar values to those of control animals. The expression of autophagic protein markers reveal a slight accumulation of both p62 and LC3II protein levels in the mucosa of TNBS-treated mice compared with the control mucosa, suggesting a reduction in the autophagic flux in the inflamed mucosa, which was observed 2 and 4 days after TNBS. Chronic treatment with trehalose induced a significant increase in LC3II protein levels and a significant decrease in p62 protein levels in the colonic mucosa of both control and TNBS-treated mice showing that trehalose was increasing the autophagic flux in both conditions. In trehalose-treated mice, the loss of body weight was significantly lower at day 1 and 2 (92.85 ± 1.28 and 96.48 ± 1.42, respectively) compared with that observed in vehicle-treated mice (90.24 ± 0.76 and 91.33 ± 1.72, respectively). The analysis of histological damage score revealed significant differences between trehalose (4.3 ± 0.4) and vehicle-treated mice (5.5 ± 0.6), four days after TNBS administration.

Conclusion: Chronic treatment with trehalose during three weeks activates autophagy in murine colonic mucosa and improves wound healing and functional recovery of TNBS-treated mice.

Introduction: Mechanisms of resistance to corticosteroids (CS) in ulcerative colitis (UC) are not well understood. Little is known about the influence of microRNAs (miR) in the response to CS in UC.

Aims & Methods

Aims: To compare the transcriptomic profile in rectal mucosa of patients with active UC responding and non-responding to CS.

Methods: Rectal biopsies were obtained from UC patients before and after three days of CS treatment. Patients were grouped in responders and non-responders according to Montreal's classification. miR were identified by means of a sequencing method *(Illumina)* and RNAm were study by microarrays method (*Illumina*) on those rectal biopsies with high integrity. Those miR and RNAm with a fold change ≥ 1.5 and adjusted p-value ≤ 0.05 were further studied.

Results: 32 out of 48 tissue samples reached an integrity that allowed miR sequencing or microarrays study. Comparison between groups showed a differential miR expression of miR-1246, miR-1291, miR-5701 and miR-625-3p, miR-183-5p, miR-3607-3p, miR-4770, miR-449, miR-145-3p. The only gene with differential expression after microarrays study was DDIT4. *In silico* study reveals that DDIT4 is a potential target of three of the differential expressed miR (miR-183-5p, miR-625-3p, miR-3607-3p) and also that this gene is linked to the mTOR pathway (and indirectly with autophagy).

Conclusion: There is a different profile of rectal microRNAs between responders and non-responders to CS. Our findings suggest that regulation of mTOR and autophagy pathways by miR might be involved in the response to CS in active UC.

P0897 ULCERATIVE COLITIS PATIENTS AND THE FAMILY'S ENTEROBACTERIA BUSH COMPARATIVE INVESTIGATION

K. Fukuda[1], Y. Fujita[1]
[1]*Gastroenterology, St Luke's International Hospital, Tokyo, Japan*

Contact E-mail Address: fukukats@luke.ac.jp

Introduction: The role of intestinal microflora in the aetiology of inflammatory bowel diseases (IBD), including ulcerative colitis (UC) and Crohn's disease is broadly assumed. The Terminal Restriction Fragment Length Polymorphism (T-RFLP) is a molecular biology technique for profiling microbial communities in faecal samples. We have recently reported the application of T-RFLP to validate the discriminant score of intestinal microbiota as a biomarker of disease activity in patients with UC. However, because T-RFLP cannot distinguish specific bacterial strains, it is not the best technique when one wishes to trace IBD among family members.

Aims & Methods: In the present study, instead of T-RFLP, we were interested to apply the Amplicon Sequence analysis to the intestinal flora in faecal samples from UC patients and patients' relatives as a molecular biology probe. The subjects were 90 patients with UC together with 78 relatives of the same UC patients as a control group. Twenty-seven patients had active UC (group I) and 63 had quiescent UC (group II). The later included 31 with mild inflammation in the large intestine (group IIa), and 32 without inflammation (group IIb). The patients' relatives were consanguineous (group III, n = 45), and non-consanguineous (group IV, n = 33). With the Amplicon Sequence analysis, intestinal microflora in faecal samples from 78 relatives and from the 90 patients with UC were analysed for comparative interpretations. The software we used was an SPSS (IBM Statistics 20.0).

Results: With the technology we applied, it was possible to identify over 600 different bacterial species and analyse quantitatively. Among all groups, Bifidobacterium did not show significant difference. Bacteroides, especially Fragilis and Enterobacteriaceae were markedly increased in patients with active UC. In contrast, Verrucomicrobiales species were markedly decreased in patients with active UC.

Conclusion: The most significant findings of this study include a marked increase in the Bacteroides, Fragilis and Enterobacteriaceae during active UC, while the Verrucomicrobiales species were markedly decreased in active UC patients. Further, in several previously studies, Bifidobacterium has been reported to be decreased in patients with active UC, but we did not find any clinically relevant change in Bifidobacterium in this study. The present method could reveal presence of pathologic as well as beneficial bacterial strains in IBD patients. We believe that further studies including more factors for analyses are warranted to better understand the significance of intestinal microflora in the immunopathogenesis of IBD.

Introduction: Inflammatory bowel diseases (IBD) are comprised of Crohn's disease (CD) and ulcerative colitis (UC). Unlike the inflammation in CD that can affect any part of the bowel, inflammation in UC is limited to the large bowel mucosa, thus complete large bowel resection was expected to be curative. Nonetheless, about 60% of patients who undergo total proctocolectomy with an ileal pouch reservoir develop pouchitis. Recently we performed mRNA profiling and detected an increase in Dual Oxidase 2 (DUOX2) expression in inflamed pouch biopsies as well as in CD patients. Duox2 mediates anti pathogen responses in intestinal epithelial cells by secreting reactive oxygen species (ROS) to the lumen, and its expression may be induced by microbiota.

Aims & Methods: We aimed to decipher the mechanism responsible for DUOX2 effects in the intestinal inflammation. Intestinal biopsies from normal controls, inflamed and non-inflamed UC, CD and pouch patients were collected. Disease activity was defined using clinical disease scores, as well as endoscopic and histologic assessment. DUOX2 mRNA and protein levels were assessed by RT-PCR and immunohistochemistry. DUOX2 intracellular localization as well as activity (extracellular ROS production) were assessed by flow cytometry and amplex red assay, respectively, in human intestinal epithelial cell lines (Caco2 and HT-29) in response to inflammatory cytokines (IL1b, TNFa, IFNg, IFNb) and fecal extracts obtained from IBD patients. Microbiota composition in patients with IBD as well as controls was assessed by 16S rRNA gene amplicon pyrosequencing.

Results: DUOX2 expression in the non inflamed colonic mucosa of IBD patients was increased (30 fold, $p < 0.05$). This was further augmented in the inflamed colon (≥ 150 fold, $p < 0.001$), both compared to normal controls. Similar results were obtained in biopsies generated from the ileum. Decrease in key microbial taxa was observed in fecal samples from patients with a normal pouch compared to normal controls ($p < 0.004$). Further decrease was noticed in fecal extracts from patients with pouchitis ($p < 0.0001$). DUOX2 expression

significantly increased in response to inflammatory cytokines (≥300 fold increase, $p < 0.001$) and fecal extracts derived from patients with active IBD (≥10 fold increase, $p < 0.001$). ROS production reflecting Duox2 activity, increased in response to fecal extracts derived from patients with active IBD (3 fold, $p < 0.001$).
Conclusion: Mucosal DUOX2 expression is increased in IBD, and correlates with inflammation. DUOX2 expression in epithelial cells is increased in response to inflammatory stimuli and fecal extracts, specifically from patients with active IBD. ROS production is increased in response to fecal extracts but not to inflammatory cytokines alone. Thus DUOX2 increased expression and aberrant function may have a role in augmenting intestinal inflammation in IBD.

P0899 MAPPING BIOPSY OF ENTIRE SMALL INTESTINE REVEALED SPECIFIC GENE EXPRESSION IN CROHN'S DISEASE

K. Tsuchiya[1], R. Hayashi[2], S. Hibiya[1], K. Fukushima[1], N. Horita[1], T. Shirasaki[1], M. Watanabe[1]
[1]*Gastroenterology and Hepatology, Tokyo Medical and Dental University, Tokyo,* [2]*Hiroshima University, Hiroshima, Japan*

Introduction: The discovery of genetic variants in Crohn's disease (CD) has helped us to understand the pathogenesis of CD. Notably, genetic variants of nucleotide-binding oligomerization domain containing 2(NOD2) and autophagy related 16-like 1 (ATG16L1) have indicated that mucosal barrier dysfunction is one of the most crucial pathogenesis in CD. However, the patients with CD in Asia including Japan and China did not have significant variants of these genes, suggesting that the other molecular mechanism of the pathogenesis might be involved in Asian patients differently from Caucasian patients.
Aims & Methods: In this study, we therefore aimed to elucidate the molecular mechanism of the pathogenesis in Japanese patients with CD, using mapping biopsy of entire small intestine collected by balloon-assisted enteroscopy.
We performed balloon-assisted enteroscopy to the patients with CD and healthy controls. Then we collected five biopsy specimens in equal interval positions through entire small intestine assisted by X-ray. Gene expression pattern in each region of entire small intestine was analyzed by using Self-Organizing Maps (SOM). Specific gene expression in CD was detected by the microarray analysis of 16 biopsy specimens of jejunum in 4 CD patients compared to 4 healthy controls.
Results: RNA was successfully generated from mapping biopsy specimens. SOM analysis compared CD with healthy control revealed that any inflammatory genes were not increased in jejunum of CD patients, suggesting that the pathogenesis at the pre-onset stage of CD might remain in jejunum. Microarray analysis in 16 jejunum biopsy specimens compared between 4 CD patients and 4 healthy controls showed statistically significant gene expression including 11 up regulated genes and 14 down regulated genes in CD patients.
Conclusion: The analysis of comprehensive gene expression using mapping biopsy is useful for understanding the condition in human entire small intestine. Moreover, it might be useful to elucidate the pathogenesis of CD.

Contact E-mail Address: farkas.klaudia@gmail.com
Introduction: Microscopic activity in ulcerative colitis (UC) patients with endoscopic remission is becoming more and more important in the prediction of relapse. The presence of basal plasmacytosis and the increased number of eosinophils and neutrophils in the lamina propria have been supposed to predict clinical relapse in UC patients with complete mucosal healing.
Aims & Methods: The aim of this study was to examine the correlation between the microscopic activity and the disease outcome in patients with endoscopically inactive UC. Sixty-nine UC patients (mean age at diagnosis was 31.4 years, male/female ratio: 27/42) with endoscopic remission (eMayo 0 and 1) and at least 12-month follow-up between 2008 and 2013 were enrolled in this prospective observational study. An expert pathologist evaluated all colonic biopsies for histologic activity (Geboes score) and the presence of basal plasmacytosis. C-reactive protein (CRP), partial Mayo scores and the used medications were documented at the time of the endoscopy, and the follow-up appointments: at months 6, 12 and 24 and at the last visit. Disease relapse was defined as a partial Mayo score ≥3.
Results: Histology revealed focal or diffuse basal plasmacytosis and microscopic inflammatory activity with a Geboes score ≥3.1 in 81.2% and 37.7% of patients with mucosal healing. At 6, 12 and 24 months and at the follow up visit, clinical relapsed occurred in 19%, in 14.5%, in 13%, and in 16% of the patients. The mean time of follow-up was 3 years. Neither of the presence of basal plasmacytosis, nor Geboes score ≥3.1 was predictive of disease relapse at 6, 12, 24 months and at follow-up. No difference was observed if the data were analyzed separately in subgroups of eMayo score of 0 or 1.
Conclusion: Our results did not confirm the previous hypothesis that the presence of basal plasmacytosis and microscopic inflammation predicts UC clinical relapse in patients with mucosal healing.

P0901 CRITICAL ROLE OF THE IL-33/ST2 AXIS IN COLITIS-ASSOCIATED COLORECTAL CANCER

L. R. Lopetuso[1,2], C. De Salvo[1], L. Di Martino[3], W. Goodman[1], F. Scaldaferri[2], A. Gasbarrini[2], T. T. Pizarro[1]
[1]*Pathology, Case Western Reserve University - School of Medicine, Cleveland, United States,* [2]*Internal Medicine, Gastroenterology Division, Catholic University of Sacred Heart of Rome, Rome, Italy,* [3]*Digestive Health Research Center, Case Western Reserve University, Cleveland, United States*

Introduction: It is now well-established that IL-33 and its receptor, ST2, are important factors in the pathogenesis of IBD. Emerging evidence also suggests its critical role in epithelial proliferation and potential contribution to inflammation-driven tumorigenesis that can lead to colorectal cancer (CRC). The aim of our study was to characterize the precise contribution of IL-33/ST2 axis in the azoxymethane (AOM)/dextran sodium sulfate (DSS) model of colitis-associated CRC.
Aims & Methods: C57/BL6 wild-type (WT), IL-33 KO and ST2 KO mice were given a single dose of AOM (7.4 mg/kg) followed by two cycles of 3% DSS for 7d in drinking water. Body weight, occult blood test, and stool consistency were measured daily to calculate the Disease Activity Index (DAI), and endoscopic and histological evaluation of colons were performed using established scoring systems. Aged-matched WT mice, injected with vehicle and given regular drinking water were used as controls (CT). At 8 wks post AOM injection mice were sacrificed. IHC, immunofluorescence (IF) and qPCR were done on full-thickness colons for IL-33 and ST2 localization and identification, and mRNA expression, respectively. FACS analysis was performed on resected, isolated polyps in order to functionally characterize ST2+ cells.
Results: IL-33, ST2L, and sST2 mRNA transcripts were dramatically elevated in WT vs. CT mice. IHC of treated WT mice revealed localization of IL-33 to the colonic epithelium and to cells within the LP morphologically consistent with tissue macrophages. ST2 staining was localized to the intestinal epithelium in tissues immediately adjacent to tumors, while within the tumors themselves, ST2+ cells displayed a spindle/fibroblast-like morphology with a unique distribution throughout the polyps. Little to no staining for both IL-33 and ST2 was present in CT. Using IF, ST2 co-localized with αSMA in polyps; however, ST2 staining was not exclusive for αSMA+ cells. FACS analysis showed a distinct population of CD45+ hematopoietic cells consisting of CD3/CD8+ cytotoxic T cells (CTLs), CD19+ B-lymphocytes, and CD11b+CD11c- and CD11b+CD11c+ myeloid cells. ST2 was mainly expressed by CTLs, CD11b+CD11c- and CD11b+CD11c+ myeloid cells. Non-hematopoietic cells (CD45-) also expressed ST2. DSS challenge in WT mice resulted in increased body weight loss and DAI vs. IL-33 KO and ST2 KO mice. At 5 weeks post AOM injection, experimental mice underwent survival colonoscopy. WT had already developed protruding lesions with abnormal vascular patterns, suggesting pre-tumorous lesions, while IL-33 KO and ST2 KO mice showed the absence of pre-tumorous lesions with a more impressive mucosal inflammation, likely due to reduced epithelial proliferation and repair caused by the absence of IL-33 signaling. At sacrifice, increased number and size of polyps were observed in WT vs. IL-33KO and ST2KO mice.
Conclusion: Our results suggest that activation of the IL-33/ST2 axis sustains tumorigenesis in the murine model of colitis-associated CRC. Further studies are underway to determine mechanisms of action that support these findings.

Introduction: Primary sclerosing cholangitis (PSC) is a progressive disease of the biliary tree characterised by inflammation, fibrosis and stenoses. Inflammatory bowel disease (IBD) in patients with primary sclerosing cholangitis (PSC – IBD) is considered to be a distinct phenotype of IBD with a multi – factorial origin where microbiota most likely have a substantial role. In our pilot study, our aim was to compare the microbiota composition in PSC and/or IBD groups with ulcerative colitis (UC) and healthy controls.
Aims & Methods: Total number of 15 individuals was used in presented study: 4 control healthy samples, 4 UC patients, 4 PSC-IBD patients and 3 PSC (without IBD). Fecal microbiota composition was assesed by sequencing of variable V4 and V5 region of 16S rRNA gene on Personal Genome Machine platform (Fisher Scientific). Library preparation, template preparation and template sequencing was performed according to manufacturer's protocols. Obtained data were filtered by quality and length and processed for alpha and beta diversity analyses using QIIME software package.
Results: Following significant changes in bacterial numbers were observed among tested groups: PSC versus PSC-IBD: Higher Bifidobacterium sp. (18 vs 2.71 %), Lachnospira (4.58 vs 0.68 %) and Dorea sp (5.7 vs 1.55 %) and lower Enterococcus sp. (0 vs 9.14 %), Faecallibacterium sp. (1.31 vs 4.12 %) and Prevotella/Paraprevotella sp. (0 vs 9.71 %) numbers. PSC-IBD versus UC: Higher Bacteroides sp. (17.13 vs. 4.86 %), Enterococcus sp. (9.14 vs 0 %) and Prevotella/Paraprevotella sp. (9.71 vs 2.13 %) and lower Bifidobacterium sp (2.71 vs 12.95 %) and Faecallibacterium sp. (4.12 vs 16.4 %) numbers. The clustering of samples according to the type is stronger with the unweighted UniFrac metric than with the weighted metric, suggesting that differences in community membership (rather than community structure) discriminate better among groups.

Conclusion: Members of genus Faecallibacterium and Prevotella showed highest variations with regards to PSC /PSC-IBD/UC groups comparison. Control samples showed higher species richness than patients' samples. Our data suggest that microbiota composition differs among patients with PSC (without IBD), PSC – IBD and UC. Presented data should be considered as preliminary, as more samples are needed for statistical analyses to support detected observations.

Introduction: The parasympathetic nervous system and vagal nerve in particular are responsible for anti-inflammatory signaling from the central nervous system (CNS) to the periphery. α7 homopentamer nicotinic acetylocholine receptors (nAChRs) have been implicated in the transduction of these signals to the gastrointestinal (GI) tract, but the underlying mechanisms are still unclear.
Aims & Methods: The aim of this study was to investigate the anti-inflammatory effect of the novel, selective α7 nAChR partial agonist, EVP 6124 in mouse models of experimental colitis, and to determine the mechanism underlying its activity. To assess the anti-inflammatory activity of EVP 6124, we used trinitrobenezenesulfonic acid (TNBS)- and dextran sulfate sodium (DSS)-induced models of colitis. Macroscopic score, ulcer score, colon length and thickness, as well as myeloperoxidase (MPO) activity were recorded. To confirm the selectivity of the test compound, we used α7 nAChRs antagonist methyllycaconitine (MLA). Moreover, we used hexamethonium (HEX) to investigate whether centrally- or peripherally-located nAChRs are involved in the effects of EVP6124. Quantitative immunohistochemistry (IHC) was used to measure the infiltration of macrophages, neutrophils, T cells and B cells in the colon. Furthermore, we employed flow cytometry to determine the effect of EVP6124 on frequencies of $FoxP3^+$and $IL\text{-}17A^+$ T cells in the mouse colon. Additionally, we assessed the effect of EVP6124 on the viability of mouse spleen-derived monocytes. Changes in α7 nAChR mRNA expression in the colonic tissue during colitis and after treatment with EVP 6124 were quantified by real time RT PCR.
Results: The intraperitoneal (i.p.) administration of EVP6124 (3 mg/kg, twice daily) attenuated TNBS- and DSS-induced colitis in mice, as indicated by significantly reduced macroscopic parameters and MPO activity; this effect was blocked by the i.p. administration of MLA (3 mg/kg, twice daily). Treatment with EVP6124 significantly reduced the infiltration of macrophages, neutrophils and B cells in the colon of TNBS-treated animals, as indicated by the quantitative IHC. In the TNBS model the frequency of pro-inflammatory $FoxP3^+IL\text{-}17A^+T$ cells was significantly reduced in the colon of EVP6124-treated animals. In the DSS model treatment with EVP6124 increased the frequency of immunosuppressive $FoxP3^+T$ cells and reduced pro-inflammatory $IL\text{-}17A^+T$ cells. Moreover, EVP6124 reduced the viability of mouse spleen-derived monocytes in a dose-dependent manner. α7 nAChR mRNA was significantly increased in the colitic animals vs. healthy controls.
Conclusion: We show that stimulation of α7 nAChR with a partial agonist EVP6124 alleviates colitis via alteration of the number and/or activation status of the immune cells in the gut. Therefore, we highlight the potential of EVP6124 to become an anti-IBD drug, especially given that initial studies with EVP6124 in healthy volunteers showed that this compound is safe and well-tolerable.

Introduction: The pathogenesis of inflammatory bowel disease (IBD) involves an imbalance of the gut microbiota generating an inappropriate activation of the mucosal immune system in genetically predisposed individuals. The human commensal microbiota contains a large number of Bacteroidetes species that may cause inflammation in animal models.
Aims & Methods: The aim of this study was to detect and evaluate the influence of a major type of intestinal commensal bacteria belonging specifically to the order Bacteroidales on the activity of Crohn disease (CD). In addition, the effect of these bacteria isolated from CD patients on gut inflammation was evaluated in mice after transplantation.
Methods: We performed a case control study on the intestinal bacteria of the phylum Bacteroidetes from faeces of CD and healthy controls (HC) using a polymerase chain reaction (PCR) designed to detect human-specific genetic markers targeting Bacteroidetes-like 16S rRNA genes in fecal DNA samples. The PCR products from the 16S rRNA genes were digested with *Hinf*I, *Pci*I, *Dpn*II and *Aci*I enzymes and restriction fragment length polymorphism (RFLP) were determined. RFLP and sequencing analysis indicated that a total of 6 bacterial genotypes do exist: N1, C1, C2, C3, C4 and C5 (of which N1 genotype is probably a strain of *Bacteroides dorei* and C1, and maybe C2, strains of *B. vulgatus*). The relationship between CD activity (CDAI > 150) and microbiota was also evaluated. Microbiota from CD patients was transplanted into mice gut to evaluate their ability to induce inflammation. Results are shown in percentages.
Results: 11 CD patients (8 with active CD -aCD- (CDAI > 150), and 3 with inactive CD –iCD-), and 11 HC were included. The predominant Bacteroidetes genotype in feces from HC and iCD was N1 (in 100% of samples), whereas this genotype was found in only 28% of patients with aCD. 18% aCD patients showed the C1 genotype, 9% the C1 and C3 genotypes together, 18% the C4 genotype, and 27% the C1 and C4 genotypes together. The transplant of bacteria from CD patients to mice led to large bowel inflammation, and the stool of the transplanted mice consisted in 30% C4 genotype and had a high level of Bacteroidetes cluster in comparison with the mice transplanted with bacteria from HC.
Conclusion: The fecal microbiota of CD patients is different from those of HC in that they present a wide variety of Bacteroidetes cluster genotypes. The C4 genotype by itself, or together with the C1 genotype, seems to be intimately related to the activity of the disease. These results were also confirmed in transplanted mice.

Contact E-mail Address: Manuel.Noben@med.kuleuven.be
Introduction: Various mechanisms contribute to the pathogenesis of inflammatory bowel diseases (IBD), including defects in epithelial barrier function, Paneth cell or goblet cell dysfunction, and a microbial dysbiosis. The epithelium is constantly renewed by intestinal stem cells (ISCs) located at the bottom of the crypts. The *ex vivo* ISC-containing organoids, have demonstrated to be a suitable model to investigate cancer and cystic fibrosis.
Aims & Methods: Given the reported defects in epithelial barrier and Paneth cell function, we evaluated if the organoid forming capacity of colonic crypts, as well as organoid transcriptional profiles, from IBD patients differ from that of healthy controls (HC).
Colonic mucosal biopsies from 9 HC, 14 ulcerative colitis (UC) patients, and 12 Crohn's disease (CD) patients were used to culture organoids as previously described.[1, 2] After the second passage, organoids were differentiated for 4 days by withdrawal of Wnt3a, nicotinamide and p38-inhibitor from the medium. RNA and histology samples were then processed and analysed using qPCR (SYBR Green qPCR SuperMix-UDG, Invitrogen) and immunohistochemistry for ISCs and differentiated cell types (goblet cells, entero-endocrine cells, Paneth cells, enterocytes), as well as proliferation and apoptosis (Ki-67 and cleaved caspase 3 staining).
Results: There was no difference in initial organoid forming capacity between controls and IBD patients (HC 85.9%; UC 78.6%; CD 83.1%, HC vs. UC $P = 0.2794$, HC vs. CD $P = 0.2204$, and UC vs. CD 0.8370). Additionally, no intrinsic differences in expression of the ISC-marker Lgr5 or differentiated cell types were detected. However, in the undifferentiated organoids there was a significant increase in chromogranin A (CHGA) expression in CD patient-derived organoids ($P = 0.0384$, table 1). In differentiated organoids there was a significantly decreased expression of proliferating cell nuclear agent (PCNA) in organoids from CD patients when compared to HC organoids ($P = 0.0099$). The biological implications of these findings are currently being evaluated by immune-stainings of organoid sections.

Table 1: Comparison of deltaCt values per group. UC = ulcerative colitis (n = 7), CD = Crohn's disease (n = 8), HC = healthy control (n = 9).

Comparison colonic organoids	Gene	P-value
UC vs HC undifferentiated	Chromogranin A	0.8125
CD vs HC undifferentiated	Chromogranin A	**0.0384**
UC vs CD undifferentiated	Chromogranin A	0.1137
UC vs HC differentiated	PCNA	0.0541
CD vs HC differentiated	PCNA	**0.0099**
UC vs CD differentiated	PCNA	0.4179
UC vs HC undifferentiated	Mucin2	0.0939

Conclusion: Our data shows that intestinal crypts isolated from IBD patients form organoids as efficient as crypts from healthy controls. Gene expression of markers of stemness and differentiation showed only subtle differences, and the biological implications remain to be clarified via immunohistochemistry.

Contact E-mail Address: dr.mwlodarczyk@gmail.com
Introduction: Inflammatory bowel diseases (IBD) are characterized by crypt infiltration with neutrophils, which can be stimulated by externalization of an adhesion molecule CD99. Neutrophil infiltration is associated with upregulation of cyclophilin A (CyPA). However, studies on CD99 and CyPA in IBD patients have not been performed yet.
Aims & Methods: The aim of the study was to determine the CD99 gene and protein expression and extra- and intracellular concentration of CyPA in ulcerative colitis (UC) and Crohn's disease (CD) patients in comparison to healthy subjects. Patients with Crohn's disease (CD) and ulcerative colitis (UC) as well as healthy controls were enrolled in our study. All participating subjects were matched by age and gender. The samples comprised serum and colonoscopy biopsies from non-inflamed and inflamed (in UC or CD) colon areas. The CD99 mRNA was analyzed by RT-PCR, and CD99 and CyPA protein levels by immunoenzymatic methods (ELISA and Western blot).
Results: In UC patients, a tendency towards lower CD99 protein ($p = 0.084$), but not mRNA was observed compared with control. There was no relationship between CD and control in CD99 mRNA and protein level ($p = 0.735$ and $p = 0.446$, respectively). The UC patients had significantly lower CD99 mRNA in non-inflamed tissue and higher in inflamed colon areas compared with CD ($p = 0.035$ and $p = 0.021$, respectively). The extracellular CyPA level was 4.6- and 2.8-times higher in UC and CD than in control ($p = 0.017$ and $p = 0.137$, respectively). Reversed correlations were found between CyPA and CD99 in inflamed tissues of UC and CD patients.
Conclusion: Our study indicated that patients with UC had increased CD99 and CyPA both in plasma and tissue. Moreover, CD99 gene expression correlated inversely with intracellular CyPA level in inflamed and non-inflamed colon tissue in UC, but not CD. We suggest that there may be a link between CD99 and CyPA in IBD etiology. It is likely that CD99-CyPA interaction influences the inflammatory process in colitis, as in our study both CD99 and CyPA were increased in inflamed colon areas from UC patients. However, further studies are necessary to confirm those observations and to describe how, if at all, CyPA releasing influences CD99 signaling in IBD.

Introduction: In patients with ulcerative colitis (UC) chronic inflammation leads to dysplasia development in 10-20% of cases. Our previous studies demostrated that immunesurveillance mechanisms mediated by CD80-CD28 signalling may lead to dysplasia regression [1]. The persistence of low-grade dysplasia (LGD) in UC in two consecutive observations may be an indication for restorative proctocolectomy.
Aims & Methods: Our hypothesis is that a failure of immune surveillance mechanism may play a role in dysplasia persistence and we aimed to identify possible immunological markers of LGD persistence in colonic mucosa not affected by dysplasia.
We prospectively enrolled 95 UC patients who underwent screening colonoscopy who had biopsies taken from their sigmoid colon. Forty of them had at least a second colonoscopy and 6 patients had dysplasia in both exams suggesting a persistence of LGD in their colon. Real-time RT-PCR for TLR4, CD4, CD38, CD69, CD80 and CD8beta mRNA expression was performed. Flow cytofluorimetry for CD8+ lymphocytes expressing CD28 or CD38 and for epithelial cells expressing CD80 or HLA ABC were performed. Non parametric statistics, ROC curves analysis and logistic multiple regression analysis were used.
Results: We observed a lower CD38 and CD8beta mRNA expression in the healthy colonic mucosa of patients with LGD persistence ($p = 0.027$ and $p = 0.005$, respectively) as well as a lower level of activated cytotoxic T-cells (CD8 + CD38+) ($p = 0.042$). ROC curve analysis showed that lower level of activated cytotoxic T-cells (CD8 + CD38+) as well as low CD4, CD38, and CD8beta mRNA expression predicted with adequate accuracy the LGD persistence at a second colonoscopy. In particular, CD8beta mRNA levels showed the best accuracy (AUC = 0.87 [95%CI = 0.70-0.96], $p < 0.001$). At multivariate survival analysis in a model including CD8beta mRNA levels, disease duration and inflammatory grade showed that only CD8beta mRNA levels were independent predictor of dysplasia at follow up (OR = 0.033 [95%CI = 0.002-0.433], $p = 0.01$).
Conclusion: These data suggest a failure in immunesurveillance mechanisms in the colonic mucosa of UC patients who do not manage to clear dysplasia. Thus, low level of CD8beta mRNA expression in not dysplastic colonic mucosa might be used in the decision making of UC management as a predictor of persistence of dysplasia.

P0908 COMPARATIVE GENOMICS BETWEEN AIEC/NON-AIEC STRAIN PAIRS FOR THE DETECTION OF GENETIC ELEMENTS IMPLICATED IN THE ADHERENT-INVASIVE E. COLI PHENOTYPE

M. Martinez-Medina[1], M. Lopez-Siles[1], M. Ferrer-Guixeras[1], C. Camprubi-Font[1], C. Abellà-Ametller[1], J. Garcia-Gil[1]
[1]*Biology, University of Girona, Girona, Spain*

Contact E-mail Address: marga.martinez@udg.edu
Introduction: Adherent-invasive *Escherichia coli* (AIEC) have been implicated in the aetiology of Crohn's disease (CD) but the molecular basis of its pathogenicity is still not well resolved. Obtaining molecular tools specific for AIEC is of great relevance as the current available techniques to identify the pathotype are based exclusively in phenotypic screening of cultured bacteria, which is highly time-consuming.
Aims & Methods: Our aim was to identify genetic elements that could be involved in the AIEC phenotype in order to gain insight into the mechanisms of pathogenicity of the pathotype and to find out molecular targets for its identification. The genome of three pairs of *E. coli* strains with identical pulsed field gel electrophoresis fingerprints and virulence gene profiles but differing in the AIEC phenotype (AIEC and Non-AIEC respectively) was sequenced *de novo* combining HiSeq and PacBio using paired-end libraries. The three pairs covered different phylogenetic groups and, with the exception of one strain, each pair shared the same serogroup. Genome assembly, functional annotation and comparative genomics between pairs was performed to obtain genetic differences between AIEC and non-AIEC strains. Additionally, single nucleotide polymorphisms (SNPs) were searched by comparing the Non-AIEC strains with both their AIEC pair and a reference AIEC of the same phylogroup. We used the genome of AIEC LF82 for the O6:H1-B2 pair, the AIEC 576-1 for the ONT:HNT/O46:H32-D pair, and the AIEC 541-1for the O22:H7-B1 pair.
Results: Quality analysis indicated the reads achieved quality scores above Q30, thus the inferred base call accuracy was above 99.9%. Genome length of AIEC strains O6:H1-B2, ONT:HNT-D and O22:H7-B1 was 5.16, 4.86 and 4.79 MB respectively. Their non-AIEC counterpart presented +30,515bp, +12,270bp and –54,427bp respectively. After a selection of confirmed differences *in silico* we have identified 11, 15 and 28 genetic differences respectively, including SNPs, insertions and deletions. Of them, 29 were found in genes that were in commonly shared in all the strains but the mutations were not AIEC-specific. New SNPs calling comparing the three pairs with reference AIEC strains of the same phylogroup allowed the identification of 185, 182 and 354 SNPs commonly shared by AIEC strains and not found in the Non-AIEC pair respectively, which lead to missense variants. To the moment, no AIEC-specific sequence widely distributed in all AIEC was found among the selected genes. Selected genes included

adhesins, transporters, enzymes, toxins and transcriptional regulators that could be involved in the pathogenicity of the strains.
Conclusion: New genes that could be involved in the pathogenicity of AIEC have been identified. *In vitro* studies are needed to demonstrate their role. Additional coding and non-coding sequences must be analyzed to find out putative genetic markers for AIEC. Identifying the genetic elements associated with the AIEC phenotype may help to better understand the mechanisms of pathogenicity of the pathotype and also could imply a significant advance in the detection of new therapeutic targets for CD.

Introduction: The inflammatory bowel disease (IBD) per se and the therapies used for the treatment of this disease could have effect on the sex and sexuality of male patients. Also, as medical therapy in IBD has advanced, more patients are healthy enough to consider conception. The aim of the present study was to evaluate the impact of IBD on the male sexual function and satisfaction.
Aims & Methods: A multicentre, transversal study was performed in male subjects with IBD and controls (CTR) between April 2010 and March 2014. All the participants had between 18 and 45 years old and were assessed by a medical history and physical examination before inclusion. The presence of varicocele, altered FSH, LH, prolactine or testosterone levels or having any pathology related to subfertility was considered as exclusion criteria. To evaluate the male sexual function *The International Index Erectile Function questionnaire* (IIEF-15) validated in Spanish language were used. The global score and the five items about sexual function (erectile function, orgasmic function, sexual desire, intercourse satisfaction and overall sastisfaction) were calculated from each patient. To investigate if anti-TNF therapy affected male sexual function, the IIEF-15 scores were calculated in CD patients with biological therapy and compared with patients without this therapy.
Results: Fifty-two patients with IBD (30 CD, 22 ulcerative colitis (UC)) and 22 CTR were included. When the 3 groups (CD, UC and CTRL) were compared, no significant statistical differences were found respect to global score (IEEF15 CD 66.1 ± 7.7; UC 62.5 ± 12.9; CTRL 68.3 ± 8.7; $p > 0.05$), erectile function (CD 26.1 ± 7.5; UC 25.2 ± 7.6, CTRL 28.6 ± 3.6, $p > 0.05$), sexual satisfaction (CD 11.3 ± 4.6, UC 10.6 ± 4.4, CTRL 13.1 ± 3.5; $p = > 0.05$), orgasmic function (CD 9.2 ± 2.1; UC 9.6 ± 0.6; CTRL 10 ± 0. $p > 0.05$) or sexual desire (CD 7.1 ± 2.0, UC 7.2 ± 2.2, CTRL 7.5 ± 1.8, $p > 0.05$). However, patients with UC had worse global satisfaction in IEF15 than CD patients (CD 8.5 ± 1.2; UC 7.2 ± 2.4; CTRL 9.1 ± 1.1 $p = 0.03$). The IIEF-15 score was no difference in patients with CD with ($n = 10$) and without anti-TNF ($n = 20$) therapy ($p < 0.05$).
Conclusion: The male sexual function based on IIEF-15 questionnaire is not affected by IBD or anti-TNF drugs. Nevertheless, patients with UC have lower sexual satisfaction than patients with CD or controls.

Introduction: Single nucleotide polymorphisms (SNP) in the gene locus encoding protein tyrosine phosphatase non-receptor type 22 (PTPN22) have been associated with inflammatory disorders, including IBD. Presence of the SNP rs2476601 results in a gain-of-function PTPN22 protein product and is associated with increased risk to develop autoimmune disorders, such as type 1 diabetes, rheumatoid arthritis, and systemic lupus erythematosus, but reduces the risk for Crohn's disease (CD) onset. We have previously shown that protein and mRNA levels of PTPN22 are reduced in intestinal biopsies from CD patients, and that loss of PTPN22 results in enhanced inflammatory cytokine secretion from mononuclear cells treated with interferon-gamma or the bacterial product muramyl dipeptide. In this study, we now addressed how presence of the gain-of-function variant in PTPN22 influences the susceptibility to intestinal inflammation in mouse models of colitis.
Aims & Methods: Colitis was induced in 10-12 week old female mice by administration of 2% DSS for 7 days (acute DSS colitis), administration of four cycles of DSS (1.5% DSS for 7 days, followed by 10 days normal drinking water each; chronic DSS colitis), or by transferring naïve T cells into RAG2-/- recipients. Wild-type (WT), PTPN22 deficient (PTPN22-/-), or mice expressing the IBD associated gain-of-function variant in PTPN22 (PTPN22-619W mice) were used for the study.
Results: While PTPN22-/- mice suffered from aggravated acute DSS colitis as determined by pronounced weight loss, increased endoscopic and histologic colitis scores ($p < 0.05$ each), PTPN22-619W mice reacted only weak to the DSS treatment when compared to WT littermates ($p < 0.05$ for weigh development, $p < 0.01$ for other parameters). In chronic DSS colitis however, PTPN22-/- mice suffered from a milder disease course (characterized by reduced weight loss [$p < 0.05$], decreased histological severity [$p < 0.05$]) from the third cycle on, while PTPN22-619W mice tended to show a more pronounced disease course from the third DSS cycle on. In the T cell transfer model, PTPN22-/- T cells induced a more severe colitis as observed by an enhanced histological pathology ($p < 0.05$), while weight loss was not affected when compared to mice receiving WT T cells. In contrast, mice transfected with PTPN22-619W T cells were protected from disease development in the first four weeks, and later on developed a mild disease course (moderate weight loss [$p < 0.01$], reduced shortening of the colon [$p < 0.05$], mild histological disease scores [$p < 0.05$]) when compared to mice receiving WT T cells.
Conclusion: During acute inflammation, loss of PTPN22 results in enhanced colitis severity, while presence of the gain-of-function PTPN22 variant protects from colitis development. In chronic disease, compensatory mechanisms are able to reverse the increased disease susceptibility in PTPN22-/- mice, finally resulting in reduced disease severity, while presence of the gain-of-function variant is no longer able to protect from colitis. We here describe for the first time how the IBD-associated variant in PTPN22 affects colitis development what helps to explain why this variant is associated with a reduced risk for CD onset.

P0911 ENTERIC GLIAL ALTERATIONS IN INFLAMMATORY BOWEL DISEASE

M. Freyssinet[1], T. Clairembault[2], S. Coquenlorge[2], J. Jaulin[2], C. Trang[1], E. Coron[1], S. Bruley des Varannes[1], M. Neunlist[2], M. Derkinderen[2], A. Bourreille[1]
[1]*Institut des Maladies de L'appareil Digestif, Imad, Chu Nantes,* [2]*U913, Inserm, Nantes, France*

Introduction: Enteric glial cells are the most abundant cells of the enteric nervous system. In inflamatory bowel disease (IBD) patients, enteric glial cells (EGC) present some differences in the expression level of glial markers. Whether these changes are determined by the pathological environment or represent a constitutive feature of pathological EGC is unknown. The purpose of our study is (i) to determine *ex vivo*, the expression of glial markers in colonic biopsies from patients who have a Crohn's disease (CD), an ulcerative colitis (UC) and from control patients (CONT); (ii) to determine if the stimulation of EGC from rats in a primary culture by an inflamed environment could reproduce glial changes observed on human biopsies; (iii) try to reproduce glial changes observed in biopsies by the treatment of EGC from control patient in a primary culture, with supernatant from biopsies previously analyzed.
Aims & Methods: Biopsies of IBD patients (18 CD, 9 UC and 15 CONT) were performed by endoscopic procedures in inflamed area (I) and in non inflamed area (NI) for each patient. Culture of rat EGC were subjected to chronic inflammatory stress represented by TNFα and interleukin-1β (TI; 1ng/ml) or lipopolysacharide (LPS; 0.1μg/ml) for 4 days. Culture of human EGC from control patients (CONT) were obtained from surgical specimens. They were treated with supernatant from colonic biopsies at the concentration of 5% in a serum free medium. Supernantants were obtained after incubation of each colonic biopsie from IBD patient (I area and NI areas biopsies). Expression of the glial markers Sox10, S100β and glial fibrillary acid protein (GFAP) were assessed by quantitative real time PCR and Western blot analysis.
Results: Concerning the biopsies, the mRNA expression levels of Sox 10 and S100β were significantly elevated in I and NI areas of CD patients compared to UC patients ($p < 0.001$) and to CONT patients ($p < 0.001$). Intermediate isoform of GFAP was increased in inflamed area of CD patients compared to controls ($p < 0.05$). TI treatment of EGC from rats induced a significant overexpression of the three glial markers. LPS stimulation of EGC from rats also induced an over-expression of Sox10 and S100β but did not affect GFAP expression. We have not reproduced the increased expression of Sox 10 and S100β mRNA expression by human EGC treatment with supernantant from colonic biopsies of CD patient.
Conclusion: Our work shows that GFAP expression was differentially regulated by inflammatory cytokines and endotoxins. *Ex vivo*, LPS treatment reproduces the over-expression of Sox 10 and S100β in EGC cultures from rats, as observed *in vivo* in colonic biopsies of CD patients. However, treatment of human EGC in a primary culture with supernatant obtained from these biopsies, did not change the glial marker expression in human EGC .

Introduction: Mesenchymal stromal cells (MSCs) have emerged as a promising therapeutic option for various diseases due to their immunomodulatory properties and ability to actively participate in tissue repair processes. However, these

abilities are not intrinsic and therefore different strategies to induce and enhance their beneficial effects are currently under investigation. Recently, we observed that intraperitoneally injected MSCs settled as spherical shaped clusters, i.e. spheroids, onto the serosal fat surrounding the colon in experimental colitis.
Aims & Methods: In the present study we assessed whether luminal administration of MSCs in spheroids has a therapeutic effect. We infused 200 or 800 *in vitro* generated MSC spheroids, each consisting of 2,500 MSCs, intraluminally in C57BL/6 mice with established dextran sulphate sodium (DSS)-induced colitis. Body weight was measured daily and disease score consisting of the presence of loose stool, visible faecal blood and macroscopic inflammation was determined at sacrifice. Endoscopy was performed to evaluate mucosal damage and subsequent healing. Mucosal cytokine levels were measured in the homogenates of distal colon. In addition, myeloperoxidase activity in the homogenates of distal colon was measured as an index for neutrophil infiltration. Furthermore, we counted the number of macrophages in the lamina propria of the distal colon.
Results: MSC spheroids alleviated DSS-induced colitis when infused intraluminally resulting in less body weight reduction (9.2% after treatment with 800 MSC spheroids versus 16.4% and 15.9% after treatment with 200 MSC spheroids and PBS-treated mice, respectively; both $p = 0.02$), a lower endoscopic activity score and lower disease activity scores at sacrifice, related to the dose of MSC spheroids infused. Mucosal cytokine levels of interleukin-6 and interferon-gamma as well as numbers of macrophages and neutrophils in the distal colons were decreased particularly after intraluminal infusion of the high dose MSC spheroids.
Conclusion: Intraluminally infused MSC spheroids promote mucosal wound healing and attenuate experimental colitis, accompanied by less phagocytes and proinflammmatory cytokines in the mucosa.

Introduction: Glucocorticoids (GCS) are known to modulate a number of immunological responses. Within tissues expressing glucocorticoid and mineralocorticoid receptors including the colon, GCS metabolism is regulated by the isozymes of 11 beta hydroxysteroid dehydrogenase (11βHSD). 11βHSD 1 acts as an oxoreductase, converting inactive cortisone into active cortisol while 11βHSD 2 acts as a dehydrogenase producing cortisone. Variations in expression may have a role in Inflammatory Bowel Disease (IBD).
Aims & Methods: To examine the expression of 11βHSD 1 & 2 in IBD.
Following informed consent, patients with known IBD aged 18-80yrs were recruited; exclusion criteria (1) Steroid ≤6 weeks, (2) Coagulopathy, (3) Pregnancy, (4) Cushing/Conns Syndrome (5) Quiescent disease. Disease activity was assessed using biochemical (C Reactive Protein (CRP)), clinical (Harvey-Bradshaw Index/Mayo Score) & histological parameters. Controls with a normal colonoscopy without a history of IBD were also recruited. Two additional biopsies were obtained including inflamed & non-inflamed samples from IBD patients where possible, whereas a single additional colonic biopsy was obtained from controls. Biopsies were stored in RNA later & analyzed in batch, using Quantitative real time RT-PCR (TaqMan) & commercially available Probes & Primers (Invitrogen). Relative transcript levels were determined using 18S as a reference gene. Relative expression of 11βHSD 1 & 2 were expressed as a mean and compared between groups using a student t test and 11βHSD 1:2 ratios were calculated and compared between groups using a Mann-Whitney U test with a p value of <0.05 considered significant.
Results: To date 28 IBD (16 Crohn's Colitis and 12 Ulcerative Colitis) and 15 control patients have been recruited. IBD and control cohorts were demographically similar with 55% (n = 15) vs. 67% (n = 10) being female, with a mean age of 45 years (17-76 years) and 55 years (19-70 years) respectively. Overall based on histology 46% (n = 13) had mild disease, 43% (n = 12) had moderate disease and 11% (n = 3) had severe disease. In all 68% (n = 19) and 57% (n = 16) had elevations in their HBI/Mayo scores (HBI range 0-21, Mayo 0-12) and CRP (range 1-192.5mg/l) respectively. Overall mean levels of 11βHSD1 in IBD patients and controls were 197 au and 261 au respectively and were not significantly different while mean 11βHSD2 expression levels were significantly lower in IBD patients vs. controls (35 au vs. 176 au, p = 0.001, 95% CI -226- -57.8). Of interest 11βHSD1:2 ratios were much higher in patients with IBD compared with controls (52:1 vs. 1.6: 1, p = 0.001). Overall within the IBD cohort disease activity did not affect 11βHSD1 or 2 levels, however among IBD subjects with matched histological inflamed and non inflamed tissue samples (n = 15) there was a trend towards lower 11βHSD2 levels (51au vs. 10 au, p = 0.051).
Conclusion: Patients with IBD have altered glucocorticoid metabolism with increase 11βHSD1: 11βHSD2 ratios mainly due to a reduction in 11βHSD2 expression. Further work on 11βHSD2 regulation is warranted and may represent a novel therapeutic pathway in IBD patients.

P0914 LOW-DOSE LINDANE INGESTION AGGRAVATES SUSCEPTIBILITY TO COLONIC AND INTESTINAL INFLAMMATION IN MICE MODELS OF CROHN'S DISEASE

M. Body-Malapel[1], M. Djouina[1], P. Desreumaux[1], C. Gower-Rousseau[1], C. Vignal[1]
[1]*Lille Inflammation Research International Center, UMR 995 INSERM, Lille University, CHRU, Lille, France*

Contact E-mail Address: mathildebody@gmail.com
Introduction: Lindane (LIN) is an organochlorine pesticide. Although LIN has not been used as insecticide in Europe and USA since the 1970s, it is still currently included in the constitution of more than 500 commercial products. In addition, LIN is still used in developing countries. Because of its bioaccumulation potential, LIN is found in high concentrations in environment and food chain. The main contamination way in humans is consumption of lipid-rich diet such as fish and dairy products.
Aims & Methods: Our aim was to assess the effects of oral intoxication with low doses of LIN on gut inflammation in 3 different murine models.
C57Bl6 males were exposed during 1 month to oral intoxication with LIN (0, 5 and 50 µg/kg bw/day). Then 2 types of colitis were induced, either by single intrarectal injection of Trinitro benzene sulfonic acid (TNBS, 100 mg/kg bw), or by oral administration of dextran sodium sulfate (DSS, 2.5%) during 9 days. Besides, enteritis was induced by single gavage of indomethacin (10 mg/kg bw). Then mice were euthanized and gut inflammation intensity was assessed by macroscopic, histological and molecular parameters.
Results: In TNBS-induced colitis, mice intoxicated with LIN showed colitis macroscopic scores significantly higher (+228 % at 5 µg/kg/j, p = 0.001, and +145 % at 50 µg/kg/j, p = 0.03) compared to untreated mice with colitis only. Myeloperoxidase activity in colon of intoxicated mice was significantly enhanced in the 2 groups treated with LIN compared to untreated mice (+588 %, p = 0.002 at 5 µg, and + 153 %, p = 0.003 at 50 µg). Colitis histological score and *IL-1 b* mRNA levels were also higher in colons of mice intoxicated with LIN, with a significant 160 % (p = 0.03) and 762% (p = 0.003) increase respectively at the dosage of 5 µg compared to untreated mice with colitis only. Similar results were obtained in DSS-induced colitis, as mice having received the 2 dosages of LIN showed an increase of their colon weight/size ratio of 121 and 128% for the dosages 5 et 50 µg (p = 0.005 and p = 0.001 respectively), and an increase of colon myeloperoxidase activity (+301 and 287 %, p = 0.0007 and p = 0.009 respectively). Mice intoxicated with 5 µg showed also a significant increase of colitis histological score and colon *IL1-b* mRNA levels (+177%, p = 0.01, and +762%, p = 0.01, respectively). Following indomethacin-induced enteritis, jejunum of mice exposed to 5 and 50 µg LIN showed a significant increase of lesions areas (+171% p = 0.03 and +253% p = 0.003), lesions numbers (+146%, p = 0.008 and +180%, p = 0.0002) and *Il1-b* mRNA levels (+192%, p = 0.02, and +350%, p = 0.04).
Conclusion: Oral intoxication with low doses of lindane induces an aggravation of gut inflammation in 2 murine models of colitis and in 1 model of enteritis. The role of this persistent organic pollutant in inflammatory bowel diseases deserves further investigations.

P0915 ALTERED MUCOSAL 5-HT SIGNALING IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE

M. S. Shajib[1,2], J. J. Kim[1,2], T. Aziz[2], P. Moayyedi[1,3], W. Reinisch[1,3], J. K. Marshall[1,3], W. I. Khan[1,2]
[1]*Farncombe Family Digestive Health Research Institute,* [2]*Pathology & Molecular Medicine,* [3]*Division of Gastroenterology, Department of Medicine, McMatser University, Hamilton, Canada*

Introduction: The gastrointestinal (GI) tract is the largest producer of serotonin (5-hydroxytrptamine; 5-HT) in the human body. Enterochromaffin (EC) cells are the best characterized subset of enteric endocrine cells and are the main source of 5-HT in the gut; tryptophan hydroxylase (*Tph*)1 is the rate-limiting enzyme involved in the bio-synthesis of 5-HT by EC cells. The diverse effects of 5-HT on various GI functions is mediated by multiple 5-HT receptor subtypes present on a variety of cells in the gut. Previously, we have shown that mice which have significantly reduced gut 5-HT levels exhibit reduced severity of experimental colitis, while replenishing gut 5-HT increased the severity of colitis. These seminal findings identified 5-HT as a key molecule in the pathogenesis of experimental colitis, but further research is needed to translate these observations for clinical utilization. While there are segregated reports on the changes of different components of 5-HT signaling in inflammatory bowel disease (IBD), there is a lack of studies with thorough examination on the changes of 5-HT content and 5-HT receptors in IBD.
Aims & Methods: A comprehensive assessment of key elements of gut 5-HT signalling in patients with Crohn's disease (CD) with a view to validate 5-HT as a new target for improved therapeutic strategy in CD. This study was approved by the local ethics committee. Mucosal biopsies were collected from the colon of consenting patients with CD and from healthy controls (HC), undergoing routine colonoscopy for colorectal cancer. Inactive specimens were collected from CD patients in remission, or from non-inflamed regions of patient with active disease. Non-inflamed regions were designated as those without any endoscopic features of inflammation and at least 10 cm from any area of active inflammation. A pathologist unaware of the diagnosis performed histological evaluation of the biopsies collected (n = 10, 11 and 8 from HC, inactive and active CD segments, respectively). Additionally, relative gene expression of *Tph1*, serotonin reuptake transporter (SERT) and 5-HT receptors (5-HTR_1, 5-HTR_3, 5-HTR_4; 5-HTR_7) were determined by quantitative polymerase chain reaction (qPCR).
Results: Histological evaluation of biopsies confirmed the macroscopic assessments of the endoscopist during sample collection. There was significant upregulation of *Tph1* and downregulation of SERT expression in active CD samples compared to both inactive and control samples. Investigations into 5-HT receptor expression by qPCR revealed significant increases in 5-HTR_{3A} and 5-HTR_7 expression in active CD samples compared to inactive and control samples. 5-

HTR_4 expression was significantly elevated in both active and inactive CD samples compared to control, irrespective of disease activity and 5-HTR_{1A} expression was minimal in all groups compared.
Conclusion: Our findings establish that increased inflammation in patients with CD is associated with alterations in various aspects of 5-HT signalling (5-HTR_{3A}, 5-HTR_7, 5-HTR_4, *Tph1*, and SERT). Given the emerging role of 5-HT as a powerful modulator of inflammation and immune response, a better understanding of 5-HT signaling in intestinal inflammation in CD may ultimately lead to effective strategies targeting this pathway in CD.

Contact E-mail Address: monica.aguilerap@gmail.com
Introduction: Visceral pain is a hallmark of Irritable Bowel Syndrome (IBS). Dysbiotic states of the gut microbiota and alterations in host-bacterial interaction systems appear to contribute to the pathology of IBS. However, the exact mechanisms underlying these pathways are unknown.[1,2,3]
Aims & Methods: The aim of this study was to investigate the relationship between the intestinal nociceptive system and Toll-like receptors (TLRs) in colonic tissue of IBS patients and to assess if this relationship is also altered when simulating a dysbiosis due to TLR-hyper-stimulation in rats. The expression of sensory-related [cannabinoid receptor 1 (CB1) and 2 (CB2) and vanilloid receptor type 1 (TRPV1)] and host-bacterial interaction markers (TLR2, TLR4, TLR5, TLR7) and antimicrobial peptides (AMPs, defensins) in sigmoidal colonic biopsies of IBS patients (n = 12) and healthy controls (n = 11) was assessed (qRTPCR). Additionally, Sprague Dawley male rats were treated intracolonically with a TLR4 agonist (LPS, Escherichia coli O5:B55, 0.2 mg/rat) or a TLR7 agonist [Imiquimod (IMQ), 0.1 mg/rat], (n = 6 each group) for 5 days. Colons were collected for analysis of sensory markers, TLRs, AMPs and cytokines (qRT-PCR), quantification of secretory-IgA levels (s-IgA; ELISA) and histopathological analysis.
Results: Colonic biopsies of IBS patients showed a significant up-regulation of CB1 and CB2 (both $P < 0.001$), TRPV1 ($P < 0.05$) and TLR2 and TLR7 (both $P < 0.001$) expression when compared to healthy individuals. CB1, CB2 and TRPV1expression positively correlated with TLR2 and 7 expression in IBS patients ($P < 0.001$ in all cases). Minor changes were seen in the expression of TLR4, TLR5 and defensin 5.
Using TLR4 and 7 agonists to mimic a dysbiotic state in rats and the TLR-induced responses associated to IBS samples, we found that selective repetitive TLR stimulation induced a mild colonic immune activation characterized by an increase of pro- and anti-inflammatory cytokines expression and changes in levels of s-IgA without overt histological changes, compatible with features associated to IBS. Both TLR agonists also up-regulated the colonic expression of host TLRs (TLR2 > TLR7 > TLR5 > TLR4). Moreover, intracolonic instillation of LPS induced a significant increment in the colonic expression of CB1, CB2 and TRPV1, while IMQ down-regulated the expression of TRPV1. In general, higher changes were seen when stimulating with LPS when compared to IMQ. Similar to IBS biopsies, TLRs stimulation lead to minor changes in the expression of AMPs (defensins).
Conclusion: Altogether, our findings point towards an active communication between the microbiota and intestinal neuro-immune pathways, mainly by connecting the immune TLR-dependent signalling to the intestinal nociceptive system (endocannabinoid and vanilloid systems). Additionally, stimulation of TLRs by luminal factors (simulating dysbiosis) appears to be enough to induce intestinal immune and nociceptive signalling pathways which may be part of the underlying pathophysiological mechanisms of IBS, thereby linking the microbiota to intestinal neuro-immune pathways and visceral pain.

P0917 20 YEAR FOLLOW UP OF BRITISH TWIN PAIRS WITH INFLAMMATORY BOWEL DISEASE

H. Gordon[1], T. Orchard[2], S. Ng[3], A. Steel[1], A. Cocker[4], M. Harbord[5]
[1]*Gastroenterology, Chelsea and Westminster Hospital,* [2]*Gastroenterology, St Mary's Hospital, London, United Kingdom,* [3]*Medicine and Therapeutics, Chinese University of Hong Kong, Hong Kong, Hong Kong,* [4]*SSAT, Chelsea and Westminster Hospital,* [5]*Gastroenterology, Chelsea and Westminster, London, United Kingdom*

Contact E-mail Address: hannahgordon@doctors.org.uk
Introduction: IBD twin studies have shown similar disease phenotype within concordant pairs. Longitudinal follow up suggests pairs with CD remain concordant for location whereas twins with UC diverge (1). This study is a retrospective longitudinal analysis of UK twin pairs with IBD.
Aims & Methods: The UK IBD Twin and Multiplex Registry was searched for twin pairs who took part in a previous twin study. Data from 1994 and 2014 was reviewed. The following were analysed: zygosity, concordance, Montreal classification, admissions, surgical history.
Results: The UK IBD Twin and Multiplex Registry was searched for twin pairs who took part in a previous twin study. Data from 1994 and 2014 was reviewed. The following were analysed: zygosity, concordance, Montreal classification, admissions, surgical history.
Results
Demographics: N = 94 twin pairs. UC:CD 48:46. Mean age 59.
Pair Concordance:

	CD 1994	CD 2014	UC 1994	UC 2014
MZ	33.3% (4:12)	41.7% (5:12)	21.4% (3:14)	21.4% (3:14)
DZ	9.1% (3:33)	9.1% (3:33)	11.4% (4:35)	17.1% (6:35)

3 previously discordant pairs became concordant. The mean time between diagnosis was 9.1 years.

Montreal Classification
Concordant Pairs: There were no mixed CD:UC pairs. Of the 17 concordant pairs, 10 had complete information from both twins in both datasets.
IBD: A was identical in 6/12 (50%) concordant pairs.
CD: L was identical in 3/6 (50%) pairs in both 1994 and 2014. B was only available from 2014, and was identical in 3/6 (50%) pairs. P was identical in 2/5 (40%) twins in 1994 and 3/7 (43%) twins in 2014.
UC: A was identical in 3/4 pairs (74%). L was identical in 4/4 (100%) pairs in 1994 and 2014.
All IBD sufferers
UC: Disease classified as proctitis decreased from 1994 to 2014 (30.4% vs 17.9%), with a corresponding increase in pancolitis (41.1% vs 50%)
CD: Cases classified as L3 increased from 6/52 (11.5%) to 22/53 (41.5%). Presence of perianal disease also increased (9.6% vs 23.1%).
Extraluminal manifestations increased from 4/109 (3.7%) to 13/112 (11.6%).
Surgery
Concordant pairs: Concordant twin pairs were concordant for history of previous surgery in 9/12 (75%) pairs in 1994 and 7/14 (50%) pairs in 2014.
All IBD: In 1994 32/109 (29.4%) IBD sufferers had undergone surgery, increasing to 52/112 (49.1%) in 2014.
Admission
Concordant pairs: Concordant twins were concordant for history of admission in 10/14 (71.4%) pairs in 1994 and 10/15 (66.7%) pairs in 2014.
All IBD: 46/109 (42.2%) IBD sufferers had at least one admission in 1994; this increased to 76/112 (67.9%) in 2014.
Conclusion: Pair concordance of this cohort supports that heritability of CD is greater than UC. Within concordant pairs with CD, disease location is less correlated than in other cohorts. Conversely, concordant pairs within UC were more similar and converged over time. Sample size limited analysis. Disease progressed over time.

P0918 RISING INCIDENCE OF INFLAMMATORY BOWEL DISEASE IN CANTERBURY, NEW ZEALAND

H. Su[1], V. Gupta[2], A. S. Day[34], R. B. Gearry[1,2]
[1]*Department of Gastroenterology, Christchurch Hospital,* [2]*Department of Medicine,* [3]*Department of Paediatrics, University of Otago,* [4]*Department of Paediatrics, Christchurch Hospital, Christchurch, New Zealand*

Contact E-mail Address: heidisu@hotmail.com
Introduction: A population-based study of inflammatory bowel disease (IBD) in the Canterbury province of New Zealand demonstrated an incidence of Crohn's disease (CD) in this region of 16.5 per 100,000 population in 2004, along with a high rate of IBD overall. At the time, this was one of the highest rates of CD in the world.
Aims & Methods: The current study aimed to ascertain the incidence of IBD in the same geographical area of New Zealand ten years later (during the 2014 calendar year). Patients diagnosed with IBD between January 1st 2014 and December 31st 2014 within the Canterbury region in the private and public sectors were identified and characterised. Diagnosis and disease classification was ascertained using standard accepted criteria. Projected population data for age and gender for the region were utilised to calculate incidence rates for IBD overall and for CD, ulcerative colitis (UC) and inflammatory bowel disease-unclassified (IBDU). Incidence rates were also age-standardized using the World Health Organization Standard Population. Furthermore, all patients were phenotyped according to the Montreal Classification.
Results: During the 2014 year, 205 patients were diagnosed with IBD in Canterbury. This group comprised 134 patients with CD, 69 with UC and 2 with IBDU. Patients were aged between 5 and 88 years, with most patients with CD and UC diagnosed between 20 and 54 years of age. The crude incidence rate

for IBD for 2014 was 39.8 per 100,000 (95% CI, 34.4 – 45.3). In addition, the incidence rates for CD was 26.0 (95% CI, 21.6 – 30.4), for UC 13.4 (95% CI, 10.2 – 16.6), and for IBDU 0.39 (95% CI, -0.15 – 0.93) per 100,000 population. For patients with CD, disease location was evenly distributed (ileal 30%, colonic 36% and ileocolonic 34%) and 94% had inflammatory disease, with only 6% having stricturing or penetrating disease at diagnosis. Twenty-two percent of patients with CD had upper gut involvement, whilst 13% had perianal disease at diagnosis. Similarly, patients with UC had even distribution of pancolonic, left-sided and proctitis.
Conclusion: This population-based study demonstrates further substantial increases in the incidence of IBD in this well-delineated area of New Zealand. Overall, incidence rates were 1.5 fold greater than when assessed ten years earlier, with an even greater increase in the incidence of UC. The reasons contributing to these continued increases remain unclear. However, further increases in rates of IBD indicate growing health system demands in the coming years.

P0919 NEOPLASIA RISK AFTER COLECTOMY IN INFLAMMATORY BOWEL DISEASE PATIENTS – A SYSTEMATIC REVIEW AND META-ANALYSIS

L. A. Derikx[1], L. H. Nissen[1], L. J. Smits[1], B. Shen[2], F. Hoentjen[1]
[1]*Gastroenterology and Hepatology, Radboud university medical centre, Nijmegen, Netherlands,* [2]*Gastroenterology and Hepatology, Cleveland clinic, Cleveland, United States*

Contact E-mail Address: Lauranne.Derikx@radboudumc.nl
Introduction: Although colectomy substantially reduces the risk to develop colorectal cancer (CRC) in inflammatory bowel disease (IBD) patients, neoplasia may still develop following colectomy in the residual rectum or ileal pouch. Conclusive data regarding this risk are scarce, which has resulted in the absence of evidence-based postoperative endoscopic surveillance recommendations. We therefore conducted a systematic review and meta-analysis in order to determine prevalence, incidence, and risk factors for neoplasia development in the different post-surgical scenarios after colectomy, including: 1. patients with a permanent end ileostomy and rectal stump, 2. patients with an ileorectal anastomosis (IRA) 3. patients with an ileal pouch-anal anastomosis (IPAA).
Aims & Methods: PubMed, Embase, Web of Science and Cochrane Library were searched to identify studies which reported prevalences or incidences of colorectal neoplasia following colectomy or specifically assessed risk factors for neoplasia development. Two researchers independently performed study selection, quality assessment and data extraction. Prevalence's were pooled and compared across subgroups with a logistic regression model. Risk factors were analyzed in a pooled random effect model, if possible, or otherwise critically appraised.
Results: Thirteen, 35 and 33 articles, including 1011, 2762 and 8403 patients, for respectively the rectal stump, IRA and IPAA group, were included for prevalence and incidence calculations. CRC prevalence following colectomy was significantly higher in the rectal stump group (2.1%, 95% CI 1.3-3.0) and IRA group (2.4%, 95% CI 1.7-3) compared to the IPAA group (0.46%, 95% confidence interval (CI) 0.32-0.61), with an odds ratio (OR) of 6.4 (95% CI 4.33-9.50). In the IPAA group, the pooled cumulative incidence of pouch/cuff carcinoma 25 years after IPAA construction was 3.4%. A history of CRC was the most important risk factor (IRA: OR 12.8, 95% CI 3.3-49.2; IPAA: OR 15.0, 95% CI 6.6-34.4). Furthermore, IBD duration and ulcerative colitis rather than a diagnosis of Crohn's disease (OR 10.2) emerged as risk factors for rectum or pouch neoplasia.
Conclusion: The calculated prevalence and incidence for colorectal neoplasia following colectomy appeared relatively low, especially in the IPAA group. Major determinants for cancer development following colectomy were the presence of a residual rectum with a 6.4-fold increased risk, and a CRC-history with a 15.0- (IPAA) or 12.8-fold (IRA) increased risk. These findings may aid in developing individualized post surgical endoscopic surveillance strategies in order to optimize prevention of CRC in this patient population.

P0920 THE IMPACT OF GENDER ON WORK ACTIVITY IMPAIRMENT AND QUALITY OF LIFE IN INFLAMMATORY BOWEL DISEASE (IBD) IN SOUTHERN ITALY

M. Cappello[1], M. Mazza[1], R. Alloro[1], M. Mendolaro[1], P. L. Almasio[1], A. Craxì[1]
[1]*Di.Bi.Mis - University of Palermo - Italy, UOC Gastroenterologia Ed Epatologia, Palermo, Italy*

Contact E-mail Address: cmarica@tin.it
Introduction: IBD impact on patients' major life activities, such as school, work, self-care, and quality of life. Published literature has reported higher rate of unemployment, sickleave and working disability. Data on gender influence are scanty, especially in Mediterranean countries.
Aims & Methods: Aim of our study was to compare work activity impairment and quality of life between female and male patients with IBD followed-up in a referral center from southern Italy. 102 patients with IBD (53 females, 49 males) consecutively observed in the IBD clinic were recruited. Data on clinical and demographic characteristics (age, type of IBD, disease behavior (Montreal) and activity (HBI, Mayo score), smoking habits, familial predisposition, current treatment, educational and marital status, current employment) were registered on a dedicated database. All patients agreed to fill in the WPAI (Work Productivity and Activity Impairment) questionnaire and the EQol-5D (European Quality of Life – 5Dimension) VAS scale.Data of the National Institute of Statistics (ISTAT) on employmentrates in Italy were used for comparison.
Results: There were no significant differences between males and females regarding age, educational and marital status and disease characteristics except disease activity rate, which was higher in males. There was a significant difference in the employment status since 58.5% of women were unemployed versus 34.7% of men ($p = 0.02$). Overall, there were no differences in WPAI scores (absenteeism, presenteism, overall work and regular activities impairment) and EQoL between males and females. In male patients with active disease absenteeism ($p = 0.04$), presenteism ($p = 0.02$) and work productivity impairment ($p = 0.04$) rates were significantly higher as compared to patients in remission, quality of life was not affected, in females with active disease we observed a higher rate of absenteeism ($p = 0.04$) and impaired daily regular activities ($p = 0.04$) as well as quality of life ($p = 0.015$).
Conclusion: Gender significantly influences occupational status in IBD, since women are more often unemployed. Work productivity is impaired in both men and women with active disease, but in women daily regular activities and quality of life are more significantly affected than in men. These data, if confirmed in other geographical areas, should be kept in mind in clinical management of IBD female patients.

P0921 COLONIC METAPLASIA OF THE ILEUM AS A PREDICTIVE MARKER OF CLINICAL RELAPSE AFTER ILEO-COLONIC RESECTION FOR CROHN'S DISEASE: A PROSPECTIVE STUDY AT 4 YEARS

M. Ascolani[1], C. Mescoli[2], S. Onali[1], E. Calabrese[1], E. Lolli[1], A. Ruffa[1], G. Sica[3], G. Palmieri[4], F. Pallone[1], M. Rugge[2], L. Biancone[1]

Contact E-mail Address: biancone@med.uniroma2.it
Introduction: Colonic metaplasia of ileum has been reported in Crohn's Disease (IBD), particularly in severe/established ileal lesions. Differently, CD ileum with no lesions or with early post-operative recurrence showed to express the small intestine type mucin phenotype (1).
Aims & Methods: In a prospective study at 4 years, we aimed to address whether colonic metaplasia of the ileum may represent a marker of clinical relapse after ileo-colonic resection for CD. At this purpose, a cohort of CD patients (pts.) already followed up for 1 year (1), was clinically followed up for additional 3 years after surgery. Clinical recurrence at 4 years was assessed in the same cohort of 19 CD pts. with recurrence and colonic metaplasia assessed at 6 (T1) and 12 months (mos) (T2)(1). In the same pts. colonic metaplasia of the ileum was already evaluated at surgery (T0), at T1 and T2 (1). The expression of sulfomucins (colon phenotype) and sialomucins (small intestine mucin and phenotype) in the ileum was evaluated by immunohistochemistry (1). In the present study, compliant CD pts. were followed up for 4 years after surgery, with clinical recurrence (CDAI > 150) assessed yearly. The correlation between the percentage of expression of sulphomucin and clinical recurrence at4 years was assessed. Statistic: Results were expressed as median (range). Coefficient of correlation, the unpaired T test used as appropriate.
Results: Clinical follow up at 4 yrs was completed by 17 CD pts. (12 males, age 41 yrs, range 17-57). Endoscopic recurrence occurred in 13/17 pts. at T1 and in 14/17 pts. at T2. (median: T1: 2., range 0-4; at T2: 0, range 0-4). Clinical recurrence was assessed at 6 mos, 1.2.3 and 4years (pts. $n = 1, 3, 3, 2, 1$, respectively). A significant correlation was observed between the percentage of expression of sulphomucin in the ileal surgical samples and the CDAI at 4 yrs ($r = 0.62$ $p = 0.007$), but not at 6 mos, 1, 2 or 3 yrs. A significant correlation was also observed between the percentage of expression of sulphomucin in the ileal biopsies at 6 mos and the CDAI at 6 mos ($r = 0.68$; $p = 0.003$), but not at 1, 2, 3 and, 4 yrs. The percentage of expression of sulphomucin in the ileal biopsies at 12 mos was significantly correlated with the CDAI at 2 yrs ($r = 0.53$; $p = 0.02$). The median expression of sulphomucins in the ileal surgical samples was significantly higher in the subgroup of pts. developing clinical recurrence at 2 yrs. (40, 10-99 vs 5, 0-50; $p = 0.04$), but not at the other observations. The median expression of sulphomucins in the ileal samples at 12 mos was higher in the subgroup of pts. developing clinical recurrence at 1 and 2 yrs (median, range: 30, 1-40 *vs* 0, 0-35; $p = 0.025$ and 30, 0-40 vs 0, 0-35; $p = 0.029$, respectively), but not at 3 yrs (15, 0-30 *vs* 0, 0-40; $p =$ n.s.).
Conclusion: In CD ileum, the development of a "metaplastic" colonic-mucosa phenotype, as observed in the surgical specimens and in severe early post-operative recurrence, may represent a predictive marker of clinical relapse in pts under regular follow up after ileo-colonic resection.

P0922 SMALL BOWEL CANCER ASSOCIATED WITH CROHN'S DISEASE

M. Shinozaki[1]
[1]*Surgery, University of Tokyo, Tokyo, Japan*

Contact E-mail Address: mshino-tky@umin.ac.jp

Introduction: Population-based studies revealed that patients with Crohn's disease (CD) have increased risk of developing small bowel cancer in comparison with the background population. However, little is known concerning to the cancer in detail, because the number of the patients are relatively small.
Aims & Methods: This study aimed to clarify the clinicopathological characteristics between small bowel cancer and colorectal cancer in CD.
We performed a literature search in Ichushi (Japanese medical literature database) between 1983 and March, 2015 for small bowel cancer and colorectal cancer associated with CD. Two hundred and seventy-one cases were picked up, and we excluded six cases, because the location of the cancer was not specified clearly. Thus, 265 cases were included in this study. The cases were classified to two groups: patients who had small bowel cancer(s) (S group: n = 55) and those with only colorectal cancer(s) (C group: n = 210), which included perianal fistula cancer.
Results: The age at cancer diagnosis was higher in S group (53.5 (29-81); median (range)) than in C group (43 (25-89); $p < 0.0001$). The duration of CD was similar between S group (16 (0-40) years) and C group (15 (0-52) years; $p = 0.41$). The age at CD diagnosis was also higher in S group (39(12-69)) compared with C group (25 (9-84)). S group had more proportion of ileitis than C group (58% vs. 10%), whereas 81% of the patients in C group had ileocolitis, and the difference was statistically significant ($p < 0.0001$). In S group, the cancer diagnosis was made before treatment only in 16%, and 70% of these patients had not been diagnosed before pathological examination of the resected specimen. Well differentiated and moderately differentiated adenocarcinoma occupied three quarters of the tumor in S group whereas only 44% in C group ($p < 0.0001$). On the other hand, the proportion of mucinous carcinoma was only 4% in S group, and that was 40% in C group ($p < 0.0001$). The clinical stage according to the Union for International Cancer Control classification was 4%/8%/39%/12%/39% (stage 0/1/2/3/4) in S group, and that was 3%/14%/35%/29%/19% in C group, and the proportion of stage 4 was significantly higher in S group. Although the resection rate was higher in S group than in C group (98% vs. 87%; $p = 0.0055$), the prognosis was equivalent (41% were alive in S group and 44% in C group).
Conclusion: We found some differences between the two groups with regard to the age at cancer detection, the age at CD onset, the timing of cancer diagnosis, the histology of the cancer, and clinical stage of the cancer. We should always give attention not to miss small bowel cancer at CD operation.
Disclosure of Interest: None declared

P0923 NATURAL HISTORY OF CROHN'S DISEASE IN ELDERLY PATIENTS DIAGNOSED OVER THE AGE OF 70 YEARS: A POPULATION-BASED STUDY

M. Fumery[1], H. Sarter[2], B. Pariente[3], C. Charpentier[4], L. Armengol Debeir[4], J.-L. Dupas[1], L. Peyrin-biroulet[5], C. Gower-Rousseau[6], G. Savoye[4], on behalf of EPIMAD

Contact E-mail Address: mathurinfumery@gmail.com
Introduction: Elderly-onset (>60 years at diagnosis) Crohn's disease (CD) seems to be associated with a better outcome than CD diagnosed earlier in life.
Aims & Methods: Our aim was to compare the natural history of CD in elderly patients older than 70 years (y) at diagnosis with that of elderly patients diagnosed between the age of 60 and 70 y in the EPIMAD population-based registry. Three-hundred and seventy patients with elderly-onset CD diagnosed between January 1988 and December 2006 were identified. Among them, 188 (63%) were older than 70 y at diagnosis. Characteristics at diagnosis as well as natural history, surgery needs and drug exposure were recorded with a median follow up of respectively 4.5 y [1.1;8.3] in CD diagnosed after 70 y and 7.8 years [3.3;12.1] in CD diagnosed between 60 and 70 y.
Results: CD incidence in patients older than 70 y was 2.3/100 000 inhabitants. The proportion of males was lower in patients diagnosed after 70 y than in those diagnosed between 60 and 70 y (31% vs 45%, $p = 0.006$). Clinical presentation at diagnosis was similar in both groups with respect to symptoms as bloody stools, perianal location and extra-intestinal manifestations. Pure colonic location (L2) was more frequent among patients > 70 y both at diagnosis (73% vs 57%, $p = 0.004$) and maximal follow-up (70% vs 47%, $p < 0.0001$). Disease extension (from L1 or L2, to L3) was less frequent in patients > 70 y (7% to 15%, $p = 0.03$). The most frequent behavior in the two groups was inflammatory both at diagnosis (75% vs 80%, $p = 0.43$) and maximal follow up (69 vs 70%, $p = 0.55$). There was no significant difference in patients > 70 y compared to those between 60 and 70 y regarding treatment with 5ASA (71% vs 76%, $p = 0.27$), oral corticosteroids (39% vs 45%, $p = 0.86$), and anti-TNF (4% vs 7%, $p = 0.63$). However, the use of immunosuppressants was significantly less frequent in patients > 70 y (12% vs 25%, $p < 0.001$). Risk for surgery was similar in both groups (29% vs 28% $p = 0.35$).
Conclusion: Natural history of CD in elderly patients diagnosed over the age of 70 y seems to be milder than that in elderly patients diagnosed between 60 and 70 y. The exposure to immunosuppressants and biologics is low in patients diagnosed over 70 y with no difference in surgery needs. This needs to be taken into account when establishing therapeutic strategies.

Contact E-mail Address: Corinne.GOWER@chru-lille.fr
Introduction: Delay in diagnosis (DD) of Crohn's disease (CD) may be responsible for complications and for poor response to treatment. The description of DD over time in a population-based CD cohort and its determining factors are unknown and may help implementing corrective measures. The aim of this study was to report in a 21-year population-based cohort the variation over time of DD and to identify associated factors including sociodemographic factors.
Aims & Methods: Sociodemographic and clinical characteristics of all CD patients issued from the EPIMAD registry and diagnosed from 1990 to 2010 were included. DD was defined as the time between onset of symptoms and CD diagnosis (months). DD was considered as long when in the upper quartile of this time period. Sociodemographic data included the living area of each patient at the time of diagnosis (urban, periurban or rural), the distance between the patient's living area and the nearest gastroenterologist, and the deprivation index of the living area (FDep99). Clinical data were classified according to the Montreal classification. Univariate and multivariate analyses were performed using a logistic regression to identify the baseline characteristics of patients associated with a long DD.
Results: 8,704 patients with CD were recorded including 57% of females; 10% of them had < 17 years at CD diagnosis (A1), 67% between 18 and 59 years (A2) and 23% >60 years (A3). The majority (65%) of patients had an ileocolonic CD and 5% had perianal lesions; 17% had a stricturing and 10% a penetrating behaviour. During the whole study period, median DD was 3 months [Q1 = 1; Q3 = 7] with no change over time. A long DD was > 7 months and was associated in univariate analysis with the absence of weight loss ($p = 0.04$), the presence of extra-intestinal manifestations ($p = 0.02$), pure ileal involvement (L1) ($p < 0.0001$) and stricturing behaviour ($p = 0.002$). In multivariate analysis, only the absence of weight loss (OR = 1.16 [1.04-1.28]) and pure ileal location (OR = 1.36 [1.18-1.56]) were associated with a long DD. Socioeconomic characteristics were not associated with a long DD.
Conclusion: In this 21-year population-based study of CD patients, median DD was 3 months with no change over time and no influence of socioeconomic baseline characteristics. Only two clinical features (absence of weight loss and L1 location) were associated with a long DD.

P0925 FACTORS THAT ARE ASSOCIATED WITH THE OCCURRENCE OF FISTULAE AND STENOSIS IN CROHN'S DISEASE PATIENTS IN THE SWISS IBD COHORT

J. Zeitz[1], C. Labenz[1], L. Biedermann[1], N. Fournier[2], P. Frei[1], B. Misselwitz[1], S. Scharl[1], S. R. Vavricka[1], M. Fried[1], G. Rogler[1], **M. Scharl**[3], on behalf of Swiss IBD Cohort Study Group
[1]*University Hospital Zürich, Zürich,* [2]*Centre Hospitalier Universitaire Vaudois, Lausanne,* [3]*Division of Gastroenterology and Hepatology, University Hospital Zürich, Zürich, Switzerland*

Introduction: Fistulae and stenosis represent a frequent and severe complication in Crohn's disease (CD) patients. For an optimal treatment it is essential to identify factors being associated with the development of CD-associated fistulae and stenosis to guide the clinical management or, ideally, prevent their occurrence. Our study aimed to identify independent predictors of fistulae and stenosis in CD patients from the patient collective of the Swiss inflammatory bowel disease cohort study (SIBDCS).
Aims & Methods: We retrieved data of 1'600 CD patients (47.6% males, median age: 39ys) from the nationwide SIBDCS. The development of fistulae and stenosis in relation to smoking status, disease location, age at diagnosis, medications and history of intestinal resection surgery were analyzed.
Results: In the univariate analysis female gender was associated with a lower risk for perianal fistulae (OR 0.64; CI 0.48-0.86; $p = 0.003$) while younger age at diagnosis of CD was associated with perianal (OR 0.98; CI 0.97-0.99; $p = 0.002$ and OR 0.98; CI 0.97-0.99; $p = 0.002$) and multiple fistulae (OR 0.98; CI 0.96-0.99; $p = 0.027$ and OR 0.98; CI 0.96-0.99; $p = 0.035$). Colonic and ileo-colonic manifestation at the time of initial CD diagnosis was associated with the occurrence of perianal or multiple fistula (OR 2.30; CI 1.41-3.77; $p = 0.001$ and OR 2.18; CI 1.40-3.77; $p = 0.001$). Independent factors that were associated with perianal fistulae by multivariate analysis were smoking at time of CD diagnosis (OR 1.508, CI 1.103-2.061, $p = 0.010$), presence of stenosis (OR 1.422, CI 1.023-1.978, $p = 0.036$), colonic (OR 2.505; CI 1.489-4.215, $p = 0.001$) or ileo-colonic CD at diagnosis (OR 1.797 CI 1.137-2.844, $p = 0.012$) and ever treatment with either antibiotics (OR 2.167, CI 1.594-2.945, $p < 0.001$) or anti-TNF antibodies (OR 2.296, CI 1.678-3.141, $p < 0.001$). The latter four aspects are also associated with the presence of multiple fistulae. Multiple fistulae are further associated with a history of intestinal resection (OR 3.098, CI 1.890-5.079, $p < 0.001$). Female gender protects form perianal fistulae (OR 0.571, CI 0.420-0.775, $p < 0.001$).

Colonic involvement at CD diagnosis (OR 0.531, CI 0.305-0.925, $p < 0.026$) protects from the onset of stenosis. History of intestinal resection (OR 6.476; CI 4.866-8.617, $p < 0.001$), anemia (OR 1.529; CI 1.106-2.115, $p = 0.010$), presence of fistulae (OR 1.424; CI 1.075-1.887, $p = 0.014$), disease duration per year (OR 1.018; CI 1.003-1.032, $p = 0.016$) and treatment with antibiotics (OR 1.524; CI 1.167-1.990, $p = 0.002$) or steroids (OR 1.756; CI 1.242-2.481, $p = 0.001$) were independently associated with the occurrence of stenosis.
Conclusion: In particular markers of a severe disease course, such as younger age at diagnosis, history of intestinal resection, use of steroids or anti-TNF antibodies are associated with the occurrence of CD-associated fistulae and stenosis.

P0926 THE ROLE OF SMOKING IN THE NATURAL HISTORY OF CROHN'S DISEASE: A SYSTEMATIC REVIEW AND META-ANALYSIS

N. To[1,2], D. Gracie[1,2], R. Pounder[3], A. Ford[1,2]
[1]*Leeds Gastroenterology Institute,* [2]*Leeds Institute of Biomedical and Clinical Sciences, University of Leeds, Leeds, UK., Leeds,* [3]*Royal Free Hospital, and University College Medical School, London, United Kingdom*

Contact E-mail Address: n.to@leeds.ac.uk
Introduction: There is strong evidence that smoking is a strong risk factor for the development of Crohn's disease. The role of smoking on disease progression is less definitive. Some studies support the notion that it increases the risk of complications, resulting in more flares of disease activity and surgical intervention. However, the results of other studies are conflicting. We therefore conducted a systematic review and meta-analysis of current available data to examine this issue.
Aims & Methods: We carried out a search of MEDLINE, EMBASE and EMBASE. Eligible studies were cross-sectional surveys, cohort studies, or case-control studies examining the impact of smoking on the natural history of Crohn's disease, defined according to clinical, radiological, histological, or endoscopic criteria in a minimum of 50 patients. Outcomes of interest were flares of disease activity, or need for surgery, according to smoking status. There were no language restrictions, and a recursive search of bibliographies of all eligible articles was performed. Two independent investigators judged eligibility and extracted data on each article, with a third investigator resolving any disagreements between the two. Study quality was assessed according to published criteria. Dichotomous data were pooled using a random effects model, and the association between smoking status and flare of disease activity, or need for surgery, was summarized using an odds ratio (OR) with a 95% confidence interval (CI).
Results: The search strategy identified 3374 citations, of which 164 appeared relevant to the study question, and were retrieved for further evaluation. Of these, 40 were eligible for inclusion, including a total of 2769 patients. Overall, 1243 (69.5%) of 1788 smokers had a flare of disease activity, compared with 1431 (64.3%) of 2225 non-smokers (OR = 1.56; 95% CI 1.21-2.01). Following a "curative" resection for Crohn's, 165 (59.6%) of 277 smokers had a subsequent flare, compared with 138 (45.8%) of 301 non-smokers (OR = 1.66; 95% CI 0.99-2.79). There were 882 (33.1%) of 2661 smokers who required any surgery during follow-up, compared with 982 (30.4%) of 3235 non-smokers (OR = 1.19; 95% CI 0.99-1.44). When the association between smoking and need for first surgery was examined, there were 508 (51.4%) of 989 smokers who required a first operation, compared with 575 (30.5%) of 1883 non-smokers (OR = 1.71; 95% CI 1.30-2.41). Finally, in those who had undergone a first operation, 404 (47.5%) of 850 smokers underwent a second operation, compared with 276 (30.2%) of 913 non-smokers (OR = 1.61; 95% CI 1.40-1.85).
Conclusion: As has previously been described, smoking adversely impacts the natural history of Crohn's disease, with a 56% increase in flares of disease activity during follow-up, and a 19% increase in need for surgery. First surgery rates are increased by 71% in smokers, and reoperation rates after first surgery by 61%. Smoking cessation interventions should be implemented in all patients with Crohn's disease who smoke.

Contact E-mail Address: fmocciaro@gmail.com
Introduction: Motivational interviewing (MI) is a patient-centered counselling also proven useful in inflammatory bowel disease patients. Some skills are at the base of a successful MI: the ability to ask open ended questions, the ability to provide affirmations, the capacity for reflective listening, and the ability to periodically provide summary statements to the patients.
Aims & Methods: We report data from a case-control study (1:1 ratio) on MI applied to IBD patients. Between June 2014 and March 2015 we collected data from 2 IBD referral centers both with knowledge on MI skills but only one of these (case group) currently applied this technique during the visits. At the end of visit all patients filled out an anonymous questionnaire.
Results: 200 patients (108 males [54%]) with a mean age of 40.3 ± 15.5 years were evaluated. Ninety-two patients were affected by Crohn's disease (46%), 96 by ulcerative colitis (48%), and 12 by indeterminate colitis (6%). Patients' characteristics were quite similar between case and controls: male 51% vs. 57%, mean age $35.5.1 \pm 14.1$ vs. 44 ± 15.1, Crohn's disease 48% vs. 44%, ulcerative colitis 46% vs.50%, indeterminate colitis 6% vs. 6%. At final analysis 162 patients (81%) were previously evaluated by a gastroenterologist with an acceptable satisfaction rate (68%) which significantly decreased in those at the first outpatient visit (54%, $p < 0.001$). Satisfaction rate on general practitioner was low both in all patients and in those at the first visit (48% and 28%). The lowest satisfaction rate was reported in patients at the first visit ($p < 0.001$), in patients affected by indeterminate colitis ($p = 0.003$), in patients with long disease duration ($p = 0.004$); 78% of patients would have liked the use of explanatory pictures during the visits. Patients already followed-up in the referral centers reported a good overall satisfaction rate (87%) which reached 100% in those at the first visit. Nevertheless in the latter group, on a scale from 1 to 5, "5" (100% satisfied) was reported by 97% of patients on MI-group (case group) compared to 54% of controls: $p < 0.001$. No differences in terms "physician's communication skills", "perceived empathy" and duration of visits (41.9 ± 8.6 vs. 40.2 ± 9.4 minutes) were observed.
Conclusion: Our study showed as IBD patients followed-up in referral centers are satisfied of their physician rather than gastroenterologists without experience on IBD. MI is a communication tool very well appreciated by IBD patients and can help "IBD experts" to reach the best communication skills especially in pts at the first visit. Explanatory pictures should be used to help patients to better understand their clinical condition.

P0928 CONTRAST-ENHANCED ULTRASONOGRAPHY IN THE EVALUATION OF CROHN'S DISEASE ACTIVITY: CORRELATION WITH ILEOCOLONOSCOPY

F. Dias De Castro[1], J. Magalhães[1], P. Boal Carvalho[1], S. Monteiro[1], S. Leite[1], M. J. Moreira[1], J. Cotter[1,2]

Contact E-mail Address: franciscadcastro@gmail.com
Introduction: The role of contrast-enhanced ultrasonography (CEUS) for assessing CD activity is still evolving.
Aims & Methods: Our aim was to determine the performance of conventional US and CEUS to detect CD activity assessed by ileocolonoscopy taken as the reference.
Thirty-five patients with small bowel CD were prospectively studied. Clinical disease activity was assessed by the Harvey–Bradshaw Index (HBI). All patients underwent ileocolonoscopy and also a conventional US followed by a CEUS using a microbubble contrast agent (SonoVue®). US examinations was performed using a Hitachi HI VISION Avius®, employing a multi frequency convex abdominal transducer. Disease small bowel activity was assessed by ileocolonoscopy (reference) and patients were graded, for the purpose of statistical analysis, as inactive (normal or mild disease) or active (moderate or severe inflammation). Qualitative and quantitative parameters from the sonographic analysis included maximum bowel wall thickness, vascularity pattern by Doppler US and quantitative measurements of contrast bowel wall enhancement using CEUS (peak intensity and time to peak). Statistics were performed with SPSS v.20.0.
Results: Disease severity was as follow: no inflammation in 10 patients (29%), mild in 5 patients (14%), moderate in 4 patients (11%) and severe in 16 patients (46%). Only 6 patients (17%) had significant clinical activity (HBI $\geq$ 5 points). In patients with active endoscopic disease, wall bowel thickness of the terminal ileum was higher than in patients with inactive disease (7mm vs 5mm, $p = 0.029$), the same association was observed for the presence of moderate to severe vascularity by Doppler ($p = 0.006$). For CEUS the peak intensity was related with disease severity (10.5 vs 21.5, $p = 0.001$) with an excellent capability to predict endoscopic activity in ileoscopy (area under the ROC curve 0.896, 95% CI 0.786-1.0). The time to peak could not predict endoscopic activity in ileoscopy (23.2 sec vs 22.7 sec, $p = 0.7$).
Conclusion: Wall bowel thickness, Doppler US and CEUS peak intensity are valuable parameters for an accurate detection of small bowel inflammatory activity in CD. Conventional US and Contrast-enhanced US could in the future have a major role in the assessment of inflammatory activity in CD patients, and probably in the evaluation of therapeutic response.

P0929 CHANGE IN CLINICAL PRESENTATION OF IBD PATIENT ADMITTED TO THE HOSPITAL FROM EMERGENCY DEPARTMENT AND/OR OUTPATIENT CLINIC: RESULTS FROM A 1996-2013 RETROSPECTIVE STUDY FROM AN ITALIAN TERTIARY CENTER

F. Scaldaferri[1], M. T. Pistone[1], V. Ojetti[1], A. Poscia[2], L. R. Lopetuso[1], M. Volpe[2], E. Schiavoni[1], E. Gaetani[1], D. Mc Namara[3], G. Cammarota[1], A. Gasbarrini[1], F. Franceschi[1]
[1]*Internal Medicine Department, Gastroenterology Division, Catholic University of Sacred Heart of Rome,* [2]*Institute of Hygiene, "Polyclinic A. Gemelli" Hospital, School of Medicine, Catholic University of the Sacred Hearth, Rome, Italy,* [3]*Trinity College, Dublin, Ireland*

Introduction: Recently a big change in management and organization of IBD patients occurred thought Europe, including Italy, because of introduction of anti-TNF-a, introduction of IBD units, etc. Few studies exist on clinical features of IBD admitted to hospital and its change during the time.
Aims & Methods: Aim of this study was to describe clinical presentation, outcome of hospitalization, need for surgery and complications of IBD patient

admitted to the hospital from emergency or outpatient clinic. 5407 admissions from 1996 to 2013 at Policlinico "A. Gemelli" hospital were analyzed, identified from ICD-9-CM code referring to IBD. All records were classified to define: type of access (if from outpatient clinic or from emergency department); admission code if suspicion of IBD or flare or Complications or Unrelated Reason); diagnosis at the discharge according to ICD-9-CM; clinical outcome of the hospitalization if diagnosis/follow-up, Treatment, outcome not related; surgical outcome if no/ unrelated surgery, Related surgery, complications. Data are stratified for type of IBD, type of access, time (Pre vs. Post-biological, being the cut-off year 2003 for the CD and 2007 for the UC). Statistical analysis was performed by chi2 test for qualitative variables and the Student's t test for quantitative variables. Statistical significance was defined for p values less than 0.05.

Results: IBD represent around 1% of all admission to tertiary center. 557 out of 5407 patients (10.3%) were admitted for abdominal pain and were then diagnosed for IBD. Admission rate from emergency were 19 % ot total for both CD and UC, with a mean admission per patient of 2.5 ± 3.9 (min 1 and max 53 admissions). In CD patients complications were higher if admitted from emergency department while in UC higher if admitted from outpatient clinic; fistulas and obstruction were complication associated primarily to CD while bowel cancer and osteo-articular diseases for UC. Stratifying for admission before and after introduction of anti-TNF we observed an increase of admission for recurrence of the disease; an increase in medical and surgical treatments; an overall increase in complications, with a decrease of some important complications and the rise of extra-intestinal cancer in UC.

Conclusion: Clinical presentation, outcome of hospitalization, need for surgery and complications in IBD patient varied in recent years differently according to type of disease, type of admission at the hospital and also timeframe, being introduction of anti-TMF-a and re-organization of outpatient clinic major determinants of it. This is a starting point for a better cost-effective and integrated management of IBD.

Introduction: Inflammatory bowel disease (IBD) can reduce patient's health-related quality of life (HRQoL). The aim of the present study was to compare HRQoL in ulcerative colitis (UC) and Crohn's disease (CD) 20 years after diagnosis with the background population, and to identify factors associated with reduced HRQoL.

Aims & Methods: IBD patients from a population-based inception cohort (IBSEN) were invited to a follow-up visit 20 years after diagnosis. In addition to a structured interview, clinical examination, blood and stool samples and a colonoscopy, patients answered the Short Form 36 (SF-36), the Norwegian Inflammatory Bowel Disease Questionnaire (N-IBDQ) and the Fatigue Questionnaire.

Results: 72% (438/604) of patients with a confirmed UC or CD diagnosis completed the HRQoL questionnaires. Females scored lower than males in SF-36 dimensions and N-IBDQ total scores, stratified by diagnosis (Table 1). Seven out of eight SF-36 dimensional scores were statistically significantly reduced compared to the Norwegian reference population. However, only the difference in the general health (GH) dimension between CD patients and the reference population (67.3 vs. 77.4) appeared to be of clinical importance with a z-score of 0.65, which is a moderate difference according to Cohen's effect size. C-reactive protein > 5, current symptoms and not working were independent factors associated with reduced scores in SF-36 dimensions in CD patients (CRP > 5: role physical (RP) 72 vs. 42, bodily pain (BP) 72 vs. 60, GH 66 vs. 54; current symptoms: RP 79 vs. 52, BP 80 vs. 61, GH 72 vs. 56, vitality (VT) 60 vs. 44, $p < 0.01$; not working: physical functioning (PF) and BP (91 vs. 76 and 78 vs. 57, $p < 0.001$)). In UC patients a simple clinical colitis activity index (SCCAI) > 2.5 and having chronic fatigue (CF) were associated with reduced SF-36 dimension scores (SCCAI: RP 81 vs. 48, BP 75 vs. 53, GH 72 vs. 53, VT 61 vs. 47; CF: PF 89 vs. 74, RP 80 vs. 45, BP 74 vs. 50, GH 72 vs. 51, VT 62 vs. 38, $p < 0.01$).

Table 1: : SF-36 dimensional scores and N-IBDQ total scores

UC			CD		
	Male	Female		Male	Female
PF***	91 (88-93)	82 (79-85)	**PF*****	91 (87-96)	79 (74-83)
RP***	81 (75-87)	65 (59-71)	**RP***	73 (64-82)	56 (47-65)
BP**	74 (70-78)	65 (61-69)	**BP***	75 (69-80)	65 (59-71)
GH*	70 (67-74)	65 (61-69)	**GH***	68 (63-73)	58 (53-63)
VT***	62 (59-66)	53 (50-56)	**VT****	57 (52-62)	46 (40-51)
SF*	87 (83-90)	81 (77-84)	**SF**	83 (77-89)	75 (69-81)
RE**	87 (81-92)	74 (69-80)	**RE**	77 (68-86)	67 (58-77)
MH	81 (78-83)	78 (75-80)	**MH***	80 (76-84)	72 (68-76)
N-IBDQ total score**	187 (183-191)	178 (174-182)	**N-IBDQ****	185 (179-196)	172 (166-178)

Estimated marginal mean scores adjusted for age and education. PF physical function, RP role physical, BP body pain, GH general health, VT vitality, SF social function, RE role emotional, MH mental health. *$p < 0.05$, **$p < 0.01$, ***$p < 0.001$. (95%CI) 95% confidence intervals.

Conclusion: In this population-based IBD cohort HRQoL measured 20 years after diagnosis was in general comparable to the reference population. However, HRQoL in female IBD patients was lower than in males. Independent factors associated with reduced HRQoL were: CRP > 5, current symptoms and not working in CD, SCCAI > 2.5 and chronic fatigue in UC.

Contact E-mail Address: gbamias@gmail.com

Introduction: Low vaccination rates against hepatitis B virus (HBV) have been reported in patients with IBD, as well as sub-optimal responses to vaccination. ECCO has currently advised for vaccination of non-immune IBD patients with an aim of achieving levels of anti-HBs > 100 IU/l for adequate seroprotection, in particular when immunosuppressive therapy is planned. The appropriate management in this setting remains to be fully specified.

Aims & Methods: We have initiated a multi-centre study in the metropolitan area of Athens, Greece, to evaluate a) the percentage of Greek IBD patients with protective anti-HBs levels; b) the response to vaccination; and, c) the effect of various patient and disease-related parameters on the efficacy of vaccination. We reviewed the clinical records of all IBD patients with a regular follow-up at 4 tertiary hospitals at the Athens Metropolitan area. All patients were tested for HBsAg, anti-HBs and anti-HBc antibodies. Patients younger than 65-y-old with negative tests for both HBsAg and anti-HBc were managed as follows: a) negative anti-HBs without/unknown history of vaccination: 3-dose vaccination (0, 1, 6 mo) with 20 μg, b) history of vaccination: anti-HBs levels >100iu/l: annual follow-up of anti-HBs levels; anti-HBs 10-100iu/l, 1-3 20 μg doses with anti-HBs measurement after each dose; no anti-HBs, 1-3 40 μg doses with anti-HBs measurement after each dose. Vaccination was considered complete when anti-HBs > 100iu/l were detected. In patients with negative anti-HBs levels after 3x20 μg doses, vaccination was repeated with a double dose (40 μg) with anti-HBs measurement after each dose.

Results: We have included 446 IBD patients so far in our study (CD = 267, UC = 176, IC = 3, male = 226, age: 42.2 ± 15.3, 16-89). Among 328 patients with recent HBV serology, there were 5 with chronic HBV infection (HBsAg+) and 29 patients with previous exposure to HBV (HBsAg-, anti-HBc+). Protective immunity due to previous vaccination (HBsAg-, anti-HBc-, anti-HBs+ > 100iu/L) was detected in 23.8% (n = 78). Sub-optimal anti-HBs levels were seen in 10.1% (n = 33). The majority of tested patients were negative for all three markers (HBsAg, anti-HBc, and anti-HBs), indicating lack of effective vaccination (n = 183, 55.8%). If only patients less than 65-y-old were analyzed (n = 280), effective immunity was still absent in 54.3%. There was significant association ($p < 0.001$) between age and presence of protective immunity that is probably due to the widespread application of HB vaccination at early ages in the last 2 decades in Greece. Vaccination was commenced in 125 patients so far, with 64 having finished their regimen. Response has been assessed in 31 patients with 18 (58.1%) achieving sufficient response and 13 requiring double dose vaccination.

Conclusion: A significant percentage of Greek IBD patients lack protective immunity against HBV. The "classical" vaccination regimen often fails to induce adequate levels of anti-HBs antibodies. Increased awareness, intensified vaccination protocols and frequent testing of response may be required in this population.

Introduction: Intestinal alkaline phosphatase (iAP) functions as a gut mucosal defense factor by detoxifying pro-inflammatory bacterial and endogenous components. The aim of this study was to compare the expression of iAP in inflamed colon mucosa to that in non-inflamed colon mucosa of inflammatory bowel disease (IBD) patients.
Aims & Methods: Colon mucosal specimens were obtained from IBD [18 with ulcerative colitis (UC), 17 with Crohn's disease (CD)] during colonoscopy. iAP from each specimen was quantified using ELISA. The expression levels of profinflammatory cytokins in IBD patients were determined by real-time polymerase chain reaction. The activation of iAP in cells treated with enteropathogenic *Escherichia coli* (EPEC) was determined by Western blo
Results: A total of 35 consecutive patients (18 UC, 17 CD) were included in this study. In IBD patients, the protein level of iAP in inflamed mucosa was significantly (average fold: 2.34; $p < 0.001$) higher than that in non-inflamed mucosa. The mRNA levels of inflammatory genes IL-6, TNF-α and TLR-4 in inflamed mucosa were significantly higher than those in non-inflamed mucosa ($p < 0.05$). There was significant correlation between endogenous iap and CDAI in CD patients ($p = 0.038$, $r = 0.506$). In EPEC-treated epithelial cells, the protein levels of iAP were significantly higher than that in cells not treated by EPEC ($p < 0.05$).
Conclusion: Endogenous iAP was increased in inflammatory mucosa in IBD patients with protective role against gut inflammation at suboptimal levels. Further study is needed to determine the role of iAP in patients with IBD.

P0933 PREVALENCE AND DISEASE COURSE OF INFLAMMATORY BOWEL DISEASE DIAGNOSED IN ASYMPTOMATIC PATIENTS DURING SCREENING COLONOSCOPY

I. Rodriguez - Lago[1], M. Fernández - Calderón[2], J. Fernández[1], I. Moraleja[1], I. Idígoras[3], I. Portillo[3], J. L. Cabriada[1], on behalf of IBD Study Group from the Basque – Navarre Society of Gastrointestinal Diseases
[1]*Gastroenterology Department, Galdakao Hospital, Bilbao,* [2]*Gastroenterology Department, Mondragón–Alto Deba Hospital, Mondragón,* [3]*Colorectal Cancer Screening Programme. Basque Country Health Service, Bilbao, Spain*

Contact E-mail Address: iago.r.lago@gmail.com
Introduction: There is sparse evidence about the prevalence of Inflammatory Bowel Disease (IBD) in asymptomatic patients. We have data from retrospective studies in different countries ranging from 0.7 to 1.6%. Interestingly most of the patients developed symptoms related to the disease during the next 5 to 10 years of follow up. We have conducted a study to evaluate the prevalence, disease characteristics and treatment requirements in patients diagnosed of IBD during screening colonoscopy in asymptomatic patients in our area.
Aims & Methods: We have retrospectively reviewed the medical chart of all the patients who underwent a colonoscopy under the colon cancer screening programme in the Basque Country (Spain). This study was designed and conducted in two hospitals from the IBD Study Group from the Basque – Navarre Society of Gastrointestinal Diseases. The screening in our area started in 2009 and it covers people between 50 and 69 years from a population of 2.2 million people. All patients were assessed with fecal occult blood test (FOBT) and, if this test was positive, a colonoscopy was performed. The inclusion criteria in the present study included a diagnosis of IBD established by endoscopy and confirmed by histology during the colon cancer screening programme.
Results: A total of 70.299 FOBT were done in our two hospitals. In 4.717 (6.7%) of these cases a colonoscopy was performed. We have found 14 patients (0.3%) diagnosis of IBD: Ten cases of ulcerative colitis (UC), two of Crohn's disease (CD) and two of indeterminate colitis. Nine of them are women, and most of them have never smoked. The median age at diagnosis was 55 years [51.5-60]. UC extension was classified as E1 in 3 patients, in 4 as E2 and in 3 as E3. All four patients with CD and IBD unclassified suffered only colonic involvement. Endoscopic activity was scored as UCEIS 5 [4-5.5]. Only one patient suffered perianal disease and extraintestinal manifestations, both at diagnosis. Median follow-up time since the diagnosis was 12 months [8.5-29.5]. Five patients (35%) developed symptoms during this period (rectal symptoms/ diarrhoea/ rectal bleeding). Treatment was indicated with mesalazine in 11 cases, steroids in 3 and 2 with azathioprine. No patients required methotrexate or biologics. Only one patient required surgery because of a mass in transverse colon at diagnosis to rule out an underlying cancer.
Conclusion: We have found a 0.3% prevalence of IBD during screening colonoscopies in our area. All cases had exclusive colonic involvement. After a medium – term follow – up the disease behaviour is relatively mild. Our preliminary data need to be explored in future studies with a greater number of patients and a longer – follow up.

P0934 CLINICAL INEFFICACY OF GOLIMUMAB IN ULCERATIVE COLITIS PATIENTS IS INDEPENDENT OF IMMUNOGENICITY

I. Detrez[1], A. de Vries[2], E. Brouwers[1], G. Van Assche[3], S. Vermeire[3], M. Ferrante[3], A. Gils[1]
[1]*KU Leuven, Leuven, Belgium,* [2]*Sanquin, Amsterdam, Netherlands,* [3]*University Hospitals Leuven, Leuven, Belgium*

Introduction: Golimumab (GOM, Simponi®), a therapeutic antibody targeting tumor necrosis factor (TNF) alpha, has recently been approved for treatment of moderate to severe Ulcerative Colitis (UC). The PURSUIT-SC induction study showed that 51.0% of patients responded clinically upon sub-cutaneous administration of GOM 200/100 mg at weeks 0 and 2.
Aims & Methods: (1) To develop monoclonal antibody (MA)-based immunoassays for the determination of GOM and anti-GOM concentrations (2) To evaluate the clinical significance of these assays in a small cohort of 15 UC patients receiving GOM maintenance dosing (50 mg or 100 mg) after induction of therapy. For the quantification of GOM serum concentrations, both a MA-based TNF-coated ELISA and a MA/MA-based sandwich-type ELISA were developed. Assay performance was assessed using 64 patient serum samples. External analytical validation was performed through collaboration with Sanquin. For quantification of the anti-GOM antibody response, a bridging ELISA was developed and samples were analyzed neat and after an acid-treatment step. Clinical response and C-reactive protein (CRP) were determined.
Results: Analyzing 64 serum concentrations of GOM-treated UC patients revealed an excellent correlation between the two immunoassays: Spearman's rho 0.981, $p < 0.0001$; intra-class correlation coefficient (ICC) of 0.972. The sandwich-type ELISA demonstrated higher sensitivity and specificity as compared to the TNF-coated ELISA and is therefore our preferred assay. External validation of the sandwich-type ELISA using 20 patient serum concentrations showed a good Pearson's r (0.969, $p < 0.0001$) and ICC (0.926). Treatment of seven out of 15 UC patients was terminated within 14 weeks due to inefficacy. However, in all serum samples tested, anti-GOM levels were <3.2 ng/mL even when an acid dissociation step was included to dissociate the GOM/anti-GOM complexes. Comparing consecutive GOM levels of a representative responder *versus* a representative non-responder revealed significantly different pharmacokinetics, which were also reflected in the clinical and biochemical response parameters of these patients (Table 1).
Conclusion: In this study, highly sensitive MA-based immunoassays were developed for the specific quantification of serum GOM and anti-GOM concentrations and applied on a cohort of 15 UC patients. Despite major differences in pharmacokinetics between responders and non-responders, no antibodies against GOM were detected. Based on these preliminary results, we hypothesize that efficacy could be improved by higher or more frequent GOM doses for patients with inadequate treatment responses or by increasing GOM absorption.

Introduction: In patients with Crohn's disease, liver test abnormalities (LTA) are a frequent phenomenon. Although clinical experience may suggest a relationship between disease severity and presence of LTA, this has not been extensively studied. In celiac disease, presence of LTA has been associated with the degree of mucosal damage. In Crohn's disease, the degree of mucosal damage is associated with a poor prognosis. In this study, we aim to investigate whether the presence of LTA is associated with a poor prognosis in newly diagnosed Crohn's disease patients.

Aims & Methods: We performed a retrospective cohort study in all patients diagnosed between 2004 and 2011 in a tertiary IBD centre and 2 large teaching hospitals. All new cases of Crohn's disease were included in the study when liver test results from before the start of treatment were available. Patients with liver disease, manifest at diagnosis or during follow up, were excluded. Patients were scored for patient characteristics, occurence of complications (such as stenosis or perforation), hospitalizations and surgeries. Liver test abnormalities (LTA) were defined as a value of either alkaline phosphatase (AP), Gamma Glutamyl transferase (GGT), Aspartate Aminotransferase (AST) or Alanine Aminotransferas (ALT) above the upper limit of normal. Complicated behavior at diagnosis was defined as having any form of non-B1 behavior at diagnosis.

Follow-up was ended after 60 months or at the occurence of a complication.

Results: In 383 newly-diagnosed patients with Crohn's disease, LTA were found in 135 patients.

No differences in Montreal classification at diagnosis were found between patients with and without LTA. Patients with LTA more often developed complications compared to patients without LTA (either stenosis or perforation; 33% vs 15% resp., $p < 0.001$). Using a multivariate analysis, LTA ($p < 0.001$, Hazard ratio (HR)2.3), complicated behavior at diagnosis ($p = 0.019$, HR 1.7), CRP at diagnosis ($p = 0.032$, HR 1.003) and involvement of the small bowel ($p = 0.05$, HR 1.9) were associated with the occurence of a new stenosis or perforation.

During the 5 year follow-up period, 54% of patients with LTA were hospitalized, compared to 35% of non-LTA patients ($p = 0.001$). Using a multivariate analysis, both presence of LTA at diagnosis ($p = 0.005$, HR 1.56) and complicated behavior at diagnosis ($p = 0.003$, HR 1.5) were associated with an increased risk for hospitalization.

Eighty out of 135 patients with LTA had an increased AP, and 27 of these 80 patients developed complicated disease behavior compared to 54 out of the 303 patients without LTA (33% vs. 15%, $p = 0.003$). Out of the 80 patients with an increased AP, 44 were hospitalized during the 5 years follow up compared to 117 of 303 patients with normal AP (55% vs 38%, $p = 0.011$).

Conclusion: In this study we have demonstrated that presence of LTA at diagnosis is associated with a poor prognosis, as both the risk for developing a new complication or the need for hospitalization were higher in the LTA-group. Presence of an increased AP at diagnosis has the highest predictive value.

P0936 NORMALIZED HS-CRP AND EARLY MUCOSAL HEALING AFTER INDUCTION CAN PREDICT SUSTAINED RESPONSE IN PATIENTS WITH CROHN'S DISEASE AFTER ONE YEAR INFLIXIMAB THERAPY

J. Tang[1], X. Gao[1], M. Zhi[1], P. Hu[1]
[1]*Department of Gastroenterology, The Sixth Affiliated Hospital of Sun Yat-sen University, GuangZhou, China*

Contact E-mail Address: tangjiansys@163.com

Introduction: High sensitive C-reactive protein (hs-CRP) and early mucosal healing are thought to be usefulin monitoring disease activity during infliximab therapy, but how to combine these two index to be a more useful tool to predict sustained response remains unclear. We aimed to investigate the predict value of hs-CRP combined with early mucosal healing in patients undergoing infliximab therapy.

Aims & Methods: 76 patients were retrospectively enrolled after initiating infliximab therapy in our center. All patients responded to infliximab after induction had been scheduled for every 8 weeks shooting. Hs-CRP was tested at 14wks after induction. Normalized hs-CRP was defined as hs-CRP = 0-3mg/L. Endoscopic examinations were carried out at 14wks and 52wks. Mucosal healing was defined as no ulcer or only scar.

Results: Hs-CRP was normalized in 57%(44/76) of all patients. Patients with normalized hs-CRP had higher mucosal healing rate and lower loss response rate than the other group at 52wks (53%vs37.50%, $P = 0.04$; 15%vs40%, $P = 0.02$). 55% (42/76) of all patients reached mucosal healing at 14 wks. Patients with early mucosal healing also had higher mucosal healing rates and lower loss of response rate at 52wks (64%vs17%, $P < 0.01$; 17%vs42%, $P = 0.04$). Normalized hs-CRP combined with early mucosal healing had significant value in predicting sustained response and mucosal healing at 52wks. 70% (21/30)patients with normalized hs-CRP and early mucosal healing reached mucosal healing and 93% (28/30) of them maintained a sustained response to infliximab at 52wks.

Conclusion: Normalized hs-CRP and early mucosal healing after induction can effectively predict mucosal healing andsustained response in patients undergoing infliximab therapy.

P0937 POST-INDUCTION SERUM INFLIXIMAB TROUGH LEVEL AND ANTIBODYARE ASSOCIATED WITH ONE YEAR OUTCOME AFTER INITIATING THERAPY IN CROHN'S DISEASE

J. Tang[1], X. Gao[1], M. Zhi[1], P. Hu[1]
[1]*Department of Gastroenterology, The Sixth Affiliated Hospital of Sun Yat-sen University, GuangZhou, China*

Contact E-mail Address: tangjiansys@163.com

Introduction: Serum infliximab trough level(S-IFX) and antibody were documented to correlate with sustained infliximab response. Aim of this study was to identify relationship between trough levels, antibodies and clinical outcome in a cohort on maintenance infliximab therapy.

Aims & Methods: 64 patients were retrospectively enrolled. All received a scheduled maintenance therapy after response to infliximab induction. S-IFX and antibodies were tested in at 14 weeks after initiating treatment. Rate of loss response and endoscopic activity were evaluated at 52weeks.

Results: At week14, S-IFX was 5.28 ± 7.24ug/ml and 23%(15/64) of all patients developed antibodies. S-IFX was significantly lower in patients with antibody (2.91 ± 5.40ug/ml vs 6.00 ± 7.61ug/ml, $P = 0.02$). During 52 weeks follow up, 28% (18/64) patients lost of response to infliximab. The patients who lost of response had lower S-IFX than patients had sustained response (2.16 ± 3.05ug/ml vs 6.50 ± 8.02ug/ml, $P = 0.03$) while no significant difference was found on drug antibodies (38% vs 22%, $X = 2.50$, $P = 0.11$). At week 52, 62 patients had undergone ileo-colonoscopy and 30 patients reached mucosal healing. Mucosal healing group had relatively higher S-IFX than who did not reach mucosal healing (8.11 ± 9.33ug/ml vs 2.56 ± 2.90ug/ml, $P < 0.01$) but no statistical difference for antibodies between these two groups (17% vs 28%, $P = 0.28$). S-IFX had a predictive value on sustained response and mucosal healing in 52 weeks follow up. When S-IFX > 2ug/ml, the sensitivity for predicting sustained response and mucosal healing were76% and 83%, the specificity were 72% and 56% (AUC = 0.76, $P < 0.01$;AUC = 0.78, $P < 0.01$). Baseline albumin level and BMI were 41.44 ± 6.95g/l and 21.45 ± 3.56 in sustained remission patients. S-IFX was correlated to albumin level and BMI (r = -0.79, $P < 0.01$;r = -0.46, $P < 0.01$).

Conclusion: Post-induction serum IFX trough level could predict sustained response and mucosal healing in CD patients undergoing IFX treatment. Nutritional status before treatment was correlated to serum IFX trough level.

P0939 EARLY POST-OPERATIVE ENDOSCOPIC EVALUATION AFTER ILEOCECAL RESECTION IN CROHN'S DISEASE REDUCES CLINICAL RECURRENCE

J. Carvalho[1], A. Oliveira[1], L. Lourenço[1], M. Cardoso[1], V. Anapaz[1], C. G. Rodrigues[1], L. Santos[1], S. F. Alberto[1], A. Martins[1], J. Reis[1], J. R. Deus[1]
[1]*Gastroenterology, Hospital Professor Doutor Fernando da Fonseca, Lisbon, Portugal*

Contact E-mail Address: cbranco.joana@gmail.com

Introduction: In Crohn's disease, the recurrence rate after ileocecal resection is high, around 20-25% per year without therapy[1,2], and is best predicted by endoscopy rather than clinical indeces[1]. Since 2010, the *European Crohn's and Colitis Organization guidelines* recommends performing ileocolonoscopy 6 to 12 months after surgery to predict clinical behavior[3], which has therapeutic implications.

Aims & Methods: The aim of this study is to evaluate the impact of this endoscopic evaluation on early post-operative clinical recurrence.

This is a retrospective analysis of a cohort of Crohn's disease patients submitted to ileocecal resection at our Hospital with updated follow-up until 2014. Patients were distributed into two groups, whether they had or not performed ileocolononoscopy within 12 months after surgery, group P or NP respectively. We evaluated different levels of reccurence: clinical, defined as symptomatic disease needing corticotherapy or an escalating immunossupresive regimen; endoscopic, defined by Rutgeert's endoscopic score; and surgical, defined as necessity of surgical reintervention.

Results: We included 66 patients, of whom 34 (51.5%) women, with an average age at diagnosis of 34.5 ± 13.6 years, average age at surgery of 37.1 ± 13.7 years, median follow-up time after surgery of 152 ± 120 months; 35 (53%) with penetrating disease and 10 (15.2%) with perianal disease. Previous to surgery, 9 (13.6%) patients were on immunosupressive therapy, 4 (6%) of them on combined therapy. All patients have undergone post-operative prophylaxis with messalazine, in 16 (24.2%) of them azathioprine was added and in 4 (6%) biologic therapy was started. There were 27 (41%) patients on group P and 39 (59.1%) on group NP. We have found endoscopic reccurence in 46 (69%), clinical reccurence in 35 (53%) and surgical reccurence in 8(12.1%). Patients on group P had less clinical reccurence than group NP (66.6% vs. 33%; $p = 0.01$).

Conclusion: Early endoscopic evaluation after ileocecal resection in Crohn's disease has a positive impact on clinical evaluation as this group of patients shows less clinical reccurence than patients that are not systematically submitted to this evaluation and this is in accordance to previous published data[4].

P0940 COMPARISON MR ENTEROGRAPHY AND COLONOSCOPY IN DETECTING FINDINGS OF INFLAMMATORY BOWEL DISEASE IN CHILDREN

J. Sieczkowska[1], B. Marcinska[2], M. Dadalski[1], D. Jarzebicka[1], J. Kierkus[1], E. Jurkiewicz[2]
[1]*Department of Gastroenterology, Hepatology, Nutrition and Pediatrics,*
[2]*Department of Diagnostic Imaging, The Children's Memorial Health Institute, Warsaw, Poland*

Contact E-mail Address: joannasieczkowska@wp.pl

Introduction: Diagnostic process for Inflammatory bowel disease (IBD) based on magnetic resonance of small bowel and endoscopy. Magnetic resonance is considered as the first-line imaging modality because of high efficacy for detecting IBD findings and lack of ionizing radiation. Before colonoscopy bowel cleansing is necessary. It is often problematic and bad tolerated by young patients. Specially in children the procedure of general anesthesia is needed.

Aims & Methods: The aim of this study was to compare detecting findings of disease by colonoscopy with MR-enterography proceeded for small bowel assessment. We tried to asses utility of MR-enterography in detecting lesions in the colon.

A retrospective assessment of 59 children with suspected or diagnosed IBD was done. All of the patients underwent colonoscopy and MR-enterography for small bowel disease localization within no longer than 23 weeks (only 1 patient had gap between studies 41 weeks). Localization of disease was described in 7 segments of the end part of small and large bowel: terminal ileum, cecum, ascending colon, transverse colon, descending colon, sigmoid colon, rectum. During MR procedure was assessed wall thickening bowel wall enhancement and presence lesions after DWI.

Results: The most common localization of findings of disease viewed by colonoscopy was ileum (88%). In rectum disease was in 56% of patients. The sensitivity and specificity for detecting lesions in the rectum bowel wall enhancement was in 42.3% and 96.7%, DWI 32% and 93.6%, wall thickening 26.9% and 96.7%; sigmoid colon 45.5% and 97.1%, DWI 40.9% and 88.6%, wall thickening 36.4% and 97.1%; descending colon 41.2% and 97.5%, DWI 29.4% and 95%, wall thickening 41.2% and 97.5%; transverse colon 50% and 100%; 43.8% and 100% for DWI and 43.8% and 100% for wall thickening; ascending colon 53.3% and 95.4%; DWI 46.7% and 95.4%, wall thickening 53.3% and 100%; cecum 57.1% and 93.1%, 50% and 93.2% for DWI, 50% and 97.7% for wall thickening; terminal ileum 53.9% and 79.6%, 61.5% and 77.3%, 61.5% and 77.3% respectively.

Conclusion: MRI characterized very high specificity in detecting disease lesion in colon. Unfortunately sensitivity wasn't enough high. Lack of IBD findings in MR does not exclude presence of disease. The sensitivity was better in higher segments of the bowel, what can suggest that additional rectal contrast may be obligatory for better detection of lesions in lower part of the colon.

Disclosure of Interest: None declared

P0941 ROUTINE COLONOSOPIC BIOPSIES – SHOULD PRACTICE CHANGE?

J. Easaw[1], A. Bennett[1], F. Leslie[1], A. Ramakrishnan[1]
[1]*Gastroenterology, University Hospital of North Midlands Nhs Trust, Newcastle Under Lyme, United Kingdom*

Contact E-mail Address: arulraas@yahoo.com

Introduction: American society for gastrointestinal endoscopy[1] (ASGE) and Joint advisory group on Gastointestinal endoscopy (JAG) suggest routine colonic biopsies as quality indicator and auditing our practice to identify microscopic colitis. UK studies suggest low incidence of microscopic colitis[2] and additional costs making one wonder whether we should be doing this routinely and/or auditing our practice?

Aims & Methods: We perfomed a retrospective database search of colonoscopy requests from July-December 2013 with keywords diarrhoea, loose stools & change in bowel habits to audit our practice as a quality indicator as per ASGE and JAG. Demographics, endoscopic findings & histology were collected from electronic records.

Results: From the 1124 requests, 407 colonoscopies were performed with the indication for diarrhoea, loose stools or change in bowel habit. Colonic biopsies were taken in 325 cases (79.9%) and right sided biopsies were specifically taken in 279 cases (68.6%). 60% of our colonoscopies were reported as macroscopically normal (241/407) and only 5.2% (17/325 colonoscopy biopsies) cases of microscopic colitis were picked up on routine biopsies. Among diagnosed with microscopic colitis, the mean age was 60.1 years (range 38-80, 76% > 50 years) with a female to male ratio of 14:3. Micropsopic colitis was diagnosed at an average biopsy cost of £1545 (total £26,266 spent on biopsies to identify 17 patients, not factoring colonoscopy tariffs or endoscopist/histopathologist time).

Conclusion: Our rate of routine colonoscopic biopsies in patients with diarrhoea[3] and the pickup rate of microscopic colitis[4] is similar to previous reports. We conclude that one case of microscopic colitis (5.2%) is diagnosed for every 20 colonoscopy perfomed for diarrhoea at a biopsy cost of £1545; age/sex may help in increasing pickup rate and to decrease routine biopsy rates.

Contact E-mail Address: GShanka3@its.jnj.com
Introduction: Infliximab(IFX) concentrations and antibodies to IFX(ATI) titers can be informative in assessing IBD response.
Aims & Methods: In collaboration with KU Leuven(Belgium), Sanquin(The Netherlands), Dynacare(Canada) and LabCorp(USA), the accuracy and reliability of commercially available IFX and ATI assays were compared to assays used by Janssen for Remicade®(IFX) IBD studies. Test samples were prepared by Janssen, blinded and frozen at -70°C and shipped to the labs; blinded analysis was also performed at Janssen. IFX concentration (49 samples) and ATI titer (32 samples) were assessed. KU Leuven* and Dynacare utilized enzyme-linked immunosorbent assay (ELISA) to measure IFX and ATI. Sanquin used ELISA to measure IFX and a radioimmunoassay to measure ATI.LabCorp used electrochemiluminescence immunoassay (ECLIA) to measure IFX and ATI. Janssen used ELISA for IFX quantification, and ELISA (''old'') and ECLIA (''new'') for ATI assessments.
Results: IFX Assays: Specificity:All assays were specific as they detected IFX alone, but not 5μg/mL of adalimumab, certolizumab pegol, golimumab or siltuximab. Selectivity: TNFα (0.5 – 50 ng/mL) did not interfere with IFX detection in any assays, whereas the presence of ATI titers > 10 interfered with IFX assessment in all assays. Accuracy: Accuracy was confirmed by 3 independent measurements of IFX (0.125-20μg/mL) spiked sera from untreated IBD patients and with IFX measured in sera from IFX-treated IBD patients. Precision: All IFX assays were precise as determined by inter-occasion reproducibility (2wks between assays of IFX-spiked IBD sera; Dynacare assessed the samples the same day). Pearson R values describing the correlation of Janssen IFX results to IFX results from Sanquin, Dynacare, KU Leuven, and LabCorp were 0.936, 0.945, 0.968 and 0.972, respectively.
ATI assays: Specificity: Assays from all labs and Janssen were specific in detecting anti-IFX antibodies; results were not affected by high titers of antibodies against other human monoclonal antibody drugs (ustekinumab and golimumab). Selectivity: The Sanquin, LabCorp and new Janssen methods were drug tolerant (IFX > 10ug/mL); ATI results from Dynacare and KU Leuven were affected by IFX concentrations at 2ug/mL or higher. Concentrations of free or bound TNFα (< 5ng/mL) did not interfere with ATI detection; but a high (supraphysiologic) TNFα concentration (50ng/mL) resulted in false positive results in all assays except Sanquin's. Precision: All ATI assays were reproducible (2wks between assays of human sera containing ATI; Dynacare assessed samples the same day).
Conclusion: Results from KU Leuven, Sanquin, Dynacare and LabCorp were similar and significantly correlated to the results of Janssen assays. These results may aid in interpretation of data from commercial assays and assays used in IBD clinical studies of Remicade®(IFX).

P0943 PERFORMANCE OF FECAL LACTOFERRIN, CALPROTECTIN, PMN-ELASTASIS AND CRP AND WBC COMPARED TO HISTOLOGICALLY DEFINED HEALING IN ULCERATIVE COLITIS

J. Langhorst[1], A. Rueffer[2], G. Dobos[3], J. Boone[4]
[1]*Chair for Integrative Medicine, University of Duisburg-Essen, Integrative Gastroenterology, Kliniken Essen-Mitte, Essen,* [2]*Enterosan, Labor L + S, Bad Bocklet-Grossenbrach,* [3]*Chair for Integrative Medicine, University of Duisburg-Essen, Internal and Integrative Medicine, Essen, Germany,* [4]*Techlab, Blacksburg, Virginia, United States*

Contact E-mail Address: j.langhorst@kliniken-essen-mitte.de
Introduction: Microscopic, histological healing may be a better predictor than the macroscopic appearance or clinical criteria for course of disease in ulcerative colitis (UC). Histological assessment revealed that indicators of acute mucosal inflammation, including crypt abscesses, mucin depletion or an acute inflammatory cell infiltrate were associated with a 2-3fold increase in the risk of UC relapse during 12 months' follow-up. Fecal inflammation biomarkers are increasingly popular because they are noninvasive and individual patients can serve as their own control. However an evaluation of a panel of biomarkers in their performance compared to a histological assessment in UC is lacking.
Aims & Methods: Three sigmoidal and rectal biopsies each were taken randomly or at the site of macroscopic active inflammation for histopathological work-up. Riley score (each category 0-3pts) was performed for signs of acute inflammation including **acute inflammatory cell infiltrate**, **crypt abscesses**, **mucin depletion** and **breaches in the surface epithelium**. The 4 categories were combined as **acute HistoScore** with a score = 0 indicating histologically defined healing and a score > 0 indicating acute inflammation**.** In addition, **chronic inflammatory cell infiltrate** and **architectural irregularities** were added and combined as HistoSumScore. The 3 fecal biomarker Lactoferrin (LF; > 7.25μg/g), Calprotectin (Cal; > 50μg/g), PMN-elastasis (PMN-e; > 0.062μg/g) as well as CRP (≥0.5mg/dl) and WBC (> 8500/μl) were correlated to the HistoSumScore and median (inactive/active), sensitivity, specificity, PPV, NPV and diagnostic accuracy were calculated based on the acute HistoScore.
Results: In 150 UC patients (79 female; age 18-75 years) 238 endoscopic procedures (75 colonoscopies; 163 sigmoidoscopies) were performed. Correlation (Spearman) with the **complete HistoSumScore** was LF cc = .408; p < 0.0001; PMN-e cc = .447; p < 0.0001; CAL cc = .458; p < 0.0001; CRP cc = .307; p < 0.0001; WBC cc = .203; p = 0.002. Comparison to the **acute HistoScore** showed the following results: **LF**: median (inactive/active): 3.9/36.5μg/g; sensitivity 71.2%; specificity 64.7%; PPV 71.2%; NPV 64.7%; diagostic accuracy: 68%; optimized cut-off: 10.2μg/g; **CAL**: median: 10.7/25.7μg/g; sens 27.2%; spec 96.1%; PPV 89.5%; NPV 51.9% diag acc: 58%; opt. cut-off: 16.6μg/g; **PMN-e**: median: 0.02/0.05; sens 38.2%; spec 84.0%; PPV 72.4%; NPV 55.3%; diag acc: 60%; opt. cut-off: 0.033μg/g; **CRP**: median: 0.1/0.4mg/dl; sens 43.3%; spec 85.3%; PPV 78.6%; NPV 54.7%; diag acc: 62%; opt. cut-off: 0.25mg/dl; **WBC**: median: 6500/6750; sens 23.2%; spec 90.3%; ppv 75.0%; npv 48.4%; diag acc: 53%; opt. cut-off: 6620.
Conclusion: The fecal biomarker show sufficient correlation and diagnostic accuracy outperforming CRP and WBC when compared to histology. Only fecal Lactoferrin shows median above the predefined cut-off in histologically active inflammation.

P0944 ENDOSCOPIC SURVEILLANCE OF COLITIS IN A DISTRICT GENERAL HOSPITAL

J. Greenland[1], B. Javaid[1]
[1]*Bedford Hospital, Bedford, United Kingdom*

Contact E-mail Address: julia.c.greenland@gmail.com
Introduction: The British Society of Gastroenterology (BSG) recommends 2-4 biopsies from every 10cm of the colon in patients undergoing colonoscopy for surveillance in patients with inflammatory bowel disease (IBD) (1). The timing of follow-up surveillance colonoscopies should be based on the risk group determined in part by macroscopic findings.
Aims & Methods: 1. To establish compliance with BSG Guidelines for IBD endoscopic surveillance in a district general hospital. 2. To conduct a questionnaire regarding IBD surveillance to direct an improvement in the service.
All endoscopy reports between 1999 and January 2015 coded as ''IBD surveillance'' were reviewed. The total number of biopsies taken in each procedure and the number of individual sites biopsied throughout the colon was recorded. This was compared to a target of a minimum of 2 biopsies at 6 sites (total of 12 biopsies). The number of colonoscopies which met this target was recorded.
Secondly, the endoscopy report was reviewed. The patients were separated into low, intermediate and high-risk groups according to the macroscopic findings. The time until their next surveillance endoscopy was recorded and compared to the BSG guidelines for each risk group.
Once the results of the above analysis were established, a questionnaire was designed to explore the reasons behind any failings in the service by asking endoscopists a number of questions.
Results: A total of 278 colonoscopies involving 108 patients were reviewed. The mean total number of biopsies taken was 11.05, and the mean number of sites biopsied was 3.28. Out of the colonoscopies reviewed, 46 out of 278 (17%), met the BSG target for biopsies.
Of the 278 colonoscopies, 55 (20%) were higher risk, 92 (33%) intermediate and 130 (47%) were lower risk. One patient had unknown category. For each colonoscopy, the number of years until the next screening colonoscopy was calculated. This was compared to the BSG target for follow up. 79% met the target year according to risk group. Of note, if the intended date for the next surveillance colonoscopy was after January 2015, the target was said to have been met.
A questionnaire was sent to 12 endoscopists and replies were received from 8. All that replied were aware of the guidelines and agreed with their importance. Time pressure was thought to play a role in failure to meet biopsy targets, with an average score of 2, where a score of 5 indicates that time pressure always plays a role.

There was also a unanimous agreement that a centralised computer database to ensure timely follow up would be beneficial. Other suggestions for service improvement included the use of pan-colonic dye spray, designated surveillance endoscopy lists and a printed version of the protocol on request cards.
Conclusion: Currently our hospital is not meeting the BSG target for IBD surveillance colonoscopies, with a failure to take adequate numbers of biopsies. The opinions of the endoscopists suggest that this is in part due to time pressure, and there could be a role for pan-colonic dye spray, which is not routinely used in our hospital presently.
The hospital is more successful in arranging appropriate follow up colonoscopies. However, there is room for improvement in the service. Feedback suggests that this could be carried out using a computerised database.

Introduction: The EuroQol (EQ)-5D-5L is a generic instrument measuring health-related quality of life that correlates with disease activity. We have previously described a high agreement between the simple clinical colitis activity index (SCCAI) self-administered by UC patients from home through an online tool with that administered in-clinic by the physician (1). Our aim was to measure which level of disease activity has an impact on QoL in patients with UC.
Aims & Methods: Patients were followed-up for 6 months. At month 3 and 6, they completed the SCCAI at home through a website(CRONICA tool), and thereafter (<48 hours later) the EQ-5D-5L at a visit in which SCCAI was also completed onsite by gastroenterologist, who was blinded to patient's score. EQ-5D-5L was analyzed as an index value according to the prespecified values for Spanish population with value 1 indicating the best health status and -0.652 the worst. SCCAI scores were analyzed as a continuous variable(from 0 to 19). Spearman's Rho correlation coefficients were used to assess the correlation between EQ5D-5L and SCCAI measured by patients online and by physician in clinic.
Results: 199 patients (mean age: 39 years [SD 11]; min: 18; max: 67, 55.8% women), contributed with 330 pairs of online completed SCCAI - EQ-5D-5L questionnaires and with 337 pairs of physician SCCAI - EQ-5D-5L questionnaires. The correlation between patients online completed self-administered SCCAI with EQ-5D-5L was moderate (Spearman's Rho correlation coefficient: 0.49 [$p < 0.001$]) and similar to that between the SCCAI assessed by the physician in-clinic and the EQ-5D-5L (Spearman's Rho: 0.53 [$p < 0.001$]).The correlations between the EQ-5D-5L scores versus the SCCAI scores were all consistent, with a lower SCCAI score corresponding to a higher EQ 5D-5L index, and approximately linear, both when comparing patient online completed SCCAI and SCCAI assessed by the physician in-clinic. (Table 1) An increase on EQ 5D-5L was already observed with a SCCAI of 2, which commonly is considered as remission.Relationship between the EQ-5D-5L and the SCCAI score measured by patients online or by physicians in the clinic.

EQ 5D-5L total Patient online SCCAI	Mean	SD	Physician in- clinic SCCAI	Mean	SD
0	0.96	0.11	0	0.97	0.05
1	0.95	0.08	1	0.93	0.13
2	0.90	0.09	2	0.88	0.13
3	0.89	0.13	3	0.87	0.14
4	0.87	0.12	4	0.84	0.13
5	0.83	0.15	5	0.83	0.12
6	0.80	0.16	6	0.75	0.17
7	0.85	0.12	7	0.79	0.15
8	0.84	0.23	8	0.56	0.26
9	0.71	0.02	9	0.91	0.01
Total	0.90	0.13	Total	0.90	0.13

Conclusion: In the CRONICA-UC study, QoL measured by the EQ-5D-5L questionnaire is affected proportionally with disease activity. Mild symptoms that are categorized as remission have an impact in QoL. This observation calls for a complete control of all symptoms in patients with UC as a requisite to obtain maximal improvement in QoL.

Introduction: Collagenous colitis (CC) often results from the use of proton pump inhibitors (PPIs) in Japan. Non-steroid anti-inflammatory drugs (NSAIDs) or selective serotonin reuptake inhibitors (SSRIs) have also been reported as trigger drugs, but less frequently. Recently, sporadic cases of CC without chronic diarrhea, that were only suspected from endoscopic findings and confirmed by histopathological examination, have been reported.
Aims & Methods: We examined the medication history, endoscopic findings, and clinical features of 93 patients who had been diagnosed with CC at our hospital and joint research institutions.
Results: The mean age of patients was 70.2 years, of which 30 were male and 63 female. Seventy-three patients (78.5%) had a history of PPI treatment. For the remaining 20 patients (21.5%) not administered PPIs, trigger drugs were NSAID in 11, SSRI in 2, and ticlopidine in 1, although a relation of CC to drugs was unknown in 6 patients. Longitudinal ulcers that were characteristic of lansoprazole (LPZ)-induced CC were observed in 20 (29.0%) of 69 patients diagnosed with LPZ-induced CC. An NSAID was concomitantly used in 11 out of these 20 patients. Four patients with longitudinal ulcers had no history of LPZ, including 2 and 1 patient with CC triggered by an NSAID and SSRI, respectively (the trigger drug was unknown in 1 patient). Six patients had no diarrheal symptoms, including 2 with severe abdominal pain and 4 with no symptom of CC. All these 6 patients had longitudinal ulcers detected on endoscopy and were diagnosed with CC on histopathological examination of biopsy specimen.
Conclusion: PPIs are recognized as being the most common trigger drugs for development of CC in the vast majority of patients in Japan. However, this study revealed other drugs to be also involved in about 20% cases. Some patients had CC without chronic diarrhea. In these cases, CC was suspected only from longitudinal ulcers found on endoscopy, which were later confirmed by histopathological examination. Our study suggests that CC is liable to be overlooked

Abstract number: P0947
Table 1: Diagnostic accuracy of POCUS compared to Endoscopy, radiologist performed Ultrasound (US), Computed Tomography (CT), and Magnetic Resonance (MR)

	Endoscopy	US	CT	MR
Sensitivity %(CI %)	89.66 (71.50 -97.29)	96.15 (78.42-99.80)	90.91 (57.12-99.52)	88.89 (51.75- 99.72)
Specificity %(CI %)	81.48 (61.25-92.97)	100.00 (59.78-100.00)	100.00 (31.00-100.00)	100.00 (39.76-100.00)
PPV %(CI %)	83.87 (65.53-93.91)	100.00 (83.42-100.00)	100.00 (65.55-100.00)	100.00 (63.06-100.00)
NPV %(CI %)	88.00 (67.66-96.85)	88.89 (50.67-99.42)	75.00 (21.94-98.68)	80.00 (28.36-99.49)

in patients who have only minor endoscopic findings or those not investigated by endoscopic examination.
Our study highlights the need for reviewing the clinical protocols and diagnostic criteria for CC, as asymptomatic CC or cases with only acute abdominal pain and no chronic diarrhea, may be overlooked if the existing diagnostic criteria for CC are followed

Introduction: Inflammatory bowel disease (IBD) is characterized by periods of disease activity not always reflected by clinical symptoms, interposed with quiescence. Early and appropriate medical intervention aimed to control disease can reduce disease progression and mitigate complications that may result in surgery and hospitalization. Ultrasound (US) is a favorable monitoring strategy, as it is safe, accurate, non-invasive, repeatable and inexpensive. In North America, computed tomography (CT) and magnetic resonance (MR) are preferred imaging modalities to monitor IBD, with limited access to US. Gastroenterologists can accurately perform bedside ultrasound during routine clinic visits for monitoring disease activity and thus facilitate early medical intervention.
Aims & Methods: The aim of this single-centre, prospective study was to evaluate the accuracy of point of care ultrasound (POCUS) performed to detect disease activity in patients with established IBD, relative to gold standard, ileocolonoscopy as well as cross-sectional imaging modalities MR/ MR Enterography, US and CT/CTE. A trained gastroenterologist performed POCUS followed by standard of care monitoring with any of the above modalities, within 3 months. Disease activity was based on presence of increased bowel wall thickness, presence of mesenteric inflammatory fat and lymph nodes, and/or blood flow as seen by color Doppler. Sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV) with 95% confidence intervals (CI) were calculated for each comparator modality.
Results: A total of 117 patients were included with 56 (48%) endoscopies, 14 (12%) CT, 34 (29%) US, and 13 (11%) MR completed within 3 months of POCUS examination. The average age was 42.7 years, 72 were female and 45 male. The accuracy of POCUS in detecting disease activity was high, with minimum sensitivity, specificity, PPV and NPV of 88.89%, 81.48%, 83.87%, and 75.0% respectively, found in all comparisons (Table 1).
Conclusion: Gastroenterologists can accurately perform bedside US during clinic to detect inflammatory activity in established IBD patients. POCUS may be an effective tool to guide early, goal directed management for these patients.

Contact E-mail Address: laura.cantoro@hotmail.it
Introduction: Disease heterogeneity, according to age of onset, may be observed in Crohn's disease (CD). The prevalence of CD is increasing worldwide. Although the peak incidence is between the second and fourth decade of life, we are observing a significant growth in the number of patients presenting at diagnosis more than 60 or less than 17 years. These ages represent the most critical ones when evaluating the risks and benefits of treatment choices and little is known about their disease history.
Aims & Methods: The aim of the present study was to compare CD phenotype at diagnosis and disease course in diagnosed patients ≤ 17 years (early) and ≥ 60 years (late). Cases included all CD patients diagnosed ≤ 17 years and ≥ 60 years with follow-up > 2 years, recorded in the registry of two IBD referral Centres in Rome. Data reported at diagnosis included gender, smoking habits, IBD family history, IBD location and CD behavior, according to the Montreal classification, extraintestinal manifestations and medical/surgical treatments performed during the follow-up period. Statistical analysis: Chi-squared test, Kaplan-Meier survival method.
Results: Of the entire cohort of 2321 CD, 160 patients met criteria for the inclusion in the study: 92 in the early-onset (EO) and 68 in the late-onset (LO) group. The median follow-up was 10 years (range 2- 34 years). A family history of IBD occurred more frequently in EO compared to LO (26% vs 4%; $p < 0.0007$). Ileocolonic location, upper gastrointestinal involvement and perianal disease occurred more frequently in EO compared to LO (56% vs 21% $p < 0.0001$; 17% vs 3% $p < 0.009$; 38% vs 19% $p < 0.01$ respectively). Disease behavior at diagnosis was inflammatory in approximately 60% in both group, however progression to complicated disease during follow-up occurred more frequently in EO (40% vs 10% $p < 0.002$). Compared to LO, EO had increased need for steroids and anti-tumor necrosis factor (TNF) alpha during the first two years from diagnosis (41% vs 6%, $p < 0.003$ and 15% vs 4%, $p < 0.05$ respectively). The cumulative probability of receiving steroids, immunosuppressant and anti-TNF alpha within 10 years from diagnosis in EO and LO was 81% and 58% ($p = 0.004$), 58% and 35% ($p = 0.04$), 36% and 16% ($p = 0.01$) respectively. There was no significant difference between the two groups regarding the cumulative probability of surgery within 10 years.
Conclusion: At our knowledge, this is the first Italian study on clinical presentation and course of CD according to age of onset. Our data are consistent with the literature being ileocolonic location and greater proportion of complicated behavior more common in EO CD. The course of disease in LO CD is more stable and less aggressive than EO CD and should be taken into account when discussing therapeutic choices.

Contact E-mail Address: laura.cantoro@hotmail.it
Introduction: The diagnosis of inflammatory bowel disease (IBD) continues to present difficulties due to unspecific symptoms and limited test accuracies. Therefore IBD patients are still under-diagnosed or diagnosed with serious delay. Diagnostic delay, particularly in Crohn's disease (CD), seems to have an important clinical impact
Aims & Methods: The aim of our study was to examine whether diagnostic delay in IBD has changed over the last thirty-three years and to investigate its correlation with CD phenotype and Ulcerative Colitis (UC) location at diagnosis. Cases included all IBD patients recorded in the registry of four IBD referral Centres in Italy. Diagnostic delay was calculated from the onset of the symptoms indicative of CD or UC to the definitive diagnosis. Data reported included date of birth, gender, IBD location and CD behavior at diagnosis, according to the Montreal classification.
Results: Of 3393 IBD patients, 2499 (74%) had a diagnostic delay ≥ 1 month, 1046 (31%) ≥ 12 month. Median diagnostic delay was 3 months, interquartile range (IQR) 0 to 13 (7 months in CD, IQR 1 to 25 and 2 months in UC, IQR 0 to 7). Mean diagnostic delay was 19, standard deviation (SD) 45, (significantly higher in CD than UC, 29 vs 11 months, SD 54 vs 34, $p < 0.0005$). In CD, mean diagnostic delay was higher in patients with penetrating/stricturing behavior at diagnosis ($n = 870$) compared to patients with inflammatory behavior at diagnosis ($n = 667$), (32 vs 23 months, SD 49 vs 57, $p < 0.0005$). 242 patients were diagnosed between 1952-1979 (historical cohort), while 3151 were diagnosed between 1980 and 2013 (modern cohort). Mean diagnostic delay was significantly higher in the historical cohort in comparison to the modern cohort (31 vs 18 months, SD 58 vs 44, $p < 0.0005$). IBD patients belonging to the modern cohort were stratified according to the time of diagnosis into three subgroups diagnosis (1980-89, 1990-99, 2000-13). There was no significant difference in the mean diagnostic delay between the three periods (18, 17 and 19 months, SD 41,37 and 50 respectively). Mean diagnostic delay in CD of modern cohort is significantly higher in the subgroup of patients ≥ 40 years at diagnosis(A3) in comparison to patients ≤ 40 years, 39(SD 74) vs 20(SD 33) months, $p < 0.001$. No significant difference was found in the mean diagnostic delay according to gender or disease location at diagnosis. No significant difference was found in the mean diagnostic delay according to gender or disease location at diagnosis.
Conclusion: Diagnostic delay in IBD was significantly decreased in recent years (1980-2013) in comparison to the past (1952-1979), however it did not change over the last thirty-three years, despite increasing the diagnostic tools. Compared with UC, diagnostic delay is higher in CD especially in penetrating/stricturing phenotype at diagnosis or age at diagnosis higher than 40 years.

P0950 IN-VIVO AXIAL-STRAIN SONOELASTOGRAPHY HELPS DISTINGUISH ACUTELY-INFLAMED FROM FIBROTIC TERMINAL ILEUM STRICTURES IN PATIENTS WITH CROHN'S DISEASE

L. M. Sconfienza[1], **L. C. Pescatori**[1], F. Cavallaro[2], G. E. Tontini[2], L. Pastorelli[3], M. Vecchi[2], F. Sardanelli[1]
[1]*Radiology,* [2]*Gastroenterology,* [3]*IRCCS Policlinico San Donato, San Donato Milanese, Italy*

Contact E-mail Address: lorenzo.carlo.pescatori@gmail.com
Introduction: A number of radiological examinations are available to evaluate the terminal ileum, all with different accuracy in detecting ileal stenosis. A critical issue, however, is the possibility of differentiating inflammatory from fibrotic strictures in patients affected by terminal ileum Crohn's Disease.
Aims & Methods: To ascertain whether RTS could *in-vivo* differentiate fibrotic from inflammatory terminal ileum strictures in patients with Crohn's disease, using magnetic resonance enterography (MRE) as a reference standard, 13 patients (10m,3f; median[interquartile interval]age = 40[33-48]years; median C-reactive protein (CRP) = 0.9[0-1.8]mg/dl; median disease duration = 46[29-205]months; median Harvey-Bradshaw Index (HSI) = 3[2.75-5.25]) affected by terminal ileum Crohn's disease were prospectively included. Patients underwent MRE, evaluating T2 hyperintensity, perivisceritis, transmural contrast uptake. RTS was performed on terminal ileum. Short-axis scans were performed, each cross-section was ideally subdivided into eight circular sectors. Colour map provided by RTS was translated into a semiquantitative scale (1 = red; 2 = green; 3 = blue).

Results: At MRE, T2 hyperintensity was seen in 7 patients, perivisceritis in 7, contrast uptake in 7. Accordingly, 7 patients were classified as having an inflammatory stricture and 6 a fibrotic one. Total median RTS score was significantly lower in patients with inflammatory stricture (16[14-16]) than that (19[18-20.75]) in patients with fibrosis ($P = 0.002$). The same result was found when the four most superficial quadrants of the loop were considered (7[6-7]vs.10[9.25-10]; $P = 0.003$). No significant correlation was seen between RTS-HSI ($r = -0.153$; $P = 0.635$), RTS-CRP ($r = 0.362$; $P = 0.247$), RTS-disease duration ($r = 0.224$; $P = 0.483$).
Conclusion: RTS is a promising imaging modality to differentiate *in-vivo* inflammatory from fibrotic terminal ileum strictures in patients with Crohn's disease.

Contact E-mail Address: laterza.lucrezia@gmail.com
Introduction: Mucosal healing (MH) is a potential target in the treatment of patients with ulcerative colitis (UC), reducing the need for surgery and the risk of colorectal cancer. MH lowers the risk of disease reactivation, but some patients relapse in spite of the presence of MH. It is reasonable to think that the microscopic disease activity beyond MH could explain these cases.
Aims & Methods: Our aim is to assess how many patients with MH have a microscopic disease activity and what kind of lesions are associated with mid-term n (after 6 and 12 months).
Our aim is to assess how many patients with MH have a microscopic disease activity and what kind of lesions are associated with mid-term reactivation (after 6 and 12 months).
We retrospectively enrolled UC patients showing MH, expressed as Mayo 0 at colonoscopy, and undergone multiple biopsies during the same exam. We reviewed the corresponding histological lesions evaluating the presence of the typical histological lesions associated with UC, such as acute or chronic inflammatory infiltrate, basal plasmacytosis, basal lymphoid aggregates, stromal changes, lamina propria eosinophils, crypt branching, crypt distortion, crypt atrophy/depletion, cryptitis, crypt abscesses, surface irregularity, mucin depletion, erosions and Paneth cell metaplasia. We evaluated the number of clinical reactivation 6 and 12 months after baseline colonoscopy.
Results: Among 63 enrolled patients, only 2 showed no histological lesions. The most common lesion was chronic inflammatory infiltrate (81%) followed by basal lymphoid aggregates (60%), acute inflammatory infiltrate (46%) and crypt distortion (33%). After 6 and 12 months, 14% and 22% of patients relapsed, respectively. The most prevalent lesion in patients relapsing after 6 months was chronic inflammatory infiltrate (100% of relapsers vs 76% of non-relapser), followed by acute inflammatory infiltrate (63% vs 40%), basal lymphoid aggregates (63% vs 62%), basal plasmacytosis (50% vs 12%, $p < 0.05$) and lamina propria eosinophils (50% vs 10%, $p < 0.05$). After 12 months, chronic inflammatory infiltrate was found in 90% of relapsers vs 83% of non-relapsers, basal lymphoid aggregates in 70% vs 53% and acute inflammatory infiltrate in 50% vs 44%, basal plasmacytosis (50% vs 8%, $p < 0.05$) and lamina propria eosinophils (40% vs 11%, $p < 0.05$), respectively.
Conclusion: A microscopic disease activity persists in the major part of patients with MH. Basal plasmacytosis and lamina propria eosinophils are more frequent in patients with disease reactivation after 6 and 12 months.

Introduction: Therapeutic drug monitoring is claimed to be an important tool in tailoring infliximab therapy to the clinical status of inflammatory bowel disease (IBD) patients. However, cut-off values for infliximab trough levels (TL) and anti-drug antibodies (ATI) need to be established for each assay method and validated in the clinical setting.
Aims & Methods: Aim of our study was to evaluate infliximab TL and ATI in patients losing response and to identify cut-off values after drug optimization, which could be significantly related to clinical outcomes at one year. We studied 71 IBD patients, 42 affected by Crohn's disease (CD) and 29 by ulcerative colitis (UC). They were on maintenance treatment with infliximab after initial response to the induction course and had experienced a loss of response defined as worsening of clinical symptoms and rise in CRP or evidence of endoscopic disease activity. We collected blood for assay of trough levels and antibodies to infliximab by ELISA method (LisaTracker-Duo Infliximab, Theradiag, Marne-la-Vallée, France). According to manufacturer instructions, levels of detection were 0.1 μg/ml for TL and 10 ng/ml for ATI. We recorded clinical status and CRP levels after drug optimization (dose increase and/or interval shortening), after six months and after one year. All TL and ATI determinations were performed in a single laboratory session and the clinicians were blinded to the results, which did not influence the clinical decisions.
Results: Of the 71 IBD patients, 15 (21%) were on concomitant treatment with azathioprine/6MP and 55 (77%) were studied after infliximab optimization. Clinical follow-up at 12 months was available for 49 of them. ATI were detected in 26/71 patients (36%) while TL were undetectable in 13/71 (17%). ATI and TL were negatively correlated (Spearman's rho -0.53, $p = 0.0001$). By ROC analysis we found that achieving a TL > 4.05 μg/ml after optimization was predictive of clinical response after 12 months (AUC 0.648, sensitivity 60%, specificity 75%, $p = 0.05$). The same cut-off was predictive of normal CRP both after 6 months (AUC 0.652, sensitivity 59%, specificity 77%, $p = 0.05$) and after 12 months (AUC 0.677, sensitivity 59%, specificity 80%, $p = 0.02$). The presence of ATI levels > 11 ng/ml was predictive of high CRP at 6 months (AUC 0.653, sensitivity 48%, specificity 82%, $p = 0.029$).
Conclusion: Monitoring infliximab TL after dose optimization and/or interval shortening for loss of response could help in predicting those patients that will display a clinical and biological (CRP) response in the following year. Further prospective studies will clarify if applying treatment algorithms based on therapeutic drug monitoring will reveal as cost-effective in IBD.

Contact E-mail Address: lukasbajer1@gmail.com
Introduction: Primary sclerosing cholangitis (PSC) is a progressive disease of the biliary tree characterised by inflammation, fibrosis and stenoses, and often associated with ulcerative colitis (UC); condition characterized by leaky gut. However, UC associated with PSC (''PSC – UC'' or ''PSC – IBD'') is described as a phenotype distinct from the conventional UC. Our aim was to compare serum levels of biomarkers of gut barrier damage in PSC-UC, UC and healthy subjects.
Aims & Methods: We used ELISA to analyze intestinal fatty acids binding protein (I-FABP) and caspase-cleaved keratin 18 (ccK18) in 74 individuals (38 with PSC, 19 with UC, 17 healthy controls) and 38 individuals (23 with PSC, 9 with UC, 6 healthy controls), respectively. Furthermore, we compared the levels of either biomarker with standard clinical (e.g. colitis extent and severity) and laboratory parameters (CRP, AST, ALT, ALP, GGT, INR).
Results: There is no significant difference between PSC-UC, UC and healthy subjects in I-FABP [median (IQR)] 503.9 (0.0 - 1548.0), 454.1 (0.0 - 747.3), 769.3 (220.9 - 1027.0) or ccK18 [median (IQR)] 174.1 (99.93 - 423.0), 90.08 (67.46 - 205.9), 98.7 (51.05 - 174.7). When the liver involvement is disregarded, I-FABP have a tendency to be higher in patients with pancolitis as compared with patients with partial colon involvement ($p = 0.07$). There is no statistically significant difference in serum I-FABP or ccK18 depending on colitis severity (without colitis, remission, mild, moderate and severe).
Conclusion: Neither I-FABP, nor ccK18 differs between PSC-UC and UC. In patients with pancolitis, I-FABP has a tendency to be higher compared to patients with smaller extent of colitis.

P0954 EFFICACY OF LOW DOSE CT FOR EVALUATION OF DISEASE ACTIVITY IN ULCERATIVE COLITIS

M. Shiraki[1]
[1]*Department of Gastroenterology, Tohoku Rosai Hospital, Sendai, Japan*

Contact E-mail Address: sankara@qf6.so-net.ne.jp
Introduction: It is important to assess the disease activity and extent of involvement in ulcerative colitis patient. Endoscopic examination, however, carries a risk of perforation of the colon often requiring surgery because of mucosal vulnerability, especially in patients with ulcerative colitis relapsing. Recently, it has been reported that cross-sectional imaging techniques can be used as a diagnostic tool for the evaluation of inflammatory bowel disease, nevertheless, there have been few reports on the efficacy of low dose CT for ulcerative colitis. We report here the efficacy of low-dose CT for ulcerative colitis during active period.
Aims & Methods: The purpose of this study is to investigate the diagnostic performance of low-dose CT for evaluation of disease activity in ulcerative colitis patient. The patients with relapsing ulcerative colitis between July 2013 and April 2014 were included in this study. All patients had undergone sigmoidoscopy and low-dose CT scan with the weight-based intravenous contrast protocol. The colon CT image was divided into six segments: rectum, sigmoid colon, descending colon, transverse colon, ascending colon, and caecum, then we evaluated wall thickening, stratification, contrast enhancement and mesenteric vascular

engorgement, assigning a CT score to each segment. Further, we calculate a total CT score by the sum of CT scores of 6 segments. To assess endoscopic severity, Ulcerative Colitis Colonoscopic Index of Severity (UCCIS) was used. All patients were interviewed before examination to calculate Mayo partial score to assess the clinical severity. We investigated the correlation between those CT scores and UCCIS. The correlation between partial Mayo score and total CT score also investigated. For the correlation analysis, the Spearman rank correlation analysis was used. For comparison between two groups we used the Mann-Whitney U test.
Results: Twenty three cases of ulcerative colitis were included in this study. We achieved a 62.3 % reduction of radiation exposure by adjusting the scan conditions and reconstruction conditions ($P < 0.00326$). The average partial Mayo score of the cases was 4.4 ± 2.0. We observed a high degree of correlation between the sum of the CT scores of the rectum and sigmoid colon and the sum of the UCCIS of the rectum and sigmoid colon ($\rho = 0.629$). Although the UCCIS of the rectum and sigmoid colon segment calculated by sigmoidoscopy and partial Mayo scores did correlate ($\rho = 0.456$), the correlation between the total CT score showed better correlation with the partial Mayo score ($\rho = 0.643$).
Conclusion: The endoscopic examination is important for evaluate disease severity in ulcerative colitis relapsing; however, it is often difficult to perform total colonoscopy due to mucosal vulnerability. On the other hand, CT can provide diagnostic images without preparation or invasiveness. This study suggested that low-dose CT could provide more effective images to assess the disease activity of ulcerative colitis compared with sigmoidoscopy.

Introduction: The exact role of gut microbiota on the etiopathogenesis of IBD, both Crohn's disease (CD) and ulcerative colitis (UC), is not well known. Most studies of human gut microbiota rely on the non-invasive collection of stool samples. However, the analysis of the fecal microbiota may not reflect the role of the mucosa-associated microbes which live in close proximity to the intestinal epithelium and that are in contact with the cells of the innate immune system directly involved in the inflammatory response.
Aims & Methods: The aim of this study was to investigate the genotypes of Bacteroidetes microbiota from colon biopsies of IBD patients and to determine their relationship with the endoscopic activity of the disease.
Methods: A prospective case-control study was designed. Colon biopsies from consecutive IBD patients and healthy controls (HC) (healthy subjects undergoing colonoscopy for colon cancer screening and having a healthy colon mucosa) were included. Inactive UC was defined as a Mayo endoscopic subscore of 0. Inactive CD was defined as a SES-CD score ≤ 2. Microbiota was characterized by using a restriction fragment length polymorphism (RFLP) analysis on PCR products targeting the 16SrRNA genes of Bacteroidetes digested with *Hinf*I, *Pci*I, *Dpn*II and *Aci*I. RFLP and sequencing analysis indicated that a a total of 8 genotypes of Bacteroidetes called N1 and C1-C7 (of which N1 genotype is probably a strain of *Bacteroides dorei* and C1, and maybe C2, strains of *B. vulgatus*) were detected in all the biopsy samples analyzed. Results are shown as percentages.
Results: 53 consecutive IBD patients (24 UC and 29 CD) and 20 HC were included. 8 patients presented inactive UC (iUC) and 16 active UC (aUC). In addition, 21 CD patients presented active CD (aCD) and 8 inactive CD (iCD). The number of genotypes present in biopsies from IBD patients was higher than in HC, in whom only the N1 (58%) and C1 (42%) genotypes appear. While the presence of N1 genotypes was relatively constant in patients with active CD and active/inactive UC, the percentage of C1 genotype in these patients was low (between 20% and 26%) compared to HC and iUC (51%). The C4 genotype never appeared in control samples and it was present in only 4% of iUC and iCD biopsies, whereas it was present in 13% and 14% of patients with aUC and aCD respectively. Moreover, C3 genotype was higher in iUC (8%) than with aUC (3%) and CD (3% with active and inactive patients). The C2, C3, C5, C6 and C7 genotypes appeared sporadically in biopsies of IBD but never in HC.
Conclusion: Bacteroidetes genotypes in colon biopsies differ between IBD patients and HC. These genotypes, and especially the C4 genotype, may be used as biomarkers for improving the diagnosis of CD and UC, as well as to investigate their potential role in pathogenesis.

Introduction: Glycoprotein 2 (GP2) and CUB zona pellucida-like domain 1 (CUZD1) belong to protein families involved in gut innate immunity processes and have recently been identified as a specific target of anti-pancreatic autoantibodies (PAbs) in Crohn's disease(CD). The aim of the present study was to determine the predictive potential of novel target specific PAbs regarding determination of disease phenotype, therapeutic strategy and long-term disease course in a prospective referral adult CD patient cohort.
Aims & Methods: Sera of 458 consecutive well-characterized IBD patients (CD: 271 and UC: 187) from a single referral IBD center and 100 healthy subjects were tested by enzyme-linked immunosorbent assay (ELISA) with isoform 4 of recombinant GP2 (anti-MZGP2 and anti-GP2 IgA/IgG) and indirect immunofluorescence test (IIFT) system with GP2 or CUZD1 expressing transfected HEK 293 cells (anti-rPAg2 and rPAg1 IgA/IgG). Clinical data were available on evolvement of complicated disease or surgical interventions as well as disease activity and medical treatment during the prospective follow-up (median, [IQR]: 108 months [65-178]).
Results: 12.4% and 20.8% of CD patients were positive for IgA/IgG type of anti-GP2 and anti-CUZD1, respectively, with a significant difference compared to UC and controls ($p < 0.01$ for both). PAb status was not associated with actual disease activity and showed long-term stability. Agreement among three different anti-GP2 assays was good (kappa: 0.44-0.70). At diagnosis, 45% of the patients had ileocolonic disease and 79.7% had inflammatory behavior, while 52% had complicated disease behavior, 35.1% had perianal disease and 41.1% had at least one resective surgery at last follow-up. Clinical associations were different for anti-GP2 and anti-CUZD1 antibodies. Presence of different anti-GP2 antibodies was associated with pediatric onset ($p = 0.012$), ileal involvement ($p = 0.032$), stenosing ($p = 0.017$) and penetrating ($p = 0.028$) disease behavior at diagnosis and PSC ($p = 0.038$). In contrast, presence of anti-CUZD1 was associated with colonic involvement ($p = 0.041$) and cutaneous manifestations ($p = 0.044$). In a group of patients with pure inflammatory luminal disease at time of the diagnosis, positivity for PAbs, mainly IgA subtypes, predicted a faster progression towards complicated disease course in time-dependent models. In Kaplan-Meier analysis, time to surgery or development of perianal disease was associated with anti-GP2 IgA ($pLogRank < 0.01$) or anti-CUZD1 IgA ($pLogRank < 0.001$) positivity, respectively. Anti-CUZD1 IgA remained an independent predictor in multivariate Cox-regression model including age at diagnosis, sex, disease location and behavior and frequent relapse as potential confounders (HR: 3.43, 95%CI: 1.68–7.02, $p < 0.001$).
Conclusion: The present prospective follow-up study has shown that specific PAbs (especially IgA subtype) are predicting complicated disease course including the development of perianal disease in CD.
Disclosure of Interest: None declared

P0957 RISK MATRIX FOR PREDICTION OF DISEASE PROGRESSION IN A REFERRAL COHORT OF PATIENTS WITH CROHN'S DISEASE

P. L. Lakatos[1], N. Sipeki[2], G. L. Norman[3], Z. Shums[3], P. Antal-Szalmas[4], G. Veres[5], **M. Papp**[2]

Contact E-mail Address: papp.maria@med.unideb.hu
Introduction: Early identification of patients with Crohn's disease (CD) at risk for subsequent complications is essential for adapting treatment strategy. The aim of the present study was to develop a prediction model including clinical and serology markers for assessing the probability of developing advanced disease 3, 5 and 7 years after diagnosis in a prospective referral CD cohort.
Aims & Methods: 271 consecutive CD patients (42.4% males, median follow-up: 10.9 years) were included. ASCA IgA and IgG and anti-OMP Plus™ IgA antibodies were determined by QUANTA Lite® ELISA (Inova Diagnostics, San Diego, CA), cut-off 25 U/ml. Detailed clinical phenotypes were determined prospectively from diagnosis during the follow-up by reviewing the patients' medical charts. The analysis was limited to patients with inflammatory disease behaviour at diagnosis. Total exposure to steroids, azathioprine or anti-TNFs were 88.2%, 73.8% and 41.7%, respectively. At diagnosis, 45% had ileocolonic disease and 79.7% had inflammatory behaviour, while 52% had complicated disease behaviour and 41.1% had at least one resective surgery at last follow-up. Two definitions were used for advanced disease: 1.) having intestinal resection or progression in disease behaviour and 2.) having intestinal resection, progression in disease behaviour, or need for thiopurines (IBSEN definition).

Results: ASCA IgA and/or IgG (but not anti-OMP Plus IgA status), disease location, and need for early azathioprine were included in the 5-year prediction matrix. The probabilities of advanced disease during this period varied from 6.2% to 55% depending on the combination of predictors. The 3- and 7-year ASCA-based model resulted in probabilities of advanced disease ranging from 0 to 45.5% and from 11.1% to 64.7%. In addition, the model including ASCA, disease location, and early need for steroids but not age at onset, was only predictive for the outcome at 5-years if the IBSEN definition was used. In contrast, the association was lost if the need for azathioprine was excluded from the advanced disease definition. Similar findings were obtained from in a Cox regression analysis, the combination of ASCA, location and early azathioprine was associated with the probability to develop advanced disease (pLogRank < 0.001), while the original model combining ASCA, early steroids and location failed to predict disease progression.

Probability of developing advanced disease 5-years after the diagnosis in patients with initial inflammatory disease based on association between ASCA IgA and IgG positivity, disease location and need for early azathioprine (AZA).

B1 behavior at diagnosis		colon only	ileal
ASCA positive	early AZA YES	50.0%	55.0%
	early AZA NO	30.8%	29.0%
ASCA negative	early AZA YES	11.1%	22.2%
	early AZA NO	6.2%	18.8%

Conclusion: Our prediction models identified substantial differences in the probability of developing advanced disease in the short and intermediate course of CD. Markers identified in this referral cohort were different from those previously published in the population-based cohort suggesting that different prediction models should be used in referral setting.

Contact E-mail Address: mariaelenaserio@yahoo.it
Introduction: Due to the full thickness involvement of the bowel wall or complications, Crohn's disease (CD) evaluation is the result of an integration of endoscopy (the gold standard) with clinical, laboratory and radiological data. The role of MRI, which excels in identyfing extramural signs of inflammation, is still unclear in CD follow-up. Moreover it is still debated whether CRP serum levels increase is due to mucosal or mural/extramural inflammation, not only via liver production but also from extrahepatic sources such as hypertrophy of the mesenteric fat, a CD common feature.Increased mesenteric fat density assessed by CT was found to correlate with plasma CRP levels in CD patients[1].
Aims & Methods: Aim of this study was to correlate enteric and extraenteric inflammatory MRI findings with endoscopic severity and CRP in a group of CD patients.
52 consecutive patients with endoscopically proven CD underwent MRI enterography for the staging at diagnosis or activity assessment (68/32%). Endoscopic activity was scored through the SES-CD (range 0-40) with active mild, moderate ad severe disease defined as 4-10,11-19 and >20 respectively. MRI activity was scored through the Magnetic Resonance Enterography Global Score (MEGS, range 0-296), which integrates both mural and extramural items, namely lymph node, fistula, abscess and comb sign, with active disease defined as ≥ 1 score. For all participants CDAI was completed and CRP and fecal calprotectin (FC) were also measured (positivity cut-off respectively >0.50mg/dl and >150µg/gr). Fibrofatty proliferation (creeping fat) of the mesentery was qualitatively defined a bowel loop separation ≥ 3 cm.
Results: We enrolled 20M/32F mean age 38 ± 15 ys, mean CD duration 5 ± 5 ys.SES-CD and MEGS correlated well between them and with clinical and biological activity(table). According to SES-CD 62% of patients had mild disease, 19% moderate and 5% severe.Increasing severity at endoscopy was significantly correlated with trasmural/extramural involvement, only with CRP positivity ($p = 0.007$). MRI did not show ability to distinguish endoscopic severity ($p = 0.14$), but revealed trasmural/extramural signs of inflammation in 60% of patients in remission, 84% mild and 100% with moderate and severe disease, mostly with CRP positivity. Moreover CRP positivity was associated with the presence of extraintestinal($p = 0.006$; lymph nodes $p = 0.009$, combsign $p = 0.001$ and abscess $p = 0.005$), not of mural involvement ($p = 0.4$). Mean CRP levels increased according to the number of extramural signs of inflammation (from absence to 4 signs $p = 0.01$), while no correlation was seen with SES-CD severity ($p = 0.7$), phenotype ($p = 0.4$) or mural inflammation ($p = 0.7$). Patients with hypertrophy of mesenteric adipose tissue showed higher levels of CRP than those without (4.2 ± 4 mg/dl vs 1.9 ± 3.2 $p = 0.005$).

	SES-CD	CDAI	CRP	FC
MEGS	$r = 0.42$ $p < 0.001$	$r = 0.59$, $p < 0.001$	$r = 0.43$ $p < 0.005$	$r = 0.27$, $p < 0.01$

(continued)

Continued

	SES-CD	CDAI	CRP	FC
SES-CD		$r = 0.51$, $p < 0.001$	$r = 0.39$ $p < 0.005$	$r = 0.35$, $p < 0.01$

Conclusions: Transmural inflammation, which is more frequent in severe disease, may still be present regardless of endoscopical activity.Positive CRP is significantly correlated to extramural activity in CD patients, thus suggesting the need of MRI for the staging of the disease independently from endoscopic severity. Moreover these data suggest that mesenteric fat may contribute to the increased CRP production.

Contact E-mail Address: lrabagot@gmail.com
Introduction: The loss of response to antiTNFa treatment occurs in about 13-18% of the patients/year. The cost and adverse events of these drugs drugs can make therapeutic monitoring of antiTNFa trough levels an adequate strategy for treatment optimization
Aims & Methods: This is a retrospective multicentric study with 40 IBD patients(pts) -77.5% Crohn disease (CD), 17.5% ulcerative colitis (UC) and 5% of undetermined colitis (IC)- treated with antiTNFa (IFX 52.5% or ADA 47.5%), and 72.5% of pts were also on immunomudulator therapy (IMM). The mean age was 42.5(22-76) with a 50% of female. AntiTNFa trough levels were measured by an **ELISA assays** (Sanquin).The consideration of supratherapeutic levels was made in relation with the range of the Elisa assay. Patients were included in: **Group 1 (57.5%) 23** out of 40 pts with secondary loss of response (**SLR**) to IFX (20pts) or ADA (3pts). **Group 2:** (40%) 16 out of 40 clinically asymptomatic pts on ADA treatment had ADA trough levels monitored per protocol during the follow up, **Group 3** (2.5%,1/40 pts) with mucosal healing.
Results: Group 1: 17.5% pts(4/23) had normal levels, **30%** of pts (7/23) **had supratherapeutic** levels and **52.5**% (12/23) **had low** levels and 25 % of them (3pts) had also detectable antiTNFa antibodies. 78.7% of pts (18 out of 23) of **Group 1** were on **IMM**. 8 out of 23 pts of **Group 1** with **SLR** had not worsening of inflammatory analytical markers 3 out of these 8 pts (37.5%) had low therapeutic levels without intensification of treatment, 2 out of those 8 (25%) had supratherapeutic levels.
Group 2: 31.2 % of pts (5/16) treated with ADA and clinically asymptomatic had supratherapeutic levels, 1 out of those 16 pts was on intensified treatment, 25% of pts (4/16) had low therapeutic levels with 2 pts on intensified therapy and 43.7% (7/16) had normal levels.Therefore we had to perform changes in 28 pts. In order to calculate the treatment-cost we use the standard cost of the different antiTNFa therapies at our hospital, considering if it is the case the price of the induction and the maintenance therapy. The cost of treatment optimization by taking into account the results of antiTNFa trough levels measurement and antibodies to antiTNFa (dose escalation if low levels, switching to another antiTNFa or switching to a different class of biologic agent if therapeutic or supratherapeutic levels) would have been 467127 euro per year for these 28 pts. Had we treated in the classic way without monitoring levels the cost would have been 530369€, So there is a 63000 euro/pt/year of savings (2250 euro per pts/year).
Conclusion: 1º Hardly 17.5 of pts with SLR had normal antiTNFa levels and 30% had high levels that should be changed to a different class of biologic agent. **2 º** Monitoring ADA trough levels during their normal F-U found a 25% of patients over-treated. **3º** 37.5 % of Pts with SLR but without inflammatory analytical markers could be treated with dose escalation until new endoscopic or radiologic studies are performed. **4º** The cost analysis show that monitoring antiTNFa levels is not only an effective way of pts management but also cost effective.

P0960 CONTRAST ENHANCED ENDOSCOPIC ULTRASOUND OF THE COLON IS A MARKER OF EARLY THERAPY RESPONSE FOLLOWING ANTI-TNF-THERAPY IN PATIENTS WITH ACUTE ULCERATIVE COLITIS

M. Ellrichmann[1], J. Bethge[1], A. Arlt[1], S. Zeissig[1], B. Brandt[1], J. Lankau[1], S. Nikolaus[1], S. Schreiber[1], A. Fritscher-Ravens[1]
[1]*Medical Department I, Interdisciplinary Endoscopy, University Hospital Schleswig-Holstein, Campus Kiel, Kiel, Germany*

Contact E-mail Address: mark.ellrichmann@uksh.de

Introduction: Though colonoscopy is an important tool in the evaluation of acute ulcerative colitis (aUC), it is limited to the mucosal surface and therefore exhibits a significant interobserver variability. As shown by our group, endoscopic ultrasound (EUS) of the colonic wall allows exact quantification gut wall with differentiation of the different layers and can therefore accurately quantify the grade of inflammation.

Aims & Methods

Aim: To evaluate EUS in sigmoid colon in patients with aUC undergoing treatment with Anti-TNF-α (adalimumab,(ADA)) for possible detection of early therapy response.

Methods: 36 patients (22m) with aUC and 20 healthy controls (HC)(12m) were examined prior and 1, 4 and 12 weeks after initiation of ADA therapy using a forward-viewing radial echoendoscope (Pentax-Hitachi, Japan). Mucosal, submucosal and total wall-thickness (TWT) were measured by EUS in the mid sigmoid. Vascularity of the gut wall was evaluated by dynamic contrast enhanced EUS (dCEUS) (contrast agent SonoVue). Contrast kinetics were quantified as Time to peak intensity (TTP). Results were compared to 20 healthy controls (HC) undergoing screening colonoscopy. The examiners were blinded to the macroscopic inflammation scores. EUS-results were correlated to the Mayo-score and histological inflammation scores (HIS).

Results: HC showed a TWT of 1.8 ± 0.03mm with clear differentiation of the different layers; TWT increased to 3.91 ± 0.21mm($p < 0.001$) in patients with aUC. In patients with clinical response to ADA therapy (n = 26; 72.2%) TWT was reduced by 27.7% ($TWT_{7d} = 2.5 \pm 0.2$mm; $p = 0.007$) within one week when compared to baseline levels with further reduction after 4 weeks ($TWT_{28d} = 2.2 \pm 0.2$mm).

In patients with non-response to ADA therapy no significant changes of TWT were observed compared to baseline after 7 ($TWT7d = 3.7 \pm 0.4$mm; $p = 0.8$) and 28 days ($TWT_{28d} = 2.9 \pm 0.3$mm; $p = 0.4$) of therapy.

TTP in HC was 13.1 ± 1.3s; in aUC TTP was accelerated to 6.8 ± 0.7s ($p = 0.0005$). In case of response TTP normalized within 1 week ($TTP_{d7} = 9.9 \pm 0.8$s) with $p = 0.008$ compared to baseline. In contrast, hypervascularity remained unchanged in patient without response to ADA therapy ($TTP = 6.6 \pm 0.5$s;$p = 0.9$).

Prior to therapy there was a strong correlation of TWT and Mayo-scores. In contrast, no correlation was observed 1 week after ADA therapy ($p > 0.05$). During the entire course of ADA, a positive relation between TWT and HIS ($r = 0.65$; $p < 0.001$) was seen.

Conclusion: TWT of the sigmoid measured by EUS precisely quantifies the level of inflammation in patients with aUC and proved reliability for the evaluation of early therapy response. It may become an important diagnostic tool for the judgement of mucosal healing in ADA therapy.

P0961 LONG-TERM OUTCOME OF INFLIXIMAB MAINTENANCE TREATMENT FOR JAPANESE PATIENTS WITH CROHN'S DISEASE

H. Tanaka[1], M. Miyakawa[1], M. Nasuno[1], S. Motoya[1]
[1]*IBD Center, Sapporo Kosei General Hospital, Sapporo, Japan*

Contact E-mail Address: hirokit@mtc.biglobe.ne.jp

Introduction: Maintenance treatment with infliximab has enabled achievement of long-term remission in patients with Crohn's disease (CD). However, very few studies have reported on Japanese patients.

Aims & Methods: The aim of this study was to evaluate infliximab maintenance treatment for Japanese patients with CD based on long-term outcomes and related prognostic factors. Retrospective data were collected from luminal CD patients who received the standard treatment of 5 mg/kg infliximab for ≥ 14 weeks between May 2002 and August 2012 at the IBD Center, Sapporo Kosei General Hospital. The effectiveness of infliximab maintenance treatment was evaluated using sustained treatment success rates, which were estimated using the Kaplan–Meier method. Sustained treatment success was defined as a lack of treatment failure. Treatment failure was defined as follows: 1) the discontinuation of infliximab due to loss of response or side effects; 2) the need for dose escalation due to loss of response or 3) the need for abdominal surgery due to CD. Prognostic factors related to sustained treatment success rates were evaluated using log-rank tests and a multivariate Cox regression analysis.

Results: Of the 276 patients included in this study (mean age, 31.2 years), 72 were females. The mean duration of the disease was 7.5 years and the mean C-reactive protein (CRP) level at the first infliximab administration was 2.18 mg/dl. One hundred fifty-two patients had ileocolitis, 68 had ileitis and 56 had colitis. In addition, 111 patients had structuring disease, 36 had intra-abdominal fistulas and 114 had perianal disease. Concomitant treatment with immunomodulators (azathioprine or 6-mercaptopurine), 5-aminosalicylic acid, elemental diet therapy and prednisolone were administered in 197, 245, 194 and 28 patients, respectively. Before initiating infliximab therapy, 96 patients had undergone at least 1 intestinal resection and no patient had had prior use of any other anti-tumour necrosis factor antibodies. The 2-, 4-, 6-, 8- and 10-year sustained treatment success rates were 62%, 50%, 40%, 30% and 30%, respectively. In the univariate analyses, a lower CRP level at the first infliximab administration (<1.00 mg/dl; $P = 0.011$) and concomitant treatment with immunomodulators ($P = 0.016$) were significant prognostic factors for higher sustained treatment success rates. The multivariate Cox regression analysis, both of these factors identified as independent predictors of said success rate.

Conclusion: Among Japanese patients with CD receiving infliximab maintenance treatment over a period of ten years, the treatment failure rate was 70% but could be decreased by combination therapy of infliximab with immunomodulators. Conversely, a higher CRP level at the time of first infliximab administration was a prognostic factor for a poor long-term outcome.

Introduction: Oxidative damage is a central feature of ulcerative colitis. Here we tested whether the antioxidant Mesna, when administered alone or in combination with n-3 polyunsaturated fatty acids (n-3 PUFAs), affects the outcome of Dextran Sodium Sulfate (DSS)-induced ulcerative colitis in rats.

Aims & Methods: After the induction of colitis, DSS-treated rats were further treated orally (p.o), intraperitoneally (i.p) or intrarectally (i.r) for either 7 or 14 days with Mesna, n-3 PUFAs or both. Rats were euthanized at the end of each treatment period. Clinical disease activity index was recorded throughout the experiment. At necropsy, colorectal gross lesions were scored. Colitis was scored histologically and the expression of myeloperoxidase (MPO), caspase-3, inducible nitric oxide synthase (iNOS) and nuclear factor κB (NF-$\kappa\beta$) in colonic tissue, was assessed by immunohistochemistry.

Results: Mesna alone was sufficient to significantly reduce colorectal tissue damage, when administered orally or intraperitoneally. Orally coadministered n-3 PUFAs enhanced this effect resulting in significant suppression of DSS colitis after 7 days and a remarkable recovery of colorectal mucosa was evident after 14 days of treatment. The amelioration of colon pathology co-existed with a significant decrease of MPO expression, overexpression of iNOS and reduction of nuclear NF-κB p65 in inflammatory cells, and the suppression of apoptosis in colonic epithelial cells.

Conclusion: The simultaneous administration of Mesna and n-3 PUFAs is particularly effective in ameliorating DSS colitis in rats, by reducing oxidative stress, inflammation and apoptosis, probably through a mechanism that involves inhibition of NF-κB and overexpression of iNOS.

Introduction: Ulcerative Colitis (UC) patients treated with tumor necrosis factor antagonists (anti-TNFs) may require therapy changes over time, which may be considered as indicators of suboptimal therapy.

Aims & Methods: A multinational, multicentre, retrospective, chart review study was conducted to assess the indicators of suboptimal therapy among adult UC patients receiving their first anti-TNF [infliximab (IFX) or adalimumab (ADA)] between June 2009 and June 2013 (index therapy).

The indicators of suboptimal therapy during 2-year follow up included: anti-TNF dose-escalation (assessed >4 months after index to allow for initial dose adjustments), augmentation with non-biologic therapy, UC-related surgery, discontinuation of first anti-TNF and switching to second anti-TNF. Dose escalation was defined as any increase in either dose, frequency, or both of the index anti-TNF therapy. Augmentation was defined as starting a new non-biologic drug or increase in dose/frequency of the concurrent non-biological drugs with anti-TNF therapy. Discontinuation of index anti-TNF was based on entry in patients' charts and excluded patients who discontinued anti-TNF because it was effective during the follow-up period. Switch was defined as a subset of discontinuation patients who initiated another anti-TNF therapy over the follow-up period. The number and percentage of patients with each indicator and ≥1 indicator was summarized descriptively by country.

Results: The study included 538 UC patients with mean age (SD) of 41.6 (14.3) years. 47% of patients were females and 73% reported moderate to severe UC at index. The percentages of patients on ADA and IFX as first anti-TNF were 8% and 92% respectively. Overall, within 2 years, 61% of UC patients had ≥1 indicator of suboptimal therapy, 26% had anti-TNF dose escalation, 21% needed augmentation with non-biologic therapy, 9% underwent UC-related surgery and 29% discontinued their index anti-TNF. Of those who discontinued index anti-TNF (N = 156), 58% switched to another anti-TNF therapy. Patients with indicators of suboptimal anti-TNF therapy by each country are shown in the table.

Conclusion: In this large multinational cohort, more than 60% of UC patients had ≥1 indicator of suboptimal anti-TNF therapy. Predominant indicators included dose escalation and discontinuation of anti-TNF therapy.

Introduction: Adalimumab (ADA) is a fully human anti–tumor necrosis factor (TNF) monoclonal antibody used for the treatment of moderate to severe Crohn's disease (CD) and ulcerative colitis (UC) in patients who have inadequately responded to conventional therapies. Safety from ongoing ADA trials continues to be collected, allowing assessment of long-term safety as the number of patients and the amount of exposure to ADA increase.

Aims & Methods: The aim is to provide an update on the long-term safety profile of ADA in CD and UC patients. Safety data were evaluated for adult patients with CD or UC treated with ADA in randomized, placebo-controlled, phase 3 and 3b trials as well as their open-label extension studies. Treatment-emergent adverse events (AEs) were coded using the Medical Dictionary for Regulatory Activities, version 17.1(2014), and collected from the first dose to up to 70 days after the last dose or through the cutoff date of 31 Dec 2014. AE rates were assessed as events (E) per 100 patient-years (PYs) of exposure to ADA.

Results: As of 31 Dec 2014, the ADA clinical safety database contained data for 3689 CD patients and 1789 UC patients, representing 4178.7 and 3371.9 PYs of ADA exposure, respectively. Overall, AE, SAE, and malignancy rates per PYs exposure were similar between the prior and the most recent data cutoffs for each disease state **(Table)**. The type of infections in the Opportunistic infections (excluding TB) category changed in 2014 resulting in an apparent decreased rate **(Table)**.

Conclusion: ADA continues to be well tolerated in patients with moderately to severely active CD and UC. No new safety signals were identified with prolonged ADA use in these patient groups.

P0965 VALIDITY AND SAFETY OF IRON SUPPLEMENTATION FOR THE TREATMENT OF MODERATE IRON DEFICIENCY ANEMIA IN PATIENTS WITH CROHN'S DISEASE—A RANDOMIZED, CONTROLLED, OPEN-LABEL, SINGLE CENTER STUDY

J. Tang[1], X. Gao[1], M. Zhi[1], P. Hu[1]
[1]*Department of Gastroenterology, The Sixth Affiliated Hospital of Sun Yat-sen University, GuangZhou, China*

Contact E-mail Address: tangjiansys@163.com

Introduction: The necessity and optimal route for iron supplementation to improve anemia in Crohn's disease (CD) has not been determined so far. We therefore performed a randomized, controlled, open label, single center study to evaluate the necessity, efficacy and safety of iron supplementation for the treatment of iron deficiency anemia (IDA) in patients with CD.

Aims & Methods: 49 patients with moderate anemia(hemoglobin(Hb):60-90g/l), transferrin saturation $\leq 20\%$ and/or serum ferritin concentrations $\leq 20\mu g/L$ were enrolled in this study. All patients were divided into three groups. Intravenous group received iron sucrose injection of 200 mg two or three times per wk until reached a total dose according to Ganzoni's Formula. Oral group received polysaccharide iron complex 150 mg per day for 12 wks. The other patients didn't received any iron supplementation. Response to anemia therapy was defined as Hgb $\geq$ 110 g/L in women, Hgb $\geq$ 120 g/L in men and/or Hgb rise $\geq$ 20g/l.

Results: 47 patients completed the study while 2 patients quitted because of surgery. At 12wks, Hgb and response rate (RR) of intravenous group (Hgb: 110.2 ± 16.2g/l, RR: 75.0%(15/20)) were superior to oral group (Hgb: 101.9 ± 17.9g/l, RR: 54.5% (6/11)) and no iron supplement group (Hgb: 99.1 ± 15.7g/l, RR: 25%(4/16)) ($P = 0.02$, $P < 0.01$). No matter received iron supplement therapy or not, Hgb in patients in remission (CDAI < 150) was remarkable higher than in patient in active phase at 12wks (101.0 ± 6.2g/l vs 81.0 ± 12.5g/l, $t = -2.2$, $P = 0.03$). Multiple logistic analysis showed that no iron supplement, active disease, complication were independent risk factors for no response to anemia therapy. 3 patient in oral group could not tolerate side effects and re-divided into intravenous group. However, no statistical difference on side effect was found between intravenous and oral group.

Conclusion: Iron supplementation therapy could significantly improve IDA in CD. Intravenous therapy was more effective than oral supplement. Iron supplementation will be more effective when disease activity under control.

Introduction: Factors suggested to influence the pharmacokinetics (PK) of infliximab (IFX) in patients with inflammatory bowel disease (IBD) have mainly been derived from clinical trials or computer modelling, clinical data are scarce.

Aims & Methods: We aimed to study the real-life PK of IFX in a large cohort of IBD patients and to identify patient, disease and treatment characteristics that influence serum concentrations and clearance of IFX. All measurements (November 2004 - August 2014) of IFX serum concentrations in IBD patients collected at a tertiary referral center were identified. Medical charts of these patients were reviewed for patient, disease and treatment characteristics (gender, age, body weight, location and behaviour of disease, dose, co-immunomodulators, serum albumin, CRP). IFX serum concentrations and antibodies to IFX (ATI) were measured using an ELISA and antigen binding test (radioimmunoassay, Sanquin Laboratories, Amsterdam, The Netherlands). PK was analysed by nonlinear mixed-effects modelling and described using a 2-compartiment PK model. All influential covariates were combined into a full model.

Results: A total of 997 distinct IFX concentrations measurements were included, comprising data from 332 IBD patients (54% male, mean age 39 years, 3 measurements/patient). Disease extent was scored by the Montreal classification for 253 Crohn's disease patients (L1: 55/253, L2: 80/253, L3: 118/253) and 79 ulcerative colitis patients (E1: 6/79, E2: 30/79, E3: 43/79). 264/332 (80%) of patients were anti-TNF naïve at start of IFX and 144/332 (43%) were receiving concomitant immunomodulation, with a mean IFX dose of 5.2 mg/kg, at time of measurement. ATIs were detected in 75/332 (23%) patients, resulting in unmeasurable serum IFX concentrations in 83% of their samples. All samples with ATI titers higher than 30 AU/mL were associated with unmeasurable IFX concentrations. The mean (inter individual variability) values for clearance, central and peripheral volume of distribution were 0.38 L/day (50%), 5.07 L (30%) and 3.59 L (32%). PK characteristics were similar for Crohn's disease and ulcerative colitis. The presence of ATIs, low body weight and serum albumin were identified as covariates independently ($P < 0.001$) affecting clearance. The presence of ATIs corresponded with an mean (SE) 4.40 (11.1) fold increased clearance. For body weight, range from 50 to 120kg resulted in a 1.31 fold increase over a 2.4 fold weight increase. Serum albumin had a -1.65 (8.4) fold inverse impact on clearance. Because serum CRP values tended to change rapidly after initiation of treatment, and use of concomitant immunomodulators was often intermittent, these factors could not be evaluated as independent covariates although the administration of continuous concomitant immunomodulators was associated with a decrease in clearance. Line of treatment was predictive of clearance, with anti-TNF naive patients exhibiting lower clearance than the previously exposed patients.

Conclusion: Antibodies to infliximab, low body weight and low serum albumin levels increase clearance of infliximab.

P0967 COMPARATIVE STRUCTURAL, FUNCTIONAL, NONCLINICAL, AND PHASE 1 SIMILARITY ASSESSMENTS OF PF-06438179, A POTENTIAL BIOSIMILAR TO INFLIXIMAB, AND MARKETED REFERENCE PRODUCTS

J. E. McClellan[1], C. Udata[2], D. Yin[2], S. Salts[2], T. R. Johnson[2], M. Derzi[3], M. Bolt[3], H. D. Conlon[3], C. F. Kirchhoff[4], L. G. Lorello[5], J. McNally[3], M. I. Rehman[6]
[1]*Pfizer Inc., New York, NY,* [2]*Pfizer Inc., San Diego, CA,* [3]*Pfizer Inc., Andover, MA,* [4]*Pfizer Inc., Chesterfield, MO,* [5]*Pfizer Inc., Groton, CT,* [6]*Pfizer Inc., Cambridge, MA, United States*

Introduction: PF-06438179 is being developed as a potential biosimilar to Remicade® (infliximab), which is a chimeric mouse/human monoclonal antibody that binds to the tumour necrosis factor (TNF) protein, in a stepwise approach following globally accepted regulatory guidelines. The similarity of PF-06438179 to infliximab reference products sourced from the United States (infliximab-US) and from the European Union (infliximab-EU) was assessed in structural, functional, in vivo nonclinical pharmacokinetic (PK)/tolerability and clinical PK studies.
Aims & Methods: Structural similarity was assessed using chromatographic peptide mapping. Functional similarity was assessed in vitro using an inhibition of soluble TNF-induced cell apoptosis assay. PK, tolerability and anti-drug antibody (ADA) response were evaluated in rats administered a single IV dose (0, 10 or 50 mg/kg) of PF06438179 or infliximab-EU. In a phase 1 study (NCT01844804), 146 healthy volunteers received a single 10 mg/kg IV dose of PF06438179 (n = 49), infliximab-US (n = 48), or infliximabEU (n = 49). All subjects provided informed consent. PK was evaluated over 8 weeks; safety and ADA were assessed up to 12 weeks. PK similarity in humans was considered to be demonstrated if the 90% confidence interval (CI) of the test-to-reference ratio of maximum concentration (C_{max}) and area under the concentration time curve (AUC) were within the 80.00%–125.00% bioequivalence (BE) acceptance window.
Results: Peptide mapping showed superimposable chromatographic profiles of PF-06438179, infliximab-US and infliximab-EU, demonstrating structural similarity. The dose-response curves of inhibition of cell apoptosis induced by all three study drugs were also superimposable, demonstrating functional similarity. In rats, PF-06438179 and infliximabEU were well-tolerated. Systemic exposures (assessed by C_{max} and AUC) in dosed animals appeared similar, with mean exposure ratios of PF06438179 relative to infliximab-EU ranging from 0.88 to 1.16. None of the rats developed detectable levels of ADA following administration of PF06438179. In healthy volunteers, the three study drugs exhibited a similar PK profile, and the 90% CI for the ratios of C_{max} and AUC were within the BE acceptance window of 80.00%–125.00% for each, individual three-way comparison. Overall safety and ADA profiles were comparable among the treatment groups.
Conclusion: Comparative studies demonstrated structural, functional, and nonclinical and clinical PK profiles of PF-06438179 to be similar to infliximab-US and/or infliximab-EU. A global, comparative clinical study is ongoing to assess efficacy and safety of PF06438179 and infliximab-EU in combination with methotrexate in subjects with active rheumatoid arthritis.

P0969 STW 5, A MULTI-COMPONENT HERBAL PREPARATION, MODERATES MOTILITY AND INFLAMMATION CHALLENGES IN THE ENTERIC NERVOUS SYSTEM (ENS)

K.-H. Schäfer[1], D. Grundmann[1], M. Klotz[1], H. Rabe[1], H. Abdel-Aziz[2], O. Kelber[2]
[1]*University of Applied Sciences Kaiserslautern, Zweibrücken,* [2]*Steigerwald GmbH, Darmstadt, Germany*

Introduction: The enteric nervous system is responsible for the undisturbed regulation of gut motiliy, secretion or resorption. Whenever the gastrointestinal tract is affect by diseases, the ENS is also part of the problem. Especially during inflammation, the ENS can be stimulated and challenged by inflammatory signaling molecules such as cytokines or hormones.
Aims & Methods: respectively the enteric nervous system. Gut segments were kept in an organ bath under perfusion conditions and motility increased by neostigmin application. STW-5 was added after the stimulation. To investigate whether the ENS was the target for the compound, we also performed electrophysiological measurements of enteric neuronal networks on microelectrode arrays. Inflammation was simulated in isolated ENS tissue. Myenteric plexus from adult mice from both jejunum and colon was isolated and either stimulated with a cytokine cocktail of Interferon-gamma, IL-1ß and TNF-alpha alone, or in combination with the multi-component herbal preparation STW-5.
The plexus tissues were kept for 24 hrs in tissue culture medium and supernatant was collected the following day. Cytokine liberation was measured using Multiplex-ELISA.
Results: The application of STW-5 reduced significantly the neostigmin-induced motility in a dose dependent manner. The electrical activity of the neuronal networks could also be increased by neostigmine and was reduced to basal activity by additional STW-5. In the inflammation approach, the supernatants from colonic and jejunal myenteric plexus showed different responses. While many cytokines were released after cytokine stimulation in both colonic and jejunal preparations, STW led to a complete downregulation of the release only in the colonic myenteric plexus.
Conclusion: The application of STW-5 reduced significantly the neostigmin-induced motility in a dose dependent manner. The electrical activity of the neuronal networks could also be increased by neostigmine and was reduced to basal activity by additional STW-5. In the inflammation approach, the supernatants from colonic and jejunal myenteric plexus showed different responses. While many cytokines were released after cytokine stimulation in both colonic and jejunal preparations, STW led to a complete downregulation of the release only in the colonic myenteric plexus.

Introduction: Biosimilar infliximab CT-P13 received EMA approval in June 2013 for all indications of the originator product. Prospective data on the efficacy and safety of the biosimilar infliximab in IBD are lacking.
Aims & Methods: A prospective, nationwide, multicentre, observational cohort was designed to examine the efficacy and safety of CT-P13 infliximab biosimilar in the induction treatment of Crohn's disease (CD) and ulcerative colitis (UC). Demographic data were collected and a harmonized monitoring strategy was applied. Early clinical remission, response and early biochemical response was evaluated at week 14. None of the patients had received infliximab within 12 months prior to initiation of the biosimilar infliximab. Safety data was registered.
Results: 201 consecutive IBD patients (122 CD patients and 79 UC patients) were included in the present cohort. The age at disease onset was 24/29 years (median, IQR: 19-35 and 22-38) in CD and UC patients, respectively. 38/43% of CD patients had colonic/ileocolonic disease localization, 34% of patients had perianal disease and 26% of the patients had gone through previous surgery. 5/38/57% of UC patients had proctitis/left-sided colitis/extensive colitis. 27/19% of patients had received previous anti-TNF therapy in CD and UC, respectively. 60/58% of CD/UC patients received concomitant immunosuppressives at baseline. 54/82% and 61%/90% of the CD (n = 94/64) patients and 72%/77% and 65%/80% of the UC (n = 60/40) patients reached clinical remission/response by week 6 and 14. There was no significant difference in the remission and response rates between patients with or without previous anti-TNF exposure. Additionally, there was a decrease in biomarkers by week 14 (mean CRP level decreased from 20.8 mg/L to W6: 11.4mg/L and W14: 6.7mg/L in CD and from 32.1mg/L to W6: 11.2mg/L and W14: 9.9 mg/L in UC). 8 patients had allergic reactions, 8 patients infections and 1 death occurred.
Conclusion: This prospective nationwide cohort shows that CT-P13 is safe and effective in the induction of clinical remission and response in both CD and UC.

Introduction: Adalimumab(ADA) and Infliximab(IFX), are an effective induction and maintenance therapy for moderate to severe Crohn's disease. The aim of this study was to evaluate their efficacy in a large Romanian population and to identify predictor factors of response.

Aims & Methods: We performed a national retrospective cohort study including 265 patients (136 ADA, 129 IFX) between 2008 and 2014, all naive to biologics. Binary logistic regression was performed with the statistical program Minitab, to identify predictors of response.

Results: Patients were half women, with a median age of 36 years, a median disease duration of 2.5 years, most of them (80%) received Azathioprine before biologic therapy, 70% aged 17- 40 years at diagnosis, almost 50% with ileocolonic involvement, 60% non-obstructive non-fistulising disease, and 20% suffered surgery (intestinal resection) before the biologic therapy. Mean therapy duration was 20 months in ADA group and 36 months in IFX group. 67% of patients had moderate flare of the disease, while 16% had mild disease activity. Complete response to ADA was recorded in 77%, secondary loss of response in 18%, while to IFX the rate of complete response was 65%, and secondary loss of response 28%, statistically comparable. With most patients with secondary loss of response to ADA (79.2%), the dose was escaladated, which reinduced response in 84.2%. 12.5% were switched to Infliximab, with a significantly lower rate of response: 33%. In 26/37 (70%) patients that lost response to IFX, the dose was increased, which resulted in regaining response in approximately 40% of patients. 12/38 subjects (30%) were switched to Adalimumab, with a better result: 83% regained response. Regarding surgical interventions, 74.5% of resected patients achieved complete response, comparable to non-resected patients (70%). Secondary loss of response was found in 20% of resected patients compared to 24.5% of the non-resected, while primary non-response was recorded in 4% versus 2%. 9 of the 23 resected patients treated with IFX suffered re-resection for POR, compared to 4 of the 28 treated with ADA, but p-value was not statistically significant 0.16. 13 of 216 non-resected subjects suffered surgical interventions on biologic therapy (6%).

Predictors of loss of response to ADA were: severe disease (CDAI >450): OR 5.67 (95% CI 0.17,185.65), presence of perianal fistulae: OR 5.87(95% CI 0.26,131.15), fistulising disease OR 3.71(95% CI 0.18,73.72). Predictors of loss of response to IFX were: age $>$ 40y: OR 63.71(95% CI 2.93, 1384.62), severe disease: OR 8.25 (95%CI 0.38,177.8), perianal fistulae OR 3.71 (95% CI0.65, 30.63).

Conclusion: In a real-life cohort, Adalimumab and Infliximab are equally effective in Crohn's disease, with a complete response rate of ~70%. Predictors of poor response to biologics were: severe active disease, perianal disease and fistulising behaviour. In case of secondary loss of response to IFX, the best solution is to switch to ADA, with 83% chance of regaining response, while in case of secondary loss of response to ADA, increasing the dose leads to 84 % chance of regaining response.

P0972 A REAL WORD REVIEW OF PATIENT COMORBIDITIES IN CROHN'S DISEASE AND THEIR IMPACT ON TREATMENT STRATEGIES AND PATIENT OUTCOMES

L. Chanroux[1], J. Casellas[1]
[1]*Research Partnership, London, United Kingdom*

Contact E-mail Address: laurentc@researchpartnership.com

Introduction: Several studies have evaluated the increased prevalence of comorbid diseases and risk factors in Crohn's disease (CD) patients and understanding the overlapping pathogenesis of comorbidities may be key to effectively managing and treating those with this complex disorder.

Aims & Methods: We used patient data collected as part of an online treatment survey conducted among a panel of gastroenterologists between April 2010 and December 2013 in France, Germany, Italy, Spain and the UK. We analysed 11,730 records of patients suffering from moderate to severe CD and classified them according to their comorbidities into 4 groups. Group 1 patients were reported as suffering from no comorbid conditions; group 2 patients suffered from cardiovascular or metabolic comorbidities including hypertension, metabolic syndrome and diabetes (CVD); group 3 consisted of patients who suffered from anxiety and/or depression and group 4 included all patients with an autoimmune disease, including rheumatoid arthritis, psoriasis, ulcerative colitis, uveitis and multiple sclerosis.

Results: Patients with CVD were on average significantly older than those from the other groups (50 years, $p < 0.05$). They were also significantly heavier (74kg) and more likely to be male (62% of patients). These patients had a greater number of comorbidities (1.3) and had been diagnosed for longer (9 years). They were more likely to have moderate CD at diagnosis but had the lowest level of biologic use (53%) with the greatest delay from diagnosis to 1st ever biologic (7 years).

Patient suffering from depression/anxiety were significantly more likely to currently have moderate or severe CD (46% and 17%, respectively) and more commonly suffered from fistulising disease (29%). A greater proportion of these patients were currently experiencing fistulae (33%) and had their upper GI tract (5%), rectum (26%) and anus (21%) affected by their disease vs. other groups. They reported the highest average CDAI score (167) and the highest proportion of patients having undergone ≥ 3 surgical interventions for their disease (5%). Rapid disease progression (55%) and frequency of relapse (26%) were more frequently chosen as reasons for initiating biologics among these patients.

Patient with autoimmune comorbidities were most likely to be receiving anti-inflammatories (13%) and biologics (72%) with the latter more commonly chosen due to patients' extra intestinal manifestations (46%). Although this group reported the highest proportion of patients having experienced remission over the course of their disease (45%) there were no significant differences in the frequency or duration of remission between the groups.

We saw no clear correlation between biologic use and improved patient outcomes and little correlation between individual disease attributes and patients' psychological status.

Conclusion: Our data confirm that CD is a heterogeneous disease with clear differences in patient profiles across the main comorbidity groups we covered. These differences appear to lead to different treatment approaches which in turn may lead to varying patient outcomes. Our results do not show a correlation between biologic therapy and patient outcomes but suggest that patients with uncontrolled disease (flaring, fistulae and high CDAI) are more likely to suffer from depression and anxiety, highlighting the impact that tight disease control can have on patients' quality of life.

P0973 IDENTIFICATION OF A CUT-OFF FOR PERSISTENT ANTI-INFLIXIMAB ANTIBODIES AS A PREDICTOR OF RESPONSE TO INFLIXIMAB MONOTHERAPY

L. Del Nero[1], G. Bodini[1], E. Giannini[1], V. Savarino[1], C. De Maria[1], I. Baldissarro[1], A. Jain[2], E. Savarino[3]
[1]*Internal medicine, IRCCS San Martino, Genoa, Italy,* [2]*Research and Development, Prometheus Laboratories, San Diego, United States,* [3]*Surgery, Oncology and Gastroenterology, University of Padua, Padua, Italy*

Introduction: The clinical and predictive role of anti-Infliximab antibodies (AIA) presence and concentration are still debated, both in Crohn's disease (CD) and ulcerative colitis (UC) patients. However, there is increasing evidence of their usefulness in order to improve the management of patients on biological treatment who experience a loss of response (LOR). AIA can be subdivided into 2 types, persistent and transient, on the basis of their occurrence on multiple samples and capability of interfering with infliximab trough levels (TL), and therefore persistent AIA seem to play a major role on treatment outcome.

Aims & Methods: The aim of our retrospective study was to evaluate the clinical relevance of persistent AIA in a single-center cohort of inflammatory bowel disease (IBD) patients. We selected from our cohort of 56 IBD patients treated with IFX mono-therapy who achieved clinical and biochemical remission after induction (IFX schedule: 5 mg/kg at week 0, week 2, and week 6), 18 patients (32.1%) who developed persistent AIA during 48 weeks follow-up. Blood samples were drawn at standardized time points (i.e., baseline, 2 weeks, 6 weeks, and every 8 weeks) before IFX infusion. TL and AIA were measured using an homogenous mobility shift assay (HMSA; Prometheus Lab, San Diego, United States). Clinical disease activity was assessed both at week 14 (i.e. after induction) and week 48 by the Harvey-Bradshaw Index (HBI, remission defined by HBI < 5) in CD patients and by the Mayo score for UC patients (remission defined by Mayo score <2). Also, protein-C reactive and erythrocyte sedimentation rate (ESR) were measured.

Results: Eighteen patients (11 CD and 7 UC, 10M/8F, median age 39.5 years, range 18-69) developed persistent AIA at a median of 2 weeks during 48 weeks follow-up. Among these patients, 12 (66.7%) experienced LOR during the follow-up period. Median AIA were significantly higher in patients who showed LOR as compared to patients who maintained remission (8.29 U/ml, range 0.62-30.52 U/ml, versus 1.41 U/ml, range 0.77-9.94 U/ml; $P = 0.04$). ROC curve identified a persistent AIA cut-off of 3.91 U/mL as the threshold with the highest accuracy for the identification of relapsers (AUROC $= 0.799$, specificity $= 75.0\%$, sensitivity $= 83.3\%$).

Conclusion: The early occurrence of elevated persistent AIA serum concentrations during IFX mono-therapy treatment is associated with high risk of LOR. Furthermore, the use of an AIA concentration cut-off of 3.91 U/mL can be useful to accurately identify patients with LOR, although these results need to be confirmed in larger series.

P0974 ANTI-TNF THERAPY IN ULCERATIVE COLITIS. SHOULD WE REMOVE 5-ASA?

M. Barreiro-De Acosta[1], I. Baston[1], D. De la Iglesia[1], R. Ferreiro[1], A. Lorenzo[1], J. E. Dominguez-Muñoz[1]
[1]*Gastroenterology, University Hospital, Santiago, Spain*

Contact E-mail Address: manubarreiro@hotmail.com

Introduction: 5-aminosalicylates (5-ASA) are effective drugs for induction and maintenance treatment in ulcerative colitis (UC) patients. However, their usefulness as concomitant treatment with Anti-TNF drugs remains uncertain.

Aims & Methods: The aim of this study was to evaluate the efficacy of this therapeutic combination in patients with moderate to severe UC. **Methods:** A

retrospective observational single-centre study was designed. Inclusion criteria were all moderate to severe UC patients that were treated with anti-TNF drugs (Infliximab or Adalimumab) between January 2007 and December 2013. Only anti-TNF naïve patients were included. Patients with pouchitis or having received previous anti-TNF treatment were excluded. Clinical and demographic characteristics were recorded as well as the number of months in which all patients were treated with anti-TNF agents. Efficacy was defined as sustained remission and measured as the duration of clinical remission in months until treatment failure (defined as the need for intensification, a switch to another anti-TNF or colectomy). The presence of significant adverse events was also evaluated. The concomitant use of 5-ASA was also assessed. The data is shown as percentages and Hazard Ratio after Cox regression analysis was performed.
Results: 55 patients were consecutively included. 31 women (56.3%) and 24 men (44.7%) with a mean age of 44.2 years. 49 patients started treatment with Infliximab (89.1%) and 6 with Adalimumab (10.9%). Regarding smoking habits, only 1 patient was smoker (1.8%) and 6 were former smokers (10.9%). 25 patients received concomitant treatment with 5-ASA (45.4%) and 30 patients received concomitant treatment with azathioprine (54.5%). Treatment failure was observed in 26 patients (47.3%), those of which 19 needed treatment intensification (73.1%). The average time of sustained clinical remission was 10.1 months, being higher in women (14.5 months) than in men (4.9 months). Regarding 5-ASA concomitant therapy, despite the fact that patients with 5-ASA maintained remission for more time (12 months) than those without 5-ASA (8.4 months), statistically significant differences were not discovered. 3 patients (5.4%) presented adverse events and had to be withdrawn from treatment, all of whom were not receiving concomitant 5-ASA. After multivariable analysis the only factor independently associated with maintaining remission was female gender HR 4.33 (95% CI, 1.35 to 13.90). No perceptible influence of concomitant treatment with 5-ASA was found.
Conclusion: Roughly half of patients with UC maintained remission with anti-TNF therapy. The concomitant use of 5-ASA did not have any influence in maintaining remission in patients with moderate to severe UC. Female gender was associated with higher rate of response in this study.
Disclosure of Interest: None declared

P0975 FACTORS ASSOCIATED WITH ANTI-TNF THERAPY FAILURE IN PATIENTS WITH CROHN'S DISEASE (CD). DOES THE TYPE OF DRUG HAVE ANY INFLUENCE?

M. Barreiro-De Acosta[1], I. Baston[1], D. De la Iglesia[1], R. Ferreiro[1], A. Lorenzo[1], J. Dominguez-Munoz[1]
[1]*Gastroenterology, University Hospital, Santiago, Spain*

Contact E-mail Address: manubarreiro@hotmail.com
Introduction: Anti-TNF monoclonal antibodies are effective drugs for induction and maintenance of remission in Crohn's disease (CD). However a significant portion of patients do not respond or lose the response during the treatment and predictive factors are not well known. There is no direct data comparing the efficacy between different anti-TNF drugs.
Aims & Methods: The aim of this study was to evaluate the factors associated with anti-TNF therapy failure in Anti-TNF naive patients with CD. **Methods:** A retrospective, observational single-centre study was designed. Inclusion criteria were all naïve patients older than 17 years old who started treatment with anti-TNF drugs, either Infliximab or Adalimumab, for moderate to severe CD between January 2007 and December 2013. Patients who had been previously treated with another anti-TNF were excluded. Patients who started anti-TNF for different indications like prevention of recurrence or refractory extraintestinal manifestations, were not included. Treatment failure was defined as the need for dose intensification due to loss of response, surgery resection, or therapy removal for ineffectiveness. The influence of demographic and clinical variables (gender, age, smoking history and type of biological agent used) on treatment failure was also evaluated. Results are shown as OR and95% CI and analyzed by the Chi square test and multivariable logistic regression analysis.
Results: 129 CD patients were consecutively included: 72 women (55.8%) and 57 men (44.2%) with a mean age of 35.9 years. 64 treatments with Infliximab (49.6%) and 65(50.4%) with Adalimumab. 52 smokers (40.3%) and 12 former smokers (9.3%). Mean Treatment failure was observed in 51 patients (39.5%): 36 due to dose intensification (27.9%), 11 due to surgery (8.5%) and 4 primary failures after anti TNF induction therapy (3.1%). No factors associated with treatment failure were identified in the multivariant analysis. Similar rates of treatment failure were found between infliximab and adalimumab($p = 0.802$).
Conclusion: More than 60% of CD patients maintained response to anti-TNF therapy, and 27% of patients required treatment intensification. No differences were found between Infliximab and Adalimumab in terms of treatment failure in patients with CD.
Disclosure of Interest: None declared

P0976 PROSPECTIVE, RANDOMIZED CLINICAL TRIAL COMPARING THE EFFICACY OF TWO VACCINES AGAINST HEPATITIS B VIRUS (HBV) IN INFLAMMATORY BOWEL DISEASE (IBD) PATIENTS

Introduction: .
Aims & Methods: To compare the success rate between 2 HBV vaccines in IBD patients: the traditional (Engerix®) and a new vaccine with an adjuvant (Fendrix®). To identify predictive factors of response to the vaccine
IBD patients with negative HBV serology and without previous vaccination against HBV were included (EUDRA CT number: 2010-023947-14), and randomized 1:1 to receive Fendrix® or double doses of Engerix® at months 0, 1, 2 and 6. Anti-HBs concentration was measured 2 months after the 3rd and 4th vaccine doses
Results: 173 patients were included. 54% of patients received Engerix® and 46% Fendrix®. Overall, 43% of patients had response (pre-defined as anti-HBs $\geq$ 100 IU/L) after the first 3 doses (165 patients have received 3 doses up to now), and 71% after the completion of the vaccination (161 have completed the vaccination). 47% of patients that did not respond after the 3th dose, responded to the 4th vaccine administration ($p < 0.0001$). The response rate after the 4 doses was 75% (95%CI, 63-84%) with Fendrix® vs. 67% (56-77%) with Engerix® ($p = 0.3$; however, the statistical power for this comparison was only 30%); considering anti-HBs^{3}10 IU/L (the standard threshold to define response), the success rate was marginally higher with Fendrix® than with Engerix® (88% [78-94%) vs. 77% [66-85%], $p = 0.06$). In patients under anti-TNF treatment, the response rate (anti-HBs^{3}100 IU/L) after the 4 doses was 67% (47-83%) with Fendrix® vs. 45% (27-64%) with Engerix® ($p = 0.09$); and considering anti-HBs^{3}10 IU/l, the success rate was 80% (61-82%) with Fendrix® and 58% (39-75%) with Engerix® ($p = 0.06$). In the multivariate analysis, older age ($OR = 0.9$, $p < 0.0001$), and the treatment with immunosuppressants ($OR = 0.12$, $p < 0.01$) or anti-TNFs ($OR = 0.09$, $p < 0.0001$) were associated with a lower response rate to the vaccination. The type of vaccine ¾Engerix® or Fendrix®¾ was not associated with the response to the vaccination ($OR = 1.8$, 95%CI = 0.8-4). The frequencies of IBD relapses during the study period were similar in patients receiving Fendrix® and Engerix® (17% vs. 22%)
Conclusion: We could not demonstrate a statistically significant higher response rate of Fendrix® (conventional dose) over Engerix® (double dose) in IBD patients, although a *beta* error cannot be excluded. A 4-dose vaccine schedule significantly increases the response compared with a 3-dose regimen. Older age and immunosuppressive and anti-TNF treatment impaired the success rate of the vaccine. The risk of clinical relapse of the disease is not increased with either vaccine
Disclosure of Interest: None declared

P0977 NUTRITIONAL ASSESSMENT IN ULCERATIVE COLITIS PATIENTS UNDER REMISSION: IS THERE A SINGLE RELIABLE TEST?

L. R. De Bona[1,2], C. F. D. M. Francesconi[1,2], A. S. Silva[1,2], **M. H. I. Lopes**[1,2], L. S. Harlacher[1], C. Flores[1,2]

Contact E-mail Address: lauradbona@yahoo.com.br
Introduction: The nutritional aspect of patients with UC has been poorly studied. The best nutritional assessment method has not been established. In the last years it has been seen a trend towards overweight and obesity among those patients, although some individuals, especially those with severe disease could be suffering from malnutrition
Aims & Methods: The aim of this study was to evaluate the nutritional status of patients with UC in clinical remission using different methods. Protocol approved by local IRB (number 130392). **Methods**: 80 individuals from a single center of southern Brazil from January 2014 to February 2015 were evaluated. Demographic data and assessment of high, weigh, body mass index (BMI), triceps skin fold (TSF) mid-arm circumference (MAC), mid-arm muscle circumference (MAMC), Subjective Nutritional Global Assessment (SGA), bioelectrical impedance (BIA), serum albumin and transferrin were performed. Statistical analysis was performed using chi-square, Wilcoxon-Mann-Whitney, Cochran and Kappa tests, assuming a 95% CI and statistic $p < 0.05$.
Results: Eighty individuals were included: 62% woman; mean age 45 ± 11.7 years and 96% Caucasian. Less then 5% were taking steroids. Malnutrition prevalence through different methods is shown on table 1. There was no association between malnutrition and disease duration and neither with extent of disease. None of the variables had any correlation when Kappa evaluation was applied. Laboratorial tests performed showed that only 1 subject had low albumin value and 28 (35%) showed low transferrin value. Considering BIA results 26.3% were considered body fat percentage above normal. Thirty seven percent were overweight and 16% obese by BMI.**Table 1:** Malnutrition Prevalence (anthropometry)

Method	N: 80
BMI < 18,5 e 22 (elderly) (%) [a]	2 (2.5%)
TSF < 50 percentile (%) [b]	58 (72.5%)
MAC < 50 percentile (%) [b]	44 (55%)
MAMC < 50 percentile (%) [b]	22 (27.5%)
SGA – mildly or significantly malnourished [d]	3 (3.8%)

Reference Range: [a] World Health Organization 1998; Lipchitz, 1994. [b] Frisancho 1981; 1990. [c]Schüssel et al, 2008. [d] Detsky et al.1987

Conclusion: Applying only one method is neither advisable nor reliable when assessing nutritional status. Our results show that a single patient could be considered malnourished by one and overweight by another. This study found a high percentage of overweight and obese UC patients in remission. However there are different frequencies depending upon the evaluation method that is used, BIA, anthropometric or BMI.

P0978 BEYOND MUCOSAL HEALING: TRANSMURAL AND EXTRAMURAL HEALING AFTER ONE-YEAR ANTI-TNFA THERAPY IN CROHN'S DISEASE

M. Serio[1], K. Efthymakis[1], A. Milano[1], A. Pierro[2], F. Laterza[1], G. Maselli[2], A. Bonitatibus[1], G. Sallustio[2], M. Neri[1]

Contact E-mail Address: mariaelenaserio@yahoo.it
Introduction: Crohn's disease (CD) is characterized by transmural (full-thickness) inflammation, frequently with extramural complications beyond to the mesentery and adjacent organs. The capability of anti-TNFα therapies in achieving and maintaining both clinical remission and mucosal healing (MH) has repeatedly been described, while only one study was designed to assess prospectively their role in transmural healing[1].
Aims & Methods: Aim of this study was to analyze transmural healing (TH) in consecutive CD patients after a one-year treatment with anti-TNFα and to correlate TH with endoscopic and clinical activity (CDAI) as well as biological markers (CRP and fecal calprotectin).
13 patients with moderate to severe ileocolic CD were enrolled. All underwent ileocolonoscopy and MRI-enterography before and after one-year treatment with anti-TNFα; clinical remission was defined as CDAI < 150, response as a 70-point reduction from baseline. CRP and fecal calprotectin (FC) (positivity cut-off respectively > 0.50 mg/dl and > 150 μg/gr) were also measured. Endoscopic activity was assessed by SES-CD, range 0-40, with mucosal healing defined as score < 3 and response as a 50% decrease from baseline. MRI activity was measured by MRI-enterography global score (MEGS), range 0-296, a score which takes into account transmural and extramural features, with active disease defined as a score ≥1, and response as above.
Results: We enrolled 6M/7F, mean age 36 ± 12 ys, mean disease duration 7 ± 5 ys. According to the Montreal classification the phenotype was L1 in 31%, L2 in 7% and L3 in 62%; the behaviour was B1 in 8%, B2 in 69% and B3 in 23%. Resectional surgery related to CD was observed in 15%. Signs of mesenteric inflammation were only lymph node enlargement or comb-sign. 3 patients were treated with IFX, 10 with ADA (all naive to anti TNFα). Mean SES-CD, MEGS, CDAI, CRP and FC values significantly decreased at one year (table). 53% had clinical remission, 77% clinical response. Biological remission was achieved in 69% and 53% according to FC and CRP respectively. MH was achieved 38%, endoscopic response in 46%. Normalization of MRI finding was achieved in 15%, 31% had transmural improvement; before therapy 85% showed at least one extramural sign of inflammation, after one year at least one sign persisted in 54% (p = ns). MEGS score after one year didn't change significantly between patients with endoscopic remission/improvement and those without (p = 0.7). CRP positivity at one year was correlated with presence of extramural involvement only (p = 0.02) and mean CRP level were higher (2.3 ± 2.4 vs 0.30 ± 0.50 mg/dl) in the presence of comb-sign (p = 0.03).

	Baseline	After one year	p value
SES-CD	10 ± 4	6 ± 4	p = 0.002
MEGS	29 ± 13	17 ± 12	p = 0.001
Transmural	22 ± 11	12 ± 9	p = 0.001
Extramural	85% (at least one sign)	54% (at least one sign)	p = ns
CDAI	227 ± 88	147 ± 103	p = 0.03
PCR	3,7 ± 4,1	1,2 ± 1,8	p = 0.03
FC	388 ± 277	177 ± 148	p = 0.03

Conclusion: Biological therapy is effective in inducing clinical, biochemical and endoscopical remission of CD while transmural inflammation may persist longer than one year. Transmural, mainly extramural, healing probably needs longer therapy to be achieved, and his activity was unrelated to endoscopic improvement while closely relates to CRP positivity and levels.

Introduction: Stenosis is the most common complication in Crohn's disease (CD). However, there are only limited data on the resolution of strictures induced by tumour necrosis factor antagonists in patients with stricturing CD.
Aims & Methods: 43 CD patients followed-up in a tertiary IBD Center between July 2006 and March 2015 were enrolled. All of them had stricturing CD (Ileal = 40, colonic = 3), diagnosed by colonoscopy and/or MRI enterography. Twenty-five subjects (58%) were given adalimumab, 18 (42%) infliximab. The primary outcome was to assess the rate of surgery due to stricturing CD. Statistical analysis included descriptive analysis, logistic regression with univariate analysis for risk factors, and Kaplan-Meier survival curve and Cox proportional hazards-regression analysis for estimation of efficacy of anti-TNFs in avoiding surgical resection. All differences were considered statistically significant for $p < 0.05$.
Results: 43 CD patients were analysed (20 males, median age 36 years, range 20-72). Median duration of disease was 3.92 years (range 0.26-29.52). After a median follow-up period of 41 months (range 7-105), 18/43 patients (41.86%) underwent abdominal surgery; 7/43 (38.8%) through the first year, 6/43 (33.3%) through the second year, 1/43 (5.5%) through the third year, 3/43 (16.6%) through the fourth year, and 1/43 (5.5%) through the fifth year. Patients treated with infliximab were more likely to delay or avoid surgery in the follow-up period (median survival time 67.47 months for infliximab vs. 49.03 months for adalimumab, HR 2.97; CI 95% 1.37 -11.10; p = 0.01). Based on univariate analysis, only penetrating behavior at baseline was more likely to be associated with the risk of surgery (OR 3.96; CI 95% 1.0.7 to 14.6; p = 0.039). Twenty patients over 43 (46.51%) continued anti-TNF therapy, 5/43 (11.62%) stopped treatment (1 for secondary loss of response, 2 psoriasis, 1 for pregnancy and 1 for recurrent tonsillitis). Patients treated with infliximab were more likely to avoid surgery than adalimumab (OR 2.80; CI 95% 0.05-2.0; SE 0.50; p = 0.0393).
Conclusion: Although in a small cohort, anti-TNF are effective in avoiding surgery in the long-term. Penetrating phenotype at baseline is associated with the risk of surgery. Patients treated with infliximab remained free of surgery longer than patients treated with adalimumab.

P0980 AZATHIOPRINE VERSUS AZATHIOPRINE-ALLOPURINOL TREATMENT IN INFLAMMATORY BOWEL DISEASE: A PROSPECTIVE TRIAL EVALUATING CLINICAL REMISSION AND ADVERSE EVENTS

M. Kiszka-Kanowitz[1], K. Theede[1], A. M. Nielsen[1]
[1]*Hvidovre Hospital, Hvidovre, Denmark*

Contact E-mail Address: marianne.kiszka-kanowitz@regionh.dk
Introduction: Low dose of Azathioprine (AZA) in combination with Allopurinol (ALLO) can be used in patients with inflammatory bowel disease (IBD) failing AZA therapy due to intolerance or to lack of efficacy. Combination of AZA-ALLO leads to increased levels of the active metabolite 6-Thioguanine-nucleotide (6-TGN) and simultaneously decreases the level of methylmercaptopurine (MeMP). Retrospective studies have shown that this combination therapy increases remission rates and eliminates some of the adverse events. Gaining experience with the combination therapy raises the question whether it is preferable to start patients on primary combination therapy instead of ordinary AZA therapy, thereby theoretically reducing intolerance and increase remission rates.
Aims & Methods: A prospective, single center, open label, randomized trial comparing efficacy and safety in AZA naïve IBD patients with normal thiopurine methyltransferase (TPMT) randomized to receive either standard weight-based dosing of AZA or combination therapy with AZA-ALLO.
Primary outcome was steroid and anti-TNFα free clinical remission (partial Mayo score ≤ 2 in UC or a Harvey-Bradshaw Index < 5 in CD) at week 24 without adverse events.
Results: 23 IBD-patients were randomized to each treatment group. 16 patients (69.6%) in the AZA-ALLO-group compared to eight patients (34.7%) from the AZA-group achieved steroid and anti-TNFα free clinical remission at week 24 without experiencing adverse events. The difference in clinical remission between the two groups was statistic significant with RR = 2.10 [CI:1.07-4.11]. Intolerance to treatment was observed in seven (30.4%) patients in the AZA-ALLO group compared to 11 (47.8%) patients in the AZA-group. Four patients in the AZA-group, otherwise tolerant to the treatment, failed to reach steroid and anti-TNFα clinical remission at week 24.
Only a single severe adverse event (severe anemia) was seen in a patient from the AZA-group. Three patients in the AZA-group and a single patient in the AZA-ALLO group had an infection. All 4 patients completed the study.
Seven patients that were withdrawn from the study from the AZA group due to intolerance or lack of efficacy accepted a trial of combination therapy with AZA-ALLO or 6-mercaptopurine (6-MP)-ALLO. Five of these patients tolerated the treatment with good clinical response. Five patients that were intolerant to AZA-ALLO treatment accepted a trial of 6-MP-ALLO, but only 2 patients tolerated this and had benefit of the treatment
Conclusion: Efficacy and tolerance rates are higher in patients treated with AZA-ALLO compared to standard therapy with AZA. These results could

imply that combination therapy with AZA-ALLO can be used in AZA naïve patients with normal TPMT, thereby achieving higher remission rates and reducing the risk of intolerance to the therapy.

P0981 INCREASED WEIGHT GAIN IN ANTI-TNF ALPHA ANTIBODY TREATED PATIENTS WITH INFLAMMATORY BOWEL DISEASE MAY BE ATTRIBUTED TO LEPTIN AND TNF ALPHA

M. Protic[1], T. Schaffer[2], T. Knezevic[1], F. Seibold[3]
[1]*Department of Gastroenterology, University Hospital Zvezdara, Belgrade, Serbia,* [2]*2. Departement Klinische Forschung, University of Bern,* [3]*Department of Gastroenterology, Lindenhof Spital, Bern, Switzerland*

Introduction: It is well known that TNF α, a critical mediator of inflammation in inflammatory bowel disease (IBD) is related to inflammation- related cachexia and anorexia. Animal studies have shown that body weight is regulated by adipocyte derived leptin. On the other hand, remarkable weight increase was observed among patients with IBD during treatment with anti- TNFα treatment. The association between weight increase, leptin and TNF α levels is unknown.
Aims & Methods: We retrospectively analyzed 132 patients with IBD, 102 on anti-TNF α therapies [Infliximab (IFX), Adalimumab (ADA)] and 30 patients on immunomodulators (IMD) (azathioprine, 6 MP) in a single tertiary IBD center. Levels of leptin, apelin and TNFα were measured in the serum of IBD patients, after at least 6 month of treatment with TNFα blockers or thiopurines by ELISA.
Results: A total of 106/132 (80%) IBD patients in our cohort had Crohn's disease (CD), while 26/132 (20%) were diagnosed as Ulcerative Colitis (UC). No significant difference was found between initial body weights of the group on anti TNF-α therapy (65.96 $\pm$18.93 kg) and IMD group (68.09 $\pm$ 17.03 kg) ($p = 0.911$). 70% (72/102) of patients increased their body weight during the anti-TNF-α treatment (range 6–48 months) for median of 3.30 kg (range 0.0-40.0). Significantly higher levels of leptin (median 5.5 ng/ml, IQR 9) were found in the patient group on TNFα blockers compared to that on IMD therapies (median 2.5 ng/ml, IQR 6) ($p = 0.049$). Considerably lower levels of TNFα (median 6 ng/ml, IQR 14) were observed among patients on anti-TNFα therapies compared to IMD group (median 14.5 ng/ml, IQR 7) ($p = 0.02$). No difference of apelin levels between two groups was detected ($p = 0.791$). No significant correlation between leptin serum levels and the increase of body weight was detected (Spearman coefficient $r = 0.041$, $p = 0.684$) as well as between the levels of TNFα and the body weight escalation (Spearman coefficient $r = 0.036$, $p = 0.741$).
Conclusion: The increase of weight gain in anti-TNF treated IBD patients may be attributed to elevated levels of leptin caused by the anti-TNF α treatment. A further mechanism is the reduction of TNFα itself.

Contact E-mail Address: guillaume.pinetondechambrun@chru-lille.fr
Introduction: At least 50% of Crohn's disease (CD) patients will need surgical resection during their follow-up. Infliximab and adalimumab are effective to prevent postoperative recurrence in CD patient naïve from anti-TNFα antibodies (anti-TNFα). The effect of previous exposure to one or more anti-TNFα before surgery on prevention of post-operative recurrence by these agents is still unknown.
Aims & Methods: The aim of our study was to investigate the efficacy of anti-TNFα to prevent CD post-operative recurrence according to previous exposure to these drugs.
We performed a retrospective analysis of CD patients, followed in a tertiary referral centre, who underwent surgical bowel resection and prophylactic treatment with anti-TNFα between January 2005 and June 2012. Infliximab, adalimumab and certolizumab pegol were considered as prophylactic treatments if started within three months after surgery. Endoscopic recurrence defined as a Rutgeerts score $\geq$ i2 and clinical recurrence defined as physician judgment. We assessed those endpoints one year after surgery and also during the follow-up.
Results: Fifty-seven consecutive CD patients with bowel resection, anastomosis and prophylactic treatment with anti-TNFα were included in the study. Twenty two patients (39%) had prior intestinal resection for CD and a majority (45, 79%) were treated with at least one anti-TNFα before surgery. Twenty-four (42%) received two or more anti-TNF before surgery and 12 (21%) patients were naïve from anti-TNFα. Thirty-nine (67%) patients had a surveillance colonoscopy one year after surgery. At one year, the global endoscopic and clinical postoperative recurrence rates were 42% (17/39) and 19% (11/57), respectively. According to previous exposure to anti-TNFα, patients with two or more anti-TNF before surgery had a higher one-year endoscopic recurrence rate compared with patients that received one or zero anti-TNFα before surgery (62%, $n = 13/21$ vs. 31%, $n = 4/13$ vs. 20%, $n = 1/5$). Also, patients with two or more anti-TNFα before surgery had a higher rate of clinical recurrence compared with patients receiving less than two anti-TNFα before surgery (37%, $n = 9/24$ vs. 12%, $n = 4/33$, $p = 0.05$). In multivariate analysis, smoking ($HR = 3.2$; IC 95%: 1.2-7.8) and previous exposure to two or more anti-TNFα ($HR = 4.3$; IC 95%: 1.3-14.0) were significantly associated to the risk of clinical postoperative recurrence in CD patients.
Conclusion: Previous exposure to two or more anti-TNFα agents was associated to a higher risk of postoperative recurrence in CD patients receiving prophylactic treatment with anti-TNFα.
This study suggested that previous exposure to anti-TNFα should be taken into account when managing prevention of post-operative recurrence in CD patients.

P0983 THE ROLE OF DIFFUSE NEUROENDOCRINE SYSTEM OF STOMACH AND INTESTINES IN THE OCCURRENCE OF IRRITABLE BOWEL SYNDROME WITH DIARRHEA IN CONJUNCTION WITH FUNCTIONAL DYSPEPSIA: THERAPY OPTIMIZATION

M. A. Osadchuk[1], **V. O. Burdina**[1], M. M. Osadchuk[1], K. S. Solodenkova[1]
[1]*I. M. Sechenov First Moscow State Medical University, Moscow, Russian Federation*

Contact E-mail Address: mikhail-osadchuk@mail.ru
Introduction: Endocrine cells (EC) of the gastric and intestinal mucosa secrete somatostatin (SS), vasoactive intestinal peptide (VIP) and motilin (MLN). The purpose of this study was to define the role of EC in the occurrence of irritable bowel syndrome with diarrhea (IBSd) in combination with functional dyspepsia (FD) and to optimize management of his comorbidity.
Aims & Methods: The study involved 45 patients with IBSd combined with FD. Inclusion criteria were age between 18 and 55 years; compatible with the Rome criteria III (2006) diagnosis of IBS and FD. The biopsy was taken during gastroscopy and colonoscopy from the antral mucosa and middle thirds of the sigmoid colon. Immunohistochemical examination was based on the use of murine monoclonal antibodies to SS, VIP and MLN (1: 100, Novocastra). All patients were randomized in a 1:1 ratio, depending on the nature of ongoing therapy. 22 patients (group 1) received therapy comprising proton pump inhibitors (PPI) in a dose of 40 mg per day, mebeverine (400 mg daily) and loperamide (until stool normalization). 23 patients (group 2) received dioctahedral smectite (1-3 sachets per day until stool normalization) instead of loperamide. Dynamic immunomorphological study was carried out at the manifestation of IBS and in remission after one month. The comparison group consisted of 20 healthy subjects.
Results: We defined increased number of EC, producing MLN and VIP, end reduced number of EC, synthesizing SS in mucous membrane of the antrum and colon in patients with IBSd in period of exacerbation, unlike the comparison group of persons. In the period of remission normalization of EC producing M, SS and VIP in the majority of patients was observed. In some patients the number of EC did not normalize, accompanied by the presence of residual symptoms. In group 1 stool normalization and epigastric pain disappearance were achieved in 20 patients at Day 4. In group 2 disappearance of the main clinical symptoms of FD and IBS was observed in 22 patients after 3 days of initiating therapy.
Conclusion: The obtained results suggest an important role of the diffuse neuroendocrine system in the occurrence of IBS with FD. Revealed changes in quantitative characteristic of EC in different parts of the digestive tract can explain the frequent combination of IBS with FD. Inclusion of dioctahedral smectite in drug therapy leads to an earlier clinical disappearance of disease but does not affect the quantitative characteristic of EC producing MLN, SS and VIP.

P0984 PREDICTORS OF DISEASE RELAPSE OF PATIENTS WITH CROHN'S DISEASE IN DEEP REMISSION: WHO AND WHEN CAN WITHDRAW THIOPURINE MAINTENANCE THERAPY?

Y. Qiu[1], R. Mao[1], B.-L. Chen[1], H. Yao[1], Z.-R. Zeng[1], **M. Chen**[1]
[1]*Department of Gastroenterology, First Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China*

Contact E-mail Address: qyun2012@gmail.com
Introduction: Few data are available on the disease course of cessation of thiopurine (TP) therapy for Crohn's disease (CD) with deep remission (DR) in routine clinical practice.
Aims & Methods: We aimed to evaluate clinical outcomes and factors associated with relapse in CD patients with DR. 109 CD patients in clinical, endoscopic remission following formal disease assessment and elective TP withdrawal were included. Prognostic factors of relapse were looked for through a proportional hazards model.
Results: After a median follow-up period of 46 months (interquartile range, 27.5-67.6 months), 50 (45.87%) patients had ER and 41 (37.61%) patients had flare, 18 (16.51%) patients undergone operation, and 25 (22.94%) patients hospitalized. The cumulative probabilities of maintaining clinical ($P = 0.48$) or endoscopic remission ($P = 0.67$), and free of bowel surgery ($P = 0.62$) or hospitalization ($P = 0.72$) at 5 years did not differ between patients maintaining TP or withdraw TP.
A scoring system based on age, CRP, disease duration and incidence of bowel complications was developed which can predict a mild prognosis after the achievement of DR, giving patients the chance of therapy de-escalation. In

selective CD patients in DR without defined risk factors, up to 70% remained in clinical remission during the 60-month follow-up after the cessation of TP therapy. Importantly, 78% of these patients sustained endoscopic remission, 93.3% also free of bowel surgery.
Conclusion: No significant difference regarding the long-term outcomes of patients with DR maintaining TP or withdraw TP. Furthermore, a group of low-risked patients among whom therapy de-escalation maybe reasonably considered has been identified.

P0985 IMPACT OF LONG-TERM TREATMENT WITH AZATHIOPRINE ON DISEASE PROGRESSION IN PATIENTS WITH EARLY CROHN'S DISEASE

Y. Qiu[1], R. Mao[2], B.-L. Chen[1], Y. He[1], Z.-R. Zeng[1], **M.-H. Chen**[1]
[1]*Department of Gastroenterology,* [2]*First Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China*

Contact E-mail Address: qyun2012@gmail.com
Introduction: The impact of azathioprine (AZA) on the damage-based long-term outcome of early Crohn's disease (CD) still controversial. We aimed to evaluate the efficacy of AZA in patients with early CD.
Aims & Methods: To identify predictive factors associated with the long-term outcome of disease.
This longitudinal cohort study examined patients from a university-based IBD referral centre (2000 to 2013 year). Cox regression analysis was performed to identify potential predictive factors of CD progression.
Results: 190 Patients with early CD were followed- up prospectively for a total of 893 patient-years on AZA. After a median follow-up of 57 months (interquartile range, 31.3-76.2 months), 29 patients underwent abdominal surgery, 48 patients hospitalized, and 68 patients experienced clinical flare. The cumulative rate of free of CD- related bowel surgery, hospitalization and flare at 5-year on AZA treatment was 0.65, 0.59 and 0.39, respectively. The median CD-related bowel surgery-free survival, CD-related hospitalization-free survival and flare-free survival were 67.9 months (95% confidence interval (CI), 60.0-75.7), 67.9 months (95%CI 55.8-88.0), and 49.3 months (95%CI 34.9-63.7), respectively. Four independently predictors of Crohn's related operations were identified: prior bowel resection (hazard ratio (HR), 9.91; 95%CI 3.74-26.24), smoking (HR, 4.79; 95%CI 1.75-13.17), an AZA treatment duration < 40 months (HR, 8.3; 95%CI 2.19-31.47) and a baseline hemoglobin < 110 g/L (HR, 5.46; 95%CI 2.21-13.48). Prolonged use ($\geq$40 months) of AZA also independently predictive of free of CD- related hospitalization (HR 3.02) but not increase risk of adverse events ($P = 0.23$).
Conclusion: Prolonged use ($\geq$ 40 months) of AZA was associated with a more favourable course of early CD (lower risk of CD- related bowel surgery and hospitalization) without increasing the risk of adverse events.

Contact E-mail Address: nadia.pallotta@uniroma1.it
Introduction: Several independent predictors for complicated, severe or aggressive Crohn' disease (CD) have been so far identified with a wide variation across studies (1). However progression disease predictors are not still clearly identified and it is not known whether the degree of bowel damage is a risk factor for disease progression. Intestinal ultrasound after the ingestion of oral contrast (SICUS) accurately measures CD small bowel intestinal lesions and complications (2).
Aims & Methods: To assess among demographic, clinical, laboratory factors and SICUS findings, those that may predict the modality of CD progression to identify with a easily used risk score patients requiring a more intensive monitoring and preventive treatments. This prospective cohort study includes 160 CD patients (93 M, median age 31 yrs; B1 25%, B2 56%, B3 19%; L1 61%, L3 32%, L2 6%; PD 29%) seen at regular 6-12 month interval, irrespective of clinical recurrence. During a median follow-up of 7.9 yrs, mean lag-time between visits 7.2 months, a total of 1464 visits (on average 9 per patient, range: 2-23), each assessing clinical, laboratory, endoscopic, and SICUS findings, were performed. By Poisson models we evaluated the predictors at each visit of having, within the next visit the need to change treatment starting azathioprine or biologics. Visit to visit interval was considered as exposure time. Independent predictors were: gender, age at diagnosis, CD duration, location and behavior, perianal disease, CDAI, GI symptoms, inflammatory markers, BMI, smoking, family history, SICUS findings, systemic symptoms, steroids at first flare, use of steroids, azathioprine and biologics, previous surgeries. Continuous variables were categorized based on the quartile values. The predictors included in the final model were chosen by a backward selection including at each step only variables with an adjusted p-value < 0.15. Standard errors of the Poisson parameter models were adjusted for visits clustering within the same patient. Risk scores were realized taking for each predictor the integer part of each model coefficient (i.e., the logarithm of the estimated incidence rate ratio (IRR)) (2) and then summing all those present at each visit, being zero the lowest possible score. Finally goodness-of-fit test was performed.
Results: Four independent factors predict the need to start biologics within the next visit: at SICUS the presence of 1) CD complications or 2) small bowel CD lesion > 20 cm in absence of CD complications, 3) presence of specific intestinal symptoms; 4) the presence of inflammatory markers. The calculated integer risk score ranged from 0 to 5 points. Three independent factors predicts the need to start azathioprine within the next visit: 1) female gender; 2) BMI value < 21; 3) CDAI at visit > 50. The calculated integer risk score ranged from 0 to 4 points.
Conclusion: In CD patients a readily available risk score allows to identify those patients in need of more intensive monitoring and therapy

P0987 COMPARATIVE SHORT-TERM EFFICACY OF CYCLOSPORIN, TACROLIMUS, INFLIXIMAB AND ADALIMUMAB AS RESCUE THERAPY IN HOSPITALIZED PATIENTS WITH SEVERE CORTICOSTEROID REFRACTORY ULCERATIVE COLITIS: A RETROSPECTIVE INVESTIGATION

N. Yoshimura[1], R. Tanaka[1], M. Sako[1], M. Takazoe[1]
[1]*Department of Internal Medicine, Division of IBD, Tokyo Yamate Medical Centre, Tokyo, Japan*

Contact E-mail Address: ynaokun@yahoo.co.jp
Introduction: The optimum therapeutic strategy for patients with severe steroid refractory ulcerative colitis (UC) is still a challenging clinical issue. Currently, cyclosporin A (CsA), tacrolimus (Tac), infliximab (IFX), and adalimumab (ADA) have been administered as rescue therapy for severe steroid refractory UC. However, there is inadequate evidence for clinical efficacy difference between these 4 medications.
Aims & Methods: We were interested to evaluate the short-term efficacy and safety of CsA, Tac, IFX, and ADA as rescue therapy to avoid colectomy in patients with severe UC after failure of corticosteroids. This was a single-centre retrospective investigation involving 213 consecutive corticosteroid (iv, up to 60mg/day) refractory inpatients with acute severe to fulminant UC. Lichtiger's clinical activity index (CAI) ≤ 16 meant severe UC, while CAI ≥ 17 meant fulminant UC. Patients received one of the following medications, iv CsA (initially 3mg/kg/day, aiming for blood levels of 400-600ng/ml, n = 92), oral Tac (initially 0.05mg/kg twice a day, aiming for blood trough levels of 10-15ng/ml, n = 46), IFX (5mg/kg at weeks 0, 2, n = 47), or ADA (160mg at week 0, 80mg at week 2; n = 28). Patients who did not improve after the first rescue therapy could switch to one of the other 3 medications as the 2nd rescue therapy or undergo colectomy. The primary clinical efficacy was evaluated at week 4 after the first rescue therapy. Further, at week 6, the efficacy of the 2nd rescue therapy was assessed. Clinical remission was defined as CAI ≤ 4. Additionally, patients received regular evaluations for adverse effects.
Results: Within 4 weeks, 156 of the 213 patients (73.2%) achieved remission with the first rescue therapy including 132 of 160 (82.5%) with severe UC and 24 of 53 (45.3%) with fulminant UC ($P < 0.05$). In the CsA group, 69 of 92 patients (75.0%) achieved remission vs 33 of 46 (71.7%) with Tac, 34 of 47 (72.4%) with IFX, and 20 of 28 (71.4%) with ADA (difference not significant). Further, for remission rate vs UC severity, with CsA, 49 of 58 (84.5%) patients with severe UC and 20 of 34 with fulminant UC (58.8%) achieved remission vs 31 of 38 (81.6%), and 2 of 8 (25.0%) for Tac, 32 of 40 (80.0%), and 2 of 7 (28.6%) for IFX, 20 of 24 (83.3%), and 0 of 4 for ADA ($P < 0.05$ for CsA vs Tac, IFX or ADA with respect to fulminant UC). After 6 weeks, 29 of 57 patients (50.9%) who had failed to respond to the first rescue therapy could avoid colectomy by switching to the 2nd rescue therapy. No patients experienced serious adverse events and there was no mortality.
Conclusion: In the first rescue therapy, the efficacy and safety of CsA, Tac, IFX and ADA were not significant different. In patients with fulminant UC, the efficacy of CsA was better than the other 3 medications for avoiding colectomy. Therefore, a 2nd rescue therapy should further reduce colectomy rate.
Disclosure of Interest: None declared

P0988 SHORTENING INTERVAL INJECTION OF ADALIMUMAB IS MORE EFFICIENT THAN DOUBLING DOSE IN CROHN'S DISEASE PATIENTS WITH LOSS OF RESPONSE

N. Duveau[1], M. Nachury[1], M. Boualit[1], R. Gerard[1], J. Branche[1], V. Maunoury[1], P. Desreumaux[1], B. Pariente[1]
[1]*CHRU Lille, Université Lille 2, Lille, France*

Contact E-mail Address: nicolas.duveau@gmail.com
Introduction: Adalimumab (ADA) is effective for the management of Crohn's disease (CD), but relevant proportion of patients treated will experience a loss of response after a primary response. Response to dose escalation to ADA is a major concern in clinical practice as only few therapeutics agents have shown their efficacy in CD. The aim of the present study was to evaluate early and sustained response to ADA dose escalation for CD patients with secondary loss of response and to identify predictors of clinical response.
Aims & Methods: We conducted a retrospective observational study, including all patients who underwent a dose escalation of ADA after a secondary loss of response from 2007 to 2015. Main outcome was clinical response to dose escalation at weeks 12 (defined by continuation of ADA with no new dose escalation, no introduction of corticosteroids or immunosuppressors, and no surgery). Kaplan–Meier analysis was used to describe duration of sustained response after dose escalation over time. Univariate and multivariate logistic

regression analyses were performed to identify predictors of response to ADA dose escalation at weeks 12 and 52.
Results: One hundred and twenty four patients were included. Among them, 81/124 (65%) had non-penetrating non-structuring disease, 31/124 (25%) structuring disease, and 12/124 (9%) penetrating disease. Fifty (40%) patients underwent previous intestinal resection. Sixty-seven (54%) patients received previous infliximab treatment. Median time to dose escalation was 44 weeks (IQR 18-117). At ADA dose escalation, 26/124 (20%) patients received concomitant immunosuppressors and 20/124 (12%) received concomitant corticosteroids. ADA dose escalation was achieved by shortening interval to 40 mg every week (ew) in 100/124 (80%) patients, and by increasing dose to 80 mg every other week (eow) for in 24/124 (19%) patients. Clinical response at weeks 12 was observed for 99/124 (79%) patients. In multivariate analysis, factors predicting response to ADA dose escalation at week 12 were a stricturing behavior (OR 2.55, 95% CI : 1.00-6.45 ; p = 0.048) and duration of ADA therapy more than 44 weeks before ADA loss of response (OR 9.83, 95% CI : 1.25-76.81 ; p = 0.029). In patients with initial response to ADA dose escalation at week 12, cumulative probabilities of sustained response were 91%, 76% and 58% at 6, 12 and 24 month, respectively. In multivariate analysis, shortening interval injection of ADA to 40 mg ew was the sole predictive factor of sustained clinical response at week 52 (OR 4.91, 95% CI : 1.00-24.24 ; p = 0.05). Among all the patients, ADA was stop after dose escalation in 2 patients because of side effect (one for myocarditis and one for paradoxical psoriasiform skin lesions).
Conclusion: ADA dose escalation can recapture clinical response at week 12 in most CD patients who experienced a secondary loss of response to ADA; the majority of patients with initial response maintained clinical response over time. Importantly, shortening interval injection to 40 mg ew (compared to increasing dose to 80 eow) was the sole predictive factor for a sustained response to ADA dose escalation.

P0989 ENDOSCOPIC DILATATION OF CROHN'S ANASTOMOTIC STRICTURES IS EFFECTIVE IN THE LONG-TERM AND ESCALATION OF MEDICAL THERAPY IMPROVES OUTCOMES

N. S. Ding[1], Y. W. Man[1], B. Saunders[2], S. Thomas-Gibson[2], N. Arebi[1], A. Humphries[2], A. Hart[1]
[1]*Inflammatory Bowel Disease,* [2]*Wolfson Endoscopy Unit, St Mark's Hospital, London, United Kingdom*

Contact E-mail Address: dingnik@gmail.com
Introduction: A clinically relevant stricture is usually defined as a luminal narrowing with pre-stenotic dilatation and obstructive symptoms. Surgical resection is an effective treatment for Crohn's anastomotic strictures, however disease recurrence after 15 years is more than 50%, often with the need for a further resection[1]. The long-term outcome of endoscopic balloon dilatation is unclear as most cohorts have a follow-up time of less than 3 years.
Aims & Methods: All endoscopic balloon dilatations performed at a single centre for patients with anastomotic Crohn's strictures between 2004-2009 were retrospectively reviewed with the aim of collecting long-term follow-up data. The stricture length, signs of disease activity and evidence of upstream dilatation were assessed from imaging. Clinical data on medical therapy and escalation to anti-TNF or thiopurines was obtained. Endoscopic data including disease activity, balloon size and therapeutic success, along with histological reports were recorded with images graded by an experienced endoscopist.
Results: A total of 54 patients were identified with a median age of 52 years (46-62). 21/54(39%) were male. The median follow-up period was 6 years(5-7) with a median disease duration of 28 years(19-32). Stricture length at cross-sectional imaging was described in all cases with a median of 20mm(10-30), features of active mucosal inflammation were described at the anastomosis in 38/54(70%) and upstream dilatation in 25/54(46%). At endoscopy, active disease was reported in 50/54(92%) of cases and a median balloon dilatation of 15mmHg was used to achieve therapeutic success in 48/54 (89%). The median number of dilatations was 2(IQR 1-9) with a time to repeat dilatation of 23months (7.2-56.9) with 31/44 (70%) of patients being managed endoscopically requiring repeat dilatations. There was one perforation which resulted in a resection of the anastomosis and temporary ileostomy.
Rutgeert's grading of endoscopic images was possible in 50/54 cases with a median of i2 (range 1-4). 10 (18%) patients had anastomotic resection with a Rutgeert's score of $\geq$i2 being positively associated with this outcome (p = 0.048). Female gender (OR 1.604 95%CI 1.093-2.352 p = 0.028), active disease at time of first endoscopy (OR 2.45 95% CI 1.145-5.234 p = 0.021) and length of stricture > 20mm (p = 0.015) predicted need for repeat dilatation. Furthermore, escalation of medical therapy to either azathioprine or anti-TNF resulted in a delay in time to repeat dilatation in Cox-regression analysis.
Conclusion: At long-term follow-up only 18% of patients required surgical resection. Of the remaining patients 32% were well with no further endoscopic intervention required. 68% required intercurrent endoscopic dilatation. This is the longest follow-up period in the literature and demonstrates that endoscopic dilatation is effective and appropriate escalation of medical therapy appears to delay the need for further interventions.

Contact E-mail Address: dingnik@gmail.com
Introduction: Primary non-response (PNR) and secondary loss of response (LOR) are major issues affecting ongoing use of biological therapy in Crohn's disease. Mucosal healing is currently the endpoint of many clinical trials and has been shown to improve outcomes. However, clinical or biochemical biomarkers of prediction for anti-TNF therapy are currently lacking.
Aims & Methods: We aim to determine factors using endoscopy and histology to predict PNR and secondary LOR with anti-TNF therapy in patients with Crohn's disease.
Patients who were commenced on anti-TNF therapy (adalimumab or infliximab) from Jan 2007- June 2014 were identified along with clinical data, including demographics and phenotype. Patients with a colonoscopy and biopsies taken within 6 months of commencement of an anti-TNF and a further group with histology obtained within 12 months of their first dose were included. Each colonic segment of the colonoscopy was evaluated for activity of disease. Histology was assessed by a gastrointestinal pathologist who was blinded to the clinical data. PNR was defined by global assessment (clinical and biochemical) of lack of improvement within 6 months of commencement of anti-TNF therapy. Secondary LOR was defined as cessation of their anti-TNF in view of clinical deterioration as assessed by their gastroenterologist. Variables influencing PNR, secondary LOR and surgery were examined using the chi-square test, Wilcoxon rank-sum test and Cox-squared logistic regression
Results: 237 patients were identified; with 91 (38%) having ileal involvement (Table 1). There was no difference between PNR and secondary LOR in patients on combination therapy versus secondary LOR (p = 0.12). PNR occurred in 36 (15%) patients and secondary LOR in 58 (24%) with 122 (51%) having ongoing anti-TNF therapy. Crypt architecture distortion was found in 64 (34%), lymphoid aggregates in 14% and granuloma(s) in 8%.
On univariate analysis, PNR was associated with smoking (p = 0.048), > 5 segments of disease at colonoscopy (p = 0.012) and granuloma(s) (p = 0.045) in a biopsy specimen. Ileal disease was associated with a greater likelihood of response (p = 0.046). On univariate analysis, secondary LOR was associated with smoking (HR 2.53 p = 0.018) and presence of lymphoid aggregates (HR 1.78 p = 0.038). Multivariate analysis for PNR was significant for smoking and > 5 diseased segments at colonoscopy. Multivariate analysis for secondary LOR factors was smoking. Cryptitis and crypt abcesses were not significant in either univariate or multivariate analyses.

Table 1: Baseline characteristics of patients

Characteristics (n = 237)	Median (IQR)
Age	30 (18-45)
Gender	45% male
Disease phenotype	Ileal involvement (38%)Stricturing disease (25%)
Duration of anti-TNF therapy	19 months (10-36).

Conclusion: Smoking is associated with PNR and secondary LOR. Extent of involvement (> 5 segments of disease at colonoscopy) was associated with PNR. Histologic factors such as granuloma and lymphoid aggregates may contribute to prediction for PNR and secondary LOR respectively.
Disclosure of Interest: None declared

P0991 THE EFFECTIVENESS AND SAFENESS OF ALLOGENEIC MESENCHYMAL STROMAL CELLS IN PATIENTS WITH REFRACTORY CROHN'S DISEASE - 5 YEARS OF OBSERVATION

O. Knyazev[1], A. Kagramanova[1]
[1]*Department of Inflammatory Bowel Disease, Moscow Clinical Research Center, Moscow, Russian Federation*

Contact E-mail Address: oleg7@bk.ru
Introduction: Crohn's disease (CD) is a chronic inflammatory disease of the gastrointestinal tract with recurrent nature of the flow. The frequency of exacerbations is approximately 20-25% at 1 year and 75% for 3 years. If the remission lasted less than 12 months, there is a 65% chance that the aggravation comes in the next 18 months. Aim. To evaluate the influence of culture of allogeneic mesenchymal stromal cells (MSCs) of bone marrow for the duration of remission in patients with refractory CD.
Aims & Methods: The 1-st group of patients with CD (n = 30) received MSCs, the dose of prednisone was not more than 20 mg/day. The second group of patients (n = 30) received standard anti-inflammatory drug therapy of 5-aminosalicylic acid (5-ASA) and glucocorticosteroids (GCS). Age of patients ranged from 19 to 49 years (Me-36 years). The disease was of moderate and high activity, length of damage - ileokolit, ileitis and colitis, the observation time ranged from 42 to 68 months. Clinical activity was assessed by the Crohn's disease activity index (CDAI). The culture of allogeneic MSCs injected drip at 2.5 million per 1 kg of body weight (0-1-26 weeks).
Results: CDAI in the 1st group was 242.6 ± 11.7 points, in the 2nd 240.9 ± 12.9 points (p = 0.83), CRP levels in 1st group was 29.3 ± 6.4 mg/l, the 2nd - 27.8 ± 4.8 (p = 0.47). After 1 year of follow-CDAI in 1st group was 70.0 ± 11.0 points, in the

2nd - 133.8 ± 22.2 points ($p < 0.001$), CRP levels in 1st group was 6.36 ± 1.5 mg/l, in the 2nd - 12.2 ± 2.9 ($p < 0.001$). After 2 years CDAI 1st group was 99.6 ± 19.3 points, in the 2nd - 147.1 ± 22.1 points ($p < 0.001$), CRP levels in 1-st group was 16.0 ± 6.0 mg/l, in the 2nd - 18.8 ± 4.4 ($p = 0.156$). After 3 years, the CDAI in 1st group was 110.5 ± 21.9 points, in the 2nd - 180.6 ± 20.3 points ($p < 0.001$), CRP levels in 1st group was 10.9 ± 2.6 mg/l, in the 2nd - 16.9 ± 3.0 ($p < 0.001$). After 4 years - the CDAI in 1st group was 120.0 ± 22.3 points, in the 2nd - 208.7 ± 17.6 points ($p < 0.001$), CRP levels in 1st group was 11.3 ± 2.6 mg/l, in the 2nd - 15.5 ± 2.4 ($p < 0.001$). After 5 years - the CDAI in 1st group was 126.0 ± 23.8 points, in the 2nd - 248.7 ± 14.6 points ($p < 0.001$), CRP levels in 1st group was 12, 3 ± 2.8 mg/l, in the 2nd - 19.5 ± 3.1 ($p < 0.001$). In the first group of patients in remission after 1, 2, 3, 4, and 5 years was kept at 70%, 56.6%, 50%, 46.7% and 33.3%, respectively. In the second group of patients at 1, 2, 3, 4, and 5-year remission was maintained at 36.6%, 26.6%, 13.3%, 6.67% and 6.67%, respectively. Complete healing of the intestinal mucosa in 60% of patients in the first group during the 1st year of observation, after 5 years - 26.7%. Over the entire period of observation never there were no malignant transformation, life-threatening infectious complications and death.

Conclusion: Transplantation of MSCs contributes to longer-term clinical and endoscopic remission in patients with refractory Crohn's disease compared with therapy with corticosteroids

P0992 CHANGES OF COLONIC MICROBIOTA AND EFFICACY OF ORAL PROBIOTIC THERAPY IN IBD

O. Plehutsa[1], R. Sydorchuk[2], L. Sydorchuk[2], I. Sydorchuk[2]
[1]*District Hospital, Briceni, Moldova, Republic of,* [2]*Bukovinian State Medical University, Chernivtsi, Ukraine*

Contact E-mail Address: supers_stars@uni.de

Introduction: The mechanisms explaining complex relationship between the commensal colonic microbiota and inflammatory bowel disease (IBD) have a common outcome, a violation of bacterial antigens exposure to effector T-cells and innate immune cells residing in the intestinal mucosa and/or alteration of the host immune response to bacteria. While the role of gut microbiota and respective immune changes has become more evident in recent years there is no sufficient database explaining the character of microbiota changes in IBD. Expanding this idea, probiotics have been the subject of intensive research, mainly focusing on bifidobacteria and lactobacteria. However, existing reports of probiotic use in IBD are contradictory.

Aims & Methods: The aim of this study was to find relation between changes of colonic microbiota and IBD, introduce rarely used probiotic, and understand whether oral probiotic therapy with *P. Shermani* has any therapeutic significance in IBD. Totally 104 individuals participate in the study. Colonic resistance studied in mucosal bioptates. Standard aerobic and anaerobic microbiology techniques with nosology identification and quantity composition of microbiota were used. Specially designed strain of *P. Shermani* (T73) with high antagonistic potential was orally given twice on a daily basis during 150-180 days in a form of suspension containing 10^{12}-10^{14} bacteria. Patients without probiotic treatment formed control. Both groups' patients received mesalazine 1500-3000 mg daily as a basis therapy. Treatment efficacy evaluated according to WGO Global Guidelines and included CDAI, SF-36 and IBDQ scores.

Results: Major autochthonic species (14 in total) were present in all samples: among them Lactobacteria, Bifidobacteria, *E. coli*, several other anaerobic species were dominating. However, Lacto- and Bifidobacteria were found in significantly lower levels compared to healthy subjects ($p = 0.02$-0.0031). The general tendency for colonic resistance in IBD was decrease of autochthonic anaerobes (Bifido-, Lactobacteria, Bacteroides spp, Clostridia spp, Bacillae spp.) and significant growth of allochtonic aerobes and facultative anaerobes (*E.coli* Hly+, Pseudomonas, Serratia, Hafniae, *P. mirrabilis* and other conditionally pathogenic Enterobacteriaceae). Enterococci were present in 60.0% of healthy and 7.14-20.69% of IBD patients. Staphylococci were present only in IBD group (17.24-31.58%). There were 16.67% and 22.22% recurrences requiring hospitalization during the study period. CDAI score at the end of study was 49.37 ± 3.14 points lower in study group ($p < 0.05$). SF-36 score difference between groups became 11.8 ± 0.84 %. Abdominal pain, stool, and drug use for symptomatic therapies improved in study group, too. However, probiotic treatment did not influence anemia and other extraabdominal symptoms. Endoscopic picture and biopsies presented no specific differences between groups after treatment.

Conclusion: Our data suggest that morbid changes of colonic mucosal microbiota, e.g. abnormal ratio of autochtonic and allochtonic species, may be considered as a strong characteristic feature of IBD. We hypothesized that results of existing studies of probiotic use in IBD are confusing due to improper selection of probiotic agent. *P. Shermani* T73 is comparatively rare and understudied probiotic, showing its usefulness for use in IBD.

Introduction: Conventional thiopurines (Azathioprine/6-Mercaptopurine) remain the cornerstone of maintaining remission in steroid-dependent inflammatory bowel disease (IBD). Despite the well-documented efficacy of these drugs, more than 50% of patients discontinue treatment due to adverse events or therapy resistance. Over the past decade, there has been renewed interest in the use of 6-thioguanine (TG), an agent historically used in haematological malignancy. With a shorter metabolic pathway, TG possesses a favourable side effect profile and it's use as an alternative thiopurine in IBD is growing. We report our experience in tolerability, safety and efficacy of TG use in a London district general hospital.

Aims & Methods: A retrospective review of electronic patient records including clinic letters, blood tests and endoscopic findings were carried out on patients commenced on TG between 2012 and 2015. Data was collected on patient demographics, indication and duration of therapy, response rates and reasons for treatment failure.

Results: A total of 28 patients received TG and median treatment duration was 14 months (range 1-40). Therapy was equally distributed amongst males and females (14:14), and mean age was 44 years (range 19-67). 14 (50%) patients had Ulcerative colitis (UC), 13 (46%) Crohn's disease (CD) and 1 (4%) Indeterminate colitis. 24 patients (86%) received TG due to adverse reactions to conventional thiopurines vs. 3 patients (11%) who were non-responders. Treatment with TG resulted in clinical remission in 86% (19/22) patients at 6 months and 75% (12/16) at 12 months. In total, 6 patients (21%) discontinued TG. 4 patients failed treatment (2 continued alternative medical therapy and 2 had surgery) and 2 suffered adverse events (headaches and confusion). Tolerability and efficacy rates were similar in both UC and CD groups. All patients underwent blood monitoring and no abnormalities in liver function tests were detected. Of those who underwent MRI liver there was no evidence of nodular regenerative hyperplasia.

Conclusion: TG was well tolerated with comparable remission rates to conventional thiopurine therapy. We advocate the use of TG therapy in selected cases where conventional thiopurine therapy has failed or resulted in adverse reactions. Larger prospective trials are required to further evaluate the efficacy and safety of TG, with a view to potentially incorporate it's use into clinical guidelines.

Contact E-mail Address: patrizia.kump@medunigraz.at

Introduction: Faecal microbiota transplantation (FMT) is investigated as a new therapeutic tool in chronic active ulcerative colitis (UC). The efficacy however, varies among distinct study protocols for FMT administration. The aim of this study was to investigate the impact of antibiotic treatment before FMT for therapy refractory chronic active UC.

Aims & Methods: 27 patients with chronic active UC were treated with an antibiotic triple therapy for 10 days. Afterwards 17/27 patients received FMT via colonoscopy into the right colon, which was repeated in 14 days intervals by sigmoidoscopy for a total of 5 applications (FMT group). 10/27 patients received antibiotic triple therapy without subsequent FMT and any other therapy (AB group). Clinical efficacy was assessed by total mayo score. Furthermore disease activity was also measured by faecal calprotectin and endoscopy. The follow up of the patients were 90 days and end of follow up to 30 weeks respectively.

Results: Antibiotic treatment led to an overall reduction of the Mayo score from 8.4 to 6.8 in all patients (9.0 to 7.3 in the FMT group; 7.5 to 5.9 in the AB group) within 10 days. In contrast to sole antibiotic therapy, FMT showed an additional benefit in the follow-up period of 30 weeks (total Mayo score FMT group 9.0 to 4.7 points vs 7.5 to 6.3 in the AB group). Adherence to therapy during follow up in the AB group was low (5/10; 50%) due to *Clostridium difficile* infection (3/10), acute UC flare (1/10) and antibiotic-associated diarrhea (n = 1/10) vs. 100% in the FMT group. Overall, at day 90 clinical remission was assessed in 4/17 patients (total Mayo score $\leq$ 2), partial responders in 6/17 patients (reduction of total Mayo score $\geq$ 3 points) in the FMT group, versus partial response in 2/5 patients in the AB group.

Conclusion: Our data demonstrate a clinical benefit of antibiotic treatment before FMT in chronic active UC, whereas antibiotic therapy without consecutive FMT in chronic active UC is poorly tolerated.

Introduction: Ustekinumab, a human monoclonal antibody against the p40 subunit of interleukin (IL)-12 and IL-23, has been shown to be effective in Crohn's disease (CD) patients refractory to anti-tumor necrosis factor (TNF) in a phase-2 trial.
Aims & Methods: The aim of the present study was to assess benefit and safety of subcutaneous (SC) ustekinumab in a multicenter cohort of anti-TNF refractory CD patients. A retrospective observational study was conducted in tertiary centers from the GETAID, including all consecutive active CD patients refractory to anti-TNF treatment, who received at least one SC injection of ustekinumab and had a follow-up of at least 3 months. The primary outcome was ustekinumab clinical benefit at 3 months, defined by a significant improvement as judged by the physician leading to continue the treatment with complete steroids weaning if given at inclusion. Ustekinumab safety and clinical benefit at 6 and 12 months were also recorded.
Results: One hundred twenty-two patients (87 females, median age: 38.8 years, IQR: 27.5-43.9) received at least one SC ustekinumab injection in 20 centers from France and Switzerland. At baseline, median disease duration was 12.9 years (IQR: 6.9-17.1); 119 (97.5%) patients experienced previous failure or intolerance to thiopurines or methotrexate and 122 (100%) patients have failed to at least one anti-TNF agent (infliximab or adalimumab, with 112 (91.8%) subjects who received both anti-TNFs) and 75 (61.5%) patients underwent prior intestinal resection. Ustekinumab was given for luminal CD to 110 (90.2%) patients and for perianal disease to 12 (9.8%). At inclusion, 18 (14.7%) patients received immunosuppressant (IS) and 19 (15.6%) steroids. Clinical benefit of ustekinumab at 3 months was observed in 79/122 (64.7%) patients in the whole population and in 8/12 (67%) patients treated for perianal disease. Concomitant IS at inclusion was the sole predictive factor of clinical benefit to ustekinumab at 3 months with an odds ratio of 5.43 (95% CI: 1.14- 25.77; $p = 0.03$). With a median follow-up duration of 9.8 months (IQR: 4.9-14.5 months), cumulative probability of maintained clinical benefit (without surgery, steroids or IS introduction) at 6 and 12 months was 92.8% and 68.2%, respectively. Twenty patients (16.4%) developed an adverse event with only one severe adverse event.
Conclusion: Clinical benefit of a SC ustekinumab induction was observed in two out of three CD patients and was maintained in majority of patients for up to 12 months. Pending results from ongoing trials, ustekinumab can be considered in CD patients refractory to anti-TNF agents.

Contact E-mail Address: per.karlen@ds.se
Introduction: Inflammatory bowel diseases (IBD) are chronic with different character and intermittent or more rarely continuous inflammatory activity. The activity ranges from mild to severe. The response to treatment varies and the choice of treatment is still partly arbitrary. Some patients represent a particular problem due to lack of response or intolerance to conventional treatment. There is a lack of data on results from maintenance treatment with Granulocyte/Monocyte Adsorption (GMA) in patients with an initial response to treatment.
Aims & Methods: 136 patients, 54 with ulcerative colitis (UC), 81 with Crohńs disease (CD) and 1 with indeterminate colitis (IC) were included in a registry covering the majority of patients treated with GMA in Sweden. The disease activity was mainly mild or moderate. 49 IBD-patients initially achieving clinical response 3 month after a GMA course received maintenance treatment with GMA. The GMA maintenance treatments were scheduled with one of the following: one session monthly, every second month, every third month and every fourth month according to relapse rate and disease severity. Included patients were followed every third month for 12 months after induction GMA treatment. Monitoring includes symptoms (short health scale), activity indices (HBI, SCCAI) and fecal calprotectin.
Results: Overall, burden of symptoms, activity indices and fecal calprotectin levels remained at the same low level throughout the maintenance treatment period.
Conclusion: Maintenance treatment with GMA is effective in patients with an initial good response.

Introduction: The aim of the study was to compare the effectiveness of metronidazole and rifaximin in the treatment of *Clostridium difficile* infection (CDI) in pediatric patients with inflammatory bowel disease (IBD).
Aims & Methods: We conducted a prospective, double-blinded, randomized trial with children age 12-18 years. Crohn's disease (CD) and ulcerative colitis (UC) were diagnosed according to Porto criteria. CDI diagnosis was based on a positive stool VIDAS® *Clostridium difficile* toxin A/B ELFA (bioMerieux, France) test. Patients were randomly assigned to receive metronidazole or rifaximin for 14 days; doses of drugs were weight-adjusted. Stool samples were collected before and 4 weeks after the end of treatment.
Results: In the present study, 26 patients were enrolled (mean age 14.3 years), including 9 with CD and 17 with UC. 14 received metronidazole and 12 received rifaximin. There were no statistically significant differences between study groups in age, gender and disease type. 4 weeks after the end of treatment *Clostridium difficile* toxins were found in 5/14 (36%) patients in metronidazole group and in 4/12 (33.3%) patients in rifaximin group (n = NS).
Conclusion: Metronidazole and rifaximin was equally effective in the treatment of CDI in pediatric patients with IBD.

Introduction: The Pediatric Ulcerative Colitis Activity Index (PUCAI) is a non-invasive clinician-based index, proven to reflect well mucosal inflammation in pediatric ulcerative colitis (UC). Under the qualification program of the FDA and EMA, we aimed here to develop a Patient Reported Outcome (PRO) measure of signs and symptoms for pediatric UC (i.e. the TUMMY index) to complement the PUCAI, when used with endoscopic assessment. The derived questionnaire will enable calculating both the TUMMY and the PUCAI scores independently.
Aims & Methods: We performed qualitative interviews- 35 with UC children (age 12.3 ± 3.2, range 4-18 years; 50% males; 83% with extensive colitis; 25% with moderate-severe disease) and 25 with their caregivers, in Israel, England, Ireland, Canada and the USA, to ensure cultural diversity. Interviews were centered at exploring signs and symptoms reflecting the colitis and which are important to children. Items were rank ordered according to the frequency of endorsement and importance, graded on a 1-5 scale by the interviewees.
Results: There was a general agreement between the total scoring of the children and their caregivers. The following items were identified in decreasing order of weights (importance X frequency): abdominal pain (4), rectal bleeding (3.5), stool frequency (2.8), stool consistency (2.8), general well-being (2.8), urgency (1.8), and nocturnal stools (1.7). Two other items were scored low and are perceived as having low accuracy (lack of appetite (1) and weight loss (0.6)). Children 13-18 years comprehended adult vocabulary, 8-12 years simple vocabulary and younger children had poor understanding and thus their disease may be more accurately scored by a caregiver-reported questionnaire.
Conclusion: In this first report of the TUMMY development, items were generated and ranked by input purely from patients. These items are now being explored for optimal vocabulary and response options. The TUMMY index will supplement the PUCAI in clinical trial outcome assessment.

Abstract number: P1000 Table: Concordance and discordance of PCDAI remission and CDAI remission in patients aged 13–17 yrs with CD treated with ADA in IMAgINE 1.

Week	PCDAI remission & CDAI remissionn (%)	No PCDAI remission & no CDAI remissionn (%)	Concordantn (%)	No PCDAI remission & CDAI remissionn (%)	PCDAI remission & no CDAI remissionn (%)	Discordantn (%)
26	44 (36.1)	59 (48.4)	103 (84.4)	18 (14.8)	1 (0.8)	19 (15.6)
52	37 (30.3)	77 (63.1)	114 (93.4)	7 (5.7)	1 (0.8)	8 (6.6)

P1000 RELATIONSHIP OF THE PEDIATRIC CROHN'S DISEASE ACTIVITY INDEX (PCDAI) AND CROHN'S DISEASE ACTIVITY INDEX (CDAI) IN IMAGINE 1

D. Turner[1], J. Hyams[2], M. Dubinksy[3], W. Faubion[4], S. Eichner[5], Y. Li[5], A. Lazar[6], B. Huang[5], R. Thakkar[5]
[1]*Shaare Zedek Medical Centre, Jerusalem, Israel,* [2]*Connecticut Children's Medical Center, Hartford,* [3]*Mount Sinai Hospital, New York,* [4]*Mayo Clinic, Rochester,* [5]*AbbVie Inc., North Chicago, United States,* [6]*AbbVie Deutschland GmbH & Co. KG, Ludwigshafen, Germany*

Introduction: The Pediatric Crohn's Disease Activity Index (PCDAI) assesses disease activity in children and adolescents with Crohn's disease (CD), and was developed to take in account more objective measures than the Crohn's Disease Activity Index (CDAI). Although both indices have similar components, the PCDAI includes additional laboratory measures and disease features specific to children and adolescents with CD. In IMAgINE 1, a 52-week (wk), phase 3, multicenter, randomized open-label induction/double-blind maintenance trial of adalimumab (ADA) in 192 patients aged 6–17 yrs with CD, both PCDAI and CDAI were calculated for patients aged 13–17 yrs.[1]
Aims & Methods: This post-hoc analysis evaluated concordance of remission status based on PCDAI and CDAI. Patients in IMAgINE 1 had CD with a baseline PCDAI score >30 and were intolerant or resistant to conventional therapy. Patients received open-label ADA induction at weeks 0/2 based on body weight (≥40 kg, 160/80mg; <40 kg, 80/40 mg). At wk 4, patients were randomized to higher (≥40 kg, 40 mg every other wk [eow]; <40 kg, 20 mg eow) [HD] or lower dose (≥40 kg, 20 mg eow; <40 kg, 10 mg eow) ADA maintenance therapy. The agreement of PCDAI remission (PCDAI score ≤10) and CDAI remission (CDAI score <150) at wks 26 and 52 was evaluated in both dosing groups combined. Non-responder imputation was used for missing data.
Results: Of 188 patients who entered the double-blind maintenance period of IMAgINE 1, 122 were aged 13–17 yrs. PCDAI remission rates at weeks 26 and 52 were 37% (45/122) and 31% (38/122), respectively; CDAI remission rates at weeks 26 and 52 were 51% (62/122) and 36% (44/122), respectively. At wk 26, 36% (44/122) patients achieved both PCDAI and CDAI remission, and 48% (59/122) had neither PCDAI nor CDAI remission (**Table**); thus, the agreement between measures was 84% (Kappa = 0.6899; $p < 0.001$) At wk 52, 30% (37/122) patients achieved both PCDAI and CDAI remission, and 63% (77/122) had neither PCDAI nor CDAI remission (**Table**); thus, the agreement between measures was 93% (Kappa = 0.8535; $p < 0.001$).
Conclusion: Agreement among PCDAI and CDAI was moderate to substantial at weeks 26 and 52. However, CDAI may over estimate remission in pediatric CD given the higher overall rates of remission by this metric. The agreement of PCDAI and CDAI with other outcome measures requires further exploration.

Introduction: Age at diagnosis of inflammatory bowel disease (IBD) in children has taken an important role and very early onset IBD (VEO-IBD; diagnosis < 6 years) seem to be a form of IBD distinct from that of older children.
Aims & Methods: We aimed to compare the incidence and phenotype at diagnosis of VEO-IBD and IBD in older children (6-17 years) from a French population-based study over a 24-year period. We extracted the pediatric IBD cohort through the population-based Registry from 1988 to 2011.
Results: In total, 1412 children (8% of all IBD) have been recorded including 42 (3%) with VEO-IBD. The incidence of overall IBD in children increased from $3.0/10^5$ in 1988-1990 to 6.3 in 2009-2011 (+110 %; $p < 10^{-3}$). The incidence remained stable among VEO-IBD children ($0.4/10^5$ from 1988-1990 to 2009-2011) while it increased from 1.6 to $3.5/10^5$ (+119%; $p < 10^{-3}$) among 6-9 years old, and from 6.1 to $13.1/10^5$ (+115%; $p < 10^{-3}$) among children ≥ 10 years old. The initial classification as ulcerative colitis (UC) or IBD unclassified (IBDU) was more common among the VEO-IBD group (40% *vs* 26%; p = 0.05). Differences in phenotype according to age at diagnosis are summarized in the Table.

Variables at diagnosis	< 6 years at diagnosis	6-17 years at diagnosis	P-value
All IBD	N = 42 (3%)	N = 1370 (97%)	
Crohn's Disease (CD)	N = 25 (60%)	N = 1007 (74%)	
UC	N = 14 (33%)	N = 329 (24%)	
Diagnosis at Hospital	**69%**	**42%**	**$< 10^{-3}$**
Male	52%	52%	0.92
Diarrhea	76%	66%	0.15
Rectal bleeding	**81%**	**45%**	**$< 10^{-4}$**
Mucous stools	**40%**	**21%**	**$< 10^{-2}$**
Abdominal pain	**43%**	**74%**	**$< 10^{-4}$**
Weight loss	**21%**	**49%**	**$< 10^{-3}$**
EIMs*	17%	17%	0.97
Growth failure (Z score weight/height < 2)	17%	10%	0.14
Diagnosis delay > 6 months	27%	30%	0.67
IBD family history	9%	15%	0.30
Complicated behavior in CD (B2 + B3**)	5%	17%	0.20
Anoperineal lesions in CD	8%	6%	0.65
Pure colonic location in CD (L2)**	**36%**	**13%**	**$< 10^{-2}$**
Proctitis in UC (E1**)	9%	30%	0.12
Extensive colitis in UC (E4**)	55%	43%	0.31

* Extra intestinal manifestations** According to Paris classification

Conclusion: According to the present retrospective population-based study, the incidence of VEO-IBD was low and remained stable from 1988 to 2011. Children diagnosed with VEO-IBD were more often diagnosed in hospital than those diagnosed after the age of 6. VEO-CD children presented more rectal symptoms, presumably in relation to a high prevalence of isolated colonic CD.

Introduction: Treatment in inflammatory bowel diseases (IBD; Crohn's disease [CD] and ulcerative colitis [UC]) has improved due to biologics. However, a problem is loss of response (LOR) maybe due to the formation of antibodies against these biologics. Our aim was to investigate antibody response against standard biologics infliximab (IFX) and adalimumab (ADA) in paediatric and adult patients with IBD and develop an algorithm to avoid a LOR.
Aims & Methods: We conducted a prospective, multi-center study assessing antibody levels in IBD patients with active disease by an enzyme-linked immunoassay (Immunodiagnostik AG, Bensheim, Germany) which is able to measure free and bound antibodies against IFX or ADA. We investigated a

Abstract number: P1003 Table: Demographics and baseline characteristics by disease severity (intent-to-treat population)

	Moderate CD (PCDAI < 40) (N = 80)	Severe CD (PCDAI ≥ 40) (N = 108)
Age, years, mean (SD)	14.0 (2.4)	13.4 (2.5)

possible correlation between LOR during therapy and positive antibodies and furthermore linked clinics with antibody levels. LOR was defined as dose escalation, discontinuation of treatment or shortening of dosage interval.

Results: One-hundred-and-eighty-eight patients were included. 27/91 of CD patients (30%) and 12/45 (27%) of UC patients with IFX therapy showed positive antibody levels. In the ADA group in 3/46 (7%) with CD and 1/6 (17%) with UC antibodies were detected. 27% of antibody-positive CD patients and 100% of UC patients with IFX therapy had a LOR, whereas 67% of antibody-positive CD patients and 100% of UC patients had a LOR under ADA. Correlation with clinics showed that most of the patients with positive antibodies showed low IFX or ADA levels with 63% and 43%, respectively. Furthermore, an algorithm was developed including drug monitoring for dose optimization and antidrug monitoring to consider switch of medication.

Conclusion: Our study suggests that occurrence of antidrug antibodies is a frequent event associated with LOR. By using an algorithm antidrug and drug monitoring may support optimal treatment of paediatric and adult patients receiving biological therapies in IBD.

Introduction: Biologic therapy is generally reserved for children with moderate to severe Crohn's disease (CD), however, distinguishing moderate from severe disease by the Paediatric CD Activity Index (PCDAI) can be difficult.[1]

Aims & Methods: To compare disease burden in patients (pts) classified as moderate *vs* severe by PCDAI in IMAgINE 1,[2] a 52 week (wk) trial of adalimumab in which pts aged 6-17 years with CD and baseline (BL) PCDAI > 30 were enrolled. All pts had failed concurrent or prior corticosteroids (CS) and/or immunomodulators (IMM) therapy. Infliximab (IFX)-exposed pts could enroll. BL characteristics, demographics, and the proportion of pts with a BL score of 10 (worst score) for at least one of the PCDAI components of abdominal pain (AP), stool frequency (SF), and general well-being (GW) were assessed in pts with moderate (PCDAI < 40) and severe CD (PCDAI ≥ 40) as defined by the median PCDAI at BL.

Results: The intent-to-treat population included 188 of 192 pts enrolled. 43% (80) had moderate and 57% (108) had severe CD at BL. Demographics, CD activity, prior and concomitant CD-related IMM and CS use, prior IFX use, and IMPACT III scores at BL were similar for both groups (Table). Median CRP was numerically higher in pts with severe *vs* moderate CD (1.76 *vs* 0.65 mg/dL), but ranges largely overlapped. A similar proportion of pts with moderate and severe CD (83 *vs* 95%) had the most severe score of 10 at BL for at least one of the PCDAI components of AP, SF, or GW.

Conclusion: Clinical characteristics and treatments administered to pts with moderate or severe disease activity by PCDAI were similar. Overall, the disease burden in the moderate pts was similar to severe pts in IMAgINE 1.

Introduction: Combining thiopurines with infliximab might reduce antibody formation against infliximab, but no paediatric data supporting this assumption are available yet.

Aims & Methods: Evaluation of the effect of concomitant immunomodulator use on formation of antibodies to infliximab (ATI) in paediatric patients with Crohn's disease (CD) and the association of ATI appearance and loss of response. In this retrospective nationwide multicentre observational study we collected clinical and biochemical data of children diagnosed with CD treated with infliximab between 2009 and 2014. ATI formation was analysed with Chi-square test and time to ATI formation with Kaplan-Meier and log rank test. Loss of response was defined as need for either surgery or switch to other medical therapy than infliximab.

Results: In total, 229 children were identified (138 men, median 25 months on infliximab). Eighty-six patients (38%) received continuous combined immunosuppression (CCI) with infliximab, 115 patients (50%) early combined immunosuppression (ECI) (median 6.2 months), followed by infliximab monotherapy, and 28 patients (12%) infliximab monotherapy (IFX). Overall 25 of 229 patients (11%) developed ATIs: 6 on CCI (7%), 11 on ECI (10%) and 8 on IFX (29%)

after respectively 6, 25, and 11 months (median). Antibodies were measured in 162 patients (70.7%). The incidence of ATI formation was higher in patients receiving IFX compared to CCI (p = 0.006) and ECI (p = 0.01), while no significant difference was found between CCI and ECI (log rank overall 0.004). Sixteen out of 25 patients (64%) developing ATIs had loss of response, versus 32 of 204 patients (16%) without ATIs (p = 0.0001, log rank 0.01). When focusing on the group early combined immunosuppression, 10 out of 80 patients (12.5%) developed ATIs when receiving less than 12 months combination therapy, compared to 1of 35 (2.9%) patients receiving more than 12 months combination therapy.

	Concomitant immunomodulator use	
	< 12 months	> 12 months
ATI, n (%)	10 (12.5)	1 (2.9)
Non-ATI, n (%)	70 (87.5)	34 (97.1)
Total	80	35

Conclusion: Combination therapy is superior to infliximab monotherapy as it significantly reduces antibody formation and loss of response in children with CD. Concerns about the lymphoproliferative risk of long-term use of thiopurines make that early combined immunosuppression for at least 12 months, followed by infliximab monotherapy, might be a safer and equally effective alternative to continuous combined immunosuppression.

P1005 CLINICAL REMISSION INDUCED BY EXCLUSIVE ENTERAL NUTRITION (EEN) IN PEDIATRIC CROHN'S DISEASE IS ASSOCIATED WITH MICROBIOME METABOLIC CHANGES TOWARD INCREASED XENOBIOTIC BIODEGRADATION AND METABOLISM

K. A. Dunn[1], J. Connors[2], B. MacIntyre[2], A. Stadnyk[3], J. P. Bielawski[1], N. Thomas[3], A. R. Otley[2], **J. Van Limbergen**[2,3]

Contact E-mail Address: johanvanlimbergen@dal.ca
Introduction: The mode of action of exclusive enteral nutrition (EEN) as induction therapy in pediatric Crohn's disease (CD), is proposed to involve changes in gut microbiome structure and function. Characterization of the microbiome has largely focused on the assessment of diversity and the identification of protective and disease-associated species.
Aims & Methods: Our aims were to compare microbial community structure and function in pediatric CD patients before and after induction of remission by EEN treatment. Community structure was assessed in terms of phylotypes, and function was assessed in terms of metabolic pathways.
Stool metagenomic sequences of 5 pediatric CD patients who underwent EEN treatment were obtained (MiSeq). Sequences were searched against the green genes database to obtain microbial composition profiles (using 16S rRNA genes). To obtain functional assignment, sequences were searched against 28 representative KEGG (Kyoto Encyclopedia of Genes and Genomes) pathways and HUMAnN to assign function. Samples collected prior to EEN treatment were compared to samples collected after 4, 8 or 12 weeks of EEN treatment. All participants achieved clinical remission (PCDAI < 10) after 12 weeks of EEN. Microbial composition profiles were analyzed using QIIME and STAMP, and functional profiles were inferred using STAMP and BiomeNet.
Results: Changes in CD patient microbial community structure before and during EEN were variable. However, functional profiling of CD patient microbiota before and during EEN treatment revealed a significant increase in metabolic functions related to biodegradation and metabolism of xenobiotics, such as benzoate ($p < 0.05$). BiomeNet uncovered changes during weeks 4 and 8 of treatment consistent with large-scale changes in metabolic interactions at the community level. We observed associated changes in community diversity: a decrease and then increase in diversity over the course of EEN treatment. Metabolic potential generally increased at the same time as diversity decreased. This could be due to the metabolic repertoire of those species that were present (as inferred from enzyme encoding gene sequences). Bayesian modeling of metabolic structures via BiomeNet revealed that the therapeutic effect of EEN might be predicted by monitoring the change in community level metabolic structures over the course of treatment.
Induction of clinical remission by EEN was characterized by a distinct cycle of change in community level metabolic structure, and the microbiome of the one patient that experienced several severe flare-ups did not complete this cycle of change. This finding suggests that community metabolic function could be monitored for the purpose of determining if the duration of EEN was sufficient to maintain a flare free state. Alternatively, patients who complete the cycle quickly might discontinue EEN early.
Conclusion: The microbiome of CD patients is functionally altered during EEN treatment. Metabolic potential for xenobiotic biodegradation and metabolism increases during treatment, but then, after 12 weeks, it returns to a state very similar to pre-treatment and controls.

Introduction: Thiopurines, 6-mercaptopurine and azathioprine (AZA), are the mainstay in maintenance therapy of pediatric ulcerative colitis (UC).
Aims & Methods: We aimed at describing the efficacy of AZA in newly diagnosed pediatric UC, comparing the outcomes of "early" (0-6 months) versus "late" (6-12 months) initiation of therapy.
Data from all children with UC treated with AZA within 12 months after the diagnosis and included in the SIGENP prospective, multicenter registry, were included. Corticosteroid (CS) free remission at 12 months was the primary outcome evaluated. The 2 groups were also compared for mucosal healing, need for treatment escalation, therapy-related adverse events and need for surgery at a 24-month follow-up.
Results: Of 401 children with a diagnosis of UC, 166 were treated with AZA within the first year of diagnosis. Seventy-one patients were excluded because of a follow-up shorter than 1 year, thus 95 were included for efficacy analyses (mean age 10.7 ± 3.8 years, 59% females). Fifty-four patients (57%) started AZA between 0–6 months (early), 41 (43%) after 6–12 months (late). Twenty-seven (51%) of the "early" patients were in CS-free remission at 1 year, compared to 24 (61.5%) of the "late" ones (p = 0.39). Mucosal healing occurred in 26 (39%) of the 66 patients for whom data on mucosal inflammation at 1 year were available, no difference was found between the two groups (32% "early" versus 45% "late"; p = 0.45). Serious adverse events occurred in 3 patients (2 fungal pneumonia, 1 pancreatitis), 2 in the "early" and 1 in the "late" group. Overall, mild side effects were recorded in 16 patients (17%; 5 leucopenia, 11 pancreatic enzyme elevation):10 in the "early" and 6 in the "late" group (p = 0.78), 3 requiring AZA discontinuation. No difference was found for the need of treatment escalation, use of infliximab over time and rate of surgery.
Conclusion: Introduction of AZA within 6 months of diagnosis is not more effective than later treatment to achieve CS-free remission in pediatric UC. The rate of mucosal healing is not related to the timing of AZA initiation. Serious adverse events related to treatment are uncommon.

P1007 MONITORING MUCOSAL HEALING WITH FAECAL CALPROTECTIN IN CHILDREN WITH ULCERATIVE COLITIS

M. Meglicka[1], M. Szczepański[1], M. Dadalski[1], J. Kierkuś[1]
[1]*Gastroenterology, Hepatology, Feeding Disorders and Paediatrics, The Children's Memorial Health Institute, Warsaw, Poland*

Contact E-mail Address: meglickam@gmail.com
Introduction: Faecal calprotectin (FC) is a good marker in monitoring mucosal healing in adults with ulcerative colitis. Its concentration in faeces is closely related to state of mucosa observed in endoscopy. There are a few studies concerning FC in mucosa status assessment in paediatrics population with inflammatory bowel disease.
Aims & Methods: The aim of the study was to assess the usefulness of FC as a biomarker of endoscopy proven mucosal healing in monitoring of children with UC. 81 patients with UC (F 43, M 38, ±14.04 years) were involved to the study and had elective colonoscopy performed, FC level and erythrocyte sedimentation rate (ESR) within a week before endoscopy measured. Each patient had also body mass index (BMI) and paediatric ulcerative colitis activity index (PUCAI) calculated. Mucosa status during endoscopy was assessed with Baron score. Full mucosal healing was defined as Baron score = 0. We have identified two subgroups: those with full mucosal healing, and patients with inflamed gut mucosa. The receiver operating characteristic curve (ROC) was used as a statistical method to establish cut-off points. The cut-off points are calprotectin threshold for simple model and posterior probability threshold for the linear discriminant analysis (LDA). The area under the curve (AUC) assesses the differentiation quality of the study group based on the model score. To increase sensitivity at high specificity the LDA with FC, ESR, BMI and PUCAI was taken.
Results: AUC for the simple model was 0.86. The selected cut-off level of discrimination between subgroup with full mucosal healing vs. subgroup with mucosal inflammation present was 274 μg/g with sensitivity 0.97 and specificity 0.62. When specificity was outweighed over sensitivity the cut-off point was 37 μg/g with sensitivity 0.32 and specificity 0.94. Due to the low sensitivity accompanying high specificity we used LDA with other parameters to increase sensitivity rate. With LDA used on FC, ESR, BMI and PUCAI the AUC was 0.88, and we could discriminate our patient with sensitivity 0.53 and specificity 0.96.
Conclusion: FC is a good marker of mucosal healing in monitoring of children with UC. FC above 274 μg/g enable to select 62% of patients with active inflammation in gut mucosa. LDA with FC, ESR, BMI and PUCAI let us

select 53% of patients with full mucosal healing. Using these two methods, step by step, we could discriminate patients with unknown mucosa status, that requires endoscopy.

P1008 REMISSION INDUCTION IN CORTICOSTEROID-NAÏVE CHILDREN AND ADOLESCENTS WITH ACTIVE ULCERATIVE COLITIS BY ADSORPTIVE LEUCOCYTAPHERESIS AS MONOTHERAPY OR IN COMBINATION WITH LOW-DOSE PREDNISOLONE AFTER FAILURE OF FIRST-LINE MEDICATIONS

T. Tanaka[1], T. Iiboshi[1], H. Goishi[1], M. Akagi[1], T. Kajihara[1], T. Miura[1]
[1]*Gastroenterology, Akitsu Prefectural Hospital, Hiroshima, Japan*

Contact E-mail Address: tomotaka@c.do-up.com
Introduction: Given that patients with active ulcerative colitis (UC) have elevated and activated myeloid lineage leucocytes including the CD14 + CD16+ monocyte phenotype known to release tumour necrosis factor-α, selective depletion of myeloid leucocytes by adsorptive granulocyte/monocyte apheresis (GMA, Adacolumn) should promote remission, or enhance drug efficacy. This strategy is most relevant in paediatrics and adolescents in whom corticosteroids raise safety concerns.
Aims & Methods: This study was to evaluate the efficacy of GMA in children and adolescents with active UC in whom conventional first-line medications had failed. In a single centre setting, between 2010 and 2014, a total of 28 consecutive children and adolescents, age 11-19 years, body weight 33-55kg were given mesalazine (n = 21) or sulphasalazine (n = 7) as a first-line medication. Twenty patients relapsed or did not respond and received GMA with the Adacolumn, 2 sessions in the first week, then weekly, up to 11 sessions. Patients who achieved a decrease of $\geq$5 in the clinical activity index (CAI) continued with GMA, while non-responders received 0.5 to 1.0 mg/kg/day prednisolone plus additional GMA sessions. At entry and week 12, patients were clinically and endoscopically evaluated, allowing each patient to serve as her (or his) own control.
Results: At entry, all 28 patients were corticosteroid naïve and none had deep colonic UC lesions together with extensive loss of the mucosal tissue at the affected sites. Eight patients achieved remission with the first-line medications and did not receive GMA. Six patients did not respond well to the first 5 GMA sessions and received prednisolone plus GMA, while 12 patients responded to the first 5 GMA sessions and received additional sessions and 2 withdrew. At entry, the average CAI was 14.2 ± 0.4, range 11-17, and the average endoscopic index was 9.2 ± 0.4, range 7-11. The corresponding values at week 12 were 2.1 ± 0.2, range 1-4 ($P < 0.001$) and 2.4 ± 0.2, range 1-4 ($P < 0.001$). Prednisolone was tapered to 0mg within 3 months. Therefore, at week 12, all 26 patients had achieved clinical remission, majority with mucosal healing (complete remission). No serious adverse event associated with GMA was observed.
Conclusion: GMA in patients with deep ulcers and extensive loss of the mucosal tissue (a major GMA non-responder feature) has not been associated with significant efficacy. In this study, GMA in young corticosteroid naïve patients with active UC refractory to the first-line medications was associated with clinical remission and mucosal healing, while in non-responders to GMA monotherapy, addition of a low dose prednisolone enhanced the efficacy of GMA and tapering of prednisolone was not associated with UC relapse. Therefore, the majority of young steroid-naïve UC patients who fail to respond to the first-line medications should respond well to GMA and avoid pharmacologicals.

P1010 CLOSTRIDIUM DIFFICILE INFECTION: COMPARISON OF DIAGNOSTIC TESTS AND CHARACTERIZATION OF STRAINS

E. G. Vilela[1], G. G. L. Cancado[2], R. O. S. Silva[3], F. C. F. Lobato[3]
[1]*Internal Medicine,* [2]*Instituto Alfa de Gastroenterologia,* [3]*Laboratorio de Anaerobio, Federal University of Minas Gerais, Belo Horizonte, Brazil*

Contact E-mail Address: evilela@medicina.ufmg.br
Introduction: *Clostridium difficile* is an anaerobic gram-positive, spore-forming, toxin-producing bacillus, which cause illnesses ranging from mild diarrhea to fulminant colitis. Laboratory diagnosis largely relies on rapid toxin detection kits through immunoenzymatic assays (ELISA), although this diagnostic approach has recently been called into question. The incidence of *C. difficile* infection has markedly increased in the last years, notably with the epidemic spread of the binary toxin producer ribotype 027.
Aims & Methods
Aims: to compare the performance of commercial ELISA kits versus cytotoxicity (CTA) and toxigenic culture (TC) assays for the diagnosis of CDI in Brazil. Furthermore, isolate and characterize, genotypically and phenotypically, the *C. difficile* strains.
Methods: Ninety six fecal samples were obtained and analyzed between January and November 2014 from inpatients admitted to Hospital das Clínicas of Universidade Federal de Minas Gerais in Belo Horizonte, Brazil. All patients were under broad-spectrum antibiotic therapy and the samples were collected during active diarrhea episodes. All samples were tested for the presence of toxins A/ B by the following commercial ELISA kits: *C. difficile* Tox A/B II (Techlab Inc., USA), Remel ProSpecT *C. difficile* Toxin A/B (Oxoid, UK), and Ridascreen *C. difficile* toxins A/B (R-Biopharm, Germany). Cytotoxicity assays were performed using Vero cells. Stool samples were also cultured and all colonies with suggestive morphologies were subjected to a multiplex-PCR protocol involving a housekeeping gene (tpi), toxins A (tcdA) and B (tcdB), and a binary toxin gene (cdtB). All strains positive for tcdA or/and tcdB were considered toxigenic. *C. difficile* isolates were analyzed by PCR-ribotyping. Minimal inhibitory concentration for metronidazole (MTZ) and vancomicyn (VAN) was determined.
Results: From the 96 sampled patients, 25 (26%) were positive according to CTA. C. difficile was isolated from 29 (30.2%) samples, of which six isolates were considered non-toxigenic and 23 (24%) were toxigenic according to PCR. The kappa concordance between TC and CTA was 0.71 (0.51-0.9). Of these patients, 15 (65.2%) were A + B + CDT-, six (26.1%) were A + B + CDT+, and two (8.7%) were A-B + CDT-. Nine PCR-ribotypes were identified among the isolates, three unpublished (SLO 197, 198 and 199). PCR-ribotype 027 was not detected. The three ELISAs exhibited sensitivities between 64 and 68% and specificities greater than 94%. All strains were susceptible to MTZ and VAN.
Conclusion: It is essential to have accurate laboratory diagnosis of *C. difficile* infection to ensure patients receive appropriate treatment. Furthermore, the detection and isolation of genes related to virulence factors in *C. difficile* strain can aid the understanding of risk factors and epidemiology of disease. Despite not having been detected the presence of ribotype 027, some strains, including those three not previously described, had the gene of the binary toxin, resulting in potential increased of the virulence. There were no strains resistant to conventional therapy, although the therapeutic success can also be influenced by other factors, such as the intestinal microbiota.

P1011 HEALTHY BUT NOT TUMOR TISSUE-DERIVED CELL-FREE DNA NEUTRALIZES THE ACTIVATION OF HUMAN MONOCYTES

I. Furi[1,2], A. Kalmar[1], A. Scholler[3,4], G. Valcz[2,4], B. Wichmann[2,4], B. K. Bartak[4], B. Molnar[2,4], Z. Tulassay[2,4]

Contact E-mail Address: furiistvan88@gmail.com
Introduction: Bacterial ligands (LPS) and self-DNA sequences are recognized by TLRs on human immune competent cells. Cell-free DNA sequences with unmethylated CpG dinucleotide motifs may be a possible non-specific immune system stimulants by the mechanism of supression the function of the Treg cells and the re-activation of anti-tumor immunity.
Aims & Methods: We compared the immunostimulatory effect of LPS (from *E.coli*) and cell free DNA originated from normal and tumor colonic tissue on isolated peripheral mononuclear cells (PBMCs) from healthy volunteers.
DNA isolation was performed from fresh-frozen surgically removed colonic samples. PBMC were donated by healthy volunteers and isolated by Ficoll-Hypaque (Sigma-Aldrich). The viability of PBMCs was determined by Trypane blue dying. PBMCs were incubated for 24 hours with 10 µg of DNA either from normal and tumor origin. After the incubation we performed the treatment with normal and tumor tissue derived DNA (TLR9 agonists) in or without the combination with LPS (TLR4 agonist) As a next step Affymetrix U133 2.0 whole-genome expression analysis was performed from the isolated total RNA.
Results: Affymetrix whole-genome microarray results reflect a massive monocyte activation of the LPS treatment through the overexpression an early phase pro-inflammatory cytokine IL-6, monocytic marker CD163, and other chemokines (CXCL1, CXCL5). We also observed an increased IFNG and IL-10 expression in PBMCs after LPS treatment. Dual activation of TLR4 and TLR9 (co-administration of tumor or healthy tissue tissue DNA and LPS) has resulted a different effect on the gene expression. Healthy tissue derived DNA and LPS co –treatment induced down-regulation of TLR4, IRG1 CXCL6, CXCL9 and CCL13.
Conclusion: LPS treatment induced a massive activation of monocytes, which could be neutralized by the co-administration of healthy tissue derived cell-free DNA through the down-regulation of the sensing receptor and response genes. We reflected the antagonism between TLRs and the possible non.-inducible effect of tumor tissue derived cell free DNA on immune competent cells through TLR9.

Abstract number: P1012 Table: Effects of inflammation and IMQ on EBF.

			Non inflamed		Inflamed

P1012 STIMULATION OF TOLL-LIKE RECEPTOR 7 ATTENUATES EPITHELIAL BARRIER DYSFUNCTION DURING COLITIS IN MICE

J. Estevez[1], V. Martinez[1]
[1]*Department of Cell Biology, Physiology and Immunology, Universitat Autonoma de Barcelona, Bellaterra, Spain*

Contact E-mail Address: javier.estevez@uab.cat
Introduction: Altered epithelial barrier function (EBF) and deregulation of mucosal immune responses are common in intestinal inflammatory disorders. Activation of innate immunity-dependent mechanisms, including those mediated by Toll-Like receptors (TLR), has immunomodulatory activity with beneficial effects in colitis.
Aims & Methods: We assessed if TLR7 participates in the modulation of EBF during states of intestinal inflammation. Colitis was induced in CD1 male mice by exposure to dextran sodium sulfate (DSS; 5 % in the drinking water, for 5 days). EBF was determined assessing the permeability to macromolecules (4 kDa fluorescein isothiocyanate–dextran, FD4) *in vitro* (apical-to-basolateral flux FD4 in an Ussing chamber system) and *in vivo* (passage of intracolonic FD4 to blood and urine). Potential modulatory role of colonic TLR7 on EBF was assessed by local stimulation of the receptor with the selective agonist imiquimod (IMQ). Changes in gene expression of tight junction-related proteins (occludin, claudin 2, claudin 3, Zona Occludens-1) and barrier-related markers (proglucagon and myosin light-chain kinase) were assessed by RT-qPCR.
Results: Exposure to DSS lead to a state of colitis, as evidenced macro and microscopically. In colitic animals the passage of FD4, as assessed either *in vitro* or *in vivo* was increased, thus indicating an altered EBF. In *in vitro* conditions, stimulation of TLR7 with IMQ in inflamed tissues (300 μg, apical or basolateral) restored the epithelial permeability to FD4 to basal levels (Table). Similarly, in *in vivo* conditions, intracolonic IMQ (300 μg/mice) attenuated the passage of FD4 to blood and urine in colitic mice, thus indicating a partial restoration of EBF (Table). In DSS-treated animals, expression of tight junction-related proteins and barrier related factors was down regulated (50-70% vs. non-inflamed animals). Local stimulation of TLR7 with IMQ did not revert these effects.
Conclusion: Stimulation of TLR7 leads to an improvement of inflammation-induced altered EBF. The mechanisms mediating these actions seem to be independent of the modulation of tight junction-related proteins and barrier modulators. TLR7-mediated innate immune responses might regulate EBF with a defensive function, preventing the passage of luminal factors and, therefore, reducing antigens exposure and the development of exacerbated immune responses and intestinal inflammation.

P1013 ABDOMINAL TUBERCULOSIS – 10 YEAR EXPERIENCE FROM A UK DISTRICT GENERAL HOSPITAL

M. Ford[1,]
[1]*The Dudley Group NHS Foundation Trust, Dudley, United Kingdom*

Contact E-mail Address: markford@doctors.net.uk
Introduction: The rate of tuberculosis has remained relatively stable over the past decade; however the proportion of cases with extra-pulmonary disease has increased from 40.9% to 47.9%. Multiple studies have shown that diagnosis of abdominal tuberculosis (ATB) is often delayed due to non-specific symptoms in patients. The aim of this study was to examine a selection of patients from a UK district general hospital with a diagnosis of ATB and the process in which that diagnosis was reached.
Aims & Methods: We performed a retrospective review of all patients at Russells Hall Hospital, Dudley, who had a diagnosis of ATB between 2004 and 2014. Demographic, clinical, laboratory and radiographical findings were collated including the time delay between hospital presentation and diagnosis.
Results: Sixteen cases of ATB were identified with a median age of 38.5 years at time of diagnosis (range 22-73 years) and a male/female split of 56% and 44% respectively. The majority (87.5%) were of non-white background; South Asian (69%), Afrocaribbean (19%) and White British (12%). The commonest features were abdominal pain (62.5%), weight loss (50%) and fevers (50%). The time between first presentation to hospital and diagnosis ranged from 2 days to 3 years. Basic investigations revealed mean haemoglobin of 11.9 g/dL (SD 1.70), CRP of 109 mg/L (SD 91.81), Alkaline phosphatase of 200 IU/L (SD 159.32), and albumin of 37.1 g/L (SD 6.54). The chest x-ray was normal in 11 patients and of the remaining abnormalities included consolidation in 3 patients, cavitating lesion in 1 patient, and the final patient did not have an x-ray. There was a wide range of sites of disease including small bowel (25%), peritoneum (25%), lymph nodes (18.75%), appendix (12.5%), liver (12.5%) and omentum (6.25%). Tuberculin test was only performed in three patients and all of which were positive. Diagnosis was based on either histology (43.75%), imaging (31.25%), microbiology (6.25%), or a combination of clinical suspicion and imaging or appearances at surgery (18.75%). The majority who received treatment (9/14) were given Rifater plus ethambutol. The remaining five patients all received a different combination of antituberculous treatment (Rifater alone, Rifinah ± Pyrazinamide and Ethambutol, Rifampicin/Isoniazid/Pyrazinamide ± Ethambutol). Two patients did not receive treatment as their diagnosis was made post-mortem. Of the sixteen patients, ten were treated and discharged, three died, two have on going review and one was lost to follow up.
Conclusion: ATB is a difficult diagnosis to make and there can be a significant time delay between symptom onset and diagnosis as the symptoms can be varied and insidious in nature. It is an easily treatable condition and a combination of abdominal pain, fevers and/or weight loss in a non-Caucasian patient should warrant further investigation.

Contact E-mail Address: cord.langner@medunigraz.at
Introduction: In colorectal cancer, the morphology at the invasive tumour margin is known to reflect the biology of disease, rendering important prognostic information. Tumour budding, defined as the presence of isolated single cells or small clusters of cells (composed of fewer than five cells), has been associated with adverse outcome. In contrast, peritumoural inflammation has been associated with favourable outcome. Of note, the antitumour activity of inflammation may lead to the destruction of tumour glands and, ultimately, the presence of small clusters of cells scattered in the tumour stroma (''pseudo-budding''). Our study aimed to analyse the relationship between tumour budding and inflammation and its possible prognostic significance in a large cohort of colorectal cancer patients.
Aims & Methods: Tumours of 381 randomly selected patients were retrospectively reviewed for the extent of tumour budding, with high-grade budding reflecting presence of 10 or more budding fociscattered at the invasive tumour margin. The intensity of the peritumoral inflammation was assessed using a four-degree scale according to Klintrup-Mäkinen criteria. Progression-free and cancer-specific survivals were determined using the Kaplan-Meier method.
Results: Overall, 221 (58%) tumours showed low grade, 160 (42%) tumours high-grade budding. 167 (44%) tumours showed no increase or only a mild and patchy increase of inflammatory cell sat the invasive tumour margin, but no destruction of invading cancer cell islets (scores 0-1), whereas in 214 (56%) tumours a band-like infiltrate of inflammatory cells with at least some destruction of cancer cell islets was seen (scores 2-3). When analysis was restricted to tumours with high-grade budding, 82 (51%) cases showed mild inflammation (scores 0-1) and 78 (49%) marked inflammation (scores 2-3). Tumour budding was significantly associated with both progression-free and cancer-specific survival in our cohort. Cases with high-grade budding and marked inflammation had a better outcome regarding progression-free ($p < 0.001$) and cancer-specific survival ($p < 0.001$) than high-grade cases with only mild inflammation. Outcome in these cases, however, was still worse compared to cases with low-grade budding, in which the extent of peritumoral inflammation had no further prognostic effect.
Conclusion: Though tumours with marked inflammation at the invasive tumour margin may showd estruction of cancer islands due to the anti-tumour effect of the inflammatory infiltrate(''pseudo-budding''), the presence of isolated tumour cells and small clusters of cells scattered in the stroma at the tumour margin does not *per se* imply favourable outcome in these cases. It is of note that tumours with high-grade budding and marked inflammation at the invasion front still bear a significantly poorer outcome than tumours with low-grade budding, in which the extent of peritumoural inflammation had no prognostic effect.

Introduction: Sepsis represents a significant burden of disease and mortality in Intensive Care Units. Ileus, the inhibition of the propulsive motility of the gastrointestinal (GI) tract, together with mucosal barrier dysfunction, will maintain sepsis by the translocation of bacteria and luminal antigens. Interleukin-6 (IL-6) is a major proinflammatory cytokine that is secreted by

immune cells such as macrophages and T cells. In previous experiments, we observed a significant increase in systemic and colonic IL-6 levels that coincided with an increase in colonic permeability.
Aims & Methods: We aimed to investigate the effect of anti-IL-6-antibodies on ileus, colonic permeability and translocation of intestinal bacteria in blood in a septic mouse model. Sepsis was induced in Swiss-OF1 mice by caecal ligation and puncture (CLP). Sham-operated animals served as controls. Mice received either one injection of anti-IL-6 antibodies 1 mg/kg i.p. (anti-IL6) or the IgG isotype control (IgG) jointly with the CLP procedure (n = 8-12/group). Occurrence of ileus was confirmed 48h post-procedure by studying the geometric center (GC) of beads. In the permeability study, mice were anesthetized and underwent a laparotomy, during which the colon was ligated and injected with 100 µL of a 9% Evans blue (EB) solution. Mice were sacrificed 1h later via cardiac puncture, and serum samples as well as homogenized colon supernatants were analyzed for IL-6 levels. Colons were rinsed and incubated for 24h in formamide to extract the EB from the colon wall. Whole blood was plated directly onto agar plates and cultured for 24h to quantify bacterial translocation.
Results: CLP-induced sepsis significantly delayed GI transit and this effect was reversed by anti-IL-6 treatment (GC: sham + IgG 5.4 ± 0.4, sham + anti-IL6 5.8 ± 0.4, CLP + IgG 2.6 ± 0.4*, CLP + anti-IL6 4.3 ± 0.5). Serum and colonic IL-6 levels rose significantly following CLP, and anti-IL6 was able to reduce them (serum: sham + IgG 4.6 ± 2.5, sham + anti-IL6 2.0 ± 0.6, CLP + IgG 276.6 ± 71.6, CLP + anti-IL6 84.5 ± 18.3 pg/mL, $p < 0.05$ for the effect of CLP and of anti-IL6; colon: sham + IgG 3.8 ± 2.4, sham + anti-IL6 2.2 ± 0.8, CLP + IgG 209.8 ± 94.6, CLP + anti-IL6 52.3 ± 14.1 pg/100 mg colonic tissue, $p < 0.05$ for the effect of CLP). CLP-induced sepsis significantly increased colonic permeability. The impaired barrier was improved by anti-IL6 treatment (sham + IgG 22.6 ± 1.7, sham + anti-IL6 29.3 ± 2.2, CLP + IgG 52.9 ± 10.4*, CLP + anti-IL6 27.8 ± 5.5 µg EB/100 mg colon). Finally, anti-IL6 numerically reduced the number of positive blood cultures in septic animals (sham + IgG 0/6, sham + anti-IL6 0/8, CLP + IgG 7/9, CLP + anti-IL6 5/9 positive cultures, Pearson's Chi-squared test $p < 0.05$ for CLP + IgG or CLP + anti-IL6 versus sham + IgG).
Conclusion: CLP caused a marked delay in GI transit with an increased colonic permeability and subsequent increased risk of bacterial translocation. Anti-IL-6 treatment significantly ameliorated GI motility, suppressed inflammation and normalized the permeability of the colonic wall. We conclude that the proinflammatory cytokine IL-6 has a major influence on colonic permeability and GI motility disturbances following CLP-induced septic ileus.

Introduction: The patients with ulcerative colitis are at increased risk of developing colitis-associated cancer, suggesting that contiuous inflammation in colon leads to the development of carcinogenesis. However, the mechanism of the carcinogenesis in colitis-associated cancer remains unknown. Recently, 3-dimentional (3D) primary organoid culture of colonic epithelial cells has been established in our group (*Nature Medicine* 2012).
Aims & Methods: We therefore aimed to assess the influence of continuous stimulation with cytokines on colonic epithelial cells in vitro, using 3D primary organoid culture.
Colonic crypts were isolated from 8-week old female mouse and were cultured by TMDU method. To mimic chronic inflammation, the mixture of tumor necrosis factor-α (TNF-α), interleukin-1β (IL-1β), interleukin-6 (IL-6), lipopolysaccharide (LPS) and flagellin were added into the medium every other day. Microarray analysis was performed after 60 weeks of cytokines stimulation. Gene Set Enrichment Analysis (GSEA) was also performed for the detection of specific cell signaling pathway. The expression of NF-κB target genes IL-8, DUOXA2 was assessed by quantitative RT-PCR. For the analysis of accumulation of NF-κB p65 in nuclei, 3D immunohistochemistry of whole organoid was performed by stain with anti-NF-κB p65 antibody. To evaluate reactive oxygen species (ROS) in live organoids, CellROX® Deep Red Stress Reagents (Life technologies) was added to medium for one day. Organoids were visualized by confocal laser fluorescent microscopy.
Results: The stimulation with TNF-α, IL-1β, IL-6, LPS and flagellin showed the significant induction of NF-κB target genes in colonic organoids. Microarray analysis with GSEA analysis showed significant induction of NF-κB signaling after 60 weeks of cytokines stimulation. Interestingly, the expression of DUOXA2 gene, which was NF-κB target genes and upregulated in microarray analysis, was gradually increased by the continuous stimulation with cytokine mixtures, suggesting that NF-κB signaling might be accumulated by the stimulating time. 3D immunostaining analysis showed that NF-κB p65 was accumulated in nuclei by longer time of the stimulation, indicating that continuous stimulation with cytokines might lead to a stronger activation of NF-κB signaling. Interestingly, accumulated NF-κB signaling by long-term stimulation remained active after the removal of all cytokines, whereas NF-κB signaling induced by short-term stimulation was completely shut down by the removal of all cytokines. ROS analysis showed that ROS were induced by stimulation with cytokines. Moreover, ROS in the organoid with long-term stimulation remained at 11 weeks after the removal of cytokines, suggesting that oxidative stress in the organoid with long-term stimulation was also irreversible.
Conclusion: Persistent inflammation leads to irreversible NF-κB signaling activation in colonic epithelial cells, suggesting that "signal spiral" might be crucial for the carcinogenesis of colitis-associated cancer.

P1017 THE DISTURBANCE OF CENTRAL DOPAMINERGIC NEURONS IN RAT MODEL OF PARKINSON'S DISEASE INCREASES SUSCEPTIBILITY TO COLONIC INFLAMMATION

T. Chervinska[1], K. Nesteruk[1], A. Pryisiazhniuk[1], T. Dovbynchuk[1], B. Kopiak[2], L. Pelyukh[1], N. Nurishchenko[1], T. Sergeychuk[1], O. Kabanov[1], L. Garmanchuk[1], V. Sagach[2], G. Tolstanova[1]
[1]*Educational-Scietific Center "Institute of Biology, Taras Shevchenko National University of Kiev,* [2]*Bogomolets Institute of Physiology NASU, Kiev, Ukraine*

Contact E-mail Address: gtolstanova@gmail.com
Introduction: The development of colonic inflammation in experimental colitis is associated with increase of the blood-brain barrier permeability and the loss of central dopaminergic neurons [1]. From the other hand, the disturbance of central dopaminergic neurons during Parkinson's disease (PD) is characterized by colonic constipation [2]. Constipation might be associated with the growth of pathogenic microflora as a result of that the disruption of intestinal barrier integrity, inflammation development and further exacerbation of PD symptoms.
Aims & Methods: The aim of the present study was to check whether the colonic inflammation is primary associated with the early stages of PD pathogenesis or PD increases the susceptibility to colonic inflammation development. Study was done on male Wistar rats (180-250 g). Model of experimental PD was induced by single unilateral 6-hydroxydopamine (6-OHDA) administration, rats were enrolled in study 1 month after. Colonic inflammation was induced by 6% iodoacetamide enema. Levels of spontaneous and carbachol-stimulated colon motility was estimated by ballonographic method *in vivo*; the activity of Mg^{2+}, Ca^{2+}-ATPase and K^{+}-ATPase in colonic smooth muscles - by the release of inorganic phosphate; colonic levels of calmodulin – by Western blot; the parietal microflora - by bacteriological culture methods; colonic endothelial permeability - by Evans blue extravasation; levels of inflammation - by colon myeloperoxidase activity (MPO), levels of I?AM-1 and arginase activity in peritoneal macrophages.
Results: 6-OHDA lesioned-rats had decreased tonic indexes of spontaneous and stimulated colon motility by 11.3 ($p < 0.05$) and 22.5% ($p < 0.01$); increased frequency of contractions of spontaneous (by 31.6%, $p < 0.05$) but not stimulated motility; increased amplitude of contractions (by 31.16%, $p < 0.01$) and decreased motor-activity index of stimulated colon motility (19.9%, $p < 0.05$) *vs* sham-lesioned rats. Delayed in colon motility in 6-OHDA rats was associated with increased colon level of Mg2+, Ca2+-ATPase activity (39.7%, $p < 0.05$), decreased K+-ATPase activity (17.0%, $p < 0.05$) & level of calmodulin ($p < 0.05$). Colon and ileum parietal microflora composition were not changed between sham & 6-OHDA-lesioned rats. It was no difference in the colonic mucosa endothelial permeability & ICAM-1 levels as well. While 6-OHDA rats had 2.3-fold depleted peritoneal macrophages functional reserve ($p < 0.05$). 6-OHDA rats were more predisposed to iodoacetamide-induced colonic inflammation *vs* sham-lesioned rats: MPO activity was higher 2.6-folds ($p < 0.05$); colonic endothelial permeability – 1.5-folds and I?AM-1 levels 5.5-folds ($p < 0.05$).
Conclusion: The delayed colonic motility is an early feature of experimental PD which is associated with low grade systemic inflammation. We showed for the first time that disturbance of central dopaminergic neurons in rat model of PD increases susceptibility to colonic inflammation development.

Introduction: Anomalies of the enteric nervous system (ENS) have been associated to motility and inflammatory disorders of the gut. Since enteric neuropathies are characterized by various histopathological pictures including loss of ganglion cells or infiltrating mononuclear cells an immune-mediated damage, possibly triggered by an infectious agent, has been postulated. Indeed, we have recently shown in rodents that following intragastric (IG) administration the neurotropic Herpes simplex virus (HSV)-1 can infect the ENS resulting in time-dependent intestinal neuromuscular abnormalities[1]. Therefore, we aimed to investigate whether adaptive immune responses are involved in the onset of ENS dysfunction following HSV-1 infection.

Aims & Methods: Male C57/Bl6 (WT) mice were inoculated intranasally with HSV-1 (10^2 pfu) and 4 weeks (W) later IG (10^7 pfu). Starting 4 W after viral IG inoculum a group of mice received anti-CD8 antibody. Six-ten W after viral IG inoculum we: a) determined gastrointestinal (GI) motility by measuring fluorescein-isothiocyanate dextran distribution; b) assessed ENS integrity by immunohistochemistry on ileal whole-mount preparations; c) characterized the lymphocytes infiltrating the longitudinal muscle myenteric plexus (LMMP) and their reactivity to HSV-1 antigens by FACS analysis; d) quantified changes in isometric muscle tension following electric field stimulation (EFS) of ileal segments. To verify the role of lymphocytes in HSV-1 induced ENS dysfunction, CD3+cells were isolated from the LMMP of mice 8-10 W after viral IG inoculum, *in vitro* pulsed with HSV-1, and injected in recipient mice. After one week the effects on isometric muscle tension following EFS stimulation of ileal segments were determined.
Results: At 8 and 10 W after IG inoculum, HSV-1 caused a significant delay in GI transit, impaired cholinergic neuromuscular transmission ($p<0.01$ vs control mice), altered expression and distribution of the neurofilaments peripherin and βIII-tubulin, whereas no anomalies were observed at 6 W after IG inoculum. In the LMMP, but not in the spleen, we observed an increase in CD3+lymphocytes starting at 6 W and persisting up to 10 W after viral IG inoculum. At 8 W after viral IG inoculum HSV-1 reactive $CD3^+CD4^+IL4^+$ and $CD3^+CD8^+INF\text{-}\gamma^+$ were demonstrated in LMMP, whereas at 10 W non-HSV-1 specifically activated CD8+ T-cells were present in LMMP. Depletion of CD8+ T-cells, by administration of monoclonal anti-CD8 antibody, abolished the ENS damage and the neuromuscular anomalies observed at 8 W after viral IG inoculum. Ileal muscle tension was significantly altered ($p<0.01$ vs control) in recipient mice receiving *in vitro* HSV-1 pulsed LMMP lymphocytes isolated at the 8th W post IG viral inoculum. Instead, the adoptive transfer of lymphocytes from 10 W infected mice resulted in dysmotility with or without *in vitro* exposure to viral antigens.
Conclusion: At different time points following infection of the ENS, HSV-1 activates lymphocyte subsets directly causing intestinal neuromuscular dysfunction. We speculate that HSV-1 infection of the ENS, as opposite to the central nervous system compartment, triggers adaptive immune responses that can alter the structure and the integrity of the neurons thus predisposing to bowel anomalies.

Contact E-mail Address: gencogencdal@yahoo.co.uk
Introduction: Primary lactase deficiency (PLD) affects more than the half of the world's population. LCT-13910 polymorphism was described and being widely used for diagnosis of PLD. The relationship between LCT-13910 polymorphism and risk for colorectal cancer is unclear.
Aims & Methods: We investigated the presence of a relationship between lactase deficiency and colon cancer and adenomatous polyps of the colon in our population. 166 patients (M:103; Mean Age: 60.7 ± 10.4), who had undergone total colonoscopy were included in the study. Anticoagulated blood was drawn from the patients following colonoscopy for genetic analyses (LCT-13910).
Results: The CC genotype in lactose gene 13910 locus, which was accepted as the genetic indicator of lactase deficiency, was determined as 83.7%. The CC genotype rate was determined as 89.1% in patients who had the history of milk intolerance and 81.5% in those with a history without milk intolerance (p = 0.236). No difference was detected between the patients who had colorectal polyp, cancer and normal colonoscopy findings with regard to lactase gene polymorphism. No difference was determined between groups when compared with regard to C or T allele and also for the number and location of the polyps, genetic polymorphism.
Conclusion: The presence of a negative relationship between lactase deficiency and milk consumption is inevitable. Therefore, a relationship should be expected between lactase deficiency and colorectal cancer; however, such a relationship could not be determined in our study.

P1020 HIGH CARCINOEMBRYONIC ANTIGEN LEVEL MAY BE A DIAGNOSTIC MARKER FOR COLORECTAL ADENOMA IN KOREAN YOUNG MEN

H. S. Lee[1], I. Yoon[1], J. H. Cho[1], S. H. Lee[1], G. H. Lee[1]
[1]*Department of Internal Medicine, Seonam University College of Medicine, Myongji Hospital, GOYANG-SI, Republic of Korea*

Contact E-mail Address: epoch0123@naver.com
Introduction: Colon cancer is the 3rd most commonly diagnosed cancer in South Korea. Colorectal cancer screening is recommended for average-risk persons beginning at age 50 in South Korea. However, prevalence of adenoma in subjects aged 40-49 years men was higher than we expected.
Aims & Methods: The aim of this study to determine the prevalence and risk factors of colorectal adenoma in persons aged 40-49 years men. 1902 asymptomatic subjects (1330 men, 69.9%, mean age of 47.9 ± 6.7) who underwent screening colonoscopy in a health examination center of Myongji hospital from 2010 to 2013 were enrolled in this study. We conducted case-control study to determine the risk factor for adenoma. The subjects were classified into two groups (adenoma vs controls and 40 – 49 years vs ≥50 years group).
Results: At least 1 colorectal neoplasm was identified in 385 patients (20.2%). 372 patients were found to have a non-advanced adenoma, 13 individuals had an invasive adenoma and no patient had a cancer. Male, old age, smoking, metabolic syndrome and elevated carcinoembryonic antigen (CEA) level were significantly associated with colorectal adenoma in univariate analysis. According to multiple logistic regression, adenoma was significantly associated with male and tended to be associated with high CEA level (p value = 0.059). To validate the diagnostic values of CEA for adenoma, AUROC was calculated. Area under the curve of CEA for colorectal adenoma in non-smoking men (n = 585) under 50 years was 0.600 (0.543∼0.656). Area under the curve of CEA for colorectal adenoma in smoking men (n = 376) under 50 years was 0.615 (0.540∼0.690).
Conclusion: Male sex, metabolic syndrome, smoking and high CEA level seem to be associated with colorectal adenoma. High CEA level may be a diagnostic marker for any colorectal adenoma for 40 – 49 years Korean men. Further studies based on a large sample size will be needed to confirm the exact role of CEA for diagnostic marker of colorectal adenoma in Korean young men.

Introduction: Intestinal tuberculosis (ITB) is still prevalent in Korea. Recently, the incidence of Crohn's disease (CD) is also increasing, therefore, differential diagnosis of CD from ITB is challenging. An INF-gamma assay (QuantiFERON-TB gold test, QFT) is regarded as a good supplementary tool for the diagnosis of ITB. However, the clinical implication of the positive results of QFT in ITB is uncertain. We investigated the clinical features of patients of ITB according to the results of QFT.

Aims & Methods: We enrolled the ITB patients who were tested for QFT in the initial diagnosis from April 2007 to July 2013. We retrospectively analyzed clinical features of ITB patients based on the results of QFT.

Results: A total of 109 patients with ITB were enrolled from 3 institutes and 82 patients (75.2%) showed positive results of QFT, whereas 27 patients (24.8%) showed negative results. In QFT-positive group, the mean age at the time of diagnosis as ITB is 44.1 ± 12 years, which is significantly higher than QFT-negative group (37.0 ± 14.8 years, $p = 0.0096$). C-reactive protein level at the time of diagnosis as ITB is significantly lower in QFT-positive group (1.3 ± 2.3 mg/dL) than QFT-negative group (6.4 ± 9.9 mg/dL, $P < 0.000$). However, no differences were found between groups regarding the presence of granuloma in colonic tissues ($P = 0.095$) or accompanying of extra-intestinal TB ($P = 0.592$).

Conclusion: QFT-positive results were gained in three-fourths patients with ITB and we confirmed that QFT is a good supplementary tool for the diagnosis of ITB. In QFT-positive group, the mean age is higher and has lower level of CRP than QFT-negative group. These results suggested the possibility that prior exposure to TB may cause mild inflammation in patients with ITB.

Introduction: Obesity is a well-established risk factor for colorectal adenoma, but its association with colorectal cancer (CRC) is not clear.

Aims & Methods: The aim of this study was to examine whether visceral adipose tissue (VAT) serves as a risk factor for CRC as well as colorectal adenomas. A retrospective case-control study was conducted with 45 patients with CRC (2 rectal and 43 colon cancers), 50 patients with colorectal adenoma and 50 normal controls. All subjects underwent various laboratory tests, computed tomography (CT) scan available for abdominal fat measurement, and colonoscopy. All patients with CRC also had available abdominal CT scan 1-2 years before the diagnosis. VAT was defined as an intraabdominal adipose tissue area measured by CT scan. Adipose tissue areas were measured at the level of the umbilicus from CT scan.

Results: Body mass index, fasting blood glucose (FBS) and VAT areas were significantly increased in adenoma and CRC groups compared to controls (all $P < 0.01$). The mean ± standard deviation of VAT area was 92.4 ± 4.8 cm^2 in normal controls, 120.9 ± 5.2 cm^2 in adenoma group and 123.2 ± 5.9 cm^2 in CRC group ($P = 0.007$ by ANOVA). On the other hand, subcutaneous adipose tissue areas were not different between the 3 groups ($P > 0.05$). Serum total cholesterol levels were significantly lower in CRC group than control or adenoma groups ($P < 0.001$). Although there was no significant difference in VAT areas between adenoma and CRC groups, VAT areas in CRC patients from CT scan taken 1-2 years before the diagnosis of CRC were significantly higher than those in adenoma group ($P = 0.045$).

Conclusion: Our study showed that both visceral obesity and insulin resistance were significant risk factors for CRC in the Korean population. However, the effect of visceral fat might be limited to the early stage of adenoma-carcinoma sequence in colorectal carcinogenesis. Further studies are warranted in the future.

Introduction: European guidelines for quality in colorectal cancer (CRC) screening recommends different surveillance intervals in patients after adenoma resection. However, these recommendations have not been validated.

Aims & Methods

Aims: To assess whether the cumulative incidence of advanced neoplasia (AN) (advanced adenoma or CRC) and CRC in patients undergoing endoscopic surveillance differs between high-risk ($\geq$5 adenomas or $\geq$ 20mm) and intermediate groups (2-4 adenomas or 10 to 19 mm or villous histology or high-grade dysplasia) of the European guidelines for quality in the CRC screening.

Methods: Retrospective cohort study of national ambit. We included subjects with high or intermediate risk adenomas detected in CRC population screening programs and in COLONPREV study from its inception until June 2011. The main dependent variable was the cumulative incidence of AN. We compared follow-up time with the Student's t test. We analyzed the differences in endoscopic surveillance and the cumulative incidence of AN and CRC between both groups with the Mantel-Haenszel test. We performed a proportional hazards regression to control for confounding variables (sex, age, quality of baseline colonoscopy program and screening test). Differences between groups were expressed as risk ratio (RR) or hazard ratio (HR) and its confidence interval at 95% (95% CI).

Results: We included 5401 subjects, 3379 people with intermediate-risk adenomas and 2022 with high-risk adenomas (men = 70.1%, mean age = 60.9 ± 5.7 years, baseline number of colonoscopies = 1.2 ± 0.5, cecal intubation = 99.2%, adequate cleansing = 99.3%). A surveillance endoscopy was performed in 64.3% of subjects (high 68.2%, intermediate 62%; RR 1.3, 95% CI 1.2-1.5) at a mean interval of 2.8 ± 1 years (high = 2.7 ± 1.1, intermediate = 3 ± 0.9; $p < 0.001$). In subjects with endoscopic surveillance, the cumulative incidence of AN in high and intermediate risk cohorts was 15.8% (58.6 cases per 1000 person-years) and 12.4% (41.9 cases per 1,000 people-year) with a RR = 1.3 (95% CI 1.1-1.6); and CRC cumulative incidence was 0.5% and 0.6% respectively (1.9 cases per 1000 person-years) with a RR = 0.9 (95% CI 0.3 to 2.2). In the proportional hazards analysis, the cumulative incidence of AN was higher in the high-risk cohort (HR 1.6, 95% CI 1.3-1.9). However, we found no differences in the cumulative incidence of CRC (HR 1.1, 95% CI 0.4 to 2.9).

Conclusion: In subjects performing endoscopic surveillance, the AN cumulative incidence is higher in the European guideline high risk group. However, we detected no differences in the CRC cumulative incidence between both cohorts.

P1024 DIAGNOSTIC RISK FACTORS FOR COLORECTAL CANCER IN PATIENTS WITH SERRATED POLYPOSIS SYNDROME

J. E. G. Ijspeert[1], S. A. Q. Rana[2], N. S. S. Atkinson[3], Y. J. van Herwaarden[4], T. M. Bisseling[4], B. A. J. Bastiaansen[1], J. E. East[3], A. Latchford[2], E. Dekker[1], on behalf of Dutch Workgroup Serrated Polyps, & polyposis (. WASP)
[1]*Academic Medical Centre, Amsterdam, Netherlands,* [2]*St Mark's Hospital, London,* [3]*Translational Gastroenterology Unit, Oxford, United Kingdom,* [4]*Radboud University Medical Center, Nijmegen, Netherlands*

Introduction: Serrated polyposis syndrome (SPS) is characterized by multiple serrated polyps (SP) throughout the colon and accompanied by an increased

life-time risk of colorectal cancer (CRC). SPS is diagnosed based on clinical criteria, which includes a very heterogeneous group of patients with a wide variation in CRC risk.

Aims & Methods: We aimed to assess CRC risk factors in a large cohort of patients with SPS and to evaluate the risk of CRC during surveillance. Patients were retrospectively enrolled from 7 centers in the Netherlands and 2 in the UK. Data were retrieved from medical charts, pathology and endoscopy reports. Criteria from the World Health Organization of 2010 were used to diagnose SPS (WHO1: ≥5 SP proximal to rectosigmoid with ≥2 of ≥10mm; WHO2: ≥1 SP proximal to rectosigmoid and a first degree relative with SPS; WHO 3: ≥20 SP of any size, but distributed throughout the colon). Patients that only fulfilled WHO criterion 2, with inflammatory bowel disease and/or a known hereditary CRC syndrome were excluded from analysis. Multivariate logistic regression was used to calculate adjusted risk factors for CRC. Incidence rate was calculated to evaluate the risk of CRC during surveillance after the resection of all lesions > 5mm.

Results: In total 435 patients with SPS were included for analysis. The mean age at diagnosis was 58 years (SD 14), 49% were male and 57% of patients had a history of smoking. Of all patients, 27% fulfilled WHO criterion 1, 41% WHO criterion 3 and 32% WHO criteria 1&3. In total 128 (29%) patients were diagnosed with CRC. Patients with ≥1 SP with dysplasia (OR 2.05; 95%CI 1.26-3.31), ≥1 advanced adenoma (OR 2.31; CI 1.46-3.66) and patients that fulfilled WHO criteria 1&3 (OR 1.70; CI 1.10-2.57) were at increased risk of developing CRC, adjusted for age at SPS diagnosis (Table 1; only significant results shown). SPS patients with a history of smoking had a decreased risk of developing CRC (OR 0.35; CI 0.22-0.55). A total of 261 patients underwent surveillance after clearing of all lesions > 5mm with a median follow up of 3.2 years (IQR 1.6-5.7) and a median interval between colonoscopies of 1.2 years (IQR 1.0-1.6). In total 3 patients were diagnosed with CRC during surveillance (2.90 events/1000 person years (95%CI 0.74-7.89).

Risk factors for CRC	Univariate OR(95% CI)	p-value	Multivariable OR(95% CI)	p-value
Age at diagnosis SPS (per year)	1.04 (1.02-1.06)	**<0.001**	1.03 (1.01-1.05)	**<0.001**
History of smoking	0.48 (0.30-0.78)	**<0.01**	0.35 (0.22-0.55)	**<0.001**
≥1 SP containing dysplasia	2.31 (1.47-3.65)	**<0.001**	2.05 (1.26-3.31)	**<0.01**
≥1 advanced adenoma	2.49 (1.62-3.85)	**<0.001**	2.31 (1.46-3.66)	**<0.001**
Fulfilling WHO criteria 1&3	1.65 (1.07-2.54)	**0.02**	1.70 (1.10-2.57	**0.02**

Conclusion: SPS patients with advanced adenomas, SPs containing dysplasia and/or a combined WHO 1&3 phenotype are at an increased risk of developing CRC. Patients with a history of smoking show a markedly lower risk of developing CRC, possibly due to the fact that the pathogenesis of disease is different in these patients. The risk of developing CRC during surveillance and after clearing of all relevant lesions is lower than earlier assessed in literature, which may reflect a more mature multi-centre cohort with less selection bias.

Disclosure of Interest: None declared

P1025 THE APC I1307K ALLELE CONVEYS DIFFERENT RISKS FOR CANCER IN MEN AND WOMEN

N. Arber[1], S. Shapira[1], A. Leshno[1], S. Kraus[1], E. Liberman[1], M. Sror[1], A. Harlap Gat[1], L. Galzan[1], M. Moshkowitz[1], M. Serhan[1]
[1]*Integrated Cancer Prevention Center, Tel Aviv Sourasky Medical Center, Tel Aviv, Israel*

Contact E-mail Address: shiranshapira@gmail.com

Introduction: ***Background:*** The prevalence of the APC I1307K missense mutation is~6% in Ashkenazi Jews (AJ) and is associated with an increased risk of colorectal (CRC) neoplasia.

Aims & Methods

Aim: To examine the association of this variant with non-CRC in a large cohort.

M&M: 13,017 consecutive healthy subjects, undergoing annual screening at Integrated Cancer Prevention Center in the past decade. This population was enriched with **1,607** cancer patients recruited from Oncology, Surgery, Gastroenterology, Urology and Hematology services. Demographics, medical history, and pathological data were recorded. Mortality data was obtained from Israel's Ministry of Health registry. The APC I1307K analyses were performed using real-time PCR on DNA extracted from peripheral mononuclear cells. The detection rates of I1307K were compared using multiple variable logistic regression adjusted for age and sex. P-values for significance were adjusted to multiple testing by FDR methods.

Results: The I1307K was detected in 803/14,624 (5.5%) individuals (8.9% and 2.4% among Ashkenazi and Sephardic Jews). I1307K carriers showed a significantly increased risk for any type of cancer with an adjusted age and sex odds ratio (OR) of 2.53 (95% CI 2.11-3.04, P < 0.0001). In men increased risk for brain (OR 12.7), lung (7.3), urinary system (4.3), pancreas (3.7), BCC (3.2), and melanoma (3) was found. Female carriers showed a greater risk only for breast (2.8) and skin (4.8) cancers. A significantly increased CRC risk was found in men similar to previous studies: adenomatous polyps OR = 1.67 (95% CI 1.23-2.25, P = 0.001); CRC OR = 1.90 (95% CI 1.35-2.69, P < 0.0001). In women increased risk only for adenomatous polyps OR = 1.69 (95% CI 1.24-2.29 P < 0.001), but not for CRC. Carriers with one cancer were at significantly increased risk for developing at least one more cancer (OR 1.80 95% CI 1.14-2.8 P = 0.011). The increased risk for > 2 cancers was significant only in women.

Overall survival between carriers and non-carriers using revealed that female carriers died at a significantly older age than non-carriers (average age of death 78.8 years, SE 2.2 vs. 70.4, SE 0.67 p = 0.003). A Cox proportional hazard regression yielded a near significant HR of 0.69 (95% CI 0.47-1.01 p = 0.055). iCarrier female cancer patients also had higher survival rate (HR 0.58, 95% CI 0.36-0.93 p = 0.022).

Conclusion: 1. The I1307K allele of the APC gene is a reliable marker for overall cancer risk (OR – 2.53) in particular in men. 2. This risk was higher than the prior described association with CR neoplasia. 3. In women the I1307K allele is only associated with an increased risk for breast and skin cancers and no increase in risk for CRC. 4. Carriage of this allele is associated with an unexplained significant 8 year increase in longevity in women.

Introduction: Hodgkin lymphoma (HL) survivors who were treated with infradiaphragmatic radiotherapy and/or high dose procarbazine have an approximately 5-fold increased risk to develop colorectal cancer (CRC) compared with the age-matched general population. The mechanism behind the transformation of normal colonic mucosa into CRC after exposure to radiotherapy or chemotherapy remains unknown. This study aims to provide insight into the development of treatment-induced CRC by evaluating the histopathological and molecular characteristics of treatment-induced CRC.

Aims & Methods: Formalin-fixed paraffin-embedded (FFPE) material from CRCs diagnosed in HL survivors was requested through the Nationwide Pathology Database (PALGA). Histopathological revision and immunohistochemical staining for mismatch repair (MMR) proteins were performed. Microsatellite stability status (pentaplex PCR) and CpG island methylator phenotype (CIMP, multiplex ligation-dependent probe amplification) status were assessed in all CRCs. Microsatellite instable (MSI) CRCs were additionally evaluated for promoter methylation of MMR genes.

Results: FFPE material of 51/64 (80%) cases was obtained, including 3 cases with 2 synchronous CRCs. The median age at CRC diagnosis was 57 years (range 30-79), 65% were male and the median latency between HL and CRC was 22 years (range 7-39). 13/54 (24%) CRCs were MSI and loss of staining was displayed for MLH1 and PMS2 (5/13) or MSH2 and MSH6 (7/13). One MSI tumor showed normal levels of all four MMR proteins. *MLH1* promoter methylation was found in 3 MSI CRCs that showed loss of MLH1 and PMS2 protein staining. One MSS tumor showed loss of PMS2 staining; all the other MSS tumors stained positive for the four MMR proteins. 21/53 CRCs were CIMP (Ogino 5/8 gene positivity). The incidences of MSI and CIMP did not vary between different treatment groups (RT alone, procarbazine alone or RT + procarbazine).

Conclusion: In this study we demonstrated a high frequency of MSI among radiotherapy- and chemotherapy-associated CRCs, which surprisingly cannot be explained by promoter hypermethylation. Normal tissue and tumor DNA sequencing of *MLH1*, *PMS2*, *MSH2* and *MSH6* is in progress.

Contact E-mail Address: morten.da2m@gmail.com

Introduction: Studies suggest that acetylcholine (ACh) plays a role in development of colorectal neoplasia (CRN). Local level of several transporters and enzymes involved in epithelial synthesis of ACh[1], muscarinic M3-receptor[2] and ACh esterase[1,3] appear dysregulated and involved in neoplastic cell-proliferation.

Aims & Methods: The aim of this study was to investigate the expression of genes coding for proteins related to epithelial synthesis and metabolism of ACh in colonic mucosa from patients with and without CRN. Furthermore, functional role of ACh was investigated. Endoscopic biopsies (N = 25) from patients with CRN (CRN-pts) and controls were acquired from macroscopically normal mucosa in the sigmoid colon. qPCR was performed for the following 17 ACh-related genes: Choline transporter-like protein (CTL) 1-5, organic cation transporter 1-3, high-affinity choline transporter-1, vesicular ACh transporter, choline acetyltransferase, carnitine acetyltransferase, muscarinic receptor M1-3, ACh esterase and butyrylcholine esterase. All tests were run in triplicates and expression levels normalized with β-actin expression. Biopsies were mounted in micro-Ussing chambers and exposed to amiloride (20 μM) and subsequently

increasing doses of ACh (0.125–2048 μM). Transepithelial electrogenic transport was measured by short circuit current (SCC). Data are reported as mean ± SEM. Statistical significance was tested using Student's unpaired *t*-test and Mann-Whitney *U*-test for equal and unequal variances of the groups, respectively. Unequal qPCR-data were first log-transformed. For categorical data Chi-square was used.

Results: *qPCR:* CTL1 and CTL4 were significantly increased in CRN-pts compared to controls. Relative expression level for CTL1 was 0.95 ± 0.06 in CRN-pts vs 0.61 ± 0.06 in controls ($p = 0.002$). Relative expression level for CTL4 was 0.57 ± 0.04 in CRN-pts vs 0.42 ± 0.06 in controls ($p = 0.04$). *Ussing chamber:* ACh induced rapid biphasic change in SCC. First part (decrease in SCC) was observed in 36 % of CRN-pts vs 78 % of controls ($p = 0.049$). For the second part of SCC response (increase), double Michaelis-Menten analysis provided the best fit indicating activation of two receptors. For both parts of the biphasic response, the EC_{50} and maximal responses showed no significant difference between CRN-pts and controls.

Conclusion: Data demonstrate increased expression of choline transporter CTL1 and ACh transporter CTL4 in mucosa from CRN-pts, indicating increased absorption/excretion of choline/ACh. Further, functional data demonstrate altered response to ACh in CRN-pts as measured by electrogenic transepithelial transport.

P1028 PERITONEAL DISSEMINATION IS MORE COMMON IN BRAF MUTATION THAN KRAS MUTATION OR KRAS/BRAF WILD TYPE IN COLORECTAL CANCER

N. Yujiro[1], M. Amaki[1], S. Natsume[1], T. Iijima[1], R. Wakaume[1], K. Takahashi[1], H. Matsumoto[1], D. Nakano[1], M. Miyaki[1], T. Yamaguchi[1]
[1]*Surgery, Tokyo Metropolitan Cancer and Infectious Diseases Center Komagome Hospital, TOKYO, Japan*

Contact E-mail Address: nakayama.fd3s@gmail.com

Introduction: Molecular alterations are well studied in colorectal cancer, however there is still need for an improved understanding of their clinicopathological features. This study aims to characterize colorectal cancer with regard to *KRAS* and *BRAF* mutations in connection with tumor distant metastasis and prognosis in patients with colorectal cancer.

Aims & Methods: We consecutively selected 96 stage IV colorectal cancer patients who underwent surgical resection at the Tokyo Metropolitan Cancer and Infectious Diseases Center Komagome Hospital from January 2008 to December 2011 after obtaining their informed consent. All samples were analyzed to identify any *BRAF* (V600E) and *KRAS* (codons 12 and 13) mutations by direct sequencing. Patients with inflammatory bowel disease, a known history of familial adenomatous polyposis, Lynch syndrome or microsatellite instable were excluded.

Results: Of the 96 colorectal cancer patients, 25 (26.0%) were *KRAS* mutation, 7 (7.3%) were *BRAF* mutation and 64 (66.6%) were *KRAS*/*BRAF* wild type. In total, 73 (76.0%) were hematogenous metastasis, 22 (22.9%) were lymphogenous metastasis and 27 (28.1%) were peritoneal dissemination. In *KRAS* mutation patients, 8 (20%) were containing dissemination. In *BRAF* mutation patients, 5 (71%) were peritoneal dissemination and 14 (21.9%) in *KRAS*/*BRAF* wild type. Dissemination were significantly more common in *BRAF* gene mutation than in *KRAS*/*BRAF* wild type (Fisher's exact test, $p = 0.01$). Median survival time were 692 days in *KRAS* gene mutation, 470 in *BRAF* gene mutation and 1143 in wild type (logrank test, $p < 0.01$).

Conclusion: Peritoneal dissemination is more common in *BRAF* mutation than *KRAS* mutation or wild type in colorectal cancer.

P1029 IDENTIFICATION OF NORE1A AS A NEGATIVE FEEDBACK REGULATOR OF TNFA-NF-ΚB SIGNALING, WHICH DIRECTS APOPTOTIC SWITCH OF TNFA FUNCTION IN COLORECTAL TUMOR CELLS

N.-H. Kim[1], K.-P. Ko[2], S.-G. Chi[2]
[1]*Department of Internal Medicine, Ilsan Paik Hospital, Inje University, Goyang,* [2]*Department of Life Science, Korea University, Seoul, Republic of Korea*

Contact E-mail Address: n-hkim@paik.ac.kr

Introduction: NORE1A (RASSF5), a member of the Ras-association domain family (RASSF) of proteins, plays an important role in various cellular processes, including cell proliferation and apoptosis. NORE1A expression is commonly silenced or down-regulated in many human malignancies, including colorectal cancer. However, the mechanisms underlying its tumor suppressive functions have not been entirely defined.

Aims & Methods: To explore whether NORE1A inactivation is associated with colorectal tumor cell resistance to TNFα-induced apoptosis, we investigated TNFα effect on NORE1A expression using semi-quantitative RT-PCR and immunoblotting assay. NORE1A regulation of TNFα-NF-κB signaling and its cellular effects were defined by luciferase reporter and flow cytometric analyses and cell proliferation and apoptosis assays.

Results: NORE1A transcription was activated by TNFα and its induction strongly increased apoptotic response of colorectal tumor cells to TNFα. TNFα activation of NORE1A was disrupted when the RIPK1-IκBα-NF-κB signaling was blocked while it was further enhanced by p65/RelA transfection, indicating that NORE1A is a novel transcriptional target of TNFα-NF-κB signaling, which stimulates apoptosis-promoting function of TNFα. We also found that TNFα-induced NORE1A causes a rapid degradation of TNFα receptor type I (TNFRI) protein and subsequently suppresses NF-κB signaling, indicating the presence of a negative feedback regulatory loop between TNFα and NORE1A. Intriguingly, NORE1A degradation of TNFR1 was found to selectively impede TNFα-mediated RIPK1-IκBα-NF-κB signaling, thus blocking NF-κB-mediated cell growth and survival, whereas it facilitates TNFα-induced caspase activation and apoptosis. We finally observed that restoration of NORE1A expression in nonexpressing tumor cells strongly enhances apoptotic sensitivity of tumor cells to TNFα, suggesting that loss of its expression in tumorigenic process might be a key event that debilitates TNFα's proapoptotc effect.

Conclusion: Our data demonstrate first that NORE1A is a negative feedback regulator of TNFα, which directs apoptotic switch of TNFα function by selectively impeding TNFα-NF-κB signaling. These results strongly suggest that NORE1A inactivation might be a critical event that drives the oncogenic conversion of TNFα function in colorectal tumorigenesis.

P1030 THE ASSOCIATION OF GENETIC VARIATION WITHIN THE WNT SIGNALLING PATHWAY WITH COLORECTAL CANCER: A META-ANALYSIS

S. S. Malik[1], K. J. Monahan[1], M. McPhail[1]
[1]*Family History of Bowel Cancer Clinic, West Middlesex University Hospital and Imperial College, London, London, United Kingdom*

Contact E-mail Address: salim.malik10@imperial.ac.uk

Introduction: 35% of colorectal cancer (CRC) risk is attributable to heritable factors, of which a large proportion remains unexplained. Genome wide association studies have conclusively identified several risk variants in the TGF-beta pathway. Both TGF-beta and Wnt pathways are key regulators of colonic crypt homeostasis and colorectal carcinogenesis. The Wnt pathway is deregulated in 93% of CRCs, however the role of Wnt pathway genetic variation in CRC risk is uncertain.

Aims & Methods: The aim is to perform a systematic review and meta-analysis to assess the association of polymorphisms within the Wnt signalling pathway and the risk of CRC.

A systematic literature review of the Pubmed and HuGENet databases was conducted. Studies were included/excluded based on pre-specified criteria. In order to assess the risk attributed to each identified variant, the 'per allele' model was utilised to calculate pooled odds ratios. Heterogeneity was investigated by subgroup analyses for ethnicity, gender and tumour location. Publication bias was investigated using funnel plots and Egger's test. Statistical analysis was conducted using the R program (version 3.1.0).

Results: Forty-three polymorphisms across 18 different genes in the Wnt pathway were identified. Meta-analyses were conducted for 12 of these polymorphisms including between 831 to 31,427 cases per polymorphism. 6 polymorphisms were significantly associated with the risk of CRC. Rs1801155 within *APC* (OR = 1.79; 95% CI 1.27-2.52) and rs10505477 at the 8q24.21 locus (OR = 1.15; 95% CI 1.12-1.19) were associated with an increased risk of CRC. rs16260 (OR = 0.94; 95% CI 0.89-0.99) and rs9929218 (OR = 0.93; 95% CI 0.90-0.95) within *CDH1*; rs6983267 (OR = 0.85; 95% CI 0.83-0.87) within *MYC* and rs7014346 (OR = 0.87; 95% CI 0.81-0.94) at the 8q24.21 locus, were associated with a decreased risk of CRC. Subgroup analysis revealed gender, ethnicity and tumour location were not sources of heterogeneity.

Conclusion: Six polymorphisms associated with CRC risk account for a significant proportion of familial risk, although are unlikely to account completely for aberrant activation of the Wnt pathway. These polymorphisms are located within *APC, CDH1 and MYC* genes and the 8q24.21 locus. Further research into their precise role in colorectal carcinogenesis is warranted. Meta-association studies of all SNPs in the Wnt pathway should be conducted to identify further risk variants. Rare variants, copy number variations and epigenetic alterations may contribute to the remaining heritability and Wnt pathway activation.

Contact E-mail Address: marcoscarpa73@yahoo.it
Introduction: In non inflammatory colorectal cancer, T cell populations were demonstrated to play a significant role in the patients prognosis although it is not clear the trigger of this immune response and its efficiency in the preneoplastic lesions. Costimulatory interactions are decisive in sensitization of T cells by antigen presenting cells and important for the elicitation of the immune responses. Our previous studies demostrated that immunesurveillance mechanisms mediated by CD80-CD28 signalling may lead to dysplasia regression in ulcerative colitis.
Aims & Methods: The aim of this multicentric study was to explore the effect of CD80-CD28 signaling in human non inflammatory carcinogenesis and in a murine model of colonic carcinogenesis.
We prospectively enrolled 105 subjects who underwent screening colonoscopy or colectomy: 45 of them had an adenoma, 45 had an adenocarcinoma and 15 were healthy subjects. Biopsies were taken from their healthy mucosa and colonic lesions. Flow cytometry for CD8 + CD28+ or CD8 + CD38+, CD4 + CD25+ and CD25 + FoxP3+ lymphocytes and for CD80+ or HLA ABC+ epithelial cells were performed.
The azoxymethane (AOM)-induced colon carcinogenesis mouse model was used to block in vivo CD80 signaling by administration of neutralizing antibodies against CD80 or isotype control. Mice were euthanized 4 and 6 months after the first AOM injection. Colons were removed and examined. Flow cytometry was performed. Non parametric statistics was used.
Results: A higher rate of epithelial cells expressing CD80 or HLA-ABC was observed in colorectal adenoma compared to healthy colonic mucosa ($p = 0.036$ and $p = 0.022$, respectively) and colorectal adenocarcinoma ($p = 0.19$ and $p = 0.008$, respectively). The rate of CD8 + CD28+ and CD8 + CD38+ lymphocytes resulted higher in colorectal adenocarcinoma than in colorectal adenoma ($p = 0.001$ and $p = 0.005$, respectively).
We observed a higher rate of CD80+, MHC-I+ and MHC-II+ epithelial cells ($p = 0.004$, $p = 0.02$ and $p = 0.002$, respectively) and of activated lymphocytes (CD4 + CD25+, CD8 + CD28+ and CD8 + CD69+) ($p = 0.002$, $p = 0.002$ and $p = 0.015$, respectively) in mice sacrificed at 4 months than in those sacrificed at 6 months. Administration of anti-CD80 significantly increased the frequency of HGD ($p = 0.02$).
Conclusion: Epithelial cells of colorectal adenoma activate their capability of antigen presentation without eliciting a strong immune response. In the AOM mouse model, the antigen presenting activity and the immune response is more activated in a very early stage of the carcinogenesis. Our hypothesis is that some inhibitors (CTLA-4 or PD-1) can interfere with the immunesurveillance mechanisms in non inflammatory colorectal carcinogenesis.

P1032 ASYMPTOMATIC RADIOLOGICALLY DETECTED COLONIC PERFORATIONS IN THE ENGLISH NHS BOWEL CANCER SCREENING PROGRAMME (NHSBCSP)

E. Derbyshire[1], A. Hungin[2], C. Nickerson[3], M. D. Rutter[1], on behalf of NHSBCSP Evaluation Group
[1]*North Tees & Hartlepool NHS Foundation Trust, Stockton-on-Tees,* [2]*Durham University, Durham,* [3]*NHS Cancer Screening Programmes, Sheffield, United Kingdom*

Introduction: Colonoscopies in the English NHSBCSP are offered to 60-74 year olds with an abnormal Faecal Occult Blood Test. Colonoscopic perforation remains one of the most serious adverse events associated with colonoscopy. Patients typically present with symptoms as a result of peritoneal irritation, however, colonic perforation may be diagnosed radiologically in patients who are entirely asymptomatic.
Aims & Methods: The aims of this study were to identify cases of asymptomatic radiologically detected colonic perforation in the English NHSBCSP, describe similarities between them and explore why such perforations occur. We identified all reported cases of colonoscopic perforation from the start of the NHSBCSP in 2006 up to and including 13/03/2014 from the web-based database used by the NHSBCSP, the Bowel Cancer Screening System. The NHSBCSP definition of perforation is: air, luminal contents or instrumentation outside the gastrointestinal tract. Bowel Cancer Screening Centres were subsequently asked to complete an online questionnaire relating to the patient's post perforation presentation, assessment management, and outcome.
Results: Of 147 perforations identified, complete data on 117 was received. Four asymptomatic radiologically detected colonic perforations were identified. Case 1 was a biopsied rectal cancer. Staging Magnetic Resonance Imaging (MRI) and staging Computed Tomography (CT) 12 and 14 days respectively following colonoscopy noted a sealed off perforation posterior to the rectum. Two cases were associated with a biopsied sigmoid cancer; one a perforation identified at staging CT 2 days following colonoscopy, the other on a same day completion CT virtual colonoscopy after the cancer was impassable endoscopically, showing gas to the right of the tumour. Case 4 was a biopsied cancer at the hepatic flexure with perforation diagnosed on staging CT 24 hours later. TNM classification was reported in 3 cancers: T3N0M0, T4N1MO and T4N2M0. Histology confirmed either well or moderately differentiated adenocarcinoma in 3 cancers. Two of these patients were recalled to hospital following CT findings, subsequently having surgery. The other 2 did not require immediate admission.
Conclusion: All asymptomatic radiologically detected perforations were associated with colorectal cancer seen on staging radiological investigation where the cancer had been cold biopsied. It is likely that only perforations associated with cancer will present asymptomatically as it is only they that have staging radiological investigation. The cancers were in the rectum, sigmoid colon and hepatic flexure. TNM classification was at least T3. Emergency surgery was not required in three of these patients. The underlying cause of this is sub group of perforations is perhaps more likely to be due to invasion of the cancer and not the biopsy, however, a larger case series is required to confirm these findings.

P1033 POSITIVE PREDICTIVE VALUE INCREASES WITH AGE IN A FECAL IMMUNOCHEMICAL TEST BASED COLORECTAL CANCER SCREENING PROGRAM

E. Wieten[1], E. J. Grobbee[1], B. E. Hansen[1], M. J. Bruno[1], E. J. Kuipers[1], I. Lansdorp-Vogelaar[2], M. C. W. Spaander[1]
[1]*Gastroenterology & Hepatology,* [2]*Public Health, Erasmus MC University Medical Centre, Rotterdam, Netherlands*

Contact E-mail Address: e.wieten@erasmusmc.nl
Introduction: There is a good correlation between concentration of fecal hemoglobin (Hb) in fecal immunochemical tests (FITs) and age. Previous studies have shown that fecal Hb concentrations in stool and positivity rate (PR) increase with age. It is currently unknown whether that increase is mainly the result of a higher detection rate (DR) of advanced neoplasia (AN) or an increase in false positive rate (FPR). Quantitative FIT enable to choose the preferred fecal Hb concentration for colonoscopy referral. So far, cutoff values have been set to one fixed level for all ages. However, age partitioned reference values for fecal Hb concentration may be warranted if FPR increases relatively more with age than DR. The aim of this study was to assess the relation of FPR and DR with age and its influence on positive predictive value (PPV).
Aims & Methods: All average risk individuals, aged 55-75 years, who completed one sample FIT in a first round of a population-based colorectal cancer (CRC) screening pilot were included. A positivity cut-off level of 10 µg Hb/gram feces (> 50 ng Hb/ml) was used. All screenees with a positive test were offered colonoscopy. We calculated age-specific PR, DR, FPR and PPV. Logistic regression analyses were performed to determine the independent association of PPV with multiple variables (sex, age, social economic status, fecal Hb concentration). Variables achieving a P value of less than 0.05 were included in a multivariate logistic regression analyses, as were variables included by the clinician's rationale (gender).
Results: Of the 10.008 invitees, 5,986 persons (mean age 60.4 (±6.8) years; 49.7% males) participated and 503 (8.4%) persons had a positive test. Attendance rate, PR and DR were significantly higher in the older age categories ($p < 0.001$). Multivariate logistic regression analyses, with age as continues variable, showed PPV increased significantly with age and fecal Hb concentration when corrected for gender, Table 1. There were no significant differences in frequencies between the observed values and the predicted values of the model (Hosmer and Lemeshow Goodness-of-Fit Test; $p = 0.183$).

Table 1: Uni- and multivariate logistic regression analyses with the positive predictive value of having advanced neoplasia as dependent variable.

	Univariate Odds ratio (95% CI)	p-value	Multivariate Odds ratio (95% CI)	p-value
Sex male	1.31 (0.90-1.90)	.154	1.17 (0.79-1.74)	.435
Age (per ten years)	1.55 (1.18-2.06)	.002	1.55 (1.16-2.09)	.004
Socio-economic status		.330		
High	*Reference*			
Middle	1.14 (0.70-1.87)			
Low	1.36 (0.91-2.04)			
Fecal Hb concentration (per 10 µg Hb/g feces)	1.07 (1.05-1.09)	<.001	1.07 (1.05-1.09)	<.001

Conclusion: PPV increases significantly with age and fecal Hb concentration in a FIT-based CRC screening program. This implies a relatively larger increase of DR compared to FPR with age. These results suggest age-partitioned reference values for fecal Hb concentration are not warranted.

P1034 SENSITIVITY OF PRETARGETED 68GA PET-CT TO DETECT COLORECTAL CARCINOMA LIVER METASTASIS IN A MOUSE MODEL: COMPARISON WITH 18FDG PET-CT

F. Foubert[1,2], M. Cherel[2,3], A. Faivre-Chauvet[2,3], S. Gouard[2,3], C. Maurel[2,3], Y. Touchefeu[1,2], E. Frampas[2,4]
[1]*Institut des Maladies de l'Appareil Digestif,* [2]*INSERM UMR 892,* [3]*University of Nantes,* [4]*Radiology department - CHU, Nantes, France*

Contact E-mail Address: marietillie@hotmail.com
Introduction: The aim of our study was to compare the performances of a pretargeted PET (pPET) imaging with anti-CEA (carcinoembryonic antigen) and anti-HSG (histamine-succinyl-glycine) recombinant humanized bispecific monoclonal antibody (TF2) and ^{68}Ga-labeled HSG peptide (IMP288) to conventional ^{18}FDG PET in an orthotopic murine model of colorectal cancer liver metastasis.
Aims & Methods: CEA expression of colorectal cancer cells (LS174T Luc) was assessed *in vitro* by flow cytometry and *in vivo* by CEA staining. Hepatic tumors were grafted by intraportal injection and tumor burden was confirmed using bioluminescence. One group was pretargeted with TF2 and received IMP288-^{68}Ga 24 hours later (n = 8). One group received ^{18}FDG (n = 8). One group had both imaging modalities (n = 7). PET acquisitions started 1 hour after radionuclide injection. Biodistributions of the ^{68}Ga labeled peptide and ^{18}FDG in tumors and normal tissues were assessed one hour after imaging.
Results: LS174T Luc cells expressed CEA. Considering tissues uptakes, Tumor/Organ ratio with ^{68}Ga-PETp were statistically significantly higher compared to ^{18}FDG PET ($p < 0.05$) with both imaging and biodistribution data. ^{68}Ga-PETp sensitivity for tumor detection was 67% versus 31% with ^{18}FDG PET ($p = 0.049$). For smaller tumors less than 200 mg, the sensitivity was 44% with ^{68}Ga-PETp versus 0% with ^{18}FDG PET ($p = 0.031$). A strong correlation was demonstrated between signals measured on PET images and biodistribution analyzes ($r^2 = 0.85$).
Conclusion: ^{68}Ga-PETp was more sensitive than ^{18}FDG-PET for the detection of colorectal liver metastasis in an orthotopic murine model. Improved Tumor/Organ ratio allows imaging and therapeutic considerations.

P1035 DIAGNOSTIC ACCURACY AND INTEROBSERVER CONSISTENCY FOR THE ENDOSCOPIC PREDICTION OF SESSILE SERRATED ADENOMAS/POLYPS

H.-J. Yang[1], J. I. Lee[1], D. Park[1], S.-K. Park[1], Y. S. Jung[1], K. Y. Choi[1]
[1]*Department of Internal Medicine and Colon Cancer Center, Kangbuk Samsung Hospital, Sungkyunkwan University School of Medicine, Seoul, Republic of Korea*

Contact E-mail Address: hyojoonyang@gmail.com
Introduction: It may be challenging to recognize sessile serrated adenomas/polyps (SSA/Ps) and to differentiate them from hyperplastic polyps (HPs) or tubular adenomas (TAs) during colonoscopy evaluation. Although several studies suggested endoscopic features of SSA/Ps, the external validity and interobserver consistency of those features are not well studied.
Aims & Methods: This study aimed to examine diagnostic accuracy and interobserver consistency of endoscopic features for the diagnosis of SSA/Ps using high-resolution white-light endoscopy.
Endoscopic images of 81 polyps (29 SSA/Ps, 19 HPs, and 23 TAs) from 43 patients undergoing screening colonoscopy between March 2005 and April 2014 at a single tertiary care center were retrospectively evaluated by 10 colonoscopists. Eight endoscopic features of SSA/Ps (indistinctive border, irregular shape, rim of debris, cloud-like surface, mucous cap, nodular surface, absence of vessels, and dark spots) were assessed for each polyp in three stages: learning set, consensus meeting, and validation set.
Results: In the validation set, the prevalence of the features was ranged from 21.7% of SSA/Ps for dark spots to 51.0% for indistinctive border. In the multivariable analysis, mucous cap (odds ratio [OR], 10.10; 95% confidence interval [CI], 6.44–16.00, $p < 0.001$), cloud-like surface (OR, 3.05; 95% CI, 1.74–5.32, $p < 0.001$), indistinctive border (OR, 2.38; 95% CI, 1.53–3.69, $p < 0.001$), rim of debris (OR, 2.04; 95% CI, 1.43–3.55, $p < 0.001$), and dark spots (OR, 1.76; 95% CI, 1.11–2.80, $p = 0.016$) were independent predictors of SSA/Ps compared to HPs and TAs. The number of the independent predictors showed excellent discrimination (area under the receiver-operating characteristic curve [AUROC], 0.80). When ≥1 of the predictors were observed, SSA/Ps could be diagnosed with a sensitivity of 85.2% and specificity of 63.9%. Nevertheless, the interobserver agreement on the independent predictive findings demonstrated only moderate to fair κ-values (range, 0.25–0.41) except for dark spots, which showed poor interobserver agreement ($\kappa = 0.12$).
Conclusion: Several features of SSA/Ps were found to provide reliable accuracy for the endoscopic prediction of SSA/Ps. However, the interobserver agreements of the features remain to be improved.
Disclosure of Interest: None declared

P1036 MODEL OF INVITATION TO ENSURE HIGH PARTICIPATION ON THE COLORECTAL CANCER SCREENING PROGRAMME OF THE BASQUE COUNTRY (SPAIN)

I. Idigoras Rubio[1], E. Arana-Arri[2], I. Portillo[1], I. Bilbao[1], J. L. Hurtado[3], M. L. Jauregui[4], L. Martinez[2], I. Gutierrez-Ibarlucea[5]
[1]*Department of Health Basque Country, Osakidetza,* [2]*Biocruces, Huc, Bilbao,* [3]*Department of Health Basque Country, Osakidetza, Vitoria Gasteiz,* [4]*Department of Health Basque Country, Osakidetza, Zumarraga,* [5]*Department of Health Basque Country, Dto De Salud, Vitoria Gasteiz, Spain*

Introduction: : The aim of this study is to evaluate the evolution of Participation Rate (PR) and trends of the Colorectal Cancer Screening Programme carried out in the Basque Country. This Programme started in 2009, based on the detection of occult blood in faeces every two years and colonoscopy under sedation as a confirmed diagnosis. According to the European Guidelines (2010) recommendations, the key point to obtain an efficient program depends on the overall PR. Involving and Coordinating staff of different health care levels and developing innovative methods can increase PR.
Aims & Methods: a) Before the invitation, the Program Coordination Centre staff plans and organizes the elected Primary Care Center involved and agrees with hospitals the capacity to perform screening colonoscopies. b) A specific program software connected with other electronic medical data bases (medical records, hospital discharges, Cancer Registries and mortality), selects (50-69 year-old residents) and excludes (CRC diagnosed, colonoscopy in the last 5 years). c) Certified training is offered to all staff in the health centers. d) A personalized invitation letter, explaining the aims and methods of the programme was sent, including a free phone line, e-mail and web-site for further clarifications. Nevertheless, the person decides to participate or not. e) Afterwards, the kit, instruction leaflet with a personal code is delivered by post. f) Once the person decides to participate, the kit can be left in Health Care Centers without any previous appointment and guaranteed quality controls.
Results: : At the beginning of the program (2009) the overall PR was 58.1%, reaching 68.9% in first round in 2013. Once analyzed by sex PR for women increased from 61.3% to 71.3% and from 54.6% to 66.3% for men. All trends of PR were positive, 1.032 for overall PR ($p < 0.001$); 1.034 for women ($p < 0.001$) and 1.029 for men ($p < 0.001$). In the second round we have observed that the PR also increased, overall PR went from 67.0% to 70.7% (Trend = 1.029, $p < 0.001$), in women from 71.4% to 73.1% (Trend = 1.019, $p < 0.001$) and in men from 62.5% to 68.2% (Trend = 1.043, $p < 0.001$). We have analyzed trends by sex/age ranges (younger/older than 60 years), and we observed that all trends were positive being higher in women and participants older than 60 years.
Conclusion: This work demonstrates that the strategy invitation in a screening programme markedly influences on PR. The choice of the kit, way of shipping/collection and other factors such as the involvement of primary care physicians could be crucial.

P1037 CLINICOPATHOLOGICAL FEATURES OF T1 COLORECTAL CARCINOMAS WITH "SKIP INVASION"

Y. Sato[1], S.-E. Kudo[1], K. Ichimasa[1], H. Miyachi[1], Y. Kimura[1], Y. Kouyama[1], K. Kato[1], S. Matsudaira[1], M. Oikawa[1], M. Misawa[1], Y. Mori[1], T. Kudo[1], T. Hisayuki[1], K. Kodama[1], T. Hayashi[1], K. Wakamura[1], A. Katagiri[1], T. Baba[1], E. Hidaka[1], H. Ishida[1]
[1]*Digestive Disease Center, Showa University Northern Yokohama Hospital, Yokohama city, Japan*

Contact E-mail Address: ssteadfastness@yahoo.co.jp
Introduction: With recent advances in endoscopic treatment, many T1 colorectal carcinomas are now resected endoscopically with negative margins. However, there are some cases with "Skip Invasion", which is defined as discontinuous foci of carcinoma cells in the deeper layer of the colon apart from the invasive front, and "Skip Invasion" cannot be diagnosed with current endoscopic procedures.
Aims & Methods: The aim of this study was to investigate the clinicopathological features of T1 colorectal carcinomas with "Skip Invasion".
Of the 23725 colorectal neoplasms excluding advanced carcinomas which have been resected endoscopically or surgically at our institution from April 2001 to November 2014, 653 T1 carcinomas surgically resected were investigated. Then clinicopathological features of T1 carcinomas with and without "Skip Invasion" were compared. The factors for the analysis were patient age, sex, tumor size, location, morphology, degree of submucosal invasion, lymphovascular invasion, tumor budding, and histological type (por or muc component).
Results: There were 4 lesions (0.6%) with "Skip Invasion". All lesions with "Skip Invasion" were observed in sigmoid colon ($p = 0.02$) and showed lymphovascular invasion ($p = 0.13$). There were no significant differences in the other factors. One of 4 lesions showed the presence of lymph node metastasis.
Conclusion: All lesions with "Skip Invasion" were in sigmoid colon and showed lymphovascular invasion. These lesions were rare, but they certainly exist and might cause poor prognosis. Further caution should be needed for lesions with lymphovascular invasion, especially in sigmoid colon.

Contact E-mail Address: kelvintsoi@cuhk.edu.hk
Introduction: Diagnostic accuracy of fecal occult blood tests (FOBTs) differ widely in studies of colorectal cancer screening. This meta-analysis aims to evaluate the diagnostic accuracy of FOBTs for the detection of colorectal cancer (CRC) in the proximal colon.
Aims & Methods: Studies assessing performance of FOBTs were searched from the OVID databases up to 28 February 2015. Studies were eligible if subjects received FOBTs to estimate the diagnosis of CRC which was confirmed by colonoscopy. Analyses were conducted separately for Guaiac-based and

Immunochemical-based FOBT (gFOBT and iFOBT). Main outcomes included sensitivity and specificity of FOBTs. Bivariate random-effects model was applied to combine the results from individual studies. Subgroup analyses were performed to evaluate the test performances based on location of neoplasia and the brands of FOBTs.
Results: A total of 47 studies with 79,605 subjects (gFOBTs: 28 cohorts; iFOBTs: 42 cohorts) were identified from 18 geographic regions. In the gFOBT group, the combined sensitivity and specificity for CRC were 62.2% (95% CI = 51.0% to 72.2%) and 93.4% (95% CI = 91.0% to 95.2%) respectively. In iFOBT group, the combined sensitivity and specificity for CRC were 84.4% (95% CI = 79.9% to 88.1%) and 92.3% (95% CI = 89.7% to 94.3%). The diagnostic performance of gFOBT was significantly lower than that of iFOBT (AUC = 91% vs 95%, p = 0.014). Subgroup analysis showed that both FOBTs have higher sensitivity and comparable specificity for CRC detection in the distal colon compared with the proximal colon. (iFOBT sensitivity: 80% vs 72%; gFOBT sensitivity: 72% vs 64%). The diagnostic performances across different brands of FOBTs were comparable.
Conclusion: The diagnostic accuracy of FOBTs for CRC is good. iFOBTs showed better performance than gFOBT, and both FOBTs showed better CRC detection on the distal colon. Annual screening with iFOBT is recommended to reduce the chance of missing detection on proximal colon.

Contact E-mail Address: k-shigita@hiroshima-u.ac.jp
Introduction: Colorectal laterally spreading tumor-granular type (LST-G) is divided into 2 subtypes according to its morphology: homogenous type and nodular mixed type. However, the present LST-G subtype classification has not been defined by concrete objective findings but the concept of morphology without definite criteria.
Aims & Methods: This study was aimed to clarify the clinical significance of concrete objective LST-G subclassification according to the diameter of their granules or nodules. A total of 636 consecutive cases with LST-G that was resected endoscopically or surgically in Hiroshima University Hospital and Hiroshima City Asa Hospital between January 2008 and December 2014 entered this study. LST-Gs were divided into three types as follows; Type1: a lesion with homogenous uniform granules (<5mm), Type 2: a lesion with granules and small nodules (5mm≤, <10 mm), Type 3: a lesion accompanied by large nodules (≥10 mm). We evaluated interobserver agreement for subclassification of LST-G and accuracy in each group. Also, we investigated case characteristics and clinicopathologic features (sex, age, tumor size, location, histology, and invasion depth) for each LST-G subtype in whole 636 lesions. In validation study, a total of 194 fine images in 97 cases with conventional endoscopy and chromoendoscopy with indigo carmine dye spraying were distributed in randomized order to medical students with no prior endoscopy experience (Student Group), less-experienced endoscopists (LEE Group) and high-experienced endoscopists (HEE Group).
Results: Interobserver agreements were >0.6 representing good agreement in all groups. Diagnostic accuracy in HEE Group was higher than students and LEE Group. Chromoendoscopy had higher accuracy rate than conventional endoscopy in LEE Group (74% vs 69%, $p < 0.05$) and HEE Group (84% vs 78%, $p < 0.05$). As for the misdiagnositc lesions, participants in all groups tended to misdiagnose Type 1 as Type 2, and Type 3 as Type 2. Meanwhile, in the lesion of Type 2, lesions were prone to misdiagnose as Type 3 in LEE Group and HEE Group but as Type 1 in Student Group. Type 2 and Type 3 lesions were significantly larger than Type 1 lesions (Type 1: 21 ± 10mm, Type 2: 39 ± 22mm, Type 3: 46 ± 20mm, $p < 0.01$). The incidence of carcinoma in Type 1 was much lower than that in Type 2 and Type 3 (3% [4/154], 62% [141/226], 63% [162/256], respectively; $p < 0.01$). The incidence of submucosal invasive carcinoma in each type (Type 1, Type 2 and Type 3) were 0% (0/154), 7% (16/226) and 15% (38/256), respectively. The incidence of submucosal deep invasive carcinoma [≥1000 mm] in Type 3 was higher than that in Type 2 (11% [29/256] vs 3% [7/226], $p < 0.05$).
Conclusion: This subclassification for LST-G according to the diameter of granules and nodules using chromoendoscopy with indigo carmine dye spraying was universal, and may be clinically useful for choosing therapeutic strategy.

Contact E-mail Address: lisandro_pereyra@hotmail.com
Introduction: Fecal immunochemical test (FIT) have been recommended for colorectal cancer (CRC) screening in several clinical practice guidelines and is the initial option in same regions due to limited availability or high costs of colonoscopy. However some studies have reported inconsistent results about FIT performance.
Aims & Methods
Aim: To compare the results of single-sample FIT with colonoscopy findings and calculate the accuracy for advanced neoplastic lesions or CRC detection.
Methods: Asymptomatic average-risk individuals scheduled for screening colonoscopy were invited to provided one stool sample one week before the exam. We used a cualitative FIT manufactured by ABONTM Biopharm (Hangzhou) co., Ltd., without diet or medication restrictions. The lower limit of haemoglobin detected by this test is 50 ng/ml. The positivity rate of the FIT in relation to colonoscopic findings and the accuracy (sensitivity, specificity, area under ROC curve) of the FIT for CRC and advanced neoplastic lesions detection were determined.
Results: Of a total of 146 individuals invited, 119 (81.5%) returned the FIT kit with adequate stool sample and completed their colonoscopy. Mean age was 58.4 (33-85) years and 58.8% were males. An advanced neoplasm was found in 14 (11.7%) individuals: a CRC in 2 (1.7%) and an advanced adenoma (>10 mm, villous histology or high grade dysplasia) in 12 (10.1%) subjects. In 31 individuals (26%) the FIT was positive. The positivity rate of the test in relation to colonoscopic findings was: 24.5% in patients with normal colonoscopy, 17.6% in hyperplastic polyps, 20% in sessile serrated adenomas, 25.8% in adenomas, 36.4% in advanced adenomas, and 100% in CRC. The sensitivity and specificity of the FIT (95% confidence intervals) for advanced adenomas or CRC was 50% (25% to 75%) and 77% (74% to 80%) respectively. The area under ROC curve was 0.99. FIT sensitivity for CRC was 100% (20% to 100%), whereas specificity was 75% (74% to 76%). For advanced adenomas, sensitivity was 42% (17% to 70%) and specificity 76% (73% to 79%).
Conclusion: In this preliminary report of a single-sample FIT before screening colonoscopy, the positivity rate was significantly high (26%) but the test only detected little more than a third of advanced adenomas. However all CRC were detected (sensitivity 100%).

P1041 CLINICAL EVALUATION OF UNEXPECTED COLONIC FOCAL UPTAKE DETECTED BY FDG-PET/CT

M. Ishihara[1], M. Tajika[1], T. Tanaka[1], N. Mizuno[2], K. Hara[2], S. Hijioka[2], H. Imaoka[2], N. Hieda[2], N. Okuno[2], T. Yoshida[2], K. Yamao[2], Y. Niwa[1]
[1]*Endoscopy,* [2]*Gastroenterology, Aichi Cancer Center Hospital, Nagoya, Japan*

Contact E-mail Address: mishihara@aichi-cc.jp
Introduction: FDG-PET/CT is recognized as a useful tool to manage colorectal cancer and has been shown to have an additional value in the detection of colorectal cancer recurrence. Some studies reported that FDG accumulated in adenomatous polyps, and the possibility that FDG-PET/CT can detect early premalignant colorectal lesions was suggested. However, few studies have evaluated FDG-PET/CT for incidental premalignant colonic lesion detection.
Aims & Methods: FDG PET/CT studies were performed for two-year periods in 5088 consecutive patients with various malignant diseases. We retrospectively analyzed the records of 240 consecutive patients who had undergone colonoscopy and FDG-PET/CT scan for malignant disease from December 2012 to November 2014 at our hospital; colonoscopy and FDG-PET/CT were done within six months of each other. Patients with a previous history of colorectal cancer were excluded from analysis.
Results: Seventy-four patients had 86 foci of incidental colonic activity on PET and were designated Group A (mean age 67.0 years, males 66%). The other 166 patients had no incidental colonic foci and were designated Group B (mean age 63.6 years, males 65%). The locations of colorectal foci were in the right side in 25 patients, in the left side in 41 patients, and in the rectum in 20 patients. In group A, 26 patients (35%) had malignant tumors (22 colorectal cancers, three malignant lymphomas, and one metastatic tumor) detected on colonoscopy. In group B, three patients (2%) had malignant tumors (two colorectal cancers and one metastatic tumor). Overall, the sensitivity, specificity, PPV (positive predictive value), NPV (negative predictive value), and accuracy of PET-CT for detecting malignant colonic tumors were 90%, 77%, 35%, 98%, and 79%, respectively. For detecting malignant colonic tumors and adenomas 10 mm or more in diameter, the sensitivity, specificity, PPV, NPV, and accuracy of PET-CT were 84%, 86%, 66%, 95%, and 86%, respectively.

Conclusion: FDG-PET/CT is a useful tool for detecting both malignant colorectal tumors and adenomas 10mm or more in diameter. Incidental colonic activity detected by PET-CT warrants further evaluation with colonoscopy. However, negative PET-CT does not rule out malignant colorectal tumors.

Introduction: Colorectal cancer (CC) is the second most common form of cancer in the world. The limitations of the currently available methods and biomarkers for CC management highlight the necessity of finding novel markers.
Aims & Methods: The aim of this work was to assess the potential of the optical methods for studying erythrocytes (Er) and blood serum (BS) of patients with CC in staging diagnosing.
A total of 36 persons (53±9 years old) with CC (histologically – adenocarcinoma) in the T1-2 stage (the 1st group) and in the stage T3-4 (the 2nd group) were examined. The control group consisted of 16 healthy people. Electric and viscoelastic Er parameters were investigated by dielectrophoresis, their membrane structure - by TLC and gas chromatography. The optical properties of BS were studied by the methods of ellipsometry. The reaction of the monoclonal antibody CD 24 with BS antigens of CC patients was studied by spectroscopic ellipsometry close to the conditions of surface plasmon resonance (SPR) (ProteOn XPR36 (BioRad).
Results: We observed differences in Er parameters, associated with the CC stage. Given in the 2nd group summarized rigidity, viscosity, electrical conductivity, the relative polarizability, indexes of aggregation and destruction were higher than those in the 1st and in the controls ($p < 0.001$-0.05). At the same time the patients of the 2nd group had marked disturbances of Er deformability, leading to the development of microcirculatory disorders and tissue hypoxia. We observed high levels of cholesterol fraction, oleic, stearic acids, high index of cholesterol/phospholipids (PHL) and low levels of total lipids, easily oxidable PHL, arachidonic acid, omega-3 index in Er membranes in the 2nd group in comparison with those in the 1st group of patients ($p < 0.0001$-0.03). Scanning ellipsometry showed marked heterogeneity in thickness and composition, the abundance of discontinuities in thin films of BS of patients in the 2nd group compared to the 1st one ($p < 0.001$). Increasing the refractive index in combination with the reduction in film thickness as CC stage was weighting has been observed ($p < 0.01$-0.05). The concentration of the antigens to the CD24 in the BS of patients (obtained by SPR) in the terminal stages of CC was higher than that in the T1-2 ($p < 0.001$). We revealed correlations between Er parameters, BS ellipsometry characteristics and biochemical parameters, which reflected the interaction between these components depending on the CC stage.
Conclusion: Identified microcirculatory disturbances probably aggravate the course of CC and, therefore, require additional therapeutic effects. Differences in Er and BS parameters associated with the stage of CC, give hope for the development of new diagnostic methods at the early stages of the disease.

P1043 CHARACTERIZATION OF THE ENDOSCOPIC AND PATHOLOGIC MEASUREMENTS OF COLORECTAL POLYP SIZES AND ITS ASSOCIATION WITH POST-POLYPECTOMY COLONOSCOPY SURVEILLANCE GUIDELINES

M. N. Costa[1], V. Pavão Borges[1], T. Capela[1], P. Russo[1], C. Bernardes[1], D. Carvalho[1], M. J. Silva[1], R. Loureiro[1], J. Esteves[1], A. David Marques[1]
[1]*Gastroenterology, Hospital de Sto. António dos Capuchos - Centro Hospitalar de Lisboa Central, Lisbon, Portugal*

Contact E-mail Address: mariananunocosta@gmail.com
Introduction: Colorectal cancer (CRC) is the main leading cause of cancer related deaths in Portugal. After removing colorrectal polyps (CRPs), ESGE[1], ASGE[2] and UK guidelines[3] recommend endoscopic surveillance based on size, number and histological findings of CRPs. While UK guidelines use the endoscopical measured size (EMS), the preferred method (endoscopical versus histological) for CRP size assessment is not specified in the ESGE and ASGE guidelines. The preferred CRP size assessment method is controversial.
Aims & Methods: To characterize the discordance and correlation between the pathological measured size (PMS) and EMS of CRPs, according to its anatomic location and histological findings.
All colonoscopies in which CRPs were observed between 1/Jan/2013 and 31/Dec/2013 were identified. CRPs removed by polypectomy snare in a single fragment and with available endoscopic and histological reports were selected. The endoscopic and pathologic measurements of CRPs sizes were performed.
Results: The PMS (mean 8.03 mm ±1.41 SD) was significantly smaller than the EMS (mean 10.46 mm ±7.36 SD) in the 552 CRPs included in the study (360 patients, 68.6% male, years median 69), independently of anatomic location (right colon, transverse colon or left colon + rectum) and EMS sub-group (≥1cm or <1cm). There was a good correlation between the EMS and PMS in the adenomas (=0.807, 95% confidence intervals [CI]) and a moderate correlation in the serreated polyps (SP) (=0.647, 95% CI). However, 32.0% of the adenomas and 63.2% of the SPs with EMS ≥ 1 cm presented PMS < 1 cm.
Conclusion: In a considerable portion of adenomas and SP where EMS is >1 cm, the PMS is <1 cm. This divergence may lead to alternative colonoscopy surveillance intervals after polypectomy, which may have both clinical and economic implications.

Contact E-mail Address: moto28hiko@icloud.com
Introduction: According to US multi societies guideline for colonoscopy surveillance after screening and polypectomy, subjects elder than 85 are recommended to stop undergoing colonoscopy. However, asymptomatic elder subjects often come to hospital only due to positive fecal occult blood test in Japan with population aging.
Aims & Methods: This study was aimed to evaluate safety and efficacy of colonoscopy for subjects elder than 85 years old. This is a retrospective cohort study. From April 2006 to March 2010, 265 subjects elder than 85 years old underwent colonoscopy at our hospital. Of them, 16 patients who underwent surveillance after surgery for colorectal cancer and 54 patients who had been already pointed out some abnormalities were excluded and total 195 subjects were included for analysis. The subjects were divided into screening groups who were free from symptoms (hemoglobin <10g/dL, abdominal pain, or hematochezia) and symptomatic group. The association between detection rate of advanced colorectal cancer and various background factors (age, sex, presence or absence of symptom, hemoglobin, or mean corpuscular volume (MCV) using Logistic Regression model. Factors which revealed statistical tendency ($p < 0.10$) were included multivariate multivariate analysis. Cumulative overall survival rate of patients with advanced colorectal cancer was calculated using Kaplan-Meier method.
Results: There were 47 asymptomatic subjects and 148 symptomatic subjects. Advanced colorectal cancer was detected in 6.5% of asymptomatic and in 17% of symptomatic subjects respectively (p=0.0946). Low MCV revealed significance, and to be female (p=0.706) and presence of symptom (p=0.0581) revealed marginal significance for detection of advanced cancer. In multivariate analysis, only low MCV was independent risk factor (Odds ratio (every 5 decrease) 1.63 [1.29-2.11]). The cumulative overall survival rate at 3 and 5 years of patients with advanced colorectal cancer was 76% and 62%, respectively.
Conclusion: Colonoscopy for symptomatic patients would not be a contraindication because prognosis of advanced colorectal cancer was not so poor in our study. MCV might be a useful predictor for determination of the indication of colonoscopy for extremely elderly subjects.

P1045 LONG TERM ONCOLOGIC OUTCOMES OF THE COLORECTAL TIS CANCER

J. Hyun[1], H. Chang[1], D. Sohn[1], K. Han[1], B. Kim[1], J. Oh[1], C. Hong[1]
[1]*National Cancer Center, Republic of Korea, Goyang-si, Republic of Korea*

Contact E-mail Address: hj11542@naver.com
Introduction: The incidence of early colorectal cancers is on rise with increase of screening colonoscopy. Thus, risk factors of lymph node metastasis or recurrence in early colorectal cancer is also important medical issue for endoscopists and colorectal surgeons.
Aims & Methods: The aim of this study was to evaluate that the depth of invasion in Tis cancer was associated with recurrence or lymph node metastasis. Additionally, this study was to assess the long-term outcome of patients with colorectal Tis cancer. A total of 496 colorectal Tis cancers from 481 patients between March 2003 and December 2013 were analyzed retrospectively. We evaluate the pathologic and clinical risk factor of colorectal Tis patients.
Results: The mean age of study population was 64.7 years and the median follow up time was 30.3 months. Of a total of 496 Tis cancers. There were no radiological lymph node metastases in 177 patients who conducted the computed tomography. 1.2% of Tis cancer showed angiolymphatic invasion. Three patients (0.62%) had proven distant or local recurrence. Local recurrences were occurred in 2 patients. And one patient who had peritoneal seeding and ovarian metastasis showed positive resection margin and tumor invading lamina propria at primary resection.

Conclusion: 1.2% of colorectal Tis cancer had positive results of angiolymphatic invasion. In recurrence cases what it were too small, all of recurrence patients had positive margin after resection. Thus, clinicians pay attention to angiolymphatic invasion and positive resection margin in pathologic results of colorectal Tis cancer after treatment.

P1046 EFFECTIVENESS AND SAFETY OF COLORECTAL ESD IN ELDERLY PATIENT

K. Ashikari[1], H. Chiba[1], D. Kurihara[1], T. Suto[1], N. Kawano[1], M. Kaai[1], S. Seki[1], A. Takahashi[1], T. Ida[1], T. Morohashi[1], T. Goto[1]
[1]*Gastroenterology, Omori Red Cross Hospital, Tokyo, Japan*

Introduction: Colorectal endoscopic submucosal dissection (ESD) has been established as a useful treatment for early colorectal tumors. The prognosis of early colorectal cancer is expected over several years without treatment. However, elderly people who often have various comorbidities might die of any other diseases, so colorectal ESD for elderly people is still controversial.
Aims & Methods: To analyze the potential benefits and risks of colorectal ESD in elderly compared to younger patients, we analyzed patients retrospectively who underwent ESD for early colorectal cancer in Omori Red Cross Hospital from 2012 May to 2015 March. We divided the patients into two groups: patients older than 80 years (group A) and patients 79 years of age or younger (group B). The two groups were compared with respect to their clinical backgrounds, medication (antiplatelet, anticoagulation), tumor characteristics, operation time, resection speed (mm^2/min), complication, rate of en bloc or curative resection, and survival rate. Statistical analysis included univariate analysis by chi-squared tests and Student's t-tests for comparing two groups (statistical significance was defined as $p < 0.05$).
Results: 156 lesions (male/female:81/75) underwent ESD procedures; 27 in group A and 129 in group B. Group A had significantly more comorbid diseases (hypertension, diabetes, renal or liver dysfunction, cardiac disorder) than group B (55.6% vs. 24.8%, $p < 0.01$). Patients in group A tended to take more antithrombotic medication than group B (22.2% vs. 11.6%, $p = 0.14$). Tumor size, specimen size, operation time, resection speed (mm^2/min), rate of complete en bloc resection, rate of curative resection, complication and survival rate were similar: 29.4 ± 18.2mm, 37.8 ± 18.3mm, 43.9 ± 35.6min, 25.8 ± 13.8(mm^2/min), 27/27 (100%), 27/27 (100%), 0/27 (0%), 26/27 (96.3%) in group A, and 29.1 ± 15.4mm, 37.6 ± 16.9mm, 44.3 ± 45.1min, 28.0 ± 15.3 (mm^2/min), 128/129 (99.2%), 124/129 (96.1%), 2/129 (1.6%), 128/129 (99.2%) in group B, respectively. Perforation occurred in 2 cases in group B. There were no differences in hospitalization periods and post-operative clinical courses between two groups. All of the 5 non-curative cases in group B are alive at the end of the follow up period (average 17.0 months. range: 6-28). Only one of 27 patients in group A died suddenly of heart failure about 1 month after the colorectal ESD, and the others are alive at the end of the follow up period (average 13.6 months. range: 1-32).
Conclusion: Colorectal ESD is almost equally effective and safe both in elderly and in younger patients. However, elderly patients have more comorbid diseases and tend to have more antithrombotic agents. Therefore, preoperative assessment of comorbid conditions and adequate perioperative care are necessary for elderly patients. Furthermore, to evaluate the exact prognosis of elderly patients performed colorectal ESD, we should continue to follow up them in longer period.

P1047 THE VALIDITY OF THREE STEPS LEARNING SYSTEM OF COLORECTAL ESD

K. Ashikari[1], H. Chiba[1], D. Kurihara[1], T. Suto[1], N. Kawano[1], M. Kaai[1], S. Seki[1], A. Takahashi[1], T. Ida[1], T. Morohashi[1], T. Goto[1]
[1]*Gastroenterology, Omori Red Cross Hospital, Tokyo, Japan*

Contact E-mail Address: kei-pushi-1@hotmail.co.jp

Introduction: Endoscopic submucosal dissection (ESD) for early colorectal cancer has become a widespread treatment over the world, but severe complications are reported still now and the appropriate training system of colorectal ESD is controversial.
Aims & Methods: In our hospital, the qualifications of an ESD trainee (A) are 1000 upper/300 lower endoscopy, 30 gastric ESD, and 20 colorectal ESD assistance. Colorectal ESD is performed with support by an expert (B) following these 3 steps. a) 0-5 cases: the position is all rectum, and have no fibrosis (F0), b) 6-20cases: tumor size is ≤50mm with no or mild fibrosis (F0/F1) and the expert gives every possible advices during procedures, c) 21cases-: The expert gives important advices or hands-on support only when the situation has technical difficulty or the trainee does dangerous procedure. We call this method "Three steps learning system (TSLS)". 154 consecutive ESD procedures performed in Omori Red Cross Hospital from 2012 April to 2015 March were retrospectively analyzed. We evaluated clinical backgrounds, outcomes of ESD procedures, and complications.
Results: A/B performed 23/131 cases respectively. The mean age, sex, comorbid diseases (hypertension, diabetes, renal dysfunction, cardiac disease), rate of having antithrombotic agents were similar between two groups. The location was C3/A1/T5/D3/S3/R8 in group A and C20/A24/T25/D17/S16/R29 in group B ($p = 0.578$). In terms of tumor shape, there was no protruded tumor in group A. There were also no significant differences in specimen size, tumor size, en bloc resection rate, and complication: 40.9 ± 23.3mm, 30.3 ± 20.4mm, 100%, and 1 case (perforation) in group A and 37.1 ± 16.0mm, 29.0 ± 15.2mm, 99.2% (130/131), and 1 case (perforation) in group B, respectively. Meanwhile, operation time and speed of resection (that is specimen size (mm^2) / operation time (min)) in group B were much faster than group A: 73.0 ± 52.6min, $16.1 \pm 8.7$$mm^2$/min in group A and 38.3 ± 39.1min, $29.9 \pm 15.0$$mm^2$/min ($p < 0.01$). The rate of fibrosis was 13.0% (F0/F1/F2: 20/3/0) in group A, 26.0% (F0/F1/F2: 97/29/5) in group B ($p = 0.18$). Self-completion rate was 18/23 (78.3%) in group A. In group A, five cases were not self-completion and the factors were followings: with fibrosis, lesion at a fold, invaded submucosa, or large lesion (≥10cm). R0 resection rate were similar, 95.7% (22/23) in group A, and 96.9% (127/131) in group B. Of the five non-curative resection cases, 4 cases were performed additional operation, and 1 case chose a conservative course. The clinical courses after procedures (fever, WBC, CRP) were also similar.
Conclusion: The advices of experts are very important for keeping safety ESD and an independence of novice is also essential. Colorectal ESD under our training system (TSLS) was appropriate and safe. However, in this study, there were few difficult lesions in group B. For verifying the validity of our system or improving self-completion rate, more cases will be required.

P1048 ADJUVANT CHEMOTHERAPY WITH TEGAFUR-URACIL PROVIDED GOOD OUTCOME FOR LOW-RISK STAGE II COLON CANCER

K. C. Hsiao[1], J. M. Hu[1]
[1]*Colon and Rectal Surgery, Tri-Service General Hospital, Taipei, Taiwan, Province of China*

Contact E-mail Address: dr.hsiao@msa.hinet.net

Introduction: The benefit of adjuvant chemotherapy with Tegafur-uracil for the low-risk patients of stage II colon cancer is still uncertain. Our primary aim is to determine the outcome of disease free survival (DFS) and 5-year overval l survival (OS) provided by adjuvant chemotherapy using Tegafur-uracil for stage II colon cancer.
Aims & Methods: From January 2004 to December 2011, 404 low-risk stage II colon cancerpatients received curative operation in a single medical center. The clinical data were extracted from the retrospectively collected colon cancer database. The patients were divided to adjuvant chemotherapy with Tegafur-uracil, adjuvant chemotherapy with 5-fluorouracil and radical surgery alone. The DFS curves and OS curves were calculated with Kaplan-Miere's analysis.
Results: Among the 404 low-risk stage II colon cancer patients, 180 (44.6%) had adjuvant chemotherapy with Tegafur-uracil, 79 (19.5%) received adjuvant chemotherapy with 5-fluorouracil, and 145 (35.9%) underwent radical surgery alone. Within the median of 49 months follow-up, recurrence developed in 36 patients (8.18%). However, patients who received adjuvant chemotherapy with Tegafur-uracil had improved OS compared to others who underwent surgery alone. Multivariate analysis showed that only adjuvant chemotherapy with Tegafur-uracil > 1 year ($P = 0.001$) was independent factors for DFS. Moreover, only age < 70 years ($p = 0.043$) and chemotherapy with Tegafur-uracil ($p = 0.001$) related good OS.
Conclusion: We suggested adjuvant chemotherapy with Tegafur-uracil, especially consecutive administration more than one year, providing good DFS and OS for the low-risk patients of stage II colon cancer after radical surgery.

P1049 CLINICAL OUTCOMES OF RECTAL NEUROENDOCRINE TUMORS TREATED BY ENDOSCOPIC RESECTION

M. Takita[1], K. Ohata[1], Y. Misumi[1], H. Tsunashima[1], T. Tashima[1], Y. Minato[1], E. Sakai[1], T. Muramoto[1], Y. Matsuyama[1], K. Nonaka[1], N. Matuhashi[1]
[1]*Gastroenterology, NTT Medical Center Tokyo, Tokyo, Japan*

Contact E-mail Address: myc0p1asm@mail.goo.ne.jp
Introduction: According to 2010 WHO classification, neuroendocrine tumors (NET) are classified into three categories (G1, G2 and G3). Of these tumors, G1 NET smaller than 10 mm, mainly located at the rectum, metastasize only rarely, and thus can be treated by endoscopic resection. However, complete resection is occasionally difficult due to their localization in the submucosal layer. In addition, even NET smaller than 10mm might have lymphovascular invasion. We conducted this retrospective study to evaluate the risk of recurrence after endoscopic treatment and to search for a suitable treatment of rectal NET.
Aims & Methods: Between January 2005 and March 2014, 137 patients with 139 rectal NET lesions underwent endoscopic treatment in our hospital. Firstly, we investigated complete and curative resection rate of EMR (EMR/EMR-C/EMR-L) and ESD groups. We defined curative resection as complete resection, smaller than 10mm, and lack of microscopic lymphovascular invasion. Resection that fail to meet either of the above three criteria was defined as non-curative. When additional surgical resection was performed, the rate of positive histological lymph node metastasis was calculated. Subsequently, we investigated long-term outcomes of endoscopic resection for rectal NET.
Results: Most of the tumors were located at Rb (80%), and the median diameter was 5.7 mm. Numbers of cases treated with EMR/EMR-C/EMR-L/ESD were 10/3/114/12. Of the 139 tumors, 129 achieved complete resection (93%). Regarding the 10 incomplete resection cases, the treatments were EMR, EMR-C, and ESD in 5, 1, and 4 cases, respectively. No tumors presented muscular invasion. 79 lesions (57%) achieved curative resection, and no recurrence was identified in this group during the follow-up periods (median 27 months). 53 of the 60 lesions with non-curative resection were followed without additional resection, but no case had recurrence during the follow-up period (median 42 months). Seven of the non-curative resection cases underwent additional resection, among whom one case had lymph node metastasis; in that case, the tumor was larger than 10mm, positive for vascular invasion, and the treatment was incomplete resection. As a whole, recurrence was identified in none of the total 139 cases during the follow-up period (median 33 months). Focusing on adverse events, 10 delayed bleedings occurred (5 EMR, 4 EMR-C and 1 ESD cases), and one perforation occurred in a patient undergoing ESD.
Conclusion: EMR-L is generally thought to be a feasible measure as an endoscopic treatment of rectal NET, even though delayed bleeding rate is relatively high. Current curative criteria including complete resection, smaller than 10mm, and no lymphovascular invasion is considered to be appropriate in that cases meeting the criteria can be regarded as cured. However, given that there was no recurrence without additional resection in cases regarded as "non-curative" resection, mainly due to lymphovascular invasion and/or larger size, observation without additional resection might be allowed, although the observation period was not long enough in the present analysis. To establish curative criteria and indication for endoscopic treatment, further studies including those with longer follow-up periods are needed.

P1050 MAGNIFYING CHROMOENDOSCOPY IS DECISIVE TO DEFINE MANAGEMENT OF COLORECTAL NEOPLASTIC LESIONS

F. S. Kawaguti[1], **M. C. Franco**[1], C. M. P. S. Pennacchi[1], B. D. C. Martins[1], F. A. Retes[1], C. F. Marques[1], C. S. Nahas[1], A. V. Safatle-Ribeiro[1], U. Ribeiro Jr[1], S. C. Nahas[1], F. Maluf-Filho[1]
[1]*São Paulo Cancer Institute, São Paulo, Brazil*

Contact E-mail Address: mcavalcantefranco@gmail.com
Introduction: Early colorectal cancer with submucosal deep invasion should not be treated by endoscopic resection due the high risk of lymph-nodes metastases. Magnifying chromoendoscopy and evaluation of pit pattern can predict the malignant potential of colorectal lesions. Accurate diagnosis of lesions allows indication of the best treatment, endoscopic or surgical.
Aims & Methods: Evaluate efficacy of magnifying chromoendoscopy in the definition of management of colorectal neoplastic lesions. Between April 2009 and August 2014, patients with colorectal neoplastic lesions with high risk of submucosal invasion (sessile $\geq$ 20 mm, depressed type and LST-type lesions) underwent magnifying chromoendoscopy. The therapeutic approach (endoscopic or surgical) was defined according to the endoscopic evaluation. Lesions with Vn pit pattern were referred to surgical resection. Lesions without Vn pit pattern were referred to endoscopic treatment and the decision of therapeutic approach was according to pit pattern, location and size. Final staging was possible with the histology of the surgical or endoscopic specimen. Lesions that were not resected or those where it was not possible to visualize the pit pattern due eroded surface were excluded.
Results: A total of 104 lesions were found in 103 patients (47% male, mean age of 64.4 years-old). Six lesions were excluded. The average size of lesions was 45.1 ± 31.9 mm. The macroscopic classification was 15.3% sessile, 4.1% depressed and 80.6% LSTs. The endoscopic treatments were polypectomy in 2.0%, EMR in 15.3%, EPMR in 13.3%, ESD in 45.9% and TEM in 9.2%. Surgical resection was referred in 14.3% of the lesions. The correlation of pit pattern with pathology was:- II: 100% adenomas with low-grade dysplasia (2/2)- IIIL: 69.2% of low-grade adenoma (9/13)- IIIS: 100% intramucosal adenocarcinoma (1/1)- IV: 72.0% of adenoma with high-grade dysplasia or intramucosal adenocarcinoma (18/25)- Vi: 86.9% of intramucosal adenocarcinoma or superficial submucosal invasion $<$ 1000 μm (40/46) / 6.5% adenocarcinoma with massive submucosal invasion $>$ 1000 μm (3/46)- Vn: 54.5% of adenocarcinoma with massive submucosal invasion (6/11); 45.5% of adenocarcinoma with invasion to the muscularis propria. The therapeutic indication based on magnifying chromoendoscopy and pit pattern classification was considered correct in 96.9% of cases (95/98). Three cases Vi pit pattern lesions were endoscopically resected and the histology demonstrated massive submucosal invasion. These patients were sent to surgical resection. Magnifying chromoendoscopy and pit pattern classification had a 78.6% sensitivity, a 100% specificity, a 100% predictive positive value, a 96.6% negative predictive value and a 96.9% accuracy to detect submucosal massive invasion, or deeper.
Conclusion: Magnifying chromoendoscopy is accurate to detect submucosal massive invasion, or deeper, of colorectal neoplastic lesions which allows correct selection of patients to surgical or endoscopic resection. The Vn pit pattern contraindicates endoscopic resection.

P1051 ENDOSCOPIC MANAGEMENT AND CLINICAL OUTCOMES OF MALIGNANT COLORECTAL POLYPS

M. W. Jung[1], S. J. Shin[1], K. M. Lee[1], S. G. Lim[1]
[1]*Gastroenterology, Ajou University School of Medicine, Suwon, Republic of Korea*

Contact E-mail Address: jmw_81@hanmail.net
Introduction: The endoscopic management of colorectal polyps containing adenocarcinoma is increasing in nowadays due to colorectal cancer screening programs. The aim of this study was to evaluate the safety and efficacy of endoscopic resection of malignant colorectal polyps.
Aims & Methods: Patients who underwent endoscopic resection for colorectal polyps which containing adenocarcinoma from August 2001 to July 2014 in Ajou university hospital of Korea. The data were retrospectively reviewed. Clinical outcomes such as complete resection rate, recurrence rate, complications were analyzed.

Results: Table1: Relationships between recurrence and complete resection status, risk of polyps

	Recurrence after polypectomy No	Yes	p value
Complete resection (CR)			
CR (n = 266)	258 (97.0%)	8 (3.0%)	
ICR (n = 143)	130 (90.9%)	13 (9.1%)	0.008
Risk of malignant polyp			
Low risk (n = 252)	245 (97.2%)	7 (2.8%)	
High risk (n = 157)	143 (91.1%)	14 (8.9%)	0.020
Total	388	21	409

Total 482 polyps in 462 patients were analyzed in this study. 444 lesions were resected by snaring polypectomy including endoscopic mucosal resection (EMR) and 38 lesions by endoscopic submucosal dissection (ESD). The high risk malignant polyps were defined as having: tumor invasion in the margin or an uncertain margin; poor differentiation (WHO classification grade III); or invasion of lymphatic or venous vessels. Low risk malignant polyps did not have any of these three histological signs. We analyzed the recurrence rate of the 409 lesions followed up for at least 3 months. The recurrence rate was 5.1% (21/408), and it was affected by complete resection status ($p = 0.008$) and risk of polyps ($p = 0.006$). Procedure-related complications developed in 20 lesions; perforations in 8 lesions (1.7%) and significant bleedings required additional endoscopic procedure in 12 lesions (2.5%).

Conclusion: Endoscopic polypectomy could be adequate and effective treatment for patients with malignant colorectal polyps, especially low-risk polyps.

P1052 TERPINEN-4-OL: A NOVEL AND PROMISING THERAPEUTIC AGENT FOR HUMAN COLORECTAL CANCER TERPINEN-4-OL

N. Arber[1], S. Shapira[1], S. Pelban[1]
[1]*Integrated Cancer Prevention Center, Tel Aviv Sourasky Medical Center, Tel Aviv, Israel*

Contact E-mail Address: shiranshapira@gmail.com

Introduction: Background: Monoterpenes are major secondary metabolites present in plants and known to be associated with the plant defense mechanisms. Terpinen-4-ol is a naturally occurring monoterpene, found in the essential oils of many aromatic plants and is the main bioactive component of tea tree oil. It has been shown to have antiviral, antibacterial, antifungal, and insecticidal effects as well as anti-oxidant and anti-inflammatory activities. It was demonstrated to induce primary necrotic cell death and cell cycle arrest in melanoma and non-small cell lung cancer cells.

Aims & Methods

Aim: To study the antitumor effects of terpinen-4-ol and its mechanism of action in various types of GI malignancies, alone and in combination with several chemotherapeutic and biological agents.

Methods: Terpinen-4-ol was administrated alone or combined with standard anti-CRC agents including, oxaliplatin, fluorouracil (5-FU), cetuximab and bevacizumab. It was also combined with humanized anti-CD24 monoclonal antibodies previously developed in our lab (*Shapira Gastro 2011*). Killing effects were measured qualitatively by light microscopy and quantitatively using the MTT assay. The *in vivo* toxicology, LD_{50} value, of various doses of Terpinen-4-ol was tested following several routes of administration (oral, intramuscular, topical, and by subcutaneous and intra-peritoneal injection). Subcutaneous tumors were produced by injection of $5x10^6$ of DLD-1 CRC cell lines into nude mice. When the tumors reached a dimension of 5 mm, the animal's treatment was initiated.

Results: The LD_{50} value of Terpinen-4-ol after intra-peritoneal injection in mice is 120 mg/kg body. Terpinen-4-ol induces a significant growth inhibition of CRC cell lines, including HCT116, DLD1 and COLO320, in a dose-dependent manner. Terpinen-4-ol and various anti-cancer agents (0.2 μM oxaliplatin, 0.5 μM fluorouracil (5-FU), 1 μM cetuximab and 50 μM bevacizumab) demonstrated a synergistic inhibitory effect of cancer cell proliferation. Subtoxic concentrations of terpinen-4-ol potentiate anti-CD24 mAb-induced growth inhibition. The anti-tumor activity of terpinen-4-ol alone or in combination with cetuximab was evaluated. Considerable reduction in tumor volume was seen following terpinen-4-ol (0.2%) treatment alone and in combination with cetuximab (10 mg/kg) (40% and 63%, respectively) in comparison to the control group that received PBS (+DMSO).

Conclusion: Terpinen-4-ol significantly enhances the effect of several anticancer agents, including chemotherapeutic and biological drugs, in particular therapeutic antibodies. The possible molecular mechanism for the activity of Terpinen-4-ol involves induction of cell death rendering this compound as a potential anticancer drug alone or in combination, for the treatment of a wide range of malignancies (was tested on pancreatic, prostate and stomach), including CRC.

P1053 SELECTIVE CYCLOOXYGENASE-2 INHIBITOR ATTENUATES PRO-METASTATIC AND ANTI-APOPTOTIC EFFECTS OF ENDOTOXIN-LIPOPOLYSACCHARIDE

O. Plehutsa[1], R. Sydorchuk[2], L. Sydorchuk[2], I. Sydorchuk[2]
[1]*District Hospital, Briceni, Moldova, Republic of,* [2]*Bukovinian State Medical University, Chernivtsi, Ukraine*

Contact E-mail Address: supers_stars@uni.de

Introduction: Growing evidence indicates that bacterial infections and following inflammation is contributing to cancer growth. Recent studies showed promotional influence of endotoxin-lipopolysaccharide (LPS) on cancerogenesis and metastatic growth, which in part is associated with involvement of cyclooxygenase-2 (COX-2). Elevated tumour COX-2 is associated with increased angiogenesis, tumour growth and promotion of tumour metastasing and resistance to apoptosis. The mode of action of COX-2 and its inhibitors remains unclear. We hypothesized that inhibiting of COX-2 may decrease inflammation contributing to metastatic growth.

Aims & Methods: Murine model including 2 groups (25 each) of adolescent mice was used. Metastatic process was modeled by i/v injection of 200 μl spontaneously metastasizing mammary adenocarcinoma cell culture suspension. Both control and experimental group animals received 200 μl suspension of 10 μg LPS per mouse. Experimental group received selective COX-2 inhibitor celecoxib orally from day 1. Metastatic growth evaluated hystochemically within pulmonary metastases. TNF-α, VEGF quantified with ELISA; COX-2 with Western Immunoblotting.

Results: Control group mice developed a mean number of 35.27 ± 6.19 macroscopic metastases by day 15. Both the weight and quantitative parameters of metastatic growth were significantly lower in study group compared to control ($p < 0.005$-0.0001). Experimental group metastatic growth was characterized by 48.8% lower mitotic index (MI) and 37.6% higher apoptotic index (AI). MI/AI ratio in the experimental group was 2.1 times lower ($p < 0.001$) than the ratio observed in control group mice. Systemic COX-2, TNF-α and VEGF were significantly lower in celecoxib group ($p < 0.005$-0.001) compared to control.

Conclusion: It is becoming evident that selective COX-2 inhibitors have a growing potential as a beneficial target for chemopreventive and tumour regression for many cancers. Although expression of COX-2 has been associated with development and progression of numerous malignancies, its precise role in promotion of cancer cell dissemination is still poorly understood. TNF-α – a major proinflammatory cytokine is released in response to LPS associated increase of VEGF production via COX-2 pathway. Current study shows that pro-cancerogenic effect of endotoxin in experimental murine model could be inhibited by neutralizing COX-2 associated pathway. Treatment with celecoxib was effective in reducing metastasis volume, suggesting that COX-2 contributes to metastatic growth. However, there is no direct evidence that all metastases are/could be sensitive to COX-2 inhibition.

P1054 SHORT-TERM RESULTS OF COLORECTAL ENDOSCOPIC SUBMUCOSAL DISSECTION

O. Urban[1], P. Fojtik[1], P. Falt[1], M. Kliment[1]
[1]*Gastroenterology, Vitkovice Hospital Ostrava, Ostrava, Czech Republic*

Contact E-mail Address: ondrej.urban@nemvitkovice.cz

Introduction: Colorectal endoscopic submucosal dissection (CR-ESD) is accepted as a minimally invasive treatment for large (≥20 mm) neoplastic lesions. It is less invasive than surgery and provides higher *en bloc* resection rate than endoscopic mucosal resection (EMR). The purpose of this study is to evaluate short-term results of CR-ESD in a single western institution.

Aims & Methods: All patients treated by CR-ESD between November 2011 and October 2014 were included. CR-ESD was indicated according to the Japanese Colon ESD Standardization Implementation Working Group criteria and was performed by using Dual-knife and/or IT-knife nano. The complete resection of the lesion, *en bloc* resection, R0 resection, the curative resection, the 30- day mortality and complications were considered as short-term results.

Results: Among 43 patients, 32 (74.4%) were males and 11 (25.6%) were females. Mean age was 69. 6 (range 53-89) years. The mean lesion size was 24 (range 5-70) mm. From a total of 43 lesions, 32 (74.4%) were localized in the rectum, 8 (18.6%) in the distal colon and 3 (6.9%) in the proximal colon. The types of the lesions were as follows: 0-Is 7 (16.2%), LST-GH 2 (4.6%), LST-GM 7 (16.2%), LST-NG 3 (6.9%), LST-NGPD 11 (25.6%), 0-IIc 2 (4.6%), 0-IIa 2 (4.6%) and post-EMR residual lesion 9 (20.9%).

The complete resection of the lesion was achieved in 41 (95.3%) of cases. The 30-day mortality was none. *En bloc*, R0 and curative resection was achieved in 30 (69.8 %), 24 (55.8 %) and 24 (55.8 %) cases respectively. From a total of 5 (11.6 %) perforations 4 were closed by clips and one remaining required emergency surgery. In 2 (4, 6%) cases, perforation resulted in incomplete resection of the lesion. Delayed bleeding occurred in 2 (4.6 %) cases, both were managed endoscopically.

The final histology in cases with complete resection was as follows: LGIEN 5 (11.6%), HGIEN 17 (39.5%), intramucosal carcinoma 8 (18. 6%), T1 sm1 carcinoma 6 (13.9%), T1 sm2 and sm3 carcinoma 2 (4.6%), T2 carcinoma 1 (2.3%), neuroendocrine tumor 1 (2.3%) and xanthelasma 1 (2.3%).

Conclusion: Colorectal endoscopic submucosal dissection in our institution appears to be feasible and safe. Nevertheless, curative resection was achieved in 55.8% of cases only. This was caused mainly by high number of post-EMR residual lesions associated with severe fibrosis. Perforation occurred in 11.6% and resulted in emergency surgery and incomplete resection in 1 (2.3%) and 2 (4.6%) of cases.

P1055 DIFFERENTIAL CHARACTERISTICS OF COLORECTAL CANCER FOLLOWING THE SERRATED PATHWAY

Ó. Murcia[1], M. Rodríguez[1], M. Juárez[1], E. Hernández-Illán[1], C. Alenda[1], A. Payá[1], L. Castaño[1], R. Jover[1]
[1]*Unidad de Gastroenterología, Hospital General Universitario de Alicante, Alicante, Spain*

Contact E-mail Address: omp_89@hotmail.com
Introduction: Recently, it has been described a new colorectal cancer (CRC) carcinogenetic pathway due to methylation of CpG islands (methylator phenotype or CIMP). There's some controversy about its prognostic and response to adjuvant Chemotherapy (CT).
Aims & Methods: The aim of this study is to determine differential characteristics of CIMP CRC and to evaluate its prognostic and response to CT. There were been included 701 CRC patients consecutively from the national and multicentre Epicolon II project. Hypermethylation of CpG islands was studied by MS-MLPA method using RUN-X3, CACNA1G, IGF2, MLH1, NEUROG1, CRABP1, SOCS1 and CDKN2A markers in 614 patients, taking into account for CIMP+ the methylation of 5 or more of these markers.
Results: The median of age was 72 years old [34-93], being men 58.9%. The median of follow-up was 57.7 months. It was produced a recurrence in 146 patients (20.8%) and 278 (39.7%) were deceased at the end of the follow-up period (82.7 months). The study of methylator phenotype was possible to value in 543 patients (77.5%), distributed in 146 CIMP+ (26.9%) and 397 CIMP- (73.1%) patients. Some features between CIMP+ and CIMP- CRCs were compared. The age of the firsts at diagnosis was higher (CIMP+ 72.8 [39-93]; CIMP- 70.8 [34-93]; $p < 0.043$) and some trend to be located at right colon was observed (CIMP+ 55.6%; CIMP-26.6%; $p < 0.001$). It was also found a higher KRAS mutations proportion in CIMP+ (43.7% CIMP+; 31.7% CIMP-; $p < 0.013$), as well as in BRAF genes (14.9% CIMP+; 0.8% CIMP-; $p < 0.001$) and DNA mismatch repair genes alterations (24.3% CIMP+; 5.6% CIMP-; $p < 0.001$), without any difference in sex field. In addition, there weren't observed any difference neither survival nor recurrence between overall CIMP+ and CIMP-. However, when we stratified by genetic profile, we observed a higher survival in CIMP+ CRC with KRAS mutation (log Rank $p < 0.023$) conversely to those with KRAS mutation but CIMP- (log Rank $p < 0.759$). It was also observed a higher intrinsic survival in microsatellite instability (MSI) and CIMP- CRCs (log Rank $p < 0.032$) than those MSI and CIMP+ CRCs (log Rank $p < 0.384$). By receiving CT with curative purpose (II with poor prognosis and III stages), some differences were found between CIMP+ and CIMP- CRCs. Patients with CIMP- CRC obtained benefits in disease-free survival terms (log Rank $p < 0.001$), something that didn't occur in patients with CIMP+ CRC (log Rank $p < 0.180$). Moreover, after stratifying by genetic profile, those microsatellite stable (MSS) and CIMP- CRCs were benefiting from receive CT in disease-free survival terms (log Rank $p < 0.001$), situation that didn't happened in MSS and CIMP+ CRCs (log Rank $p < 0.164$).
Conclusion: There are observed certain differential features in methylator phenotype CRC. Overall, those patients present a worse response to adjuvant CT with curative purpose.

P1056 THE TOP 100 INFLUENTIAL MANUSCRIPTS IN COLORECTAL CANCER: A BIBLIOMETRIC ANALYSIS

P. F. Wrafter[1], T. M. Connelly[2], J. Khan[3], L. Devane[4], W. P. Joyce[1]
[1]*Surgery, Galway Clinic,* [2]*Surgery, University Hospital Galway, Galway,* [3]*Surgery, Beaumont Hospital,* [4]*Surgery, St Vincents University Hospital, Dublin, Ireland*

Contact E-mail Address: p.wrafter1@gmail.com
Introduction: Colorectal cancer (CRC) is a significant cause of mortality and morbidity worldwide. There is a large and growing body of evidence on the topic. Recently bibliometric citation analysis has been used to determine the most influential scientific papers in several surgical fields. To date, no study has been undertaken to determine the most influential papers in the field of CRC.
Aims & Methods: To analyse the 100 most cited manuscripts in the field of CRC to highlight the key topics and studies which have led to the current understanding and treatment of the disease.
A search of the Thomson Reuters Web of Science citation indexing database was completed using the search terms 'colorectal cancer,' 'colon cancer,' 'rectal cancer,' 'colorectal carcinoma,' 'colon carcinoma,' 'rectal carcinoma' or 'colonoscopy.' Only English language and full manuscripts were included. The 100 most cited papers were further analysed by topic, journal, author, year and institution
Results: 146,833 eligible papers were returned. Of the top 100, the most cited paper (by Hurwitz) focused on chemotherapy (5340 citations). The *New England Journal of Medicine* published the highest number of papers in the top 100 (n = 24, 37,858 citations). The country and year with the greatest number of publications were the USA (n = 60) and 2004 (n = 13) respectively. The most covered topic was genetics in CRC (n = 51), followed by chemotherapy (n = 21) and surgical management (n = 6).
Conclusion: These most cited manuscripts have contributed to the current understanding and treatment of CRC. We provide an analysis and reference of what could be considered the most influential papers in CRC

P1057 OUTCOME OF SELF-EXPANDABLE METALLIC STENT(SEMS) PLACEMENTS FOR COLORECTAL OBSTRUCTION AND EXPERIENCE WITH COLONOSCOPY THROUGH A COLORECTAL STENT

A. Kawana[1], **R. Kyo**[1]
[1]*Gastroenterology, Saiseikai Yokohamashi Nanbu Hospital, Yokohama, Japan*

Contact E-mail Address: ich.kawana@gmail.com
Introduction: In January 2012, endoscopic stenting with a self-expandable metallic stent(SEMS) for malignant colonic obstruction was covered by the national health insurance in Japan. And this procedure is widely accepted in Japan.
In our institution, this procedure was performed aggressively for the cases of symptomatic malignant colorectal obstruction.
Aims & Methods: The aim of this study is to research the safety and feasibility of SEMS placement as a bridge to surgery (BTS) for malignant colorectal obstruction, and showed the utility of total colonoscopy (TCS) pass through a SEMS.
From July 2012 to July 2014, a prospective study was performed on 29 patients with malignant colorectal obstruction who treated with SEMS. Only colon cancer patients who underwent BTS SEMS placement were selected. After SEMS placement,11 patients was performed a TCS pass through a SEMS.
Results: In total, 20 patients were included. The median age 68 years (43-89 years), sex ratio 10:10, stenting sites transverse colon 3 cases, descending colon 3 cases, sigmoid colon 7 cases, rectum seven cases. The median time from diagnosis to stenting was one day, the average treatment time 29 minutes, procedural success rates was 100%, and a clinical success rates was 95%. Procedure related contingent disease has not been observed, perforation was observed in one case after placement of SEMS. The median time of the start meal after SEMS placement was two days. The median time from SEMS insertion to surgery was 21.5 days. Open surgery was performed in 16 cases and laparoscopic colectomy was performed in 4 cases. The overall stoma creation was 2 cases (perforated case and intestinal necrosis case).
In 11 cases, TCS after stenting was carried out under CO2 air, and under fluoroscopic guidance. The median time from stenting to TCS was 12 days. Average time to cecum reached was 20 minutes. Complications associated with TCS were not observed. The eight of the eleven cases were observed other lesions such as adenoma and cancer. In four cases, cancer was observed in deep colon than stent. EMR was performed in one case of adenoma, complications were not observed. EMR is performed in one cases of adenoma, complications were not observed.
Conclusion: Stenting for the BTS is safe and effective. Furthermore, TCS pass through a SEMS after SEMS placement was very useful for diagnosis. It becomes possible to evaluate the deep large intestine than stent. The incidence of concurrent colorectal cancer was reported around 8%. TCS pass through the SEMS can be possible to correct preoperative diagnosis, it is considered to be useful in the selection of the surgical procedure.

Contact E-mail Address: chu.yao@monash.edu
Introduction: The production of intestinal gases are closely linked with the genesis of gastrointestinal symptoms. However, direct measurements of these gases in vivo are limited and have involved invasive or indirect (e.g., via breath) sampling techniques (1). A novel gas-sensing capsule was recently developed to detect concentrations of specific gases in real time within the gastrointestinal tract (1).
Aims & Methods: The aim of this preliminary study was to validate the use of gas sensor capsule in an animal model following diets varying in readily fermentable carbohydrate content. Six pigs were randomised to 30 MJ diets containing either low (7 g resistant starch (RS) & 0 g oligosaccharides) or high (29 g RS & 31g oligosaccharides) fermentable carbohydrates for 4 days after 1-week of acclimatisation to human-type diets. On the second day of each diet, carbon dioxide (CO_2)-sensing capsules were administered via gavage and data transmitted every 5 minutes to an external receiver. The readout represents relative CO_2 concentration (ppm) sampled at a specific timepoint. Passage rate of the capsules were also determined.
Results: In pigs receiving a high-fibre diet, all 3 gas capsules were passed within 10 days of administration whilst only 1 of 3 capsules were passed within this time period in those on a low-fibre diet. 2 capsules failed (one did not empty from the

stomach, one transmission failure). 4 devices successfully transmitted data on CO_2 production for 8-24 hoursand results are shown in the Table. In the first 8 hours when the capsule is in the stomach and small intestine, mean CO_2 concentrations were 53 x 10^3 ppm with no clear differences between diets. The 2 capsules with long duration of transmission showed a divergence of CO_2 concentrations from 10 to 16 hours. This divergence of CO2 concentrations probably represents exhaustion of fermentable substrates of carbohydrates in the proximal colon, consistent with the anticipated site of such fermentation. The convergence of CO_2 production after 16 hours is consistent with fermentation of endogenous or of less readily fermented carbohydrates common to both diets.**Table:** Capsule sensor results. FC = fermentable carbohydrate, X = no data transmission

Capsule sensor ID	Mean CO_2 concentrations (x 10^3 ppm) at 2-hour intervals									
	0 h	8 h	10 h	12 h	14 h	16 h	18 h	20 h	22 h	24 h
Sensor 1 (Low FC)	0	55	X	X	X	X	X	X	X	X
Sensor 2 (High FC)	0	68	X	X	X	X	X	X	X	X
Sensor 3 (Low FC)	0	46	46	46	33	33	56	64	64	62
Sensor 4 (High FC)	0	41	51	54	51	54	54	54	59	X

Conclusion: We have provided a proof-of-principle for the utility of a gas-sensing capsule for measuring gas concentrations within the gastrointestinal tract with demonstration of the anticipated differences associated with variations of fermentation patterns. Further work on refining the reliability of the capsule's transmission mechanism and in identifying sites of gas measurement are needed to become a valuable, non-invasive marker of intestinal gas production.

P1059 MULTIDRUG RESISTANCE-ASSOCIATED PROTEIN 4 REGULATES LINACLOTIDE-INDUCED CYCLIC GMP AND ELECTROLYTE SECRETION

B. Tchernychev[1], P. Ge[1], D. Wachtel[1], R. Solinga[1], M. Kessler[1], S. Ranganath[1], **G. Hannig**[1], I. Silos-Santiago[1]
[1]*Ironwood Pharmaceuticals, Inc., Cambridge, United States*

Introduction: Multidrug resistance-associated protein 4 (MRP4) is an ATP-binding cassette transporter that mediates the efflux of prostaglandins and cyclic nucleotides (cAMP and cGMP). MRP4 acts as an important regulator of these secondary messengers and thereby affects signalling events mediated by cAMP and cGMP. MRP4 is expressed on intestinal epithelial cells and has recently been found to be downregulated in patients with irritable bowel syndrome with constipation (IBS-C). Moreover, intestinal MRP4 has been implicated in the compartmentalised regulation of cAMP-mediated signalling.[1] Linaclotide, a potent and selective guanylate cyclase-C (GC-C) agonist, is approved for the treatment of IBS-C in the United States and Europe and in the United States at a lower dose for the treatment of chronic idiopathic constipation. GC-C activation by linaclotide results in increased cGMP synthesis; however, the role of intestinal MRP4 in regulating the levels of intracellular cGMP has not been studied.
Aims & Methods: The objective of this study was to evaluate the role of MRP4 in the regulation of cGMP levels in linaclotide-stimulated rat colonic epithelium and to simultaneously assess the effect of MRP4 inhibition on GC–C–mediated transepithelial ion (Isc) current. Ussing chamber assays were used to study the role of MRP4 on linaclotide-induced secretion of electrolytes and cGMP. The kinetics of the deactivation of linaclotide-induced Isc was studied using a GC-C/Fc fusion protein. MRP4 expression was assessed by Q-PCR and immunohistochemistry.
Results: Staining of rat colonic epithelium with anti-MRP4 antibodies showed expression of MPR4 in the apical membrane. Stimulation with linaclotide resulted in the accumulation of intracellular cGMP and induced Isc in isolated intestinal epithelium. Pretreatment of mucosa with the specific MRP4 inhibitor MK571 potentiated linaclotide-induced electrolyte secretion and augmented intracellular cGMP accumulation. Additionally, pretreatment of colonic mucosa with the phosphodiesterase type 5 inhibitor sildenafil increased basal Isc but had no amplifying effect on linaclotide-induced ion current. Inhibition of MRP4 only affected the activation, not the deactivation, phase of linaclotide-induced Isc, an effect elicited by the GC-C/Fc chimera. Stimulation with linaclotide induced cGMP secretion from both apical and basolateral membranes of the colonic epithelium. However, MK571 inhibited cGMP efflux from the apical but not from the basolateral membranes.
Conclusion: MRP4 is highly expressed on the apical membrane of rat colonocytes, and apical MRP4 mediates cGMP efflux from linaclotide-stimulated colonic epithelium. MK571 inhibition of cGMP efflux increases Isc induced by linaclotide. The selective inhibition of apical cGMP secretion by MK571 suggests the involvement of transporters other than MRP4 for basolateral cGMP secretion. A potential role of MRP4 in IBS-C is under investigation.

P1060 LINACLOTIDE INDUCES SECRETION OF CYCLIC GMP INTO THE COLONIC SUBMUCOSAL LAYER: AN IN VIVO MICRODIALYSIS STUDY IN RATS

J. Tobin[1], S. Thomas[2], R. Solinga[1], J. Masferrer[1], C. Lunte[2], **G. Hannig**[1], I. Silos-Santiago[1]
[1]*Ironwood Pharmaceuticals, Inc., Cambridge,* [2]*University of Kansas, Lawrence, United States*

Introduction: Linaclotide, a guanylate cyclase-C (GC-C) agonist, is currently approved for irritable bowel syndrome with constipation (IBS-C) in the United States and Europe and in the United States at a lower dose for the treatment of chronic idiopathic constipation. The effects of linaclotide on intestinal transit and secretion are mediated through cyclic guanosine monophosphate (cGMP) production. In addition, cGMP mediates the effect of linaclotide on visceral pain, and it has been hypothesised that this effect is through the direct inhibition of nociceptors found in the colonic submucosa. However, the levels of cGMP in the colonic submucosa after GC-C activation have not yet been measured.
Aims & Methods: The objective of this study was to assess the release of cGMP in the rat colonic submucosa after linaclotide administration using *in vivo* microdialysis. Microdialysis probes were implanted in the submucosa of the ascending colon of anaesthetised rats. Linaclotide (3 doses: 0.5, 1.7 and 5 μg) or 200 μL vehicle alone were injected directly into the lumen of the colonic loop (n = 4–10/group). cGMP concentrations in the dialysate were measured using liquid chromatography-tandem mass spectrometry (LC-MS/MS). At the end of the study, loops were excised, and length and weight were measured. The change in cGMP concentrations before and after treatment was compared with vehicle group using a two-tailed paired student's t-test. The fluid secretion change after treatment was compared with vehicle group using one-way ANOVA followed by a Dunnett's *post hoc* test.
Results: Linaclotide administered into rat colonic loops resulted in a significant increase in fluid secretion compared with vehicle alone for all doses tested (175–198%; $P \leq 0.001$). In dialysate samples, doses of 0.5, 1.7 and 5 μg linaclotide increased cGMP release into the submucosal layer in a dose-dependent manner by 58%, 73% and 212%, respectively, compared with vehicle control. For all doses of linaclotide, significant increases in cGMP concentration were observed compared with vehicle. Additionally, the changes in cGMP release were time dependent, with the highest dose reaching maximal effect within 12 minutes of linaclotide administration.
Conclusion: Linaclotide induces fluid secretion in the colonic lumen and increases cGMP levels in the colonic submucosa. The release of cGMP into the rat colonic submucosa further supports the mechanism of action of linaclotide on intestinal visceral pain.

P1061 ROLE OF NA+/CA2+ EXCHANGER 1 AND 2 ON THE CONTRACTILITY IN LONGITUDINAL MUSCLES OF MOUSE ILEUM

K. Nishiyama[1], Y.-T. Azuma[1], S. Kita[2], H. Nakajima[1], T. Iwamoto[2], T. Takeuchi[1]
[1]*Osaka Prefecture University, Izumisano,* [2]*Fukuoka University, Fukuoka, Japan*

Introduction: Increase in intracellular Ca^{2+} concentration are crucial to the regulation of smooth muscle contraction. Ca^{2+} clearance requires Ca^{2+} transport out of the cytosol by pathways involving plasma membrane Ca^{2+}-ATPase, the Na^+/Ca^{2+} exchanger (NCX), the sarco/endoplasmic reticulum Ca^{2+}-ATPase, and mitochondria. NCX electrogenically exchanges Na^+ and Ca^{2+} across the plasma membrane depending on the membrane potential and transmembrane gradients. The physiological roles by which NCX influences gastrointestinal motility are incompletely understood, although its role in heart, brain and kidney is understood.
Aims & Methods: In this study, we focused on the effect of Ca^{2+} movement through NCX on the motility in ileum because Ca^{2+} homeostasis is central to the regulation of smooth muscle function. To determine the role of NCX1 and NCX2 in the ileum, we investigated the frequency–responses to electric field stimulation (EFS) at 1 and 3 Hz in the longitudinal muscle obtained from the ileum in wild-type mice (WT), NCX1-heterozygote knockout mice (NCX1 HET), and NCX2-heterozygote knockout mice (NCX2 HET).

Abstract number: P1065

Manometric data		Volunteers	Incontinence	Constipation
Rest	HPZ pressure (mmHg) *	50 (42-55)	42 (34-47) †	47 (40-62) ‡
HPZ height (cm) *	3.5 (3.0-4.0)	3.0 (2.5-3.8) †	3.3 (2.4-4.1)	
Squeeze	HPZ pressure (mmHg) *	81 (68-106)	56 (45-69) †	64 (54-96) † ‡
HPZ height (cm) *	4.5 (4.2-4.9)	4.1 (3.4-4.6) †	4.4 (4.0-4.9) ‡	
Push	Ratio [push/rest] mean pressure *	0.98 (0.81-1.21)	0.98 (0.89-1.14)	1.02 (0.82-1.26)
% of patients withratio > 0.8	19 (79%)	20 (71%)	21 (75%)	

*median (IQR)† $p < 0.05$ (compared to volunteers)‡ $p < 0.05$ (compared to incontinence)

Results: In the ileum, EFS induced a phasic contraction that persisted during the stimulus, and a tonic contraction that recorded after the end of the stimulus. Under the condition of EFS at 1 Hz, we found that the amplitudes of phasic contraction were significantly smaller in NCX2 HET, but not NCX1 HET, than in WT. Like phasic contraction, the amplitudes of tonic contraction were significantly smaller in NCX2 HET, but not NCX1 HET, than in WT. Under the condition of EFS at 3 Hz, the amplitudes of tonic contraction were significantly smaller in NCX2 HET, but not NCX1 HET, than in WT. However, the amplitudes of phasic contraction were same among WT, NCX1 HET, and NCX2 HET, unlike 1 Hz. Next, we determined whether NCX deficiency affects contraction in response to acetylcholine (ACh) and substaqnce P (SP) in smooth muscle cells. NCX2 HET, but not NCX1 HET, demonstrated that magnitude of ACh-induced and SP-induced contractions was smaller than that of WT.
Conclusion: In this study, we demonstrated that NCX2 regulated the motility in ileum through by controlling the sensitivity of ileal smooth muscles to ACh and SP.

P1062 ROLES OF NA+/ CA2+ EXCHANGER 1 AND 2 IN MOUSE DIARRHEA MODEL

K. Tanioka[1], Y.-T. Azuma[1], S. Kita[2], H. Nakajima[1], T. Iwamoto[2], T. Takeuchi[1]

Contact E-mail Address: su205023@edu.osakafu-u.ac.jp
Introduction: The Na+/Ca^2+ exchanger (NCX) is a plasma membrane transporter involved in regulating intracellular Ca^2+ concentrations. NCX is critical for Ca^2+ regulation in cardiac muscle, vascular smooth muscle, and nerve fibers. However, little is known about the physiological role of NCX in the gastrointestinal tract. Using in vitro magnus method, we have previously demonstrated that NCX2, but not NCX1, regulates colonic motility by altering acetylcholine release onto myenteric neurons of the distal colon. Alterations in colonic motility relates to the cause of diarrhea as one proposed mechanism.
Aims & Methods: The aim of this study was to characterize the role of NCX1 and NCX2 on gastrointestinal motility in vivo in normal conditions and diarrhea models. Both NCX1 heterozygous mice (HET) and NCX2 HET on the C57BL/6 background were comparable in all analyses to age-matched wild-type mice (WT). Diarrhea was induced by oral administration of $MgSO_4$ (2 g/kg), i.p. administration of serotonin (3 mg/kg) or prostaglandin E_2 (0.1 mg/kg). The stool output was assessed in each mouse. The number and weight of stool was counted over 9 hour for $MgSO_4$, or 60 min for serotonin and prostaglandin E_2. Stools were graded into three consistency levels as follows: normal, soft, watery.
Results: In $MgSO_4$-induced diarrhea, almost all mouse exhibited watery diarrhea. We found that the number and weight of watery stool in NCX1 HET were clearly greater than those in WT over a period of 5-6 hour. Similarly, the number and weight of watery stool in NCX2 HET were markedly greater than those in over a period 3-4 hour. In serotonin-induced diarrhea, the number and weight of watery stool in NCX2 HET were greater than those in WT over periods 0-15 min and 15-30 min. NCX1 HET displayed no changes of the number and weight of watery stool, unlike $MgSO_4$-induced diarrhea. In prostaglandin E_2-induced diarrhea, it showed no significant alteration in number and weight of watery stool among WT, NCX1 HET, and NCX2 HET.
Conclusion: We demonstrated for the first time using mouse diarrhea model that NCX1 and NCX2 have important roles in the development of diarrhea.

P1063 ROLE OF TRANSIENT RECEPTOR POTENTIAL C6 CHANNEL ON THE CONTRACTILITY IN CIRCULAR MUSCLES OF MICE ILEUM

S. Suzuki[1], Y-T. Azuma[1], S. Kita[2], H. Nakajima[1], T. Iwamoto[2], T. Takeuchi[1]

Contact E-mail Address: su205019@edu.osakafu-u.ac.jp
Introduction: Transient receptor potential cation (TRPC) channels are a group of ion channels, which are relatively non-selectively permeable to cations. TRPC channels are activated in downstream of Gq/11-coupled receptors, or receptor tyrosine kinases. There is no direct evidence for role of functional TRPC6 on gastrointestinal tract. Acetylcholine and substance P have been reported to be the representative neurotransmitters that cause contractions in the gastrointestinal tracts of nearly all animal species including human being. There neurotransmitters activate muscarinic and tachykinin receptor, respectively, that belong to G protein-coupled receptor.
Aims & Methods: The aim of the present study was to investigate the role of TRPC6 in gastrointestinal motility. Both smooth muscle-specific TRPC6 transgenic mice (Tg), and smooth muscle-specific dominant-negative TRPC6 transgenic mice (DN) on the C57BL/6 background were comparable in all analyses to age-matched wild-type mice (WT). We used an organ tissue bath system to investigate the motility of circular smooth muscle segments isolated from the ileum.
Results: In the ileum, electric field stimulation (EFS; 60 sec)-induced contraction was showed during the stimulus. The amplitudes of EFS-induced contraction were significantly greater in Tg than in WT, and significantly smaller in DN than in WT. In the experiment in which atropine was added, the first phase of EFS (~15 sec)-induced contraction was completely inhibited in all of three types. Interestingly, second phase of EFS (15~60 sec)-induced contraction were still greater in Tg than in WT, and still smaller in DN than in WT. We next tested the NK1 or NK2 receptor antagonist in addition to atropine. Importantly, NK2 antagonist, but not NK1 antagonist, markedly suppressed the increased contraction in Tg. In DN, both NK1 and NK2 antagonist inhibited the contraction.
Conclusion: In this study, we demonstrated that TRPC6 has physiological roles in the contractility of the ileum and that TRPC6 channels activated by muscarinic and NK receptors to regulate the motility. In case of overexpression of TRPC6 channels, furthermore, our results suggest that relation of TRPC6 with NK2 receptor may alter and affect the motility.

P1064 DIFFERENCES ON TIME TO PEAK OF CARBACHOL-INDUCED CONTRACTION IN BETWEEN CIRCULAR AND LONGITUDINAL SMOOTH MUSCLES OF MOUSE ILEUM

T. Takeuchi[1], N. Samezawa[1], Y.-T. Azuma[1]
[1]*Osaka Prefecture University, Izumisano, Japan*

Contact E-mail Address: takeuchi@vet.osakafu-u.ac.jp
Introduction: Cooperation between contractions on the oral side of contents and relaxation on the anal side in digestive tract is physiologically important for peristaltic movement. The muscular layer in gastrointestinal tract consists of an inner circular muscular layer and an outer longitudinal muscular layer. These muscular layers are responsible for the movement such as peristalsis. Acetylcholine (ACh) has been reported to be the representative neurotransmitter that causes contractions in the gastrointestinal tracts of nearly all animal species. Although there are many reports about contractions of longitudinal smooth muscles induced by activation of muscarinic receptor (MR), little is known about the details of those of the circular smooth muscles. Thus, a detailed investigation of the ACh-induced contraction of circular smooth muscle is needed to provide insight into the regulatory mechanisms of gastrointestinal motility.
Aims & Methods: The aim of the present study was to investigate detailed contractile response in the circular smooth muscles of the mouse ileum. To compare detailed contraction response in the circular and longitudinal smooth muscles, we used circular and longitudinal small muscle strips (0.2 mm × 1 mm) of the mouse

ileum. The time from carbamylcholine (CCh) treatment to peak of contraction, and the amplitudes of contractions were compared between circular and longitudinal muscle small strips.
Results: The time to peak phasic contractile responses to CCh was significantly 5 minutes longer in the small muscle strips of circular muscle (5.7 min) than in those of longitudinal muscle (0.4 min). The amplitudes of contractions in the small muscle strips of circular muscle were similar in that of longitudinal muscle. Tetrodotoxin and N^{ω}-nitro-L-arginine had no effect on CCh-induced contractions of circular muscle. Regarding contraction, the pD_2 values for CCh were 0.86 ± 0.05 mM for circular muscle and 0.82 ± 0.07 mM for longitudinal muscle. The selective M2R antagonist methoctramine (100 nM) had no effect on CCh-induced contraction in circular and longitudinal muscle small strips. In contrast, the selective M3R antagonist 4-diphenylacetoxy-N-methylpiperidine methiodide (10 nM) completely suppressed CCh-induced contractions in both circular and longitudinal muscle small strips. Furthermore, Ca^{2+} channel blocker nicardipine (10 nM) markedly suppressed CCh-induced contractions on the circular and longitudinal muscles.
Conclusion: In this study, we demonstrate that the time to peak, which means the time from M3R activation to contraction, was slower in circular smooth muscles than in longitudinal smooth muscles.

Contact E-mail Address: aurelien.garros@chu-lyon.fr
Introduction: Anorectal high-definition manometry (high resolution with 3D, ARHDM) allows a precise definition of pressure profile. However normal values are scarce with this device. Our aim was to determine normal values and manometric profiles in fecal incontinence (FI) and functional constipation (FC) patients in a prospective multicenter trial (NCT01710579).
Aims & Methods: One hundred and twenty seven subjects were included in 3 centers. We are presenting results for 33 healthy volunteers (HV, 25 women, mean age 48 years), 33 FI patients (33 women, mean age 58) defined by Vaizey score > 6 and constipation Kess score < 9 and 37 FC patients (35 women, mean age 53) defined by Kess score > 9 and Vaizey score < 6 . All subjects underwent endoanal ultrasound examination to detect anal sphincter defects. ARHDM was performed using a rigid probe (Given Imaging, Duluth, GA). The protocol consisted of a 2-minute resting period, 2 squeezing periods (> 30 seconds) and 2 push maneuvers. The high-pressure zone (HPZ) corresponding to the anal canal was delineated at the 20-mmHg isobaric contour. The height and mean pressure of the HPZ were measured over a 20-s period at the end of the resting period and after the beginning of each squeezing period, and over a 5-s period s after the beginning of each push period. Because rectal pressure cannot be adequately assessed with this probe, we chose the ratio [push/rest] of the mean pressures of the anal HPZ to quantify the push maneuvers (anal relaxation was considered as present if this ratio was <0.8). Data are expressed in median (IQR) and compared between groups using non-parametric tests.
Results: FI patients were significantly older ($p < 0.05$ vs the other groups). Anal resting manometric parameters were significantly different between HV and FI (Table). Anal squeezing manometric parameters were significantly different between the 3 groups. In healthy females, anal pressures were similar in those with (4 subjects) and without anal sphincter defect. In FI women, resting, but not squeezing, anal pressures were significantly lower when an anal sphincter defect was present (16 patients, 49%). Increased anal pressure or absence of anal relaxation during push maneuvers was observed in the majority of HV and patients.
Conclusion: This study established normal values for ARHDM, and showed differences between controls, patients with FI and patients with FC for resting and squeezing anal pressures, as well as for HPZ height. More than 70% of HV and patients had no significant anal pressure decrease during push: rectoanal dyssynergia must be assessed differently using this new technology.

Introduction: Percutaneous endoscopic caecostomy (PEC) has been proposed as an alternative to the Malone intervention with promising results to perform antegrade colonic enemas (ACE). However, the small number of patients and short-term follow up require further assessment of PEC. Therefore, the goal of this prospective study was to assess the feasibility and efficacy of PEC in a multicenter study and a larger group of patients.
Aims & Methods: The study was conducted in 2 centers between September 2006 and April 2014. The PEC procedure was standardized between the centers and was performed under general anesthesia during a colonoscopy. It consisted in 1) puncturing the caecum after endoscopic transillumination to introduce the Chait^{TM} catheter (Cook, USA) and 2) creating a caecopexy with 3-4 anchors. The indications of PEC were constipation, fecal incontinence and incontinence after rectal resection, refractory to medical treatment. For each indication the primary endpoint was improvement of quality of life score (GIQLI). GIQLI score, constipation score (Kess), incontinence score (Cleveland) were calculated before the PEC and at 3, 6, 12 and 24 months. The overall success of PEC procedure was defined by improvement quality of life, the absence of removal of the device, of colectomy or colostomy.
Results: A total of 69 patients were included, 67 with follow-up > 3 months (2 were lost to follow-up). Constipation, fecal incontinence and rectal resection groups comprised 43, 19 and 10 patients. Mean follow-up was 2 years in the first two groups and 6 months in the third group. GIQLI scores were significantly improved in constipation group ($p = 0.034$), incontinence group ($p = 0.026$) and rectal resection group ($p = 0.013$). In the constipation group, Kess scores were 25.9 before ACE and 20.6 at 2 years ($p < 0.05 = 0.012$). In the incontinence group, mean Cleveland scores were 14.9 before ACE and 10.4 at 2 years ($p = 0.045$). In the rectal resection group, the scores went from 14.3 to 2.7 at 6 months ($p = 0.014$). Overall, success percentages in the constipation group, incontinence group and rectal resection group were 58.1% (25/43), 73.7% (14/19) and 90.0% (9/10), respectively. Complications rates were as follows: prolonged pain on the catheter site (50.7%), local bud (41.8%), catheter suspected infection in 13 cases (19.4%). 19 devices (28.4%) were withdrawn because of functional failure or complication.
Conclusion: Percutaneous endoscopic caecostomy for antegrade colonic enemas allows obtaining a significant improvement in the quality of life in patients with colorectal disorders refractory to medical treatment. Persistent pain at the catheter site, which was the most frequent complication in our study, suggests that adaptative measures of the PEC technique are needed in order to provide optimal patient's care.

Introduction: Prucalopride, a selective, high-affinity serotonin receptor 4 agonist, stimulates gastrointestinal motility and alleviates common symptoms of constipation in adults.
Aims & Methods: The aim of this study was to perform an integrated analysis of the efficacy and safety of prucalopride 2 mg daily in men and women**.** Data were combined from six phase 3 and 4, international, multicentre, double-blind, randomized, placebo-controlled, parallel-group trials with similar study designs and endpoints. The primary efficacy endpoint was the proportion of patients

Abstract number: P1072

	Entire cohort (n = 51)	Control group (n = 26)	Study group (n = 25)	p-value
Constipation[1]	18 (35%)	0 (0%)	18 (72%)	$p < 0.001$
Laxative Use[2]	9 (18%)	0 (0%)	9 (36%)	0.001
Vomiting[3]	13 (26%)	0 (0%)	13 (52%)	$p < 0.001$
Possiting[4][t1]	4 (8%)	0 (0%)	4 (16%)	0.051
Abdominal Distention[5]	17 (33%)	1 (4%)	16 (64%)	$p < 0.001$
Abdominal Pain[6]	14 (28%)	0 (0%)	14 (56%)	$p < 0.001$
Increased Effort of defecation[7]	16 (31%)	1 (4%)	15 (60%)	$p < 0.001$
Use of Anal Stimulants[8]	18 (35%)	1 (4%)	17 (68%)	$p < 0.001$
Irritability[9]	23 (45%)	4 (15%)	19 (76%)	$p < 0.001$

[1] Defined as moderate or severe constipation[2] Defined as using drugs for a period of 1 month or more[3] Defined as vomiting once a week or more often[4] Defined as many possiting, severe, beyond age of 6 months, which required treatment[5] Defined as moderate or severe abdominal distension[6] Defined as moderate or severe abdominal pain[7] Defined as moderate or severe effort of defecation[8] Defined as using anal stimulants at least once a week[9] Defined as moderate or severe unrest

with a mean frequency of ≥ 3 spontaneous complete bowel movements (SCBMs) per week over 12 weeks of treatment. Several secondary efficacy endpoints were assessed (at baseline and at the final on-treatment assessment) using patient diaries and the validated Patient Assessment of Constipation – Symptoms (PAC-SYM) and Patient Assessment of Constipation – Quality of Life (PAC-QOL) questionnaires. Safety was assessed throughout the studies.

Results: Overall, 2484 patients were included in the integrated efficacy analysis (1237 received prucalopride and 1247 received placebo) and 2552 patients (prucalopride: 1273, placebo: 1279) were included in the integrated safety analysis. Most patients were women (78.3%) and Caucasian (79.0%), and the mean (standard deviation) age overall was 47.5 (15.3) years. The mean duration of constipation was 17.3 (15.0) years and 38.9% of patients had experienced chronic constipation for ≥ 20 years. Consistent with the results of the individual trials, significantly more patients achieved a mean of ≥ 3 SCBMs per week over 12 weeks of treatment in the prucalopride group (27.8%) than in the placebo group (13.2%, $p < 0.001$); the odds ratio was 2.68 (95% confidence interval: 2.16–3.33). Results were consistent in men and women, with response rates for prucalopride and placebo of 31.6% versus 16.7%, respectively, for men and 26.6% versus 12.2%, respectively, for women (both $p < 0.001$). At the final on-treatment assessment, the proportions of patients with an improvement of ≥ 1 point in the PAC-SYM and PAC-QOL total scores from baseline were 33.3% versus 23.9% and 37.1% versus 22.3%, respectively, in the prucalopride group versus the placebo group. Prucalopride showed a consistently good safety and tolerability profile. The most common adverse events were gastrointestinal disorders (nausea, diarrhoea and abdominal pain) and headache, mainly occurring at the start of treatment. No cardiovascular safety signals were identified. The safety and tolerability profile of prucalopride was similar in men and women.

Conclusion: This integrated analysis demonstrates the favourable efficacy and safety profile of prucalopride for the treatment of chronic constipation over 12 weeks in both men and women.

P1068 NORMAL VALUES FOR 3D HIGH-RESOLUTION ANORECTAL MANOMETRY IN CHILDREN

M. Banasiuk[1], A. Banaszkiewicz[1], P. Albrecht[1]
[1]*Pediatric Gastroenterology and Nutrition, Medical University of Warsaw, Warsaw, Poland*

Contact E-mail Address: mbanasiu@tlen.pl

Introduction: 3D high-resolution resolution anorectal manometry is the most precise tool to assess function and 3D topographic picture of pressures along the anal canal. Until now, it has been used only in adult population. The normal values in pediatric population have not been evaluated so far.

Aims & Methods: The aim of this prospective study was 3D manometric evaluation of anorectal function in children without symptoms from lower gastrointestinal tract.

Manometry procedures were performed using a rigid probe (Covidien AG, Ireland) without premedication. Pressures within the anal canal and 3D picture of sphincters were obtained. The volume of balloon to elicit rectoanal inhibitory reflex (RAIR) was established. If possible, defecation dynamics and thresholds of sensation were evaluated. Data were expressed as mean (±SD).

Results: 61 children (34 males; age: 2-17 years, mean: 8.28 years) were studied. Mean resting and squeeze sphincter pressures were 83.43 (±23.23) mmHg and 191 (±64.21) mmHg, respectively. The mean length of the anal canal was 2.62 (±0.68) cm and it was correlated with age ($r = 0.49$, $p < 0.0001$). Mean rectal balloon volume to elicit RAIR was 15.66 (±10.9) cc. The first sensation, urge and discomfort were observed at 24.42 (±23.98) ml, 45.91 (±34.55) ml and 91.58 (±50.17) ml of the balloon volume, respectively. Mean resting pressure of puborectalis muscle was 71.54 mmHg (±14.58), mean squeeze pressure was 134.10 mmHg (±35.2). There was no lesions of sphincters according to 3D topographic picture of the anal canal. There was no statistically significant differences in pressure profiles between males and females. Positive correlation between age and volume of balloon needed to elicit discomfort was found.

Conclusion: Normative data of 3D high-resolution anorectal manometry in children without symptoms from lower gastrointestinal tract were established. There were no significant gender differences concerning pressure results.

*Placebo versus prucalopride. Based on a Cox proportional hazard regression including terms for treatment group, study, country, number of complete bowel movements at baseline (0 or > 0) and sex.

BL, baseline; FoTA, final on-treatment assessment; PAC-SYM, Patient Assessment of Constipation-Symptoms.

Aims & Methods: To evaluate clinical management of CC subgroups (FC, IBS-C, NRC) by 52 Italian gastroenterologists.
Results: Rome-criteria were routinely used by 45/52 of the gastroenterologists. Data from 918 CC patients were obtained (F: 80.5%; mean age: 51.1; FC: 61%; IBS-C: 31%; NRC: 8 %). The duration of CC was > 10 years in 48%. Dyspepsia, anxiety/depression, gastroesophageal reflux and sleep disturbances were the most frequent comorbidities. Bristol 1-2 was reported in 71.6% of CC (FC: 71.8%; IBS-C: 75.6%; NRC: 48.1%; $p < 0.001$). Digital rectal examination was performed in 56.7%. Psychological consultation was requested in 11.4%, urological in 8.3% and gynecological in 12.4%. Diagnostic tests were requested in 79.6%: blood tests in 53.4%, thyroid function tests in 45% (FC: 43.2%; IBS-C: 52.4%; NRC: 35.2%; $p < 0.005$), colonoscopy in 38.7% (52.8% ≥50 years; 25.2% < 50 years; $p < 0.0001$); anorectal manometry in 34.6% (FC: 38.6%; IBS-C: 29.8%; NRC: 22.2%; $p < 0.01$), colonic transit time in 25.8% and abdominal ultrasound in 21.8%. Dietary suggestions were prescribed in 80.4%; fibers in 54.9% (IBS-C: 60.7%; FC: 53.2%; NRC: 55.6%;), probiotics in 36.1%. Macrogol was suggested in 69% (FC: 70.9%; IBS-C: 71.6%; NRC: 42.6%). Antispasmodics were prescribed in 16.4% (IBS-C: 27.6%; FC: 11.6%; $p < 0.0001$). PAC-SYM (1.6 ± 0.7) was related to the duration of constipation ($p < 0.005$), to IBS-C and to an increased number of diagnostic tests ($p < 0.001$) and therapies ($p < 0.05$). PAC-QOL (1.78 ± 0.70) was related to IBS-C, to female sex ($p < 0.05$) and to an increased number of diagnostic tests ($p < 0.05$), specialist consultations ($p < 0.005$) and therapies ($p < 0.0001$).
Conclusion: NRC have a shorter history of disease, milder symptoms and require fewer diagnostic tests. PACSYM and PACQOL display higher values in IBS-C than in FC. Digital rectal examination is performed only in 57% of patients. Although not recommended by current guidelines, abdominal ultrasound is frequently requested. Macrogol is the most prescribed laxative both for FC and IBS-C.

P1070 AN AUDIT OF THE PREVALENCE OF FAECAL INCONTINENCE IN HOSPITAL PATIENTS

A. Gumber[1], **M. Redman**[1], M. ElSharif[1], G. Kaur[1]
[1]*Surgery, Scunthorpe General Hospital, Scunthorpe, United Kingdom*

Contact E-mail Address: gkaur@email.com
Introduction: Faecal incontinence (FI) is a common and under-reported problem, with many patients too embarrassed to seek help. Optimal management relies on first identification of these patients and only then- a thorough diagnosis that identifies all contributory factors, and a systematic approach to treatment. Management options include drug therapy, topical applications, containment products, behavioural techniques and surgery. Many patients do not receive optimal care due to lack of identification. In-hospital identification when they are admitted for other reasons may be one method of improving the care of such patients.
Aims & Methods: We assessed the identification of continence problems in our hospital patients via a simple 'spot check' audit of the different wards; we used the case notes for checking the documentation by both nursing and medical staff. We looked at care plans, stool charts, follow up plans etc.
Results: Overall, 163 patient case notes were examined. 90% had nursing documentation about faecal continence documented in comparison to 48% for medical documentation. Of the 147 patients where nursing documentation was found, 10.8% were found to have FI. Only 31% of these patients would have been identified by medical documentation. If only medical documentation had been used, this would have dropped to 6.5%. Most of the patients that were identified as having FI were, as expected, elderly and on the stroke unit (44%), general elderly medical wards (37.5%), orthopaedic (12.5%) and gastroenterology (6%) wards. All patients (100%) were then referred appropriately for further management.
Conclusion: Faecal incontinence has considerable impact on patients' lifestyle and quality of life, and can cause profound distress. It is important to identify these patients with FI, establish the cause and initiate appropriate management, whilst maintaining their privacy and dignity. The impact of FI on the patient's quality of life needs to be assessed prior to planning management/specialist referral etc. Written documentation in the form of care plans, follow up arrangements, advice leaflets etc is vital to providing optimal care for our patients. We found that our nursing documentation was much better than the medical documentation which needs to be improved. Once identified, all our patients were managed appropriately.

P1071 QUALITY AND EPIDEMIOLOGY OF CLINICAL PRACTICE GUIDELINES FOR CONSTIPATION: A SYSTEMATIC APPRAISAL

H. Tian[1], C. Ding[1], J. Gong[1], **N. Li**[1]
[1]*Research Institute of General Surgery, Jinling Hospital, Nanjing University School of Medicine, Nanjing, China*

Contact E-mail Address: kevin_thl@163.com
Introduction: Clinical practice guidelines (CPGs) play an important role in healthcare. The guideline development process should be precise and rigorous to ensure that the results are reproducible and not vague. The main objective of our work was to identify published constipation guidelines and assess their quality with the Appraisal of Guidelines for Research and Evaluation instrument (AGREE) and their suitability regarding adaptation for future guidelines.
Aims & Methods: To assess the methodological quality and epidemiology of clinical practice guidelines on constipation. We performed a systematic literature search on constipation CPGs of five databases (included MEDLINE and EMBASE) and guideline websites were searched till to April, 2015. The methodological quality of the guidelines was assessed by four authors independently using the AGREEII instrument.
Results: From 1234 citations, 22 relevant guidelines were included. The overall agreement among reviewers was moderate (Intra-class correlation coefficient = 0.84; 95% confidence interval [CI], 0.56-0.86). The mean scores were moderate for the domains "scope and purpose" (51.77) and "rigor of development"(56.73), however, there were low for the domains "clarity of presentation" (23.73), "stakeholder involvement"(32.23),"applicability"(29.14) and "editorial independence"(29.59). Four sixths domains scores were lower when compared with international average level. According to the AGREE instrument, six guidelines can be strongly recommended, 10 with provisos and alterations while the remaining cannot be recommended for adaptation due to poor methodological quality.
Conclusion: Overall, the quality of the guidelines assessed was low when compared with the international CPGs average level. The quality and transparency

Abstract number: P1075
Table 1: Top 5 accuracy websites with corresponding scores and Google rank positions.

Website	Accuracy QEI(0-44)	Quality GQS(1-5)	DISCERN(16–80)	LIDA(0-100%)	Readability FRE	FKG	Google rank

www.nlm.nih.gov/medlineplus	34	4	57	81%	59	8th	4

of the development process and the consistency in the reporting of constipation guidelines need to be improved. Many other methodological disadvantages were identified. In the future, constipation CPGs should base on the best available evidence and rigorously developed and reported. Greater efforts are needed to provide high-quality guidelines that serve as a useful and reliable tool for clinical decision-making in this field.

P1072 LONG-TERM OUTCOME OF INFANTS WITH SUSPECTED HIRSCHSPRUNG'S DISEASE BUT NORMAL RECTAL BIOPSY

D. Graph[1], O. Kharenko[1], J. Waxman[1], T. Frankel[1], D. Turner[1], **O. Ledder**[1]
[1]*Shaare Zedek Medical Center, Jerusalem, Israel*

Contact E-mail Address: orenl@szmc.org.il

Introduction: Hirschsprung's disease (HD) must always be considered in very-early onset constipation. While HD has a well describes clinical course, little is known about those infants in whom HD was excluded.

Aims & Methods: We aimed to describe the long-term clinical outcomes of infants with clinical suspicion of HD which was excluded by rectal suction biopsy.

This is a single-center double-cohort comparative study. Infants who underwent rectal mucosa biopsy for suspected HD were age and gender-matched with healthy controls. A survey relating to clinical outcomes, stooling patterns and other gastrointestinal-related conditions was sent to parents. Pathology slides were re-reported by an experienced histopathologist blinded to the clinical data.

Results: A total of 51 infants were included (25 case, 26 control; median 51 months (IQR 32-83) months of follow-up). Nine (36%) of the case group required prolonged laxative use for constipation during the first year of life compared with 0 (0%) of controls ($P < 0.001$). Case infants were significantly more likely to be hospitalized or be diagnosed with a chronic gastrointestinal-related condition than controls (33% vs 12%, $p = 0.01$; and 19% vs 8% respectively, $p = 0.04$).

Conclusion: Constipation in infancy is associated with long term gastrointestinal related disorders and should be considered clinically significant even when the diagnosis of HD is excluded. Infants with early onset abnormal stooling patterns should be monitored with adequate pediatrician or pediatric gastroenterologist follow-up.

P1073 IMPACT OF SWITCHING FROM A BRAND TO A GENERIC MACROGOL ON PRESCRIPTIONS AND DOSES FOR PATIENTS WITH CHRONIC CONSTIPATION IN THE UK

V. Bajaj[1], A. Naidoo[1]
[1]*Norgine Limited, Uxbridge, United Kingdom*

Contact E-mail Address: vbajaj@norgine.com

Introduction: Patients with constipation switching from a branded to a generic macrogol may require a higher number of prescriptions and doses (defined as packs of 20 sachets). Repeated switching on the basis of cost savings alone can irritate patients and can erode trust and compliance (GPC 2013[1]).

Aims & Methods: This analysis compares prescription numbers and doses (20 sachets/pack) for chronic constipation patients switched from branded macrogol (MOVICOL) to generic macrogol (LAXIDO), and those who switched back. Retrospective real-world, longitudinal patient and prescribing data from 397 UK GP practices (2,186 GPs, 13,567 patients; Jan-Dec 2013; Cegedim Strategic Data Ltd, a division of IMS Health) were analysed in two cohorts of chronic constipation patients: (1) patients prescribed branded macrogol, switched to generic; (2) patients prescribed branded macrogol, switched to generic (Switch-1) and returned to the brand (Switch-2). All patients were tracked from initiation to treatment end. Annualised prescriptions and doses/patient changes in each cohort were analysed (one- and two-sided t-test for two-sample assuming unequal variances).

Results: Males/females aged ≥13 years were analysed. In cohort (1), $N = 3109$, $M = 0.63$, $SD = 8.29$, prescription numbers (+8%) and doses (+13%) per patient/year showed an average increase. Absolute increase in prescription numbers (+0.6) and doses (+1.7) were significant ($p < 0.05$), and observed across all age groups (elderly [65+], middle-aged [36-64], young adult [19-35], adolescent [13-18]). In cohort (2), $N = 91$, $M = -3.41$, $SD = 1.65$, prescription numbers (-24%) and doses (-11%) per patient/year showed an average reduction during Switch-2. Additionally, absolute increase in prescription numbers (+5.0) and doses (+4.9) at Switch-1 was significant ($p < 0.05$).

Conclusion: Chronic constipation patients switched from branded to generic macrogol required a significantly higher number of prescriptions and doses than previously required. Patients who switched back from the generic to the branded macrogol required fewer. Factors impacting changes in prescription e.g. efficacy, convenience, and compliance require further investigation.

This analysis was funded by Norgine.

P1074 EFFECT OF PRUCALOPRIDE ON SYMPTOMS OF CHRONIC CONSTIPATION IN MEN AND WOMEN: AN INTEGRATED ANALYSIS OF SIX RANDOMIZED CONTROLLED CLINICAL TRIALS

Y. Yiannakou[1], H. Piessevaux[2], M. Camilleri[3], J. Tack[4], E. M. Quigley[5], M. Ke[6], S. da Silva[7], A. Levine[8], R. Kerstens[9]

Introduction: Prucalopride, a highly selective 5-hydroxytryptamine receptor-4 agonist, stimulates intestinal motility and is effective at alleviating symptoms of chronic constipation (CC).

Aims & Methods: This analysis aimed to compare the effect of prucalopride ≤2 mg on constipation symptoms in men and women, using the validated Patient Assessment of Constipation-Symptoms (PAC-SYM) questionnaire. An integrated analysis was performed on data from six phase 3 and 4, multicentre, double-blind, randomized, placebo-controlled, parallel-group trials investigating the efficacy and safety of prucalopride in CC. All six studies had similar study designs, allowing pooling of results and sex-specific sub-analyses. The treatment period was 12 weeks in five of the six studies, and 24 weeks in the sixth study.

Results: Overall, 2484 patients (597 men, 1887 women) were included in the analysis. Of these, 1237 received prucalopride and 1247 received placebo. The mean (standard deviation) age was 47.5 (15.3) years and duration of constipation was 17.3 (15.0) years. For both men and women at baseline, stool symptoms were rated greater in severity (moderate to severe) than abdominal and rectal symptoms (mild to moderate for both). The mean decrease in overall PAC-SYM score from baseline to final on-treatment assessment (FoTA) was significantly greater for men and women in the prucalopride group (both, –0.7) than in the placebo group (men, –0.5, $p = 0.019$; women, –0.4, $p < 0.001$) (Table). The proportion of patients with a change of ≥1 point in overall PAC-SYM score at FoTA was quantitatively greater for men and women in the prucalopride group (men, 31.1%; women, 33.9%) than in the placebo group (men, 24.5%; women, 23.7%); similar results were reported for all subscores.

Conclusion: The symptoms of CC improved in both men and women receiving prucalopride, as assessed using PAC-SYM scores.

P1075 SYSTEMATIC REVIEW OF QUALITY OF PATIENT INFORMATION ON COLORECTAL CANCER SCREENING ON THE INTERNET

E. H. Schreuders[1], E. J. Grobbee[1], E. J. Kuipers[1], M. C. Spaander[1], S. J. Veldhuyzen van Zanten[2]
[1]*Gastroenterology and Hepatology, Erasmus MC, Rotterdam, Netherlands,* [2]*Division of Gastroenterology, University of Alberta, Edmonton, Canada*

Contact E-mail Address: e.schreuders@erasmusmc.nl

Introduction: Efficacy of colorectal cancer (CRC) screening programs is dependent on screenees' participation. The internet is increasingly used by individuals for health information and can be an important tool to support decision making. The aim was therefore to evaluate the accuracy, quality and readability of patient-oriented websites on CRC screening.

Aims & Methods: Websites were identified by Google.com™ using the search term: ''colorectal cancer screening'' OR ''bowel cancer screening'' OR ''colon cancer screening''. To assess accuracy, a Quality Evaluation Instrument (QIE) was developed and pretested, which awards points (0-44) on various aspects of CRC screening. In addition, websites were evaluated using a validated five-point Global Quality Score (GQS), two validated internet quality instruments (LIDA; 0-100% and DISCERN;16-80) and two reading scores; Flesch Reading Ease (FRE) and Flesch-Kincaid Grade Level (FKG). Since internet searchers do not typically view more than one page and usually choose one of the first results displayed by the search engine, two raters independently assessed the first 3 Google pages totaling 30 websites. Portal links to other sites, duplicates and news articles were excluded. For QEI assessment, consensus in case of disagreement was achieved through discussion with a third reviewer. For other parameters the mean score of both website raters was used.

Results: Out of the first 30 hits, 20 websites met the inclusion criteria. The mean QEI score was 25.5 (range 9-41) and the median GQS was three (range 2-5). There was a strong positive correlation between the QEI and the validated GQS (Spearman's $r = 0.81$; $p < 0.001$). Also the validated LIDA and DISCERN had a moderate correlation with the QEI; $r_s = 0.45$ ($p = 0.05$) and $r_s = 0.65$ ($p < 0.01$) respectively. There was no correlation between the Google rank and QEI ($r_s = -0.36$; $p = 0.12$). The mean FRE was 48 (range 27–76). Only 30% of the websites had a reading level acceptable for the general public (FRE > 60). The mean FKG was 11 (range 5.4–15.9), indicating the text would be understandable to an average 11th grade US student. The mean LIDA overall score was 68% (range 25-86%) and the mean DISCERN score was 46 (range 27-68).

Conclusion: There is marked variation in quality of websites on CRC screening. The developed QEI was strongly correlated with previously validated quality instruments, making it a valuable tool to identify high-quality, accurate CRC screening websites. Notable is the poor correlation between quality and Google ranking. As people generally only read the first 10 hits, our findings suggest that they will miss out on high quality CRC screening websites. Improvements in quality and readability are required to provide patients with reliable information to make informed decisions on CRC screening participation.

P1076 GUAIAC-BASED FAECAL OCCULT BLOOD TESTS VERSUS FAECAL IMMUNOCHEMICAL TESTS FOR COLORECTAL CANCER SCREENING IN AVERAGE-RISK INDIVIDUALS

E. J. Grobbee[1], E. H. Schreuders[1], A. H. van Roon[1], L. van Dam[1], A. G. Zauber[2], I. Lansdorp-Vogelaar[3], G. J. Borsboom[3], E. W. Steyerberg[3], M. E. van Leerdam[4], M. C. Spaander[1], E. J. Kuipers[1]

Contact E-mail Address: e.grobbee@erasmusmc.nl

Introduction: Faecal occult blood tests (FOBT) to screen for colorectal cancer (CRC) fall into two main categories: a guaiac-based FOBT (gFOBT) or the more recently developed faecal immunochemical test (FIT). More evidence has become available about FOBT screening which suggests that FIT may be superior to the commonly used gFOBT. The aim of this systematic review was to compare the diagnostic test accuracy of FIT and gFOBT screening for detecting advanced neoplasia (AN) and CRC in average-risk individuals.

Aims & Methods: This abstract is based on a pre-peer review of a formal Cochrane Review. Upon completion and approval, the final version of the manuscript is expected to be published in the Cochrane Database of Systematic Reviews. Studies were identified by searching electronic databases Medline, Embase, Cochrane Library, BIOSIS Citation Index, and SCI-expanded (31 January 2015) without restrictions on date or language. We included randomized and/or comparative studies in which asymptomatic average-risk individuals ≥ 40 years of age underwent gFOBT and/or FIT screening. Studies in which all participants underwent both a FOBT followed by colonoscopy were included. Data were analysed using a bivariate linear mixed model (Reitsma et al., 2005). Results of the tests reporting a cutoff of 10 mcg Hb/g faeces (FIT10) or 20 mcg Hb/g (FIT20) are shown.

Results: The search identified 5,355 titles, of which 526 were fully assessed and 23 studies were included. Seven studies compared more than one test and in 6/7 studies participants underwent more than one test; resulting in a total of 32 tests in 85,403 participants. For 11 FITs the data for FIT10 were retrieved, and for 8 FITs data for FIT20. All included gFOBT studies used a cutoff of at least one positive card. The sensitivity for detection of AN ranged between studies from 0% to 33% for gFOBT, from 5% to 67% for FIT10, and from 50 to 100% for FIT20. Sensitivity for AN was lower for gFOBT with a pooled sensitivity of 16%, compared to 32% for FIT10 ($p = 0.001$), and 27% for FIT20 ($p = 0.007$). Sensitivity for CRC ranged between studies from 57% to 67% for gFOBT, from 75% to 100% for FIT10, and from 63% to 94% for FIT20. Sensitivity for CRC was lower for gFOBT with a pooled sensitivity of 41%, compared to 80% for FIT10 ($p = 0.003$), and 72% for FIT20 ($p = 0.002$). No significant differences in specificity were found for AN between gFOBT (94%), FIT10 (95%) and FIT20 (96%), nor for CRC between gFOBT (94%), FIT10 (93%) and, FIT20 (93%).

Conclusion: This meta-analysis shows that FIT is superior to gFOBT in detecting advanced neoplasia and colorectal cancer in average-risk individuals. The specificity of both tests is similar. These results strongly support the current European guidelines for implementing FIT-based CRC screening programs and the switch from gFOBT to FIT testing for existing programs.

Introduction: Colorectal cancer (CRC) screening programs are implemented worldwide and many are based on fecal immunochemical testing (FIT). Data on participation and yield over consecutive rounds of FIT screening are limited. In the Netherlands, pilot-studies have been performed with OC-sensor (Eiken, Japan) and the recently started nationwide program is using FOB-Gold (Sentinel, Italy). Yet, little evidence is available how these two tests compare. The aim of this study was to evaluate the two tests on usability, participation and diagnostic yield.

Aims & Methods: The comparison was performed in the 4th round of a population-based FIT-screening cohort in the Netherlands. Demographic data of randomly chosen 20.000 individuals between 50-74 years living in the Amsterdam and Rotterdam regions of the Netherlands were obtained from municipal population registers (March 2014 to December 2014). All invitees in previous biennial rounds were re-invited except for those who tested positive in earlier rounds or those passing the upper age limit. Invitees were randomized to receive an OC-sensor or an FOB-Gold test. The test was considered positive if hemoglobin concentration was ≥ 10 μg Hb/g feces. Participation rate, positivity rate, and positive predictive value (PPV) for advanced neoplasia (AN) and CRC were calculated. The detection rate was defined as the proportion of participants being diagnosed with AN.

Results: In total 19,290 eligible persons (median age 61, IQR 57-67; 48% males) were invited: 9,669 invitees received the OC-sensor and 9,621 the FOB-Gold test: 62.4% returned the OC-sensor and 62.5% the FOB-Gold test (n.s.). Inappropriate use or unanalyzable tests occurred in 0.7% invitees using the OC sensor vs. 1.9% invitees using FOB-Gold test ($p < 0.001$). For OC-sensor, 7.9% were positive, compared to 6.5% for FOB-Gold ($p = 0.002$). The PPV for AN in the OC-sensor group was 31.2% (95% CI:27.1-38.5), versus 32.1% in the FOB-Gold group (95% CI: 27.5-37.3) (n.s.). The detection

rate was slightly higher for OC-sensor 2.2%, than for the FOB-Gold 1.9% (n.s.).

	Total	OC-sensor	FOB-Gold	*p*
Participation rate (%)	62.4	62.4	62.5	n.s.
Unanalyzable tests* (%)	1.3	0.7	1.9	< 0.001
Positivity rate (%)	7.2	7.9	6.5	0.002
Detection rate				
AN (%)	2.1	2.2	1.9	n.s.
CRC (%)	0.2	0.2	0.2	n.s.
Positive predictive value				
AN (%)	31.6	31.2	32.1	n.s.
CRC (%)	3.5	3.0	4.0	n.s.
True positives (AN) per 1000 invited (n)	12	13	11	

Conclusion: In this fourth round of biennial population based FIT-screening, both FITs OC-sensor and FOB-Gold seemed comparable regarding participation rate and positive predictive value. Significant differences between the tests were found on unanalyzable tests, with more additional FOB-Gold tests needed to be sent to invitees due to inappropriate use, and positivity rate, resulting in more colonoscopies to be performed for a positive OC-sensor.

Contact E-mail Address: silverkes@naver.com
Introduction: Colorectal cancer (CRC) is the third most common cancer and the second most frequent cause of cancer death of female and fourth most of male in South Korea. Most CRCs develop through the adenoma–carcinoma sequence, which allows for screening and prevention of CRCs by screening colonoscopic examination and polypectomy. However, there have been limited data on personalized optimal time interval of next surveillance colonoscopic examination. The aim of our study is to recommend personalized interval by analysis of various clinical factors obtained by health care examination.
Aims & Methods: We enrolled the patients who underwent two times more voluntary, complete screening colonoscopy at health care unit of Korea University Medical Center Anam Hospital from July 1, 2004 to July 31, 2010. The clustering analysis using the partitioning around medoids algorithm and Hierarchial cluster were conducted including the 32 clinical, geographic and laboratory data. For each cluster, we then performed survival analysis that provides the probability of having polyps according to the number of days until next colonoscopy.
Results: Totally 8332 patients underwent screening colonoscopy, among them 625 patients performed repeat colonoscopy exam. 625 patients divided four clusters by clustering analysis. Adenoma detection at first screening colonoscopy was the most potent risk factor of develop of adenoma at next screening. Male gender, triglyceride (>134 mg/dL), and age (>56 years old) were significant factor for decision of the personalized interval of next screening colonoscopy. For example, male patient, who had adenoma at fist screening, the predicted risk of adenoma is 50% after 25 months.
Conclusion: Our study can provide personalized time interval of next screening colonoscopy according to patients' individual clinical data. Further study are necessary for validation our results.

Contact E-mail Address: formos337@yahoo.com.tw
Introduction: Whether Ursodeoxycholic acid (UDCA) has a chemopreventive role or not for colorectal cancer (CRC) remains unclear. UDCA has been efficiently employed as a cytoprotective agent *in vitro* and is reported to prevent CRC in patients with primary sclerosing cholangitis and ulcerative colitis.[1,2] In contrary, a recent study showed that high doses of UDCA was associated with increased CRC risk for similar groups of patients.[3] Many patients with chronic hepatitis has been prescribed with off-label use of UDCA in Taiwan, a high endemic country for chronic viral hepatitis B.
Aims & Methods
Aims: We sought to investigate the association between UDCA therapies and CRC.
Methods: A nationwide cohort population-based study was performed using the Taiwan National Health Insurance Research Database. Patients who were taking UDCA from years 1998-2007 and were ≥ 20-year-old from one million beneficiaries were enrolled. Those patients with antecedent malignancy or taking insufficient UDCA (UDCA ≤ 28 prescribed daily dose (P.D.D.) or 300mg/day) were excluded. For a sensitivity analysis, those CRC patients found within 1 year of the first dose of UDCA were also excluded. Propensity scores were used to match the UDCA users (treated cohort) with UDCA-nonusers at a 1:1 ratio, based on age, gender, comorbidities and medications. Both groups were followed until CRC diagnosis or the end of year 2010.
Results: 7,328 UDCA users were identified to take more than 28 P.D.D. After matched by propensity score, 5,385 patients in treated and control cohorts were identified for final analysis. The median follow-up time was 7.3 ± 2.9 years. The hazard ratio of CRC development for UDCA-users over non-users after adjustment for propensity score was 0.772 (95% C.I. 0.222-2.685). For patients taking 28-84 P.D.D.,85-179 P.D.D., 180-364 P.D.D., and ≥ 365 P.D.D., the hazards ratio for CRC were 0.774 (95% C.I. 0.365-1.64), 0.717 (95% C.I. 0.247-2.087), 0.738 (95% C.I. 0.220-2.471), and 1.372 (95% 0.554-3.400), respectively. The results suggested that no dose-responsive curve could be observed between hazards ratio for CRC and UDCA dosage.
Conclusion: In this nation-wide survey, the largest cohort till now, there existed no evidence to support the chemopreventive role of UDCA in CRC. Routine use of UDCA to prevent CRC is not recommended.

P1080 A RANDOMIZED CONTROLLED TRIAL OF AN EDUCATIONAL VIDEO TO IMPROVE QUALITY OF BOWEL PREPARATION FOR COLONOSCOPY

H. Kim[1], J. Park[1], M. Kim[1], K. Kwon[1]
[1]*Internal Medicine, Inha University Hospital, Incheon, Republic of Korea*

Contact E-mail Address: kimhg@inha.ac.kr
Introduction: High-quality bowel preparation is necessary for colonoscopy. A few studies have been conducted to investigate improvement in bowel preparation quality through patient education. The reported methods for patient education on bowel preparation are various, however have not been well studied. The aim of this study is to evaluate the effect of our own educational video for bowel preparation.
Aims & Methods: A randomized and prospective study was conducted. All patients received regular instruction for bowel preparation during a pre-colonoscopy visit. Those scheduled for colonoscopy were randomly assigned to view an educational video instruction (video group) on the day before the colonoscopy, or to a non-video (control) group. Qualities of bowel preparation using the Ottawa Bowel Preparation Quality scale (Ottawa score) were compared between the video and non-video groups. In addition, factors associated with poor bowel preparation were investigated.
Results: A total of 502 patients were randomized, 250 to the video group and 252 to the non-video group. The video group exhibited better bowel preparation (mean Ottawa total score: 3.03 ± 1.9) than the non-video group (4.21 ± 1.9; $P < 0.001$) and had poorer bowel preparation (total Ottawa score ≥6: 91.6% vs.

78.5%; $P < 0.001$). Multivariate analysis revealed that males (odds ratio [OR] = 1.95, $P = 0.029$), diabetes mellitus patients (OR = 2.79, $P = 0.021$), and non-use of visual aids (OR = 3.09, $P < 0.001$) were associated with poor bowel preparation.

Conclusion: The addition of an educational video significantly improved the quality of bowel preparation.

Introduction: This is the first study to assess the socio-economic burden of moderate-to-severe IBS-C in six European countries (France, Germany, Italy, Spain, Sweden and UK). Here we present the pooled economic and quality of life (QoL) results from all participating countries.

Aims & Methods: Observational, retrospective-prospective (6 months each) study of patients diagnosed in the last five years with IBS-C (Rome-III criteria) and with moderate-to-severe disease at inclusion (IBS-Symptom Severity Scale [IBS-SSS] score ≥ 175). The primary objective was to determine annual direct and indirect costs. Secondary objectives included assessing QoL at baseline: IBS-QoL and EuroQoL-5D (EQ-5D) questionnaires. Work productivity was assessed using the Work Productivity and Activity Impairment:IBS-C questionnaire (WPAI:IBS-C). All costs were calculated in local currency and adjusted (for inflation) to 2012 values. Post-hoc currency conversion was performed for cost comparison purposes.

Results: 525 patients were included in the study (60% severe by IBS-SSS); mean (±SD) age 45.3 ± 15.8 years, 86.9% female. The most prevalent symptoms at baseline were constipation (85.7%) and abdominal pain (85.1%). In the week prior to baseline, mean presenteeism (WPAI:IBS-C) was: 36.5%±29.0% of time; absenteeism: 8.4%±21.4%; work productivity loss: 39.4%±30.1%; daily activity impairment: 44.2%±28.6%. Mean IBS-QoL was 54.9 ± 22.7 (scale: 0-100 [worst-to-best]; 63.3 Italy–42.8 UK). Mean EQ-5D was 55.5 ± 21.7 (scale: 0-100 [worst-best]) and 89.4% and 62.3% of patients reported moderate-to-severe problems in pain/discomfort and anxiety/depression, respectively. Over the year, 73.1% patients consulted a primary care physician (88.4% UK–58.0% Italy), and 89.7% a gastroenterologist (100% France, Italy, UK–69.6% Germany); mean 4.9 (6.9 UK–2.1 Sweden) and 2.8 (4.0 Germany–1.7 Sweden) visits, respectively. 18.1% (24.0% UK–11.1% Sweden) patients required emergency department visits/hospitalisation (mean stay: 13.8 ± 24.0 days) and 62.1% had a diagnostic test (mean: 4.0 ± 2.7 [4.1 Spain–3.4 France, Italy]). 65.3% (90.4% UK–41.1% Italy) of patients took prescription drugs for their IBS-C and 67.2% (82.1% Italy–56.3% Spain) took non-prescription drugs. The mean annual direct costs per patient for national healthcare systems: €2,108 (UK) – €937 (Italy); cost for the patient: €568 (Spain) – €244 (France); indirect cost: €11,249 (Sweden) – €339 (Italy). Total annual cost: €12,827 (Sweden) – €1,761 (Italy).

Conclusion: Moderate-to-severe IBS-C symptoms have a high impact on QoL and work productivity of patients. With current management practices, both direct and indirect costs were high for all participating countries. Differences in annual direct costs were due to differences in healthcare resource utilisation, mainly diagnostic tests and medical consultations. Hospitalisations and/or emergency room visits was the largest direct cost driver for all countries.

Introduction: Assessing referrals can be challenging if the content of the referral letter is inadequate. There is a lack of knowledge regarding which information is essential in referral letters to gastroenterologists.

Aims & Methods: The aim of the study was to create a score to assess the quality of information in referrals to gastroenterology departments in Norway. A secondary aim was to assess whether this score correlates to the gastroenterologists' subjective assessment of the referral. 25 gastroenterologists participated in a survey regarding important information in referral letters. They were asked to select the 15 most important variables for 9 common indications. Each variable was assigned either 3, 2 or 1 points according to importance. The result was used to create a thirty point score (TPS). Subsequently, 327 referral-letters were collected from 7 primary gastroenterology referral centers. The quality of the information in the referral-letters was subjectively assessed on a 10 cm Visual Analogue Scale (VAS) and then assessed using the TPS. Pearson correlation analyses were performed to measure the association between the VAS and the TPS.

Results: The 327 referrals had an average score of 13.2(range 1-25) and an average VAS of 4.7(range 0.2-9.5). The overall correlation between the TPS and the VAS was moderate($r = 0.42$)(table 1). However, it ranged from fair($r = 0.24$) to substantial($r = 0.70$) for the various indications.

Table 1: Comparison of referral information quality assessed by VAS and TPS.

Reason for referral	N. referrals (%)	Mean score(95% CI)	Mean VAS (95% CI)	Correlation coefficient	P
Abdominal pain	50 (15.3)	12.6 (11.0-14.2)	4.5 (3.9-5.2)	0.70	0.001
Dyspepsia	47 (14.4)	11.8 (10.6-13.0)	4.3 (3.7-4.9)	0.27	0.069
Hematochezia	34 (10.4)	15.4 (13.8-17.0)	5.1 (4.4-5.9)	0.48	0.004
Change of bowel habit	48 (14.7)	14.8 (13.4-16.3)	5.1 (4.4-5.8)	0.58	<0.001
Diarrhoea	38 (11.6)	11.3 (9.9-12.7)	4.6 (4.0-5.2)	0.38	0.019
Dysphagia	36 (11.0)	11.2 (9.6-12.8)	5.0 (4.3-5.8)	0.29	0.089
Constipation	27 (8.3)	13.6 (12.2-15.0)	4.5 (3.8-5.1)	0.23	0.255
Weight Loss	21 (6.4)	14.9 (12.5-17.2)	4.8 (3.9-5.8)	0.63	0.002
Jaundice	26 (8.0)	14.3 (12.4-16.2)	4.9 (3.9-5.8)	0.24	0.236
Total	**327**	**13.2 (12.6-13.7)**	**4.7 (4.5-5.0)**	**0.42**	**<0.001**

Correlation coefficient interpretation: 0-0.2 = slight, 0.2-0.4 = fair 0.4-0.6 = moderate, 0.6-0.80 = substantial, 0.8-1.0 = almost perfect.

Conclusion: The referral information quality was modest, with considerable variation. There was a fair-substantial correlation between the TPS and the subjective quality assessed by VAS. Referral structure and appropriateness may contribute to explain some of the remaining discrepancy between the two assessments.

P1083 INCREASED PARTICIPATION IN COLORECTAL CANCER SCREENING DURING A PILOT OF A FAECAL IMMUNOCHEMICAL TEST FOR HAEMOGLOBIN (FIT) IN ENGLAND

S. Moss[1], C. Mathews[1], T. J. Day[2], S. Smith[3], S. P. Halloran[4,5]
[1]*Centre for Cancer Prevention, Wolfson Institute of Preventive Medicine, Queen Mary University of London, London,* [2]*NHS Cancer Screening Programmes, Sheffield,* [3]*NHS Bowel Cancer Screening Midlands and North West Programme Hub, Rugby,* [4]*NHS Bowel Cancer Screening Southern Programme Hub,* [5]*University of Surrey, Guildford, United Kingdom*

Contact E-mail Address: s.moss@qmul.ac.uk

Introduction: The NHS Bowel Cancer Screening Programme (BCSP) in England has used a guaiac faecal occult blood test (gFOBt) since 2006. In April 2014 the BCSP commenced a six-month FIT Pilot study to assess the clinical, financial and organisational implications of adopting FIT.

Aims & Methods: Two regional BCSP Hubs (Southern and Midlands & North West) and associated Screening Centres participated in the pilot study. One in 28 invitees was offered FIT rather than gFOBt. 30,000 FIT invitations provided adequate power for analysis of FIT uptake compared with gFOBt. The OC-SENSOR FIT system (Eiken Chemical Co. Ltd., Japan) was used with a cut-off for positivity of 20 μg haemoglobin [Hb]/g faeces (100 ng Hb/mL buffer).

Results: 40,930 subjects were invited to participate with a FIT and 1,126,087 with a gFOBt during the pilot period (April - October 2014). Uptake of FIT was significantly higher than gFOBt (66.5% vs. 59.4%; OR 1.36). The increase in uptake was significantly greater for previous non-responders (FIT 25.8% vs. gFOBt 14.2%; OR 2.09), compared with subjects invited for the first time (61.2% vs. 50.3%; OR 1.56) and those who had participated previously (90.3% vs. 86.1%; OR 1.50). The increase in uptake was higher in males (FIT 64.6% vs. gFOBt 56.4%; OR 1.41) than females (68.3% vs. 62.1%; OR 1.31) and was apparent for all quintiles of deprivation. Of particular note is the increase in uptake with FIT compared with gFOBt in the most deprived and traditionally 'hard-to-reach' quintile (53.7% vs. 45.8%; OR 1.37).

Overall positivity was 7.8% with FIT (cut-off 20 μg Hb/g faeces) and 1.7% with gFOBt (OR 4.83). The increase in positivity was similar in males and females and in all deprivation quintiles, but increased with age. Significantly more colorectal cancers (CRC) (0.27% FIT vs. 0.12% gFOBt; OR 2.19) and advanced adenomas (1.74% vs. 0.35%; OR 4.97) were detected with FIT. The PPV for all neoplasms was significantly higher with FIT (55.9% vs. 51.9%; OR 1.17). At a cut-off of 150 μg Hb/g faeces (750 ng Hb/mL buffer), which yielded a positivity for FIT (1.8%) similar to gFOBt, FIT had a higher detection rate and PPV for advanced adenomas and all neoplasms.

Conclusion: FIT significantly increased uptake of screening and provides an opportunity to adjust the faecal Hb concentration cut-off for positivity and thus the burden on colonoscopy resource. Further analysis will determine how the faecal Hb concentration measured by FIT could be incorporated into a multivariate risk score for CRC.

P1084 TRIAL OF THE NEW BOWEL PREPARATION METHOD FOR CT COLONOGARAPHY

T. Tsuchida[1], M. Imai[1], Y. Yamada[1], M. Kubota[1], T. Okamoto[1], S. Haruki[1], T. Suzuki[1], K. Utano[2]

Introduction: CT colonography (CTC) is a useful examination of colorectal cancer screening, and accuracy verification of CTC has been promoted in Japan. When performing the CTC, bowel preparation method is used similar method as colonoscopy. However, taking a large volume of bowel cleansing solution has contributed to reduce the acceptability of the examinee in colonoscopy.

Aims & Methods: We propose a new bowel preparation method to take a laxative and a water-soluble contrast agent without taking a large volume of bowel cleansing solution. Using this method, we evaluated the acceptability of the examinees and the accuracy of the CTC image. The subject of this examination was 30 examinees, including 16 men and 14 women with a mean age of 53.8 years old, who received CTC at the Cancer Screening Center of Cancer Institute Hospital. Examinee received a one capsule of laxative (Amitiza) and 50ml of water-soluble contrast agent (Gastrografin) on the night prior to CTC. Morning of CTC, examinee received 50ml of water-soluble contrast agent again. The day prior of CTC, all examinee were allowed a low-residue meal kit. For evaluation, the colon was divided into six segments (rectum to cecum). The observed amount of residual stool regardless of tagging was assessed on axial images using a 4-point scale: 0 = no stool, 1 = small stool, 2 = moderate-size stool, and 3 = large stool. The observed presence of residual fluid was assessed on axial images using a 4-point scale: 0 = no fluid, 1 = minimal fluid, 2 = moderate fluid, and 3 = substantial fluid. The homogeneity of fecal tagging was assessed using a 5-point scale: 0 = no tagging, 1 = poor tagging, 2 = inhomogeneous tagging, 3 = good tagging, and 4 = excellent tagging. We performed an evaluation questionnaire of acceptability to examinees.

Results: The observed amount of residual stool was an average 0.5 points, the observed presence of residual fluid was an average 1.7 points, and the homogeneity of fecal tagging was an average 4.0 points. From the results of the questionnaire survey, it was 3 person answered ''preparation was unacceptable", and there was small impact on the daily life and work.

Conclusion: The main advantage of this preparation method is that it is not necessary to take a large amount of bowel cleansing solution. Furthermore, preparation conditions are also excellent. Since acceptability of the examinees for this preparation method is generally good, it is expected to contribute to the popularization of CTC.

Introduction: Limited or no data is available on the impact of multidisciplinary team-(MDT) for complex benign colorectal polyps. Optimising the chance of successful and safe polyp resection at a single hospital visit is fundamental to offering a quality service.

Aims & Methods: A bi–weekly polyp MDT meeting was established in January 2013 to discuss the optimal management and resection strategies of all complex polyp referrals. The team comprises gastroenterologists/endoscopists, colorectal surgeons, pathologists, radiologists and a medical and nursing co-ordinator. The purpose of this pilot prospective study was to assess the impact of the MDT approach on the management of complex benign colorectal polyps.

Results: 96 polyp cases were discussed from January-2013 to October-2014. Inclusion criteria were defined as complex large polyps, those with difficult endoscopic access and recurrent fibrotic polyps after previous failed endoscopic excision. Most cases were tertiary referrals (78%). Reasons for referrals: very large complex polyps (55%)/difficult endoscopic access (54%)/previous unsuccessful polypectomy (36.4%). Majority of the polyps were in recto sigmoid (51%)/in caecal pole including ileocaecal valve or appendix (31.8%).

In 39.6% of cases the provisional management plan was changed after discussion at the polyp meeting. Apart from the conventional endoscopic techniques, the polyp MDT consensus proposed alternative approaches in 65% of cases to achieve a radical and complete excision of polyps. A single-hospital visit was recorded in 26% (25/96). The remaining cases (71/96) needed further diagnostic work-up and outpatient review (67/76), referral to the polyposis team (2/76), no polyp was found on two occasions.

Successful complete polyp removal was achieved in 85/96(88.5%) using conventional, novel and endo-surgical techniques; Endoscopic excision without surgical assistance in 39.6%(38/96), novel endo-surgical approaches in 25%(24/96 – Trans-Anal-Submucosal-Endoscopic-Resectio/TASER, Full-thickness-Laparo-endoscopic-EXcision/FLEX, Transanal-Endoscopic-Micro-Surgery/TEMS), laparoscopic-assisted-endoscopic-resection in 13.5%(13/96), surgical resection in 10.4%(10/96). Remaining 11 cases were managed as follows; surveillance in 4, no polyps found on examination of 2 cases, palliative care in one (carcinoma with metastases), 2 patients referred back to the base hospital for surgical resection, and one patient procedure is postponed due to co-morbidities and the other declined to have the procedure. 7 polyps were found to harbour carcinoma; all but one had surgical resection. The proposed MDT management plan was successfully followed in 82.3% of cases.

Conclusion: The polyp MDT provided a consensus on the key therapeutic issues for complex benign colorectal polyps and lead to a change in management plan in almost half of the patients. The multi-disciplinary approach helped to streamline patient care and avoid incomplete resection attempts.

Abstract number P1087 Table: Validation of scoring systems in predicting need for clinical intervention and 30-day mortality

1. Need for clinical intervention

Score*	Sensitivity(%)	Specificity (%)	Positive predictive value (%)	Negative predictive value (%)
RS > 0	95.68	36.09	64.58	100
CRS > 2	89.51	60.9	73.6	82.65
GBS > 0	100	2.26	55.48	100
mGBS > 0	100	3.01	55.67	100

1. **30-day mortality**

Score*	Sensitivity(%)	Specificity(%)	Positive predictive value (%)	Negative predictive value (%)
RS > 0	93.33	19.29	5.83	98.18
CRS > 2	86.67	34.29	6.6	97.96
GBS > 0	100	1.07	5.14	100
mGBS > 0	100	1.43	5.15	100

*Scores cutoff for 'high risk of intervention': RS > 0; CRS > 2; GBS > 0; mGBS > 0.

P1086 DIEULAFOY'S LESION CLINICAL AND EPIDEMIOLOGICAL ANALYSIS OF A RARE CAUSE OF GASTROINTESTINAL HEMORRAGE

D. M. Joao[1], N. Fernández[1], L. V. Ayala[1], L. Monteserin[1], P. Linares[1], J. L. Olcoz[1]
[1]*Gastroenterology, Hospital Universitario de León, León, Spain*

Contact E-mail Address: dianajoaomatias@gmail.com

Introduction: Dieulafoy's lesion, defined as submucosal tortuous artery of wide caliber, is a rare cause of gastrointestinal bleeding. As it's origen is an arterial bleeding, there is high risk of complications and morbimortality.

Aims & Methods

Aim: Analyze characteristics, risk factors, treatment and evolution associated to Dieulafoy s lesion.

Methods: Retrospective study since January 2000 and December 2013 of patients who underwent endoscopy resulting in Dieulafoy's lesion diagnosis. we have evaluated epidemiological varies, clinical presentation, risk factors, treatment and clinical outcome.

Results: We gathered data from 77 patients, medium age 74 years, 52% males. Dieulafoy's lesion supposed 1.4% of gastrointestinal bleeding admitted at our centre in this period. The most frequent locations were gastric (57%), duodenal (30%) and colon (12%). The common clinical presentation was melena (38%), followed by hematemesis (34%) and rectorragy (10%). The medium haemoglobin levels at diagnosis were 8.2 g dl and average admission was 8.4 days. The most prevalent risk factors were hypertension (60%), cardiovascular disease (53%), diabetes mellitus (31%) and paroxysmal atrial fibrillation (26%). One third of the patients had history of antiplatelet use, 28% were under anticoagulants and less than a half of them used proton pump inhibitors (PPI) (46%).

40% of patients needed more than one endoscopy for diagnosis. The more common treatment was sclerosis hemoclip (39%), needing a second treatment in 26% of the cases. Moreover, 70% of the patients needed blood transfusion (average 3.26 units patient). The recurrence was 18%. 9/77 patients deceased (11.7%), all with history of upper GI bleeding.

According to location, the colon and duodenum lesion were higher among women and gastric among men ($p < 0.05$). Colon lesions were associated in higher proportion with coronary heart disease ($p < 0.05$). Duodenal lesions debuted with more anaemia ($p < 0.05$), more transfusional need ($p < 0.01$), more blood units per patient ($p < 0.05$) and greater recurrence ($p < 0.05$).

Conclusion: Dieulafoy's lesion, nevertheless its low incidence, presents important morbimortality, with high transfusion rate. It is associated with cardiovascular disease. The duodenal location es the one with greatest repercussion. Even though there were endoscopical advances, Dieulafoy's lesion is still a diagnostic and therapeutic challenge nowaday.

Contact E-mail Address: estefania.mr.86@gmail.com

Introduction: The clinical severity of an episode of upper gastrointestinal bleeding (UGIB) is highly variable. Numerous scoring systems have been developed to identify patients who have been affected adversely. Nevertheless, the use of these scoring systems in clinical practice is limited.

Aims & Methods: The aim of our study was to validate the application of different risk scoring systems in UGIB [Complete Rockall Score (CRS), clinical Rockall Score (RS), Glasgow-Blatchford Score (GBS) and modified Glasgow-Blatchford Score (mGBS)] within our country, and to compare in their utilities for prediction of clinical intervention and 30-day mortality. A retrospective and observational study was designed. 295 consecutive patients with acute UGIB admitted to a tertiary care hospital during a 1-year period were included. The primary outcome was the need for clinical intervention (blood transfusion, endoscopic, radiological or surgical intervention), and the secondary outcome included 30-day mortality. All of the above risk scoring systems were calculated for each enrolled patient. The validity of the tests was assessed using the receiver operated characteristics curve analysis (AUC), sensitivity, specificity, and positive and negative predictive values.

Results: The mean time until the requirement of upper endoscopy was of 12.76 ± 7.68 hours. 162 of the 295 patients (54.92 %) needed clinical intervention. 34 patients (11.53 %) developed recurrent bleeding and 30-day mortality was 5.08 % (UGIB-related mortality 3.73 %). The results in terms of sensitivity, specificity, and positive and negative predictive values for need for clinical intervention and 30-day mortality are shown in the table attached. The prognostic accuracy of GBS (AUC 0.849) and mGBS (AUC 0.854) were the highest achieved.

Conclusion: GBS and mGBS risk scoring systems are useful to select patients with low risk UGIB who could avoid hospitalisation. None of the scoring systems proved effective enough to predict mortality.

P1088 COMPARISON OF AIMS65, GLASGOW-BLATCHFORD SCORE AND ROCKALL SCORE IN A EUROPEAN SERIES OF PATIENTS WITH UPPER GASTROINTESTINAL BLEEDING

E. Redondo-Cerezo[1], J. G. Martínez-Cara[1], R. Jiménez-Rosales[1], E. López-González[1], M. D. C. García-Marín[1], M. López de Hierro[1], J. de Teresa[1]
[1]*Gastroenterology Department, University Hospital "Virgen de las Nieves". Granada. Spain, Granada, Spain*

Contact E-mail Address: eredondoc@gmail.com

Introduction: AIMS65 is a recently developed score designed to predict in-hospital mortality, length of stay and costs of gastrointestinal bleeding.

Aims & Methods: Our aim was to revalidate AIMS65 score as predictor of inpatient and 6-months mortality in a southern European population. Our secondary objective was to compare the AIMS65 score's performance with that of the GBS and RS with regard to mortality and the secondary outcomes of (A) a composite clinical endpoint of severity; (B) transfusion requirements; (C) rebleeding; (D) delayed mortality and (E) hospital length of stay. 309 patients with a diagnosis of upper gastrointestinal bleeding were included. AIMS65, Glasgow-Blatchford score and Rockall score were calculated to all of them. Every relevant clinical and biochemical data were collected, as well as transfusion requirements, endoscopic therapies, surgical or radiological treatments, and clinical outcomes for 6 months after admission. Clinical outcomes were in-hospital mortality, delayed mortality, rebleeding, composite endpoint, blood transfusion requirements, and hospital length of stay.

Results: Overall in-hospital mortality was 9.4%. On ROC analyses, AIMS65, GBS and RS were similar when predicting inpatient mortality (0.76 vs 0.78 vs 0.78). Regarding endoscopic intervention, AIMS65 and GBS were almost identical (0.62 vs. 0.62) but AIMS65 was useless when predicting rebleeding compared to GBS or AIMS65 scores (0.56 vs. 0.70 vs 0.71). The three scores proved to be very useful when predicting the need for blood transfusions. No patient with as AIMS65 = 0, GBS ≤ 6 or RS ≤ 4 died. When considering the composite endpoint of significant clinical outcomes, an AIMS65 score of 0 did not excluded patients which were considered high risk, but did a GBS ≤ 1 or RS ≤ 2. Considering the prediction of a prolonged in-hospital stay (> 7 days), the three scores had similar AUROC. Delayed mortality was better predicted by AIMS65 than GBS or Rockall.

Table 1: Score components

Age (years)	65	51-78
Albumin (g/dl)	3.1	2.7-3.7
International normalized ratio	1.48	1.1-1.5
Sistemic blood pressure	111	95-126
Pulse	90	75-102
Hemoglobin	9.7	7.8-11.6
Urea	81.31	44.5-94.5
Hematemesis	151	48.9%
Melena	223	72.2%
Hematochezia	25	8.1%
Mental status change	25	8.1%
Syncope	45	14.6%

Conclusion: AIMS65 is a good score for patients with upper gastrointestinal bleeding, especially in predicting inpatient and delayed mortality, selecting high-risk patients and the ones who need intervention, similar to what has been reported with the Glasgow-Blatchford and the Rockall score, but more applicable to daily practice.

Contact E-mail Address: mgfernan@clinic.ub.es
Introduction: Gastric and duodenal polypectomy is a common technique but there is little information about potential complications. However, an increased risk of bleeding has been reported in retrospective series with small number of patients.
Aims & Methods: To prospectively evaluate the complications that occurred during consecutive gastric and duodenal polypectomies.
This is a multicenter, longitudinal and prospective study of all patients undergoing polypectomy of gastric or duodenal polyps ≥ 5 mm using a polypectomy snare. Patients with PT $< 50\%$ and platelets $< 50{,}000$ or clopidogrel in the 7 days prior to the polypectomy were excluded. Prophylactic measures of hemorrhage were allowed in certain predefined cases. Intraprocedural hemorrhage was defined as bleeding that lasts more than 30 seconds and severity was graded from 1 to 4. Late hemorrhage was defined as melena or hematochezia since discharge from endoscopy unit and up to 30 days. Patients were followed during 30 days with serial phone calls. Predictive factors of complications were analyzed.
Results: 310 patients were included. The indications for gastroscopy were iron deficiency anemia in 94 (30.3%), gastric polyps control in 73 (23.5%), dyspepsia/GERD in 49 (15.8%), GI bleeding in 35 (11.3%), dysphagia in 6 (1.9%), pernicious anemia in 6 (1.9%) and others in 46 (14.8%). A total of 287 (92.6%) polyps were located in the stomach and 23 (7.4%) polyps in the duodenum. Most lesions were polypoid (46.1% 0-Ip and 40.1% Is). Histopathological diagnosis was: 215 hyperplastic polyps (69.4%), 39 adenomas (12.6%), 23 fundic gland polyps (7.4%), and others 33 (10.6%). A total of 113 patients (36.5%) had antiplatelet/anticoagulant regimen. The mean size of polyps was 14.8 ± 8.7 mm and 69% were hyperplastic. We found 46 complications in 45 patients (14.5%): hemorrhage (n = 33, 73.3%), abdominal pain (n = 10, 22.2%), perforation (n = 1, 2.2%), aspiration pneumonitis (n = 1, 2.2%), respiratory depression (n = 1, 2.2%). Most complications occurred during the procedure (n = 29, 64.4%). The severity of intraprocedural hemorrhage was grade 1 in 48.1%, grade 3 in 48.1 % and grade 4 in 3.7%. In 23 patients (69.7%) hemorrhage ocurred despite the use of prophylactic measures and in all cases hemostasis was achieved (15 with endoscopic treatment and 8 spontaneously). The only factor associated with bleeding was the type of polyp (hyperplastic 18/33 vs other types 197/277, $p < 0.04$).
Conclusion: The incidence of foregut polypectomy complications is higher than reported in the colon. Hyperplastic polyps are at increased risk of bleeding and prophylactic measures do not reduce the risk.
Disclosure of Interest: None declared

P1090 AIMS65 SCORE IS A USEFUL PREDICTOR OF MORTALITY IN PATIENTS WITH NONVARICEAL UPPER GASTROINTESTINAL BLEEDING: URGENT ENDOSCOPY IN PATIENTS WITH HIGH AIMS65

H. S. Moon[1], J. S. Kim[1], S. H. Kang[1], J. K. Sung[1], H. Y. Jeong[1]
[1]*Internal Medicine, Chungnam National University School of Medicine, Daejeon, Korea, Republic Of*

Contact E-mail Address: mhs1357@cnuh.co.kr
Introduction: To validate the AIMS65 score for predicting mortality of patients with nonvariceal upper gastrointestinal bleeding and to evaluate the effectiveness of urgent (<8 h) endoscopic procedures in patients with high AIMS65 scores.
Aims & Methods: This was a 5-year single center, retrospective study. Nonvariceal, upper gastrointestinal bleeding was assessed using the AIM65 and Rockall scores. Scores were assessed under the receiver-operating characteristic curve (AUROC) for mortality. Patients with high AIMS65 scores (≥ 2) were allocated to either the urgent or non-urgent endoscopic procedure group. In-hospital mortality, success of endoscopic procedure, recurrence of bleeding, admission period and dose of transfusion were compared between the groups.
Results: A total of 634 patients were analyzed. The AIMS65 score successfully predicted mortality (AUROC = 0.943; 95% CI, 0.876-0.99) and was superior to the Rockall score (AUROC = 0.856, 95% CI, 0.743-0.969) in predicting mortality. The high AIMS65 scored group included 200 patients. The urgent endoscopic procedure group had reduced hospitalization periods ($P < 0.05$).
Conclusion: AIMS65 score may be useful in predicting mortality in nonvariceal upper gastrointestinal bleeding patients. Urgent endoscopic procedures in patients with high scores may be related to reduced hospitalization periods.

P1091 URGENT BEDSIDE ENDOSCOPY FOR NON-VARICEAL UPPER GASTROINTESTINAL BLEEDING IN INTENSIVE CARE UNITS

H.-S. Shin[1], H. Chung[1], J. C. Park[1], S. K. Shin[1], S. K. Lee[1], Y. C. Lee[1]
[1]*Department of Internal Medicine, Yonsei University Severance Hospital, Seoul, Korea, Republic Of*

Contact E-mail Address: NYOSUN84@yuhs.ac
Introduction: Urgent bedside esophagogastroduodenoscopy (EGD) for upper gastrointestinal bleeding (UGIB) in the intensive care unit (ICU) is essential for prompt identification and hemostasis of the source of hemorrhage. However, the clinical characteristics and outcomes of endoscopic hemostasis have not been well studied.
Aims & Methods: The aim of this study was to investigate clinical characteristics of hemorrhage and outcomes of endoscopic hemostasis in patients with nonvariceal UGIB (NVUGIB) after admission to the ICU.
A total of 62 ICU patients (ICU group) and 288 non-ICU patients (non-ICU group) with NVUGIB who underwent urgent EGD in Yonsei University Severance Hospital from January 2010 to April 2014 were included. We compared the demographics, clinical characteristics, technical success rate for endoscopic hemostasis, rate of rebleeding and mortality between two groups.
Results: The mean ages were 66.1 and 64.1 years (p = ns) and the number of comorbidities were 2.65 and 1.61 ($p < 0.05$) in ICU group and non-ICU group, respectively.
The most common initial clinical presentations were acute drop in hemoglobin level in ICU group (23/62, 37.1%) and melena in non-ICU group (180/288, 62.5%). ICU group presented higher blood urea nitrogen level (47.1 vs. 35.4 mg/dL), lower serum albumin level (2.5 vs. 3.2 g/dL), and higher Rockall score (7.01 vs. 5.37) with statistical significance.
The most common endoscopic finding was gastric ulcer with oozing hemorrhage (Forrest Ib) in both groups and initial technical success rates for endoscopic hemostasis were similar (91.5% vs. 94.6%, p = ns).
However, ICU group was significantly associated with higher 7-day rebleeding rate (37.1% vs. 10.4%, $p < 0.05$), shorter mean interval for rebleeding (1.4 vs. 3.4 days, $p < 0.05$), higher 30-day mortality rate (54.8% vs. 2.1%, $p < 0.05$), and higher bleeding-related mortality rate (16.1% vs. 1.4%, $p < 0.05$).
Conclusion: Despite similar technical success rate of endoscopic hemostasis, recurrent bleeding rate and bleeding-related mortality rate were significantly higher and interval for rebleeding was shorter in ICU patients. To reduce rebleeding rate and bleeding-related mortality rate, close monitoring and preemptive second-look endoscopic surveillance within 24 hours may be beneficial in the ICU setting.

Contact E-mail Address: johannes.wilhelm.rey@t-online.de
Introduction: Suspicion of gastrointestinal bleeding (GIBLEED) is a prevalent diagnosis in emergency departments. Despite existing gastroenterological and endoscopic scores to estimate the risk of GIBLEED, the primary clinical assessment remains challenging for both, emergency doctors and interventional gastroenterologists. The five step Manchester Triage System (MTS) is an easy to use and validated score that is often applied for the initial assessment of patient in emergency rooms (ER). The MTS classifies patients into five priority levels, ranging from level 1 (emergency, should receive immediate medical attention) to levels 2-5, corresponding to a suggested medical evaluation within 10, 30, 60, and 120 minutes, respectively. The MTS was established to manage clinical risk of administrating medical attention. The aim of our retrospective analyse was, to determine if the MTS correlates with presence of a GIBLEED.
Aims & Methods: All patients who were admitted between January 2014 and December 2014 to our emergency department in a maximum care hospital (HSK Clinic Wiesbaden) were retrospectively analyzed. All relevant computer-based clinical patient records that included MTS priority levels were evaluated and associated with endoscopic findings.
Results: In summary 5689 gastroenterologic emergencies were treated at our emergency room. 284 patients (4.9%) (Mean age 64.3 years) were under suspicion of having GIBLEED. 47.5% of these patients were introduced to the emergency service. among these, 162 patients (57.04%) were admitted for immediate treatment. 160 patients (56.3%) received endoscopic diagnostic. 33.1% of patients who were transferred to the endoscopy by the emergency service team showed a confirmed endoscopic diagnosis of GIBLEED, compared to 49.1% who were self-referring to the ER ($p = 0.007$). Endoscopic intervention for hemostasis was needed in 22 patients (13.8%). The success rate of hemostasis was 96.6%. While 61.2% of all patients assigned to MTS levels 1, 2, and 3 received endoscopy, endoscopy rates in patients of levels 4 and 5 were only 26.3% ($p < 0.01$). Gastrointestinal bleeding was endoscopically confirmed in 40% of patients with level 1 to 2, 34% in level 3 and 5.3% level 4 to 5, which shows a significant correlation of MTS score and GIBLEED ($p = 0.043$, χ^2 test).
Conclusion: The MTS is an appropriate way to estimate the likelihood of GIBLEED for patients presenting in emergency departments. Patients at levels 1-3 should receive immediate endoscopic work up. Elective endoscopy can be performed in patients classified with levels 4-5.

Introduction: Patients presented to hospitals with coffee ground vomiting or black-color stool may not be actually suffering from active upper gastrointestinal bleeding (UGIB). Hospital admission can be avoided if active UGIB or high-risk lesions are excluded at the emergency room (ER).
Aims & Methods: This is a prospective randomized study comparing the use of capsule endoscopy as a triage tool versus standard care in the management of UGIB at the ER of an acute hospital. Patients presented to the ER at an acute hospital with symptoms suggestive of UGIB were recruited into this study. Vital signs (blood pressure, pulse, conscious state), complete blood count and serum chemistry were monitored at the ER. Patients who were not in hemodynamic shock, coma or actively vomiting blood were randomized to receive either capsule endoscopy (CE) by using PILLCam ESO (GIVEN) or (ST) standard care of hospitalization and early endoscopy within 24 hours. Patients in the CE group with capsule video showing clean stomach (no fresh blood or coffee ground) and no signs of active bleeding or high-risk lesions were discharged home and followed by out-patient endoscopy within 3 days. CE patients showing the following signs : 1. >5 ml coffee ground or fresh blood in stomach; 2. active oozing or spurting blood from upper gastrointestinal tract; 3. visible vessel or blood clot at ulcer base; 4. esophageal or gastric varices with red wale sign or fibrin clot, would be admitted for endoscopy within 24 hours. Patients in the ST group were admitted to hospital for resuscitation, observation and endoscopy within 24 hours.
Results: 71 patients were recruited and randomized to CE ($n = 37$) or ST ($n = 34$). Three patients in CE group were excluded because of known history of variceal bleeding (1x), retained capsule in esophagus (1x) and fever which precluded early endoscopy (1x). There were 34 patients in both CE and ST groups for analysis. The basic demography, blood pressure and pulse rate, baseline blood count and chemistry of the CE and ST groups were comparable. 7 patients in CE group were considered high-risk and hence required admission, whereas all 34 in ST group were admitted. Among the 7 CE patients (20.6%) admitted, 3 were confirmed to have high-risk lesions or active bleeding (GV/EV 1x; GIST with coffee ground 1x; GU with fresh blood 1x). None of the 27 CE patients discharged home were subsequently found to have active bleeding, except one found to have GU with visible vessel. None of the patients in both CE and ST group had early recurrent bleeding or died.
Conclusion: Capsule endoscopy can select most of the high-risk patient presenting with coffee group vomiting or melena for hospital admission and urgent endoscopy. Capsule endoscopy is a feasible and safe triage method in the management of UGIB.

P1094 CHRONIC ANAEMIA DUE TO GASTROINTESTINAL BLEEDING, WHEN DO GASTROENTEROLOGISTS TRANSFUSE? A NATIONWIDE SURVEY IN THE NETHERLANDS

K. Grooteman[1], E. van Geenen[1], J. Drenth[1]
[1]*Gastroenterology and Hepatology, Radboud University Medical Center, Nijmegen, Netherlands*

Contact E-mail Address: karina.grooteman@radboudumc.nl
Introduction: Transfusion strategies have become more restricted over the past decade. Most guidelines state that in patients with chronic anaemia, symptoms are the most essential trigger to transfuse. This might differ for acute gastrointestinal bleeding, where prophylactic transfusions might be necessary at an earlier stage. Our hypothesis is that decision-making for transfusion among gastroenterologists varies considerably.
Aims & Methods: Our aim was to identify preferences and predictors of transfusion decision-making in chronic anaemia due to gastrointestinal bleeding.
To achieve this aim, a computerized adaptive choice-based conjoint survey was administered between February and April of 2015 to gastroenterologists in the Netherlands. The survey quantified the relative importance of 7 patient attributes, including haemoglobin levels, haemoglobin stability, age, iron indices, the presence of anaemia related symptoms, cardiovascular comorbidities and the number of transfusions in the past half year. Triggers of transfusion were studied in a scenario of chronic anaemia due to bleeding from angiodysplasias.
Results: A total of 112 gastroenterologists completed the survey (response rate $= 28\%$; mean age $= 47$ years; 24% women). Of 7 attributes assessed, absolute haemoglobin level was the most important incentive of transfusions, accounting for 42% of decision-making, followed by age (15%), haemoglobin stability (12%), anaemia related symptoms (10%), cardiovascular comorbidities (10%), the number of transfusions in the past half year (6%) and iron indices (5%). An inflection point was found at a haemoglobin level of 8.0 g/dL, above this value gastroenterologists would not prescribe a transfusion. The average part-worth utilities for the different haemoglobin levels (>9.5 g/dL, 8.0-9.5 g/dL, 6.4-7.9 g/dL, <6.4 g/dL) were respectively -161 (SD 23), -27 (SD 19), 55 (SD 20), and 133 (SD 23).
Conclusion: Independent of all other factors, absolute haemoglobin level was found as the most important clinical factor to transfusion decision-making. In contrast, the presence of anaemia related symptoms and iron indices was of relatively little importance. This contradicts the current Dutch transfusion guideline.

Contact E-mail Address: elisabetta.goni@gmail.com
Introduction: Chronic atrophic gastritis (CAG) is a stomach precancerous condition, often related to *Helicobacter pylori* (*H.p.*) infection. This condition is characterized by hypo- or achloridria due to loss of appropriate gastric glands. Gastropanel® is a non-invasive test able to detect both CAG and *H.p.* infection. This test, which provides information on both morphological and functional status of the gastric mucosa, is often referred to as "serological biopsy".
Aims & Methods
Aim: The aim of the present study is to investigate, by means of Gastropanel®, the prevalence of CAG in a large primary care population.
Subjects and Methods: Ten thousand dyspeptic patients, from two different areas of North-East of Italy, were enrolled. The first one (Group A) included 7,400 patients (M:F = 1.2:2.0 mean age 53 years) from 2003 to 2014 while the second one (Group B) involved 2,600 patients (M:F = 1.5:2.3, mean age 56 years) from 2011 to 2013. Upper GI endoscopy with biopsies sampling, evaluated histologically according to the Sydney classification and the O.L.G.A. staging system, as well as Gastropanel® (Biohit Oyj, Helsinki, Finland) were performed in every patient.
Serological diagnosis of CAG was made when PGI serum levels were < 25 microg/L and G-17 concentrations > 14 pmol/L. Histological diagnosis of CAG followed the criteria of *both* Sydney system and O.L.G.A. staging.
Results: Overall, CAG was diagnosed by serology in 716 out of 10,000 patients. In Group A population, 608 patients (mean age 57 years old) has a CAG, 2,492 (mean age 54) a non-atrophic gastritis related with *H.p.* infection was performed

while 879 patients (mean age 44 years) presented with a normal gastric morpho-functional assessment. In Group B population, CAG was found in 108 patients (mean age 58 years) and *H.p.*-related gastritis in 643 (mean age 59) while a normal pattern was detected in 721 patients (mean age 47).
Conclusion: Overall, in a primary care setting, a picture of CAG was found in 7.2% of patients. The prevalence was higher in Group A than in Group B (8.2% and 4.2%, respectively) for unknown reasons. The mean age of subjects with CAG was higher than that of patients with NAG *H.p*-related and normal population in both areas.
These findings suggest that CAG is more prevalent than previously thought and confirm that Gastropanel® is an effective non invasive tool for the screening of this precancerous condition.

P1096 ESTABLISHING A PROMPT ENDOSCOPY PROGRAMME FOR PATIENTS WITH DYSPEPSIA AND ALARM FEATURES REDUCES THE NUMBER OF SECONDARY CARE CONSULTATIONS

F. J. Garcia-Alonso[1], D. Bonillo-Cambrodón[1], M. Hernández Tejero[1], A. Bermejo[1], A. Algaba[1], A. Guardiola[1], P. Valer[1], I. Guerra[1], F. Bermejo[1]
[1]*Gastroenterology, Hospital Universitario de Fuenlabrada, Fuenlabrada, Spain*

Contact E-mail Address: fj.garcia.alonso@gmail.com
Introduction: Dyspepsia is commonly encountered by primary care providers (PCP) and motives a significant number of endoscopies and secondary care consultations. A guideline issued by both the Spanish Society of Gastroenterology and the Spanish Society of Primary Care recommends prompt endoscopy in subjects with alarm features (anaemia, weight loss, dysphagia, gastrointestinal bleeding or abdominal findings) or appearance of symptoms after 55 years of age. We present the development of a prompt endoscopy programme (PEP) for dyspepsia with alarm features in primary care.
Aims & Methods: In June 2013 a PEP for patients with dyspepsia and alarm features was created with the cooperation of a primary care clinic (PCC) attending 36577 people, with a median of 58 monthly new gastroenterological secondary care consultations. After data analysis in August 2014, the programme was made available to all PCCs related to our hospital, which attends roughly 225000 people.
Demographic, clinical, endoscopic and histological data were prospectively retrieved, as well as secondary care consultations after endoscopy. A satisfaction survey was undertaken in the PCC participating in the pilot programme. Proper indication of prompt endoscopy was defined in the presence of at least one red flag or age >55. Significant findings were defined as cancer, ulcers or severe esophagitis.
Results: In the pilot study 113 patients were included with a median age of 57.4 (IQR: 45.9-64.1), 61.1% of them were women. Symptoms had been present for a median 4.5 months (2.5-12.5). 84.2% (95% CI: 75.8-92.6%) of endoscopies had been properly indicated. Monthly secondary care consultations from the PCC during the pilot study period compared with previous years were reduced in 10.5 patients (5.6-15.5).
Including all subjects attended, a total of 296 patients have undergone endoscopy with a median age of 56.3 (45.4-64.4), 61.5% were women. Proper indications were made in 81.8% (77.3-86.2%) of patients. Most common alarm features were: age over 55 (55.7%), weight loss (25.5%) and anaemia (20.8%). 38.9% presented 2 or more red flags. Upper epigastric pain (72.8%) was the most common symptom, but 50% also fulfilled criteria of gastroesophageal reflux disease, which was more frequent than bloating (40.9%) and early satiety (31.6%).
Significant findings were encountered in 14.5% (11-19%); gastroesophageal cancer in 1% (3 gastric cancers), peptic ulcers in 11.1% and severe esophagitis in 2.7%. Other cancers were found during a 2 months follow-up in 1% (colon adenocarcinoma, metastatic cancer of unknown origin and multiple myeloma). *H pylori* was diagnosed in 38.9% and a normal endoscopic appearance was present in 30.5%. The positive and negative predictive values of alarm features were 17.4% (12.8-22.7%) and 98.1% (90.1-100%) respectively 17.6% of patients were submitted to the gastroenterology out-patient clinic.
The satisfaction survey was completed by 24 PCP. All of them considered the PEP useful for their daily practice, although only 66.7% had used it. Most non users (87.5%) referred having met no patients with alarm features.
Conclusion: Availability of prompt endoscopy for dyspepsia with alarm features is considered a valuable asset by PCP and reduces the number of secondary care consultations.

Contact E-mail Address: rejchrt@lfhk.cuni.cz
Introduction: Epidemiology of uninvestigated dyspepsia was studied in the Czech Republic for the first time in 2001 (1). The aim this current multicentre prospective study was to evaluate dyspepsia using the same methods in a representative sample of general unselected population from the same geographical areas 10 years later.
Aims & Methods: A total of 22 centres entered the study. They were spread over the whole country, corresponding well to the geographical distribution of the Czech population. A total of 1,836 subjects (863 males and 973 females; aged 5-98 years) took part in the study and responded to the question on prevalence of dyspepsia. Complete data on variables used in our analysis was available for 1,685 subjects. The proportion of subjects reporting dyspepsia did not differ significantly between the restricted sample and the group excluded from multivariable analyses. Helicobacter pylori (Hp) status was investigated in all subject by means of 13C-urea breath test.
Results: In subjects aged 5-24 years, when we analyzed determinants of dyspepsia by type (subgroup A: dyspepsia as the only long-lasting symptom vs. subgroup B: dyspepsia as a part of the complex of other complaints or previously recognized diseases), we noted somewhat stronger increase in risk of dyspepsia A with age (OR 1.15 per 1 year of age, 95% CI 1.05-1.26, adjusted for gender) and with current use of antibiotics (OR 3.23 in users vs. non-users, 95% CI 0.87-11.9). In subjects aged 25+ years, when analyzed by type of dyspepsia, a statistically significant negative association of age with dyspepsia of type A became apparent (OR 0.95 per 1 year of age, 95% CI 0.94-0.97) while the association between age and dyspepsia type B was also statistically significant albeit positive (OR 1.02 per 1 year of age, 95% CI 1.01, 1.04). Furthermore, subjects who were single were at lower risk of dyspepsia type B (OR 0.46 in single vs. married, 95% CI 0.21-0.99, adjusted for age and gender). The unexpected protective effect of elementary education appeared also to be stronger for dyspepsia type B (OR for elementary vs. university educated 0.25, 95% CI 0.07-0.86, adjusted for age and gender). Hp negative subjects reported dyspepsia in 4.1% (aged 5-24 years) and 18.1 % (aged 25+ years). In Hp positive subjects, dyspepsia was present in 7.1% (aged 5-24 years; OR 1.45, 95% CI 0.41, 5.16) and 16.3% (aged 25+ years; OR 0.85, 95% CI 0.60, 1.21, adjusted for gender and age).
Conclusion: Despite the substantial decrease of Hp infection in the Czech Republic over the past 10 years, the prevalence and basic socio-demographic determinants of uninvestigated dyspepsia did not change significantly.

P1098 IN VITRO EFFECT OF LEVOSULPIRIDE ON THE MAIN CONTRACTILITY PATTERNS IN THE HUMAN JEJUNUM, GASTRIC ANTRUM AND FUNDUS

D. Gallego[1], O. Ortega[2], C. Arenas[1], I. López[2], E. Mans[2], P. Clave[2,3]

Contact E-mail Address: pere.clave@ciberehd.org
Introduction: To assess the effect of drugs currently in use to ameliorate symptoms of functional dyspepsia and gastroparesis in human tissue it is important to evaluate their mechanism of action on isolated human samples. Therefore, the aim of the present study was to evaluate the effect of the prokinetic drug levosulpiride on the main in vitro contractility patterns of the human stomach and jejunum.
Aims & Methods: Circular muscle strips from stomach (antrum and fundus) and jejunum from patients undergoing bariatric surgery were studied using organ baths to evaluate: the effect of levosulpiride on the spontaneous contractility and on electrical field stimulation (EFS)-induced release of neurotransmitters from enteric motor neurons.
Results: Levosulpiride, a $5HT_4$ agonist/D_2 antagonist, caused an increase in the EFS-induced cholinergic contractions, in the gastric antrum ($37 \pm 15.18\%$ of increase at $100\mu M$, $pEC_{50} = 4.46 \pm 0.14$; $p < 0.05$, $n = 8$) and jejunum ($45.4 \pm 22.03\%$ of increase at $100\mu M$, $pEC_{50} = 3.78 \pm 6.81$; $p < 0.05$ $n = 5$), whereas it did not cause a significant increase in the gastric fundus. It also caused a slight tone decrease and frequency of the spontaneous contractions increase in the jejunum whereas it did not have any major effect on the spontaneous contractility in the stomach. It did not have any effect on EFS-induced relaxations caused mainly by nitric oxide (NO) in the stomach (antrum and fundus) and by NO and ATP in the jejunum.
Conclusion: Our results suggest that the prokinetic effects of levosulpiride are mainly due to facilitating the release of acetylcholine by enteric motor neurons in the gastric antrum and the jejunum.

P1099 AN HERBAL MEDICINE FOR THE SYMPTOMATIC RELIEF OF MILD GASTROINTESTINAL DISCOMFORT, ALTHAEA ROOT EXTRACT, HAS PROTECTIVE EFFECTS ON HUMAN MUCOSA CELLS

F. J. Zippel[1], N. Hellenbrand[1], C. Fink[2], O. Kelber[2], **H. Abdel-Aziz**[2], A. Hensel[1]
[1]*Institute of Pharmaceutical Biology and Phytochemistry, University of Muenster, Münster,* [2]*Scientific Department, Steigerwald Arzneimittelwerk GmbH, Darmstadt, Germany*

Contact E-mail Address: olaf.kelber@bayer.com

Introduction: The use of herbal medicinal products in gastrointestinal complaints is very common in Europe. To these belongs the extract of the root of the herb *Althea officinalis* L. (marshmallow root), which is traditionally used "for the symptomatic relief of mild gastrointestinal discomfort", an indication which has been confirmed by the European drug regulatory agency EMA [1], besides its more common use in the treatment of pharyngeal irritation and associated dry cough. As this use has been often rated as being merely symptomatic [1], a study has been conducted with the aim to identify mechanisms of action which point to an active, causal therapeutic effect in mucosal cells, beside its well-characterized protective physical effect [2].

Aims & Methods: Therefore the mechanisms of action of a well defined extract of Althea officinalis roots, STW 42, and of polysaccharides from the extract (RPS) were tested in a human mucosal cell line (KB-cells, origin: nasopharynx), and for comparison purposes, a human fibroblast cell line [3, 4].

Results: In KB-cells, RPS (1-10 µg/mL) significantly increased cell vitality, measured as reduction of the tetrazolium salt WST-1, in contrast, STW 42 had no significant effect at that time. Cellular proliferation, measured by ELISA in the BrdU-Test was significantly stimulated by STW 42 (10 µg/L), while RPS had this effect only at 100 µg/mL. RPS, labelled by fluorescein 5-isothiocyanat (FITC), was internalised by KB-cells, not fibroblasts, after incubation for 14 h.

Conclusion: According to these results, STW 42 may have an active influence on mucosal cells and fibroblasts. *Althaea* polysaccharides can even be internalised by mucosal cells. This points to a not merely demulcent, but actively protective effect on the mucosa. By stimulating mucosal regeneration, it potentially could even have a causal therapeutic effect in mucosal disturbances.

P1100 STRUCTURAL CHANGES OF ENTERIC GLIAL CELLS AND MOTILITY DISORDERS OF THE STOMACH AS RESPONSES TO EARLY LIFE STRESS (MATERNAL SEPARATION) AND ACUTE STRESS IN ADULTHOOD IN RATS

K. Tominaga[1], Y. Fujikawa[1], T. Tanigawa[1], T. Watanabe[1], Y. Fujiwara[1], T. Arakawa[1]

Introduction: Enteric glial cells (EGCs) play an important role in physiological neurotransmission. However, its regulatory mechanism(s) under various stresses (mental, physical, acute, and/or chronic) remains to be elucidated. We investigated changes in mRNA expression and structural changes in gastric EGCs in the time course of the stress intensity in a maternal separation (MS) model, a model of early life stress affecting central glial cells.

Aims & Methods: Male Wistar rat pups underwent MS for 3 hours starting on postnatal days 2-14. At 8 weeks of age, we used the water immersion method as an acute stress (AS) model and excised the whole stomach at 24 hours later. For the AS, MS, MS + AS, and control groups, we evaluated mRNA expressions of glial fibrillary acid protein (GFAP) using real time RT-RCR. Whole mount longitudinal muscle-myenteric plexus preparations were used for immunohistochemistry of EGCs (GFAP) with pan neuronal marker (HuC/D). We evaluated gastric emptying time using the phenol red method.

Results: GFAP mRNA expression was increased by 2-fold at 1 hour after AS compared to the controls ($p < 0.05$). However, in the MS + AS group, AS did not affect GFAP mRNA expression. The two-dimensional area with apparent overlap of these EGC processes with the neurons was expressed as a percentage of the area encompassing the HuC/D-positive neurons. The area ratio significantly increased according to the stress intensity (10.2%, acute stress; 10.0%, maternal separation; 26.4%, maternal separation with acute stress vs. 5.1%, control). The density of GFAP-positive EGC processes that apparently overlapped with the neurons and the extent of bulbous swelling of terminals increased according to the stress intensity. Two types of glial processes were observed: filamentous (no obvious neck or bulbous terminal swelling) and leaf-like (a neck region with a bulbous terminal swelling). Mean ratio of leaf-like processes to total processes per ganglion was 4% in the control group, which was increased to 17% by AS for 8 hours. The mean ratio was 13% in the MS group, and began to increase from 1 hour in a time dependent manner in the MS + AS group and reached up to 25% at 8 hours. In the MS group, gastric emptying was significantly delayed compared with those in control group in addition to aging. At 17 weeks, MS with AS induced the significant delay in gastric emptying.

Conclusion: Maternal separation with additional acute stress in adulthood caused structural changes in gastric EGCs, which may be critically important for glio-neural dysfunction of functional gastrointestinal diseases.

P1101 FUNCTIONAL DYSPEPSIA IS SUSCEPTIBLE TO CD14, GNB3, TRPV1 -BUT NOT MIF- GENE POLYMORPHISMS IN A WESTERN POPULATION

K. Triantafyllou[1], A. Kourikou[1], M. Gazouli[1], G. P. Karamanolis[1], G. D. Dimitriadis[1]

Contact E-mail Address: ktriant@med.uoa.gr

Introduction: Functional dyspepsia (FD) might be susceptible to gene polymorphisms related to inflammation (CD14, MIF), motor (GNB3) and sensory dysfunction (TRPV1). Association studies have shown diverse results among different populations. Herein, we present the final results of our association study in a Western population; preliminary results were presented at UEGW 2012[1].

Aims & Methods: We aimed to examine the association between CD14, GNB3, MIF and TRPV1 gene polymorphisms and FD (Rome III criteria). We studied gene polymorphisms using polymerase chain reaction-based methods and we measured disease symptoms burden with a modified GSRS scale.

Results: We studied 100 dyspeptic (62 with epigastric pain syndrome; 41% *H. pylori* positive) and 119 healthy individuals. The frequencies of the TT genotype and T allele of the CD14 polymorphism were significantly associated (OR [95%CI], p) with FD (2.4 [1.16-5.01], 0.02 and 1.55 [1.05-2.28], $p = 0.03$, respectively). TT genotype and T allele frequencies of GNB3 showed also significant association with FD (4.73 [1.25-17.83], 0.02 and 2.14 [1.27-3.61], 0.006, respectively). While the distribution of GG, GC and CC MIF gene genotypes was similar between controls and FD patients, GC TRPV1 genotype and C TRPV1 allele were more common in controls ($p = 0.06$) and in FD patients ($p = 0.07$), respectively. Among dyspeptics, CD14 TT genotype was related to significantly lower epigastric pain burden score compared to the CC and CT genotypes (3.72 ± 0.18 vs. 4.36 ± 0.11 and 4.17 ± 0.12, $p = 0.012$). Similarly, the presence of CD14 T allele was related to lower epigastric pain burden score compared to the C allele (3.98 ± 0.1 vs. 4.36 ± 0.11, $p = 0.012$).

Conclusion: FD is susceptible to CD14, GNB3 and TRPV1 gene polymorphisms while CD14 gene polymorphisms are also associated with epigastric pain burden in our Western population.

P1102 ASPARTIC ACID IS EFFECTIVE FOR EARLY SATIETY (FUNCTIONAL DYSPEPSIA): EFFECTS OF AMINO ACIDS ON THE GASTRIC EMPTYING EVALUATED BY BREATH TEST AND THE GASTRIC ADAPTIVE RELAXATION EVALUATED BY BAROSTAT IN RATS

M. Uchida[1], C. Iwamoto[1], O. Kobayashi[1]
[1]*R&D Division, Food Science Research Laboratories, Meiji Co., Ltd., Odawara, Japan*

Contact E-mail Address: masayuki.uchida@meiji.com

Introduction: Amino acid has been reported to have many physiological functions. Glutamic acid enhances contraction of the antrum and tryptophan inhibits gastric emptying. However, the effects of the other amino acid have not been clarified on the gastric function. On the other hand, Sanaka *et al.* (*Dig Dis Sci.* 2010) reported that PPI therapy enhanced the gastric adaptive relaxation and inhibited the gastric emptying, suggesting the relationship between gastric adaptive relaxation and gastric emptying. In addition, it has been known that gastric emptying and gastric adaptive relaxation closely relate to functional dyspepsia.

Aims & Methods: In the present study we evaluated 20 amino acids on the gastric emptying and gastric accommodation to find useful amino acid for the therapy of functional dyspepsia. Male SD strain rats were used after one night fasting. *Breath test:* Gastric emptying was evaluated by breath test (Uchida *et al., J Pharmcol Sci.* 2005). After the oral administration of liquid test meal containing [1-^{13}C]acetic acid, rats were placed in the chamber. The expired air was collected at 5-min intervals until 70 min after the test meal administration, with additional measurements at 90 and 120 min. The $^{13}CO_2$ levels in the expired air were measured by placing the breath-sampling bags into the sample joint of the UBiT-IR300 infrared analyzer. Gastric emptying was evaluated by the change of expired $^{13}CO_2$, Cmax, Tmax and AUC120min. Amino acids were administered orally 30 min before test meal administration. *Barostat study:* Gastric accommodation was evaluated by barostat. Balloon was introduced into the stomach through the mouth of anesthetized rats without the need for balloon surgery (Uchida and Shimizu, *J Smooth Muscle Res.* 2012). The balloon volume increased gradually just after an increment in the balloon pressure (1 to 8

mmHg), and reached a plateau within 1 min. This increased volume just after the increment of the balloon pressure was defined as adaptive relaxation. Amino acids were administered orally 30 min before barostat study.
Results: There were no amino acids enhancing the gastric emptying. Tryptophan significantly delayed the gastric emptying as compared with control and significant enhanced the gastric accommodation. Many amino acids inhibited gastric emptying and enhanced gastric adaptive relaxation. Significant positive correlation was observed between gastric emptying (Tmax) and gastric accommodation. Above findings show that amino acids delaying gastric emptying enhance the gastric accommodation. Only aspartic acid significantly enhanced the gastric adaptive relaxation, but did not influence the gastric emptying.
Conclusion: Functional dyspepsia is divided into postprandial distress syndromes and epigastric pain syndromes. Early satiety is one of the postprandial distress syndromes. This disease is supposed to be caused by the dysfunction of gastric adaptive relaxation. In this study, we found that aspartic acid significantly enhanced the gastric adaptive relaxation, but did not influence the gastric emptying. Therefore, aspartic acid may become useful material for the therapy of early satiety.

Contact E-mail Address: mtkhayyal@gmail.com
Introduction: One of the main gastric disorders encountered in functional dyspepsia (FD) is a delay in gastric emptying and changes in gastric functional activity. The present study was designed to observe whether the established efficacy of the multi-component herbal preparation STW5 in FD[1-4] could owe its beneficial effects at least in part to preservation of gastric emptying and other parameters of gastric function. STW5 consists of standardized extracts of *Iberis amara, Melissa officinalis, Matricaria recutita, Carum carvi, Mentha piperita, Angelica archangelica, Silybum marianum, Chelidonium majus, and Glycyrrhiza glabra*. A novel stress model for FD has been devised to resemble the clinical situation where FD has been attributed to emotional stress in early life, followed by further exposure to stress in adulthood[5].
Aims & Methods: Weanling rats were separated from the mother cage for 3 hours/ day until day 21 from birth. After reaching adulthood 4 weeks later, they were restrained for 90 min / day for 1 week. During these sessions animals were given STW 5 orally in daily doses of 2 and 5 ml/Kg. One day after the last session, the gastric emptying time of the animals was determined using a phenol red meal. In a separate group of rats, blood samples were taken for assaying the stress hormones corticosterone and corticosterone releasing factor. Fundus strips were removed after sacrifice to test their sensitivity ex-vivo towards carbachol, serotonin, adrenaline and potassium chloride. Furthermore, duodenal homogenates were examined for expression of CSE, RelA, Nrf-2 and the tight junction proteins ZO-1 and occludin using qPCR.
Results: Rats subjected to the sequential stress procedure showed marked delay in gastric emptying, an effect which was counteracted dose dependently by STW5. Sensitivity of the fundus ex-vivo to the tested agents was markedly depressed by stress, but tended to be normalized after treatment with STW5. The stress hormone levels were elevated by the model but tended to be normalized by the herbal preparation. The expression of Nrf-2 and ZO-1 was reduced but that of occludin was raised by the model but normalized after treatment.
Conclusion: The results contribute to our understanding of the beneficial properties of STW 5 in FD. Thus the disturbance in gastric function often observed in patients with FD could be effectively prevented by the herbal preparation, STW5.

P1104 ALDIOXA IMPROVES BOTH OF DELAYED GASTRIC EMPTYING AND IMPAIRED GASTRIC ACCOMMODATION, WHICH ARE PATHOPHYSIOLOGIC MECHANISM OF FUNCTIONAL DYSPEPSIA

T. Asano[1], S. Aida[1], K.-I. Tanaka[1], T. Masaoka[2], H. Suzuki[2], T. Mizushima[1]

Introduction: Functional dyspepsia (FD) is a highly prevalent gastric functional disease defined as persistent or recurrent gastric discomfort and epigastric pain without underlying organic causes, in which delayed gastric emptying and impaired gastric accommodation play important roles. Although FD markedly reduces the patient's quality of life, its therapeutic protocol, including pharmacotherapy, has not been established.
Aims & Methods: In order to find candidate drugs for FD by drug repositioning strategy, we here screened compounds that could improve delayed gastric emptying from a library of medicines already in clinical use. Gastric emptying in mice was assessed by the phenol red method or the [^{13}C]-labeled acetic acid breath test. The intracellular cAMP level was determined by ELISA. Membrane fractions prepared from Chinese hamster ovary (CHO)-K1 cells expressing human α-2 adrenergic receptor and [^{3}H]-clonidine were used in filter-binding assay. Gastric accommodation in rats was examined using a barostat apparatus.
Results: Aldioxa (dihydroxyaluminium allantoinate) is a medicine used clinically to treat gastric ulcers and gastritis. Oral administration of aldioxa improved clonidine (α-2 adrenergic receptor agonist)-induced delayed gastric emptying. The dose of aldioxa required to suppress delayed gastric emptying was much lower than that required to suppress indomethacin-induced gastric lesions in mice. Other gastroprotective drugs (geranylgeranylacetone and sucralfate) had no effect on delayed gastric emptying. Aldioxa also suppressed the delayed gastric emptying induced by restraint stress, but did not affect the basal level of gastric emptying in intact mice. Administration of allantoin, but not aluminium hydroxide, restored the gastric emptying. Treatment of cells with clonidine decreases intracellular cAMP levels, which could be suppressed by the simultaneous treatment with aldioxa or allantoin. Both aldioxa and allantoin inhibited clonidine binding to the α-2 adrenergic receptor. We also found that aldioxa or aluminium hydroxide but not allantoin restored gastric accommodation in rats subjected to wrap restraint stress.
Conclusion: Results suggest that the oral administration of aldioxa restores gastric emptying activity via its antagonistic activity on the α-2 adrenergic receptor, with the allantoin moiety of this drug is involved in this restoration. The results also suggest that the aluminium hydroxide moiety of aldioxa is involved in the improvement of impaired gastric accommodation. We propose that aldioxa is a candidate drug for FD, because its safety in humans has already been confirmed clinically and its ameliorating effect on both of delayed gastric emptying and impaired gastric accommodation are confirmed here.

P1105 RIFAXIMIN FOR THE TREATMENT OF FUNCTIONAL DYSPEPSIA: A DOUBLE-BLINDED RANDOMIZED PLACEBO-CONTROLLED TRIAL

V. Tan[1], K. Liu[1], F. Lam[1], I. Hung[1], W. K. Leung[1]
[1]*Medicine, The University of Hong Kong, Hong Kong SAR, Hong Kong*

Contact E-mail Address: vpytan@hku.hk
Introduction: Evidence suggests that gut dysbiosis may be partly causal in the genesis of pain and bloating in irritable bowel syndrome and treatment with the non-absorbable antibiotic rifaximin reduces these symptoms. Functional dyspepsia (FD), is another functional gastrointestinal disorder, where pain, bloating and belching can be particularly problematic. We evaluated a two-week course of rifaximin for the treatment of FD.
Aims & Methods: Consecutive subjects with a diagnosis of FD according to the ROME III criteria with a normal gastroscopy were recruited from two centres in Hong Kong. Subjects were randomized into two treatment arms, 400mg three times a day (TDS) of rifaximin or 400mg TDS of placebo. The investigators and study subjects were blinded to the allocation. Subjects were followed for 8 weeks in total. The primary end point of adequate relief of global IBS symptoms and the key secondary end points of adequate relief of bloating or belching, were assessed at week-2, week-4 and week-8. Lactulose hydrogen breath test was performed at baseline and at the end of the study.
Results: A total of 86 subjects were randomized to either rifaximin or placebo. Significantly more subjects in the rifaxmin than in the placebo group experienced adequate relief of global FD symptoms at the end of the study period, week 8 (76.5% vs. 52.6%, $P = 0.04$), with a strong trend in the preceding 6 weeks favouring rifaximin. Rifaximin was also superior to placebo in providing adequate relief of belching and bloating in subjects at week-4 however this improvement did not endure to week-8. Finally, a sub group analysis revealed that female subjects experienced earlier (79.2% vs. 40.6%, $P = 0.006$ at week 4) and more sustained improvements in their global dyspeptic symptoms (80.0% vs. 51.6%, $P = 0.048$ at week 8), as well as improvements in their belching and bloating at week-4. The oro-caecal transit time as measured by the lactulose hydrogen breath test was prolonged in subjects treated with rifaximin compared to baseline however there were no differences between subjects in terms of hydrogen production as measured by area under the curve calculations. The incidence of adverse effects were similar in both groups.
Conclusion: In subjects who met the ROME III criteria for FD, treatment with rifaximin led to adequate relief of global dyspeptic symptoms, belching and bloating. This was particularly marked in female FD subjects.

P1106 ACTIVATION OF DUODENAL BITTER TASTE RECEPTOR BY QUININE HYDROCHLORIDE EFFECTS ON INTRAGASTRIC PRESSURE PROFILES AND NUTRIENT TOLERANCE IN HEALTHY VOLUNTEERS

M. Ottenburgs[1], J. Tack[1], **A. Rotondo**[1]
[1]*KULeuven, Leuven, Belgium*

Contact E-mail Address: alessandra.rotondo@med.kuleuven.be
Introduction: Bitter taste receptors are expressed in the stomach and the duodenum but their function is unclear. We previously reported inhibition of gastric accommodation and nutrient volume tolerance by intragastric administration of bitter tastants[1].
Aims & Methods: We assessed the effects of duodenal infusion of a potent bitter tastant, quinine hydrochloride (QHCl) on intragastric pressure (IGP, a measure of gastric accommodation), nutrient tolerance and satiation.
We conducted a single-blind cross-over trial in healthy volunteers (HVs) with intraduodenal administration (via a feeding catheter) of 10 μmol/kg QHCl or placebo 30 min before the experimental protocol started.
A high-resolution manometry (HRM) probe was placed via the nose till the duodenum in 12 HVs (age 27 ± 3; BMI 22 ± 1). A nutrient drink (ND; 30% fat, 42% carbohydrate, 28% protein) was intragastrically infused (60mL/min) until maximum satiation, when it was stopped. Satiation score was scored every minute on a 0-5 scale. Thereafter, IGP was measured for 2 hours after the meal. During the entire experiment, HVs were asked to their sensations of hunger, appetite and the epigastric symptoms (fullness, bloating, nausea, belching, cramps and pain), every 5 min on a 10-cm horizontal visual analogue scale (VAS).
IGP was measured as average pressure over 5 channels in the fundus at least 1 cm below the LES; 5 minutes before ND start was taken as baseline. All data are expressed as mean $\pm$ SEM. Outcomes of ND tolerance, total area above the curve (AAC) and max IGP drop during ND infusion, AAC of satiation score and VAS during both conditions were compared with a paired t-test.
Results: The intraduodenal administration of placebo or QHCL did not affect baseline IGP profile or symptoms. During the intragastric ND infusion, the IGP decreased initially and gradually increased thereafter in both conditions. QHCl administration failed to affect the max IGP drop (6.4 ± 0.6 mmHg for placebo vs 5.7 ± 0.7 mmHg for QHCl, ns), or the AAC (61 ± 11 mmHg*min for placebo vs 57 ± 12 mmHg*min for QHCl, ns) indicating a lack of an effect on gastric accommodation. Also the post-prandial IGP profile did not differ between both treatment arms. However, satiation scores after QHCl tended to be lower than in placebo (AUC 118 ± 6 ml vs. 107 ± 6 ml; $p = 0.09$) and the volume of ND ingested at maximum satiation was significantly higher after QHCl (835 ± 138 ml vs. 1031 ± 116 ml, $p = 0.05$).
Conclusion: In contrast to intragastric administration effects, intraduodenal administration of the bitter agonist QHCL did not affect gastric accommodation, but tended to inhibit meal-induced satiation and increased nutrient volume tolerance. The mechanism involved in this orexigenic action of intra-duodenal QHCL warrants further study.

P1107 DOES AN IMPAIRMENT OF ANTIOXIDANT CAPACITY IN OBESE HUMAN GASTRIC ANTRUM CAUSE THE ALTERATION IN VASOACTIVE INTESTINAL PEPTIDE (VIP)- PATHWAY?

A. Scirocco[1], M. Carabotti[1], G. Silecchia[1], A. Ignazzi[2], G. Tellan[1], L. Pallotta[1], A. Cicenia[1], M. A. Maselli[2], E. Corazziari[1], C. Severi[1]
[1]*University Sapienza, Rome,* [2]*Irccs "Saverio de Bellis", Castellana Grotte (BA), Italy*

Contact E-mail Address: annunziata.scirocco@uniroma1.it
Introduction: Genome-wide association analysis has identified a relation between obesity and the Vasoactive Intestinal Peptide (VIP) pathway. Obesity is characterized by systemic oxidative stress with an imbalance between the increase in reactive oxygen species (ROS) production and the decrease in cellular antioxidant capacity. Low levels of antioxidant capacity may impair cell signaling pathways in terms of membrane G proteins, second messengers (ie.cAMP) and transcripts encoding for endothelial nitric oxide synthase (eNOS). These signaling pathways and messengers are involved in vasoactive intestinal peptide (VIP), induced relaxation of human gastric antrum.
Aims & Methods: Aim of this study was to evaluate in obese patients oxidant capacity and its influence on antrum smooth muscle relaxation. Smooth muscle cells (SMC) and strips were isolated from human gastric antrum obtained from 14 normoglycemic-normocholesterolemic morbid obese patients (40.92; 372; 56 Antioxidant capacity was evaluated by antioxidant assay kit and the contribution of oxidative stress by the use of Apocynin (APO:1µg/ml) that inhibits NADPH oxidase the main producer of ROS. VIP (1μM) relaxant effects were tested on maximal cholecystokinin (CCK 1nM)-induced contraction on SMC and strips whilst the effect of adenylate cyclase activator forskolin (FSK,10 mM) and the 2nd messenger cAMP (0.1 mM) only on SMC. qPCR analysis was performed for transcripts for VPAC2, inflammatory cytokine (COX-2) and eNOS, the data were normalized to β-actin mRNA levels. Data are expressed as mean $\pm$ SE, $p < 0.05$ considered significant.
Results: Obese gastric muscle presented a low antioxidant capacity (30 ± 12 equivalent of trolox) associated to an hyporesponsiveness to VIP. In obese, VIP-induced relaxation was reduced both in SMC ($14.5 \pm 7.3\%$, $p < 0.05$) and strips ($13.8 \pm 5.2\%$, $p < 0.05$) in comparison to control (SMC:$79.96 \pm 5.78\%$; strips: $78.1 \pm 7.4\%$). This reduced VIP effect was associated in SMC with: 1) a decrease of VPAC2 messenger (obese: 3.63 ± 0.06 vs control: 6.27 ± 0.79, $p < 0.05$); 2) no transcripts for eNOS that was present in control (6.6 ± 0.4); 3) an increase of COX2 messenger (obese: 4.93 ± 0.63 vs control: 1.10 ± 0.08, $p < 0.05$); 4) an impairment of cAMP- and FSK- induced SMC relaxation, in comparison to control (cAMP: 44.9 ± 7.6 vs $73.4 \pm 5.8\%$; FSK: 54.95 ± 2.3 vs $71.80 \pm 11.8\%$, $p < 0.05$). The inhibition of NADPH oxidase by APO partially restores all these alterarations. A 2-fold increase of antioxidant capacity was observed (50 ± 0.5 equivalent of trolox), such as VIP-induced relaxation was restored (79.60 ± 11.84). VPAC2 messenger expression increase (4.02 ± 0.03, $p < 0.05$) as well as eNOS messenger (1.12 ± 0.08, $p < 0.05$).
Conclusion: An impairment of antioxidant capacity in human obese is are involved in alteration of VIP- induced relaxation of gastric antrum.

Contact E-mail Address: bures@lfhk.cuni.cz
Introduction: Tacrine was the first acetylcholinesterase inhibitor approved for therapy of Alzheimer's disease. Tacrine has dose-limiting side effects, including diarrhoea, nausea, vomiting and abdominal discomfort. It has currently been withdrawn in some countries mostly due to the risk of hepatotoxicity and been replaced by its derivate 7-methoxytacrine (7-MEOTA).
Aims & Methods: The aim of this study was to assess the impact of these two compounds on gastric myoelectrical activity by means of surface cutaneous electrogastrography (EGG) in experimental pigs.
Twelve pigs (*Sus scrofa f. domestica*, weighing 30-35 kg) entered the study. A single dose of tacrine (200 mg i.m., $n = 6$) or 7-MEOTA (200 mg i.m., $n = 6$) was administrated. Cholinesterase (acetylcholinesterase and butyrylcholinesterase) activity was determined in whole blood. Acetylcholine iodide was added as a substrate and liberated acetic acid was titrated with sodium hydroxide using an automatic titrator in potentiostatic mode. All EGG recordings were performed under general anaesthesia in the morning after 24 hours of fasting. Basal (30 minutes) and study recordings (150 minutes) were accomplished using an EGG stand (MMS, Enschede, the Netherlands). Running spectral analysis based on Fourier transform was used. Results were expressed as dominant frequency of gastric slow waves, power analysis (areas of amplitudes) and power ratio assessment (ratio of the areas of amplitudes after and before study drug administration).
Results: Maximal inhibition of blood cholinesterase activity was recorded after 10 minutes, being significantly stronger after administration of tacrine ($20.5 \pm 19.2\%$) compared to 7-MEOTA ($72.8 \pm 14.4\%$), $p < 0.001$. Tacrine decreased EGG dominant frequency 10 minutes after its administration (from basal 3.1 ± 0.6 to 2.8 ± 0.6 cycles per minute; $p = 0.014$). Tacrine induced a 60-minute but not significant increase of the power (with maximal value 493 ± 533 μV^2 at 20 minutes; $p = 0.300$) and power ratio (with maximal value 2.04 ± 3.4 at 10 minutes; $p = 0.330$). Tacrine caused significant gastric arrhythmia. 7-MEOTA did not influence dominant frequency of gastric slow waves significantly. 7-MEOTA caused a short-term late increase of the power (from basal 618.3 ± 747.3 to 2540.2 ± 6130.3 μV^2 at 90 minutes; $p = 0.079$) and power ratio at 60 minutes (6.3 ± 11.2; $p = 0.003$). Blood cholinesterase activity did not correlate with any EGG parameter either after tacrine or 7-MEOTA at any time.
Conclusion: Tacrine and 7-MEOTA have different impacts on EGG. Tacrine decreased dominant frequency and induced long-lasting gastric arrhythmia. 7-MEOTA caused a short-term late increase of the EGG power in experimental pigs.

Introduction: Neostigmine is a parasympathomimetic agent that acts as a reversible acetylcholinesterase inhibitor. By interfering with the breakdown of acetylcholine, neostigmine indirectly stimulates both nicotinic and muscarinic receptors. However, there are no data on the direct effect of neostigmine on gastric myoelectrical activity.
Aims & Methods: The aim of this study was to assess the impact of neostigmine on the myoelectrical activity of the stomach by means of non-invasive surface cutaneous electrogastrography (EGG) in experimental pigs. Porcine EGG is fully

comparable with human EGG so it is suitable for various preclinical studies. Six adult female pigs (*Sus scrofa f. domestica*; 3 - 4 months old; mean weight 31.2 ± 2.1) entered the study. EGG recordings were performed under general anaesthesia (2% isoflurane in medicinal oxygen) in the morning after 24 hours of fasting. After the EGG baseline, neostigmine was administrated to the animals (0.5 mg i.m.; *Neostigmini metilsulfas*). EGG was followed by a 90-minute trial recording (MMS, Enschede, the Netherlands). Running spectral analysis based on Fourier transform was used for the evaluation. The results were expressed as dominant frequency of gastric slow waves and EGG power (areas of amplitudes).

Results: Neostigmine continuously increased the dominant frequency from basal EGG 2.6 ± 0.5 cycles per min. up to 2.9 ± 0.6 at the 60-90-minute interval ($p < 0.001$). Neostigmine continually decreased the EGG power from baseline values 1767.4 ± 2179.5 μV^2 (median 861.5) to 594.3 ± 853.8 μV^2 (median 151.0) at the 5-10-minute interval ($p = 0.036$), throughout until the 60 - 90-minute interval 117.6 ± 157.5 μV^2 (median 60.5; $p < 0.001$).

Conclusion: The standard dose of neostigmine significantly increased the dominant frequency of gastric slow waves and caused a continual long-lasting decrease of EGG power in experimental pigs.

Introduction: Previous studies have shown a decrease of nitric oxide (NO) metabolites level in patients with achalasia. However, the relationship between the type of achalasia and the level of plasma total concentration of NO metabolism (nitrates and nitrites) end products remains unknown.

Aims & Methods: to determine association between the type of achalasia and changes of plasma total concentration of end products of NO metabolism. 18 patients with achalasia (median age was 51.5 years (30-72) and 15 healthy volunteers were studied. We performed on every patient a high-resolution manometry (HRM) using a 22 channels silicone water-perfused catheter (Solar GI, MMS, Netherlands), and determined the total concentration of nitrates and nitrites. We analyzed HRM parameters: lower esophageal sphincter (LES) resting pressure (RP), integrated relaxation pressure (IRP), esophageal pressurization and distal contractile integral (DCI) according to the Chicago classification (version 3.0). The statistical analyses were performed using Statistica for Windows 6.0 (StatSoft Inc.).

Results: Type I achalasia was established in 10 patients (55.5%), type II in 5 patients (27.8%), and type III in 3 patients (16.7%). We detected an increase of IRP in all patients (21.0 mmHg (18.0; 35.2); $p < 0.001$), an increase of LES RP in 6 patients (33.3%) - 27.0 mmHg (19.0; 67.4), a decrease of DCI (290 mmHg (0-750)) in 14 (77.8%). Pan-esophageal pressurization revealed in 5 patients (27.8%), hypercontractile contractions in the distal part of the esophagus (DCI 5340 mmHg (3500; 6750)) - in 3 (16.7%). In patients with achalasia in comparison to healthy volunteers, we showed a decrease of NO metabolites (24.2 umol/l (20.5; 30.5) vs 36.8 umol/l (30.8; 48.6); $p < 0.05$). In patients with type II and III achalasia the level of NO metabolites was lower than in control group (25 umol/l (15.0; 33.5) and 22 umol/l (6.9; 30.5), respectively). Patients with type I had a normal trend (33.2 umol/l (29.9; 36.7)).

Conclusion: The level of NO metabolites depends on type of achalasia. Patients with type I achalasia have normal level of NO metabolites, while it is lower in patients with type II and to a greater extent with type III achalasia.

Introduction: Joint hypermobility syndrome (JHS) is a non-inflammatory connective tissue disorder commonly associated with gastrointestinal (GI) symptoms [1]. Ehlers-Danlos syndrome type III is a form of JHS where patients lack the Tenascin X (TNX) gene, an extracellular matrix glycoprotein. Clinically these patients manifest GI symptoms including constipation and rectal prolapse [2]. TNX knockout mice (KO) similarly suffer from rectal prolapse [3]. Previously we have shown TNX associates with vagal afferent calretinin+ nerve endings in wild type (WT) mouse stomach. In colon, TNX strongly associates with cholinergic, ChAT+ myenteric and submucous plexus neurones [4]. Therefore, localisation of TNX around nerve endings in stomach may affect gastric motor function, while association with cholinergic excitatory motor neurons suggests a role in contraction. We hypothesise TNX is important for regulating normal gastric and colonic function.

Aims & Methods: To establish the functional role of TNX in the stomach and colon using TNX KO mice. Methods: Gastric emptying rate was determined using ^{13}C octanoic acid breath test (WT:n = 13, KO:n = 9). From $^{13}CO_2$ curve, T½ (time for 50% of stomach emptying to occur) and T Lag (initial time delay in gastric emptying) were calculated. Colonic motility was assessed by manometry using a multi-lumen catheter, in an *ex vivo* colonic preparation (WT:n = 6, KO:n = 6). The number and amplitude of spontaneous contractions occurring throughout the colon over a 30 min study period were determined. Student's *t*-test was used to calculate statistical significance based on ± SEM for gastric emptying, and 2-way ANOVA for colonic motility.

Results: Gastric emptying was significantly accelerated in KO mice compared to WT (T½: WT = 158 ± 21.8 min vs. KO = 103 ± 12.9 min; $p = 0.0277$). Similarly, T Lag was significantly shorter in KO mice (T Lag: WT = 38 ± 5.7 min vs. KO = 24 ± 2.7 min; $p = 0.0194$). In the two groups colonic motility was measured in the following regions: Proximal, Mid-Proximal, Mid-Distal and Distal colon. Number of spontaneous contractions significantly decreased in all regions of the colon except for the proximal segment in KO mice compared to WT (Proximal: WT = 4.2 vs. KO = 5.6; Mid-Proximal: WT = 11.6 vs. KO = 3.17; Mid-Distal: WT = 11.6 vs. KO = 3.80; Distal: WT = 11.0 vs. KO = 3.20; $p < 0.05$). However, the mean amplitude of contractions significantly decreased only in the distal region of the colon in TNX KO mice (WT = 32mmHg vs. KO = 12mmHg; $p = < 0.05$).

Conclusion: In summary, we have identified two roles for the extracellular matrix glycoprotein-TNX. A loss of TNX causes accelerated gastric emptying which suggests that TNX is important in regulating gastric vagal afferent nerve activity. Also the absence of TNX causes a decrease in colonic contraction indicating TNX is needed to form the extracellular matrix around neurones important for neural communication, particularly in the cholinergic excitatory pathway. Collectively, the anatomical and functional data provide evidence that TNX is important in mediating normal gastric and colonic motor function.

P1112 THE EXPRESSION OF NEUROTROPHINS AND NEUROTROPHIC FACTORS IN THE ACUTE MODEL OF EOSINOPHILIC INFLAMMATION OF THE ESOPHAGUS

Introduction: Eosinophilic esophagitis is characterized by symptoms related to esophageal dysfunction (dysphagia, heartburn, and food impaction). Esophageal nerves regulate esophageal sensory and motor function, and alterations in these nerves are predicted to worsen esophageal dysfunction. However, it is unknown whether the eosinophilic inflammation in the esophagus leads to production of neurotrophins and neurotrophic factors that can induce profound alterations in peripheral nerves.

Aims & Methods: Here we aimed to characterize eosinophilic infiltration in the guinea pig model of acute allergic inflammation of the esophagus, and to evaluate changes in the expression of selected neurotrophins and neurotrophic factors in esophageal mucosa in this model. The antigen ovalbumin (OVA, 0.1% in saline) was injected into the surgically exposed cervical esophagus in the OVA-sensitized guinea pigs. The esophagus (middle portion) was harvested at various time points (2-14 days) and the eosinophil counts were evaluated in transversal sections (12μm) by using Giemsa staining. The expression of neurotrophins (NGF, BDNF) and neurotrophic factors (GDNF, artemin) was evaluated by quantitative RT-PCR. NGF, BDNF, GDNF and artemin were selected because esophageal nerves have receptors for these neurotrophins and neurotrophic factors.

Results: Eosinophils were rare in the esophagus of control naïve animals that received a vehicle injection or no injection. The maximal number of eosinophils per high power filed (hpf) was 5 ± 2 (n = 6). OVA injection into the esophagus in sensitized animals resulted in massive eosinophil infiltration of esophageal mucosa (97 ± 24 eosinophils per hpf, n = 10, $p < 0.05$ vs. control) on day 2 following the injection. The number of eosinophils was reduced on day 5 (27 ± 16, n = 4) and further reduced on day 14 (10 ± 6, n = 3), therefore the day 2 was selected for qRT-PCR analysis. The expression of BDNF was increased in the inflamed compared to control esophagus. dCT (detection threshold expressed relative to detection threshold of housekeeping gene b-actin) was 10.8 ± 0.5 vs. 9.8 ± 0.2 in control (n = 6) and inflamed (n = 7) esophagus, respectively, indicating twofold (ddCT = 1, 2^ddCT = 2) increase in BDNF mRNA ($p < 0.05$). In contrast the expression of artemin was moderately (to approximately 60%) reduced (dCT was 9.0 ± 0.2 vs. 9.7 ± 0.1, ddCT = -0.7, 2^ddCT = 0.6, $p < 0.01$). The expression of NGF (8.8 ± 0.4 vs. 8.7 ± 0.2, p = 0.8) and GDNF (12.5 ± 0.3 vs. 12.3 ± 0.2, p = 0.5) was not changed.

Conclusion: An acute allergen challenge in the esophagus leads to robust eosinophilic infiltration of esophageal mucosa that is associated with changes in the expression of neurotrophins and neurotrophic factors. This model is suitable

for the analysis of esophageal nerve plasticity in eosinophilic inflammation.

Introduction: We have previously shown that meal ingestion induces cognitive perception (sensations) with a hedonic dimension (well-being) that depend on the characteristics of the meal and the appropriateness of the digestive response.
Aims & Methods: The aim of the present study is to identify biomarkers of the cognitive response to meal ingestion.
In 18 healthy subjects, selected through a clinical questionnaire to determine the absence of gastrointestinal symptoms, the response to a test meal (Edanec, 1 kcal / ml) at an intake rate of 50 ml / min until maximum satiety were assessed. Perception measurements and blood samples for metabolomics analysis was taken at 5 min intervals before, during and 20 minutes after ingestion. Perception of hunger/satiety, desire of eating a food of choice, digestive well-being, abdominal fullness and discomfort/pain was measured on 10 cm scales. Metabolomic analysis was performed with MRI spectroscopy. Discriminative metabolites (determined by principal component analysis) were determined and quantified as the area under the peaks of the MRI spectra. Values of glucose, triglycerides, insulin, PYY and GLP-1 were measured using conventional laboratory techniques.
Results: During ingestion satiety progressively increased up to a maximum sensation (+5 score on a scale from -5 to +5) after ingestion of 976 ± 71 ml. Ingestion induced sensation of fullness and decreased digestive well-being. Twenty minutes after the meal, these sensations had partially recovered down to fasting levels. The total amount ingested by each subject correlated with basal sensation of hunger ($R = 0.8$; $p = 0.0001$), but not with other sensations or blood metabolites levels measured during fasting. Immediately after ingestion, satiation correlated with an increase in glucose ($R = 0.49$; $p = 0.038$) and valine levels ($R = 0.48$; $p = 0.043$), while well-being inversely correlated with CH3-lipids ($R = -0.72$; $p = 0.001$). Fullness sensation was associated with lower levels of GLP ($R = -0.77$; $p = 0.001$) and PYY ($R = -0.63$; $p = 0.015$). Twenty-minutes after finalizing ingestion, triglyceride levels had significantly increased and correlated with the decrease in desire to eat a food of choice ($R = -0.56$; $p = 0.016$). Throughout study, the increase in CH2-lipids correlated with lower discomfort ($R = -0.51$; $p = 0.032$).
Conclusion: Cognitive (sensations) and hedonic responses (well-being) to meal ingestion correlate with changes in circulating metabolites, that may serve as objective biomarkers of perception.

P1114 SHORT-TERM NON-INVASIVE AFFERENT VAGUS NERVE STIMULATION (NVNS) USING GAMMACORETM (GC) IN PATIENTS WITH TREATMENT REFRACTORY GASTROPARESIS

E. Paulon[1], D. Nastou[2], F. Jaboli[2], O. Epstein[2]
[1]*Gastroenterology,* [2]*Institute for Minimally Invasive Gastroenterology, London, United Kingdom*

Contact E-mail Address: emma.paulon@gmail.com
Introduction: High-frequency, low-energy gastric neurostimulation(Enterra™) is indicated for compassionate treatment of patients with refractory gastroparesis. Symptom improvement is reported in 50-60% of patients but not accompanied by improved gastric emptying. It is likely that gastric neurostimulation affects the gut-brain axis influencing autonomic afferents (1). GammaCore(electroCore, LLC) is a non-invasive, afferent selective vagus nerve stimulator(nVNS) used for the treatment of migraine and cluster headache. We report the first use of gC in patients with refractory gastroparesis.
Aims & Methods: Thirty-five consecutive patients with intractable gastroparesis were invited to undergo a course of gC whilst awaiting funding for implantable gastric neurostimulation. The gC device delivers a high-frequency, low-energy stimulus to afferent vagus fibers as they cross the neck adjacent to the carotid arteries. The device is programmed to deliver doses of 120 seconds and patients were trained to deliver 2 doses (240 secs) to the left and right vagus nerve respectively. This dosing regimen was self-administered 8 hourly (12 doses/day) for 2 weeks, increasing in week 3 to 3 doses 8 hourly (18 doses/day). Patients were asked to grade their symptoms daily using the 9 item Gastroparesis Cardinal Symptom Index (GCSI)with a 5 point Likert scale. The GCSI was completed for 2 weeks prior to commencing treatment, and throughout the treatment period. Symptom change was evaluated in patients who complied with treatment and completed the daily symptom score. The mean aggregated GSCI score at baseline was compared with the aggregated score of the final week of treatment. Clinically meaningful improvement was defined as a GCSI Likert scale reduction of ≥ 1 (2).
Results: Twenty-three of the 35 patients (65.7%) used the gamma Core as instructed and completed the daily diary. The pre-treatment mean aggregated GCSI score in these patients was 2.85 (SD 0.90). At 3 weeks,8 patients (35%) had a ≥ 1 reduction in the aggregated GSCI score. Two compliant patients who continued stimulation for more than three weeks experienced a delayed response, giving a total response rate of 43%. In 8 of the responders, improvement was evident within 1 week of commencing treatment whilst a response was evident in the 2 patients who continued treatment for >3 weeks by week 5. All the responders experienced symptom recurrence within a week of stopping treatment. No serious adverse events device related were reported.
Conclusion: In this group of patients with treatment refractory gastroparesis, one third failed to engage with short term nVNS. In compliant patients, 43% recorded a fall of ≥ 1 in their aggregated GCSI score. As gC stimulates afferent vagus fibers, it is likely that the response is mediated at the level of the gut-brain axis. In refractory gastroparesis, nVNS delivered by gC might offer a new approach to symptom control. The dosing and duration of nVNS required to obtain an optimal response remains unknown and deserves further consideration.

Introduction: The autonomic nervous system is a bidirectional hierarchically controlled brain body nexus that integrates the external environment with the internal milieu. The parasympathetic nervous system (PNS), whose main neural substrate is the vagus nerve, influences antro-duodenal motility. In animal models, the stimulation of vagal afferents have been shown to enhance antroduodenal motility. Hitherto, the influence of physiological and electrical modulation of vagal tone in humans on antroduodenal motility has not been objectively evaluated.
Aims & Methods: To investigate the synergistic effects of physiological (deep slow breathing (DSB)), and electrical (transcutaneous auricular vagal nerve stimulation (t-VNS)) modulation of vagal tone on antro-duodenal motility. 12 healthy subjects (9 female, median age 52.5 years, range 40-56) were randomized to receive either DSB/active t-VNS or sham-DSB/sham t-VNS in a crossover design. Cardiac vagal tone, a validated real time non-invasive parameter of efferent PNS tone from the brainstem (1), was measured at baseline and continuously thereafter. Antro-duodenal motility was assessed after 90 minutes of stimulation/sham using a validated real-time ultrasonographic method in response to a standardized liquid meal (2).
Results: In comparison to the sham condition, DSB/active t-VNS resulted in an increase in vagal tone (8.7 linear vagal scale +/- 3.8 vs. 6 +/- 3.9, $p = 0.02$). DSB/active t-VNS increased the frequency of antro-duodenal contractions (9.1 contractions/3 minutes +/- 2 vs. 7.1 +/- 1.9, $p = 0.04$) compared to sham. DSB/active t-VNS increased antroduodenal motility index (5.6 +/- 2.5 vs. 3.7 +/- 2.1, $p = 0.048$) compared to sham.
Conclusion: These findings provide preliminary evidence to suggest that DSB/active t-VNS increases cardiac vagal tone. Moreover, antroduodenal motility can be enhanced via physiological and electrical modulation of vagal tone. Such interventions warrant further exploration in patients groups such as those with functional dyspepsia.

Introduction: Gastroparesis is a chronic disorder that significantly impairs the quality of life of affected individuals. However, little is known about the prognosis for morbidity or death of delayed gastric emptying. The aim of study was to evaluate the prognostic value of gastric emptying study on the prediction of morbidity including cardiovascular event.
Aims & Methods: We enrolled 139 patients (93 females, 105 patients with diabetes) with symptoms of gastroparesis, who underwent gastric emptying scintigraphy from 2004 to 2013. Comorbid condition, age, gender distribution were examined as potential risk factors. We evaluated the occurrence of cardiovascular events (coronary artery disease, stroke) and other morbid diseases after gastric emptying scintigraphy.
Results: There were 114 patients with normal gastric emptying (NGE) and 25 with delayed gastric emptying (DGE). The mean age, gender, BMI and distribution of comorbid conditions including diabetes were not significantly different between the two groups. There was more frequent occurrence of cardiovascular event in 'DGE' than 'NGE' (32.0 % vs. 10.5 %, $p = 0.011$). There was more

frequent occurrence of cardiovascular event and other neurologic disease in 'DGE' (40.0% vs. 14.9%, p = 0.009).
Conclusion: A delayed gastric emptying study may predict the occurrence of cardiovascular event and negative outcomes in patients with symptoms of gastroparesis.

P1117 GASTROPARESIS IN CHILDREN: CHARACTERIZATION AND CLINICAL PRESENTATION – A RETROSPECTIVE STUDY

K. Bruil[1,2], T. Catto-Smith[1,2], M. Oliver[1,2]
[1]*Gastroenterology and Clinical Nutrition, Royal Children's Hospital Melbourne,* [2]*Theme Population Health - Gastro & Food Allergy, Murdoch Childrens Research Institute, Parkville, Australia*

Contact E-mail Address: tony.cattosmith@rch.org.au
Introduction: Gastroparesis is commonly diagnosed on the basis of scintigraphy and is associated with symptoms of nausea, vomiting, early satiety and upper abdominal pain. The pathophysiology of this condition in adults and children is not clear and the literature describing the characteristics, aetiology, treatment and outcome of gastroparesis in the paediatric population is limited.
Aims & Methods: Aims of this study were to describe the clinical presentation and aetiology, comorbidities, diagnostic findings, treatments and outcomes in children with scintigraphic proven delayed gastric emptying.
A retrospective descriptive study at the Royal Children's Hospital in Melbourne was performed on patients (0-18 years) with scintigraphy proven delayed gastric emptying (DGE). We collected data from 2004-2008 on the clinical presentation, comorbidities, aetiologic factors, other diagnostic interventions, treatments and outcomes in these children. Sub-group analysis was performed to investigate (a) age and gender related differences in symptoms and comorbidities and (b) differences in outcome based on severity of delayed gastric emptying.
Results: One hundred and five patients were included in our study with 49% being boys and 51% being girls. Median age at presentation was 6.7 years (IQR 1.2 – 12.1). Boys tended to have a lower age at presentation compared to girls. The most common presenting symptoms were vomiting (61%), weight loss or failure to thrive (38%) and regurgitation (23%). Respiratory symptoms were more reported in males and infants. Nausea was more frequently seen in older children and females. Common comorbidities were gastro-oesophageal reflux (50%), respiratory (25%) and neurodevelopmental (21%). An idiopathic aetiology was seen in 74% of children and other causes were medication use, post viral and surgery. Additional investigations performed were a barium meal (71% of children) and endoscopy (66%). Treatment included diet (32%) and medications including a proton pump inhibitor (66%), a prokinetic (73%) and in 51% a combination of both. Over half the cohort had complete or partial resolution of symptoms. No differences in outcome were found with respect to severity of delayed gastric emptying.
Conclusion: Idiopathic gastroparesis was most common in our study group however, a substantial number of patients had a comorbidity. A variety of treatments were used and over half our cohort showed symptomatic improvement. It is important to note that there was no relationship between the severity of an objective test of gastroparesis and resolution of clinical symptoms. Future research is needed to develop a consensus on gastric emptying scintigraphy in children, to define subgroups and their disease mechanisms and to provide parents and doctors with more evidence based management approaches.

P1118 ESOPHAGEAL MOTILITY BEFORE AND AFTER ENDOSCOPIC SUBMUCOSAL DISSECTION FOR SUPERFICIAL ESOPHAGEAL CANCER: A HIGH-RESOLUTION MANOMETRY STUDY

K. Takahashi[1], M. Takeuchi[1], Y. Sato[1], H. Sato[1], K. Mizuno[2], S. Hashimoto[2], M. Kobayashi[2], S. Terai[1]
[1]*Division of Gastroenterology and Hepatology,* [2]*Department of endoscopy, Niigata University Medical and Dental Hospital, Niigatashi, Japan*

Contact E-mail Address: kazuya911@hotmail.co.jp
Introduction: Endoscopic submucosal dissection (ESD) is a standard treatment for superficial esophageal cancer (EC). Postoperative stricture is one of the most common complications in esophageal ESD, and patients with postoperative strictures often suffer from dysphagia. Recently, procedures to prevent strictures, such as endoscopic balloon dilatation (EBD), endoscopic triamcinolone injection (ETI) and oral administration of prednisolone, have made it possible to avoid postoperative strictures more effectively. Nonetheless, some patients complain of dysphagia after ESD, although no postoperative strictures may be present. Although ineffective esophageal motility may be associated with dysphagia after ESD, levels of esophageal motility after ESD remain unknown.
Aims & Methods: The aim of this study was to elucidate the esophageal motility before and after ESD and the cause of dysphagia using high-resolution manometry (HRM).
Fifteen male patients (mean age: 69.8 years) who underwent ESD for superficial EC were enrolled in this study. Patients filled out a questionnaire about dysphagia and underwent HRM before and after ESD. The results of the HRM tests were analyzed according to the metrics and contraction patterns in the Chicago classification, version 3. All results were compared between before and after ESD.
Results: Data were obtained from 14 patients. The average size of the circumferential mucosal defect ratio at ESD was 52.1 ± 19.3% and 2 patients had more than sub-circumferential resection. The distal contractile integrity (DCI) before and after ESD and the frequencies of ineffective or fragmented contractions were not significantly different (1942.4 ± 1692.9 *vs.* 1907.8 ± 1515.9 mmHg-s-cm, $p = 0.826$ and 1.9 ± 2.4 *vs.* 1.9 ± 1.8 times, $p = 0.550$, respectively); however, the patient with sub-circumferential mucosal defect had a reduction in the DCI (before, 966.4 mmHg-s-cm; after, 587.8 mmHg-s-cm) and more frequent ineffective or fragmented contractions (before, 2 times; after, 5 times) after ESD. Furthermore, the patient with circumferential mucosal defects also showed a reduction in DCI (before, 3763.0 mmHg–s-cm; after, 2110.5 mmHg-s-cm) and more frequent ineffective or fragmented contractions (before, 0 times; after, 3 times).
Although no patients had noted dysphagia before ESD, four patients, including two cases with extensive ESD, developed dysphagia after ESD ($p = 0.030$).
Conclusion: Although there were no statistically significant differences between esophageal function before and after ESD, an extensive ESD could affect esophageal function and result in dysphagia. In this study, the number of patients with extensive ESD was small. Therefore, a further prospective study of patients with extensive ESD would be required for definitive conclusions.

Contact E-mail Address: amolbapaye@gmail.com
Introduction: Per-oral endoscopic myotomy (POEM) is an upcoming treatment modality for achalasia cardia. Results of POEM have been encouraging and are comparable to those after laparoscopic Heller's myotomy (LHM) or endoscopic balloon dilatation (EBD). The patients with severe cardio-respiratory diseases are relative contraindications for LHM or EBD. In this multi-center study, we analyzed safety and efficacy of POEM in sub-group of patients with severe co-morbid conditions.
Aims & Methods: Consecutive patients with achalasia cardia confirmed on endoscopy (EGD), high-resolution manometry (HRM) and barium swallow and undergoing POEM at three centers were included. Associated co-morbidities were recorded and graded according to American Society of Anaesthesiology (ASA) classification. Eckhardt dysphagia score was recorded before and after the procedure. Procedure time, technical success and complications were noted. Follow up was by EGD, HRM at 4 weeks and subsequently monthly by telephone.
Results: 61 patients were enrolled. 18 (29.50%) had severe systemic diseases classified as ASA class 3 or 4 and were analyzed. Mean age 57.41 years and females (6). Achalasia types: I – 4, II – 14, III – nil. Median symptom duration: 54 months. Comorbid diseases: cardiac 5 (ischemic heart disease – 4, permanent pacemaker – 1), pulmonary disease – 5 (COPD- 3, interstitial lung disease – 2, thoracic empyema - 1) essential hypertension (11), diabetes mellitus (4), morbid obesity (1). 8 patients (44%) had two or more co-morbid illnesses. Mean preprocedure Eckhardt score – 7.2 (Range 6 – 9); mean LES pressure 36.78mmHg (Range 17.5 – 68mmHg). Mean procedure duration was 117.2 minutes (50 – 270). There were no intra or post procedural complications or deaths. Postoperative hospital stay was < 48 hours for all patients. Clinical success was 100%. At 4-weeks follow up, mean Eckhardt score was 1.42 (1 – 2, p = 0.001) and mean LES pressure 10.06mmHg (4.7 – 19) (p = 0.005). At a mean 9-month follow up, mean Eckhardt score remained at 1.48 (Range 1 – 2).
Conclusion: POEM is safe and effective treatment for achalasia cardia even in patients with severe systemic diseases that may preclude surgical intervention.

P1120 PROTON PUMP INHIBITOR AND SELECTIVE SEROTONIN REUPTAKE INHIBITOR THERAPY FOR THE MANAGEMENT OF NON CARDIAC CHEST PAIN

K. Katopodi[1], N. Viazis[1], **G. Karamanolis**[2], J. Anastasiou[1], K. Denaxas[2], M. Giakoumis[1], T. Koukouratos[1], D. Kamberoglou[2], A. Christidou[1], S. D. Ladas[2], D. G. Karamanolis[1]
[1]*Department of Gastroenterology, Evangelismos Hospital,* [2]*Academic Department of Gastroenterology, Athens Medical School, Laiko General Hospital, Athens, Greece*

Introduction: Although gastroesophageal reflux disease (GERD) constitutes the main cause of non cardiac chest pain (NCCP), administration of proton pump inhibitors (PPIs) benefits only a minority of patients. Our prospective study aimed to evaluate the effect of PPI and selective serotonin reuptake inhibitor (SSRI) therapy on the different subtypes of NCCP patients using multichannel intraluminal impedance and pH monitoring (MI-pH).
Aims & Methods: All patients with NCCP (i.e. at least 3 episodes of chest pain per week in the previous 3 months and exclusion of a cardiac source for the chest pain) underwent impedance and pH monitoring and the total distal esophageal acid exposure and the symptom index for chest pain were calculated. All patients also underwent esophageal manometry and upper endoscopy and were excluded if erosive esophagitis, Barrett's esophagus, eosinophilic esophagitis or motility abnormalities were found. According to the results of the impedance monitoring, patients have been prescribed PPIs twice daily if abnormal distal esophageal acid exposure was noted (group A), citalopram 20mg once daily and PPI once daily if a positive symptom index for chest pain was noted (group B) and citalopram 20mg once daily if a negative symptom index for chest pain was noted (group C). In all cases therapy has been administered

for 8 weeks and treatment success was defined as the complete disappearance of the chest pain.
Results: From March 2014 till March 2015, 66 patients with NCCP were screened for entry into the study. Three were excluded because of motility abnormalities during manometry (n = 1) and the presence of esophagitis (n = 2). Therefore the study sample consisted of 63 patients. From these patients 9 exhibited abnormal distal esophageal acid exposure and received PPIs twice daily (group A), 18 patients had a positive symptom index for chest pain and received citalopram 20mg once daily and PPI once daily (group B) and 36 had a negative symptom index for chest pain and received citalopram 20mg once daily (group C). After 8 weeks of therapy, complete resolution of chest pain was noted in 8 patients of group A (88.9%), in 13 patients of group B (72.2%) and in 24 patients of group C (66.7%).
Conclusion: Using combined impedance-pH monitoring different subtypes of non cardiac chest pain patients could be identified. According to the results of the monitoring patients can receive targeted treatment with PPIs and/or citalopram with a favorable outcome for the great majority of them.

Introduction: Scleroderma esophagus is defined as esophageal disease seen in patients with known scleroderma and is characterized by distal aperistalsis and LES incompetence because of fibrosis of esophageal smooth muscle. The association between scleroderma esophagus and different subgroups of the patients with systematic sclerosis (SSc) is still conflicting.
Aims & Methods
Aim: To assesses factors (cutaneous findings, pulmonary fibrosis, cutaneous ulcers, and computed tomography (CT) findings of esophageal lumen) that are associated with the clinical presentation and esophageal motor dysfunction of scleroderma esophagus.
Methods: Fifty-four SSc patients (48 women, mean age 50.61 ± 11.67) with esophageal involvement underwent clinical interview, medical records review and high resolution manometry (HRM) in a 2-year period study. Patients completed a symptom questionnaire. CT study enrolled totally 27 patients that underwent CT of the thorax at the time of scleroderma diagnosis and thereafter measurement of the diameter of the esophageal lumen at the level of the pulmonary veins origin (normal values were considered > 9mm).
Results: On esophageal manometry, findings revealed a pattern typical of scleroderma esophagus. In the symptom questionnaire responses, the most severe symptom reported was regurgitation, while the most frequent symptom conveyed was heartburn. Between different subgroups of SSc (diffuse *vs.* limited type, with *vs.* without pulmonary fibrosis, with *vs.* without cutaneous ulcers) there was no statistically significant difference in the severity and frequency of esophageal symptoms and in esophageal motility. The only statistically significant difference was observed in patients with esophageal diameter <9mm in CT who reported more severe dysphagia compared to patients with esophageal diameter >9mm in CT (51.2 ± 19.5 vs. 9.7 ± 13.8, respectively, $p < 0.0001$).
Conclusion: Our results did not support the idea that patients with different investigated factors are associated with the clinical and manometric presentations of scleroderma esophagus. Dysphagia is the only symptom that associated with esophageal diameter <9mm in CT. Dysphagia is likely to attribute to progressive fibrosis of esophagus causing stenosis of esophageal lumen.

Introduction: Esophageal hypomotility is a frequent finding in patients with upper GI symptoms, but to date there are not pharmacological options to improve esophageal motor activity. Prucalopride(PRU) is a selective agonist for 5-HT4 receptors, used for the treatment of chronic constipation that stimulates peristalsis and colonic transit. Recent studies suggest a potential role of PRU on esophageal motility, however the data available are limited to animal models. The only evidences in humans are related to a reduced number of reflux episodes in GERD patients and a faster gastric emptying in healthy subjects.
Aims & Methods: Aim of our study has been to determine whether Prucalopride has an action on esophageal body and LES motor activity in patients affected by esophageal weak or ineffective peristalsis. Patients and methods: 6 patients (2 Male, 4 Female) undergoing esophageal High Resolution Manometry (HRM) with detection of low amplitude esophageal body contractility and/or low basal LES tone entered into the study. After basal HRM they received 2mg/day (Q. D.) of PRU half an hour before lunch for 14 days. At the end of the treatment, a second HRM was performed. Waves amplitude and duration, Distal Contractile Integral (ICD) , Basal LES tone, Integrated residual pressure (IRP), distal latency were analyzed to identify possible changes as compared to baseline.
Results: PRU was associated to an increase in basal LES tone as compared to baseline (17.8 ± 4.9 basal vs 24.5 ± 6.8 mmHg after PRU, $p = 0.01$), while no change of esophageal body motility was computed. No side effects were reported.
Conclusion: A short course of Prucalopride 2 mg/day leads to an increase in LES basal tone with no changes in esophageal body motility. The drug was well tolerated. These preliminary data suggest a potential role by PRU in the treatment of patients with a deranged function of the esophago-gastric barrier. Further randomized controlled studies are needed to reinforce this hypothesis.

Introduction: The Chicago Classification (CC) for esophageal motility disorders using high resolution manometry (HRM) is the accepted standard for the diagnosis of disorders of esophageal motility and is based on the analysis of ten 5ml water swallows (WS). It is uncertain if WS are representative of esophageal dysfunction during normal drinking and eating. Indeed, most patients do not receive any explanation for their symptoms with the current standards of using WS alone. Recent papers demonstrate a high rate of symptomatic dysmotility during solid test meal (STM) in patients with proton pump inhibitor (PPI) resistent reflux disease [1] and symptomatic dysphagia post-fundoplication.[2]
Aims & Methods: The primary aim was to compare the frequency of major and minor esophageal motility disorders using WS and STM. The secondary aim was to determine if observations during STM can establish esophageal dysfunction as a cause of dysphagia. Prospective series of patients referred for esophageal HRM between January 2010 and December 2013. WS and STM HRM studies were performed in the upright, seated position. Diagnosis of major and minor esophageal motility disorders were based on CC version 3.0 for water swallows[3] modified for use with solid swallows/test meal as appropriate [1].
Results: 750 consecutive patients (44% male; age 52.5 ± 16.9 years) referred for dysphagia (n = 360 [48%]), reflux symptoms (n = 329 [44%]) and other indications (n = 61 [8%]) were studied. Major esophageal motility disorders were present in 163/750 (22%) WS and 321/750 (43%) STM studies ($p < 0.001$). Conversely, we observed a matching decrease in the proportion of patients with minor esophageal motility disorder diagnosed with STM [152/750 (20%) compared to WS [335/750 (45%) ($p < 0.001$)]. Additionally, whereas symptoms were rare with WS (<1%), close association of dysphagia with dysmotility during STM established the clinical relevance of HRM findings in 245/360 (68%) patients. Patients with major motility disorders were more likely to have dysphagia associated with dysfunction than those with minor motility disorders or normal HRM findings (64% v. 26% v.13%; $p < 0.001$). The most common major dysmotility disorder detected by STM that were missed by WS was outlet obstruction, followed by spasm and hypercontractile dysmotility.
Conclusion: STM increases the diagnostic yield of treatable, major dysmotility by HRM studies compared to water swallows and can establish the association between esophageal dysfunction and symptoms.

Introduction: In recent years several studies have attempted to define the extent of EoE from estimating its epidemiology in different populations, by using different methodological approaches, from population-based studies to others that defined the frequency of EoE in series of endoscopies and esophageal biopsies. Although the results are widely variable, a trend to gradual increase in the prevalence of EoE has been described in recent years according to figures provided by different

authors. However, the epidemiology of EoE and its temporal trends in population-based studies have not been systematically evaluated to date, which prevents us to reliably and accurately estimate the magnitude of the problem.
Aims & Methods: A systematic review and meta-analysis was conducted to provide an accurate estimate of incidence and prevalence rates of eosinophilic esophagitis (EoE).
We search MEDLINE, EMBASE, and SCOPUS databases for population-based studies dealing with the epidemiology of EoE. The pooled incidence and prevalence rates, male-to-female and children-to-adult rate ratios, and geographical and temporal variations were calculated using a fixed or random-effects model.
Results: The search yielded 1,334 references; the final quantitative summary included 13 population-based studies from North America, Europe, and Australia, with the results showing high heterogeneity. The pooled EoE incidence rate was 4.8/100,000 persons/year (95% confidence interval [CI] 2.8–7.2) and was higher for adults (7; 95%CI 1–18.3) than for children (5.1; 95%CI 1.5–10.9).
The pooled prevalence of EoE was 24.7 cases/100,000 inhabitants (95%CI 15.3–36.2), rising to 32.7 (95%CI 18.4–51) in studies with a lower risk of bias. The prevalence was higher in adults than in children (43.4; 95%CI 22.5–71.2 *vs.* 29.5; 95%CI 17.5–44.7, respectively), and in American compared to European studies.
A steady rise in EoE incidence and prevalence rates was observed upon comparison of studies conducted before and after 2008. No significant publication bias was found.
Conclusion: EoE is a common disease that has significantly increased in North America and Europe in the last years. The population-based incidence and prevalence of EoE vary widely across individual studies, potentially because of variations in ascertainment of cases between centers and quality of research. Further large multicenter prospective research is needed to evaluate reported data.

Introduction: In eosinophilic esophagitis (EoE), treatment response is usually monitored by histological assessment of the esophagus, which requires repeated upper endoscopy. Instead, non-invasive biomarkers would be valuable. We thus examined absolute eosinophil count (AEC) and serum levels of Chemokine (C-C motif) ligand (CCL)-17, CCL-18, CCL-26, eosinophil cationic protein (ECP) and mast cell tryptase (MCT) for their utility to monitor treatment response in adult EoE-patients.
Aims & Methods: Venous blood samples of EoE-patients (n = 69) who had randomly received 14 days' treatment with budesonide (n = 51) or placebo (n = 18) were analysed. AEC and serum-CCL-17, -CCL-18, -CCL-26, -ECP and –MCT were measured before and after treatment and were correlated to patients' dysphagia score, endoscopy score and histological esophageal eosinophil density.
Results: Histological remission was achieved in 98% of the budesonide and 0% of the placebo recipients. AEC (380.2 vs. 214.7/cmm, P = 0.0001) and serum levels of CCL-17 (294.3 vs. 257.9 pg/ml, P = 0.0019), CCL-26 (26.7 vs. 16.2 pg/ml, P = 0.0058), ECP (45.5 vs. 27.5 µg/l, P = 0.0016) and MCT (5.3 vs. 4.5 µg/l, P = 0.0019) significantly decreased in budesonide, but not in the placebo recipients. There was no significant change of serum-CCL18. Only AEC significantly correlated with esophageal eosinophil density before (r = 0.28, P = 0.0236) and after (r = 0.42, P = 0.0004) budesonide treatment.
Conclusion: Response to short-term budesonide treatment of EoE can be reflected by AEC as well as by serum marker levels of CCL-17, CCL-26, ECP and MCT. AEC seems to be most valuable, being the only marker, which shows correlation to esophageal eosinophil density.

Introduction: Long-standing eosinophilic esophageal inflammation leads to stricture formation with the inherent risk of food bolus impactions. It is currently unknown if clinicians can rely purely on symptom severity to estimate the endoscopic and histologic activity.
Aims & Methods: We aimed to evaluate the relationship between symptoms, endoscopic and histologic activity. Adult EoE patients were prospectively included (clinicaltrials.gov NCT00939263). Patients completed validated Eosinophilic Esophagitis Activity Index (EEsAI) Patient Reported Outcomes (PRO) instrument that measures symptom severity (7-day recall period). The EEsAI PRO score ranges from 0-100 points. A score from 0-20 points was defined as clinical remission. Patients underwent endoscopy with esophageal biopsy sampling. Endoscopic findings were recorded according to the Endoscopic Reference Score (EREFS). Endoscopic remission was defined as follows: 1) absence of white exudates; 2) absence of moderate and severe rings; 3) absence of strictures; 4) furrows and edema could be present but not in combination. Histologic inflammatory remission was defined as ≤5 eosinophils/high power field (hpf).
Results: A total of 120 adult EoE patients were recruited (61% males, 95% Caucasians, EoE symptom onset > 5 years in 67.2%). Fifty-one patients (42.5%) were in clinical remission. The following frequency of endoscopic findings was found: 13/51 (25.5%) patients had white exudates, 25/51 (49%) had furrows, 24/51 (47.1%) had edema, 23/51 (45.1%) had mild rings, 8/51 (15.7%) had moderate rings, 6/51 (11.8%) had a low grade stricture, and 1/51 (2%) had an intermediate stricture (passage of 8-9 mm-outer diameter endoscope not possible). Histologic remission was found in 23/51 (45.1%) of patients, 8/51 (15.7%) had 6-20 eos/hpf, 14/51 (27.5%) had 21-100 eos/hpf, and 6/51 (11.8%) had > 100 eos/hpf. Only 4/51 (7.8%) patients had eosinophilic microabscesses. Of the 51 patients in clinical remission 25 patients (49%) were in endoscopic remission and 23 patients (45.1%) were in histologic remission. The sensitivity, specificity, positive predictive value, negative predictive value, and overall accuracy of a PRO score ≤20 points to predict endoscopic remission were 64%, 68%, 49%, 80%, 67%, respectively. The sensitivity, specificity, positive predictive value, negative predictive value, and overall accuracy of a PRO score ≤20 points to predict histologic remission were 54%, 64%, 45%, 71%, 60%, respectively.
Conclusion: The EEsAI PRO score with a definition of ≤20 points for clinical remission has a moderate overall accuracy in predicting endoscopic and histologic remission. Thus, in addition to assessing PRO measures, assessment of objective signs of disease activity, including endoscopic and histologic alterations, remains to be an important element in the judgment of overall disease activity.

P1127 MODULATION OF CD8+CELLS INFILTRATION AND ACTIVITY IN EOSINOPHILIC OESOPHAGITIS BY SIX-FOOD ELIMINATION DIET

Contact E-mail Address: marinaforgui@gmail.com
Introduction: Eosinophilic oesophagitis (EoE) is an inflammatory disease of the esophagus histologically characterized by an infiltration of intraepithelial eosinophils. Clinical improvement and histological normalization through an exclusion diet support an allergic origin. However, similarities in the oesophageal transcriptome between allergic and non- allergic patients and the increase in intraepithelial $CD8^+$ leucocytes suggest the existence of additional mechanisms in the pathogenesis of EoE.
Aims & Methods: To identify the role of $CD8^+$ population in the pathophysiology of EoE.
EoE patients (n = 10; age: 33 ± 10 years old) who responded clinically and histologically to a six-food elimination diet (SFED: milk, wheat, egg, fish, legumes, nuts) and healthy controls (C, n = 10; age: 53 ± 20 years old) were selected. Clinical symptoms were assessed by a non-validated score and analysed before and after SFED, and food triggers were identified. The number of eosinophils per high power field (hpf) was quantified after haematoxylin and eosin stainning in oesophageal biopsies of the C group and in the EoE group before and after SFED. The number of $CD8^+$ and $CD2^+$ cells was quantified by area (mm^2). Furthermore, gene expression of specific CD8 molecules (granzyme A, granzyme B and granulysin) and of mucosal migration molecules (α4-integrin and MADCAM1) was evaluated by quantitative RT-PCR in esophageal biopsies of all subjects.
Results: The main symptoms reported by patients were dysphagia (100%), and food impaction (50%). Diet significantly reduced clinical symptoms in all patients. Milk was identified as the trigger food in 50% of the patients.

Oesophageal epithelium of EoE patients presented greater eosinophil (EoE:63 ± 40; C:0/hpf), $CD8^+$ (EoE:512 ± 360; C:84 ± 50/mm^2), $CD2^+$ (EoE:591 ± 342; C:108 ± 50/mm^2) and $CD8^+CD2^+$ (EoE:480 ± 356; C:79 ± 49/mm^2) counts than those in group C ($P < 0.05$). SFED significantly reduced the magnitude of these populations to C values in parallel with the clinical improvement of patients. Gene expression of cytotoxic molecules and markers of cell migration was higher in EoE than in C (1.6 to 26 fold-change; $P < 0.05$) and significantly decreased to C values after SFED treatment.
Conclusion: Reduction of $CD8^+$ number and activity, in association with clinical improvement after SFED, suggest that active cytotoxic mechanisms are present in the oesophageal epithelium and contribute to the physiopathology of EoE.

P1128 THE GERDQ QUESTIONNAIRE DISTINGUISHES PROTON PUMP INHIBITOR-RESPONSIVE ESOPHAGEAL EOSINOPHILIA FROM EOSINOPHILIC ESOPHAGITIS PATIENTS

O. Bartolo[1], S. Tolone[2], C. de Cassan[1], R. Caccaro[1], F. Galeazzi[1], L. Nicoletti[1], R. Salvador[1], M. Costantini[1], E. Savarino[1]
[1]*Department of Surgery, Oncology and Gastroenterology, University of Padua, Padua,* [2]*Department of Surgery, Second University of Naples, Naples, Italy*

Introduction: Eosinophilic esophagitis (EoE) and Proton Pump Inhibitor-response esophageal eosinophilia (PPI-REE) present similar phenotypic appearance, similar histopathology but different response to antisecretory therapy. Indeed, current studies failed to observe clinical features able to distinguish the two entities. However, previous investigations did not systematically assess reflux-related symptoms by means of validated questionnaires. Recently, the GerdQ questionnaire has been validated in comparison with endoscopy and/or pH-testing for the diagnosis of gastro-oesophageal reflux disease (GERD).
Aims & Methods: We aimed to apply GerdQ questionnaire in patients with EoE and PPI-REE to assess whether a prospective and systematic evaluation of reflux symptoms may be helpful to distinguish patients with PPI-REE from those with EoE. Consecutive patients diagnosed with EoE and PPI-REE according to international criteria [a) presence of at least one typical symptom of esophageal dysfunction; b) at least 15 eosinophils per high-power field at mid/proximal esophagus; c) persisting or nor of eosinophils at mid/proximal esophagus after an 8-week PPI trial] prospectively completed a specific GERD-related questionnaire (GERDQ). The GerdQ questionnaire is a simple, self-administered and patient-centered questionnaire including six items[1]. A cut-off value higher ≥ 9 (range of 0–18) was considered diagnostic for GERD. For comparisons, a group of 27 patients with proven reflux disease was used.
Results: Fifty-two consecutive patients with histologically-detected eosinophilic infiltration (>15 eos/hpf) at mid-proximal oesophagus and with symptoms of esophageal dysfunction were included in the study. At the follow-up endoscopy plus biopsy, after 8 weeks treatment with twice-daily PPI, thirty-five (67%) patients were identified as having EoE, whereas 17 (33%) patients were diagnosed with PPI-REE. The two cohorts had similar dysphagia for solids (EoE 74% vs. PPI-REE 76%, $p = 0.651$), bolus impaction (66% vs. 70%, $p = 0.655$), but different heartburn (26% vs. 70%, $p < 0.001$), regurgitation (17% vs. 41%, $p = 0.014$) and chestpain (20% vs. 41%, $p = 0.012$). The overall GerdQ score was statistically lower in EoE vs. PPI-REE [1 (0-6) vs. 8 (2.5-11.25), $p = 0.004$]. When compared to control patients with GERD, both EoE and PPI-REE patients showed increased rate in dysphagia parameters, whereas EoE individuals reported less frequently heartburn (26% vs. 85%, $p = 0.001$), regurgitation (17% vs. 74%, $p = 0.001$) and overall GerdQ scores [1 (0-6) vs. 8 (6-12), $p = 0.001$] than control patients with GERD. In contrast, no difference was found comparing PPI-REE and control patients with GERD for heartburn, regurgitation and overall GerdQ score ($p = 0.176$, 0.192 and 1.000, respectively). Two EoE patients (6%), 8 PPI-REE patients (47%) and 15 control patients with GERD (55%) had a total score equal or above 9 (EoE vs. PPI-REE $p = 0.0001$, EoE vs. GERD $p = 0.002$ and PPI-REE vs. GERD $p = 0.757$).
Conclusion: The GerdQ is a useful complementary tool to distinguish patients with PPI-REE from those with EoE. The implementation of GerdQ could reduce the need for more aggressive therapies (i.e. topical steroids and specialised diets) and improve resource utilisation.

Introduction: Patients (pat.) with eosinophilic esophagitis (EoE) often present with dysphagia and bolus obstruction. Whereas previous investigations using conventional manometry showed no significant changes, data about motility patterns from high resolution manometry (HRM) are rare.
Aims & Methods: To investigate motility patterns of pat. with EoE using HRM in correlation with clinico-pathological subtypes and in comparison controls without dysphagia and normal findings in HRM.
26 (10 female, 16 male, median age: 46.2 range 24-72 years) EoE pat. were included and investigated endoscopically, histopathologically and by HRM while on PPI medication. Diagnosis of EoE was confirmed according to the consensus guidelines 2011. HRM was performed in the upright position according to the Chicago classification system using 10 ml swallows.
26 controls were included (7 female, 19 male, median age: 51.0; range 22-78 years) from the GI lab database. Reason for HRM investigations was mainly clinically suspected GERD. Pat. with large hiatal hernia (>1.5 cm) were excluded. Results from HRM analysis were further correlated with the clinico-pathological EoE subtype (inflammatory (n = 17) vs. fibrotic (n = 9)).
Results: Pat. with EoE presented with significant higher resting pressure of the lower esophageal sphincter (LES) and upper esophageal sphincter (UES) (LES 34.0 vs. 26.3 mmHg, $p < 0.01$; UES: 160.3 vs. 98.3 mmHg, $p < 0.01$) compared with the control group. Further, pat. with EoE frequently showed larger breaks in the 20 mmHg isobaric contour (breaks 20 mmHg 2.5 vs. 0.7 cm, $p = 0.03$). Differences were seen especially within breaks according to the transition zone and to the middle of the peristaltic wavefront (breaks 20 mmHg transition zone 1.2 vs 0.5 cm, $p < 0.01$; breaks 20 mmHg middle 0.8 vs. 0.5 cm, $p < 0.01$. Larger breaks in the transition zone and in the middle of the peristaltic wavefront were also seen in the 30 mmHg isobaric contour by in pat. with EoE (breaks 30 mmHg 2.3 vs. 1.5 cm, $p = 0.01$; breaks 30 mmHg middle 1.1 vs. 0.3 cm, $p < 0.01$). These findings were not associated with a specific clinico-pathological subtype of EoE. For other parameters of HRM (IRP4s, intrabolus pressure, distal contractile integral, contractile front velocity, distal latency) no significant changes were found in pat. with EoE.
According to the Chicago classification system, the diagnosis in HRM varies between normal appearance (n = 11) to hypomotility (n = 10) and EGJ outflow obstruction (n = 5).
Conclusion: Esophageal motor dysfunction is a common phenomenon in pat. with EoE. Breaks of the contractile integrity with hypomotility and impaired bolus transit might explain the appearance of dysphagia in these pat., independant from clinico-pathological subtype.

P1130 THE PREVALENCE OF GASTROESOPHAGEAL REFLUX DISEASE IN PATIENTS WITH IDIOPATHIC PULMONARY FIBROSIS IN KOREA

C. M. Lee[1], D. H. Lee[1], J. J. Hwang[1], H. Yoon[1], C. M. Shin[1], Y. S. Park[1], N. Kim[1]

Contact E-mail Address: gyrzax@gmail.com
Introduction: In the western population, gastroesphageal reflux disease (GERD) is highly prevalent in patients with idiopathic pulmonary fibrosis (IPF). It has been hypothesized that chronic microaspiration due to GERD may cause repetitive subclinical injury to the lung leading to pulmonary fibrosis. Although some studies suggest proton pump inhibitor (PPI) was associated with slower decline of forced vital capacity (FVC), fewer acute exacerbation, decreased radiologic fibrosis and longer survival time in patients with IPF, these effects of PPI remain unclear.
Aims & Methods: The aims of this study were to investigate the prevalence of GERD in patients with IPF in Korean population and evaluate the relation with IPF and GERD or PPI. We retrospectively reviewed a chart of 917 consecutive adult patients with IPF at Seoul National University Bundang Hospital between April 2003 and March 2015.
Results: Mean age ± standard deviation (SD) was 75.5 ± 22.7 years, and 662 (72.2%) were males. Mean duration of follow up was 2.6 ± 2.8 years. Of the 917 patients with IPF, 145 (15.8%) were diagnosed with GERD. Of these 145 patients with GERD, 38 (26.2%) were diagnosed with erosive reflux disease by mucosal breaks and 107 (73.8%) had typical heartburn and/or acid regurgitation with minimal change or normal finding on esophagogastroscopy. In the univariate and multivariate COX regression harzard model, GERD (HR, 0.51; 95% CI, 0.28 – 0.94; $P = 0.030$), including azathioprine (HR, 1.71; 95% CI, 1.05 – 2.77; $P = 0.030$), age (HR, 1.04; 95% CI, 1.02 – 1.06; $P = 0.001$), initial FVC (HR, 0.98; 95% CI, 0.97 – 0.99; $P = 0.001$), hypertension (HR, 0.45; 95% CI, 0.27 – 0.76; $P = 0.003$) and pulmonary hypertension (HR, 4.48; 95% CI, 1.06 – 18.89; $P = 0.041$) was significantly associated with IPF-related mortality. However, there was an inversely association between GERD and IPF-related mortality. In the multivariate logistic regressive analysis, PPI (OR, 1.51; 95% CI, 1.00 – 2.28; $P = 0.048$), including peptic ulcer (OR, 1.71; 95% CI, 1.01 – 2.88; $P = 0.046$), prednisolone (OR, 1.64; 95% CI, 1.10 – 2.44; $P = 0.015$), N-acetylcysteine (OR, 2.32; 95% CI, 1.66 – 3.23; $P < 0.001$), initial FVC (OR, 1.03; 95% CI, 1.02 – 1.04; $P < 0.001$) and period of follow up (OR, 1.09; 95% CI, 1.02 – 1.15; $P = 0.006$) was associated with the aggravation of FVC. In a subgroup of patients with GERD and no history of peptic ulcer, PPI was also significantly associated with the aggravation of FVC (OR, 1.91; 95% CI, 1.32 – 2.76; $P = 0.001$).
Conclusion: In Korean patients with IPF, the prevalence of GERD was relatively lower than in western. Conversely, the IPF related mortality rate was significantly lower in patients with GERD than in patients without GERD. In contrast to prior researches, PPI maybe has no protective effect for aggravation of lung function and mortality.

Introduction: Gastro-esophageal reflux disease (GERD) has been shown to worsen asthma control. But, the relationship between chronic obstructive pulmonary disease (COPD) exacerbations and GERD is less investigated, and there are conflicting results in literature.
Aims & Methods: We aimed to evaluate the presence of GERD and its symptoms in patients with COPD, and its impact on frequent exacerbation of COPD. We included 24 patients with stable mild-moderate stage COPD and 19 healthy volunteers as the control group. The patients using anti-reflux medication, non-invasive mechanical ventilation, and having acute exacerbation of COPD during previous 4 weeks were excluded. To all patients, we applied GERD symptom questionnaire, gastroscopy, high-resolution manometry (HRM) and ambulatory 24-hour pH-impedance study.
Results: Out of 24 patients with COPD, 23 were male. In control group, there were 12 male ($p = 0.14$). The mean age of the patients with COPD was 63 ± 10 years and 44 ± 10 years for the controls ($p < 0.001$). According to GERD questionnaire, only 5 (21.7%) patients had typical GERD symptoms**.** According to 24-hour pH-impedance study, mean DeMeester score was 38.1 in COPD group and 13.3 in the control group ($p = 0.005$). Seventeen (73.9%) patients in COPD group versus 5 (26.3%) patients in control group had pathologic acid reflux ($p = 0.002$). Symptom association probability (SAP) positivity rate was 17.4% ($n = 4$) in COPD group and none of the controls had SAP positivity ($p = 0.11$). Mean proximal extent rate of reflux (Z 17.cm) was 26.4 ± 12 % in COPD group. According to motility results, only 2 (20%) patients in the control group had minor motility disorder, the remainder was normal. On the contrary, 17 (70.8%) patients in COPD group had minor motility disorder, and 4 (16.7%) patients had major motility disorder ($p = 0.001$). Three (12.5%) patients in the COPD group were normal. In COPD group, 14 (58.3%) patients had weak peristalsis with large defects, 3 (12.5%) patients had weak peristalsis with small defects, 2 (8.3%) patients had jack hammer disorder, and 2 (8.3%) had distal esophageal spasm. Proximal extent of reflux was positively correlated with total number of exacerbation of COPD during a year time ($p = 0.039$, $r = 0.443$). Seven patients (30.4%) experienced frequent exacerbations of COPD in the previous year.
Conclusion: Gastroesophageal reflux is frequent in COPD, but only a qaurter of them did have typical reflux symthoms. Motility disorders and GERD was more common in COPD group compared with the controls. Proximal extent of reflux may trigger frequent exacerbation of COPD.

Introduction: Obesity has been recognized as a risk factor for gastroesophageal reflux disease (GERD) and several studies demonstrated positive association between the body mass index (BMI) and GERD symptoms. However, literatures on whether BMI is related to the erosive esophagitis are scant.
Aims & Methods: This study aimed to investigate the effect of BMI changes on the erosive esophagitis. A retrospective cohort study was performed to assess the natural course of erosive esophagitis according to the changes in BMI. A total of 1126 cases of erosive esophagitis were included in this study. The degree of erosive esophagitis was measured by esophagogastroduodenoscopy and serially checked during the follow up period. A Cox proportional hazards model was used to investigate the hazard ratios (HRs).
Results: Of the total 1126 subjects, 906 (80.5%) cases were classified as LA-A, 209 (18.6%) as LA-B, and 11 (1%) as LA-C or LA-D at baseline. During the 5.6 years of mean follow up period, 645 (57.3%) cases showed resolution of erosive esophagitis. Subjects with decreased BMI were associated with resolution of erosive esophagitis compared to those with increased BMI (Hazard ratio [HR] 1.19, 95% confidence interval [CI] 1.02-1.39). Even after adjusting for sex, age, smoking, alcohol consumption, fatty liver status, level of education, and physical activity, the association between the BMI and erosive esophagitis was not attenuated (HR 1.22, 95% CI 1.01-1.46).
Conclusion: Decreasing BMI was significantly and independently associated with resolution of erosive esophagitis.

Contact E-mail Address: aquarious@seed.net.tw
Introduction: Gastroesophageal reflux disease (GERD) is a common disease which can cause troublesome symptoms and affect quality of life. In addition to esophageal complications, GERD may also be a risk factor for extra-esophageal complications. Both GERD and coronary artery disease can cause chest pain and frequently co-exist. A link between the two diseases has been suggested. However, the association between GERD and acute myocardial infarction (AMI) remain unclear.
Aims & Methods: The purpose of the study was to investigate the incidence of acute myocardial infarction in GERD patients and to compare it with that in an age- and sex-matched general population free of GERD. We also investigate the association between the risk of myocardial infarction and the use of acid suppressing agents in the cohort of GERD patients.
We identified patients with GERD from the Taiwan National Health Insurance database. The study cohort comprised 57,189 newly diagnosed GERD patients; 271,862 randomly selected age-, gender-, comobidity-matched subjects comprised the comparison cohort. Patients with any known prior coronary or peripheral arterial disease were excluded. Incidence of new AMI was studied in both groups.
Results: A total 1236 (0.5%) of the patients from the control group and 371 (0.7%) patients from the GERD group experienced AMI during years of follow-up. After Cox proportional-hazard model analysis, GERD was independently associated with increased risk of developing AMI (hazard ratio, 1.48; 95% confidence interval, 1.31–1.66, $p < 0.001$). Within the GERD group, subjects who were prescribed proton pump inhibitors (PPIs) for more than one years had decreased the risk of developing AMI, compared with those without taking PPIs (hazard ratio, 0.57; 95% confidence interval, 0.31–1.04, $p = 0.066$).
Conclusion: The large population-based study demonstrates an association between GERD and future development of acute myocardial infarction. Further prospective studies are needed to evaluate if anti-reflux medication may reduce the occurrence of acute ischemic event in GERD patients.

P1134 REFLUX ESOPHAGITIS IS POSITIVELY CORRELATED WITH FUNDIC GLAND POLYPS——A CASE-CONTROL STUDY

Y. Wang[1], L. Lin[2], L.-Y. Zhou[1], S.-R. Lin[1]
[1]*Peking University Third Hospital,* [2]*Beijing Shijitan Hospital, Beijing, China*

Contact E-mail Address: pksunking@live.cn
Introduction: Fundic gland polyps (FGPs) is the most common type of gastric polyps, and was associated with chronic proton pump inhibitor (PPI) therapy. Most patient receive long-term PPI because of GERD, so whether FGPs is associated with PPI or GERD itself is a question.
Aims & Methods: This study aimed to elucidate the correlation between FGPs and GERD.
This case-control study included patients with FGPs (cases) and those without FGPs (controls). Consecutive patients (≥16 years of age) who agreed to complete a self-reported questionnaire and then undergo an upper endoscopy were enrolled. Patients who had undergone proton pump inhibitor (PPI) treatment for >8 weeks, had a history of familial adenomatous polyposis (FAP), or did not undergo the biopsy were excluded. The risks of sex, age, reflux symptoms, *Helicobacter pylori* infection, non-atrophic gastritis, reflux esophagitis, peptic ulcer disease, or upper gastrointestinal malignancy were assessed (odds ratio [OR] and its corresponding 95% confidence interval [CI]).
Results: A total of 4,250 patients were analyzed, including 288 with FGPs (cases) and 3,962 (controls) without FGPs. The patients with sporadic FGPs had an OR of 2.178 (95%CI, 1.613-2.941, $P < 0.001$), 1.037 (95%CI, 1.027-1.046, $P < 0.001$), 1.039 (95%CI, 0.998-1.082, $P = 0.065$), 0.970 (95%CI, 0.713-1.321, $P = 0.848$), 0.197 (95%CI, 0.121-0.321, $P < 0.001$), 1.993 (95%CI, 1.498-2.651, $P < 0.001$), 1.451 (95%CI, 1.031-2.043, $P = 0.033$), 0.782 (95%CI, 0.410-1.491, $P = 0.455$), and 0.265 (95%CI, 0.036-1.953, $P = 0.192$) for female gender, advanced age, BMI, GerdQ score ≥ 8, *H. pylori* infection, non-atrophic gastritis, reflux esophagitis, peptic ulcer disease, and upper gastrointestinal malignancy, respectively.
Conclusion: Reflux esophagitis is positively correlated with FGPs development. Female gender, advanced age, and non-atrophic gastritis are all risk factors of FGPs development. *H. pylori* infection is negatively correlated with FGPs development.

Introduction: Esophageal adenocarcinoma (EAC) microenvironment is characterized by lack of cytokines with anti-cancer effect and by high expression of immuno-suppressive factors. HER2 over-expression is associated to worse

prognosis in esophageal adencarcinoma and it is related to the depth of invasion, nodal and distant metastasis. Similarly, p53 overexpression is associated to poor disease free and overall survival.
Aims & Methods: Our aim was to evaluate the possible relationships between HER2 and p53 overexpression in esophageal cancer and the antigen presenting cells (APC) and lymphocyte function in esophageal cancer.
Mucosa samples from cancer and from healthy esophagus were obtained during esophagectomy from 64 adenocarcinoma. Frozen samples were analysed with Real Time qPCR for costimulatory molecules (Cd80, Cd86), and lymphocytes activation (Cd38, Cd69) genes expression. Immunohistochemistry for HER2 and nuclear p53 expression, CD8 and NK cells cytolytic activity (CD107a) of tumor infiltrating lymphocytes and for CD80 was performed. Non parametric statistics was used.
Results: In patients with EAC, HER2 overexpression, CD80 and CD86 expression and CD8 + lymphocyte infiltration and activation were not different than in those who without it. HER2 overexpression correlated inversely with the presence of necrosis within the tumor (tau = -0.18, p = 0.46). In patients with EAC nuclear p53 overexpression, CD69 mRNA expression within the tumor was lower than in those without it (p = 0.038 and p = 0.014, respectively). On the contrary, CD80 and CD86 expression and CD8 + lymphocyte infiltration were not different in the two groups.
Conclusion: In EAC, HER2 overexpression does not seem to affect immune surveillance mechanisms based on CD80-CD28 signaling and CD8 lymphocyte activation. Its effect on invasiveness seemed to be more related on tumor cell immortalization. On the other hand, nuclear p53 overexpression within the tumor seem to inhibit lymphocyte activation suggesting a possible role in tumor immune modulation.

Introduction: The incidence of oesophageal adenocarcinoma (OAC) continues to rise rapidly. A clinically relevant animal model of OAC is needed to help study the effectiveness of novel therapeutic strategies for OAC. Current animal models have many limitations. Models that involve the injection of cells into the flanks of rodents do not replicate the native environment of OAC. Surgical models producing permanent biliary reflux that can lead to cancer are limited by the need for highly skilled surgical techniques, difficult reproducibility and significant morbidity to the animals involved. We describe a novel orthotopic tumour model for OAC. Our model is based upon the injection of tumour cells into the rodent oesophagus under direct endoscopic visualisation.
Aims & Methods: Two human tumour cell lines were used – OAC (OE19) and colon adenocarcinoma (HT29). Both lines were stably transfected to express luciferase and maintained in 5% CO2 at 370 C. 6-8 week-old female nude athymic rats (RNU Rat) were used for all experiments. A high-resolution diagnostic endoscope was used to perform all endoscopic procedures. Animals were anaesthetised using Isoflurane with concomitant oxygen given. Under direct visualisation, OE19 or HT29 tumour cells were injected. Immediately after endoscopy, 1ml of D-Luciferin (20mg/ml) was injected i.p. to follow luciferase-expressing OE19/HT29 tumour implantation. After 15 minutes, rats were inserted into a whole body cooled charged-coupled device (CCD) camera Photon Imager system and images obtained. All animals had Bioluminescent imaging (BLI) and endoscopy performed regularly to look for evidence of tumour growth.
Results: Implanted tumour cells were detected immediately after injection using BLI. Weekly, non-invasive BLI and regular endoscopic observation detected successful orthotopic tumour growth. Histological tissue samples confirmed the presence of tumour ulcerating the overlying squamous mucosa and infiltrating into, and through, the muscularis propria. This mirrors closely the behaviour of a primary human OAC.
Conclusion: We have developed a novel, more clinically relevant, orthotopic tumour model for OAC. By utilising rodent gastroscopy, our model replicates the native environment in which OAC grows and provides an opportunity for us to better understand the natural history of OAC in a manner that confers considerably less morbidity to animals than current models allow.

P1137 HOW OFTEN IS UPPER GASTROINTESTINAL CANCER MISSED DURING ENDOSCOPY? DATA FROM A DISTRICT GENERAL HOSPITAL (DGH)

A. Vaziri[1], D. Morris[1]
[1]*Gastroenterology, East and North Hertfordshire NHS Trust, Stevenage, United Kingdom*

Contact E-mail Address: arashvaziri86@gmail.com
Introduction: Recent studies report between 6 to 14% of patients with a gastric and oesophageal cancer had an oesophagogastroduodenoscopy (OGD) up to three years prior to diagnosis that did not report malignancy. This has prompted a national effort to improve the quality of OGD. We have examined our records from a DGH which serves a population of 500,000 patients to assess how often cancers could be missed and whether there are any factors which are associated with this. We define a possible missed cancer as one where there was a previous endoscopy within the last 3 years.
Aims & Methods: Our aim is to achieve quality improvement to OGD via the analysis and modulation of contributing variables. We retrieved computerised records of 65 patients diagnosed with gastric and oesophageal cancer over a year from between April 2013 and April 2014. We investigated our endoscopy database for whether the patients had endoscopies within the last 3 years. We reviewed the previous endoscopies for a number of factors including the age of the patient, the grade of the endoscopist, the finding at prior endoscopy, the number of biopsies taken and the pathology report at any noted abnormal sites, the use of sedation for the patient, the comfort scores and the urgency of the procedure. We then compared the results of this analysis with a comparison group of all the patients who had been diagnosed as having oesophageal or gastric cancer at their first endoscopy.
Results: There were 48 oesophageal cancers and 17 gastric cancers. In 6 (9.2%) of these cases there had been an endoscopy within the preceding 3 years. The average age of patients in the missed cancer group and comparison group were 71 and 69.6 respectively.
A greater proportion of patients in the missed cancer group were sedated (100% vs 69%). A smaller proportion of patients in the missed cancer experienced moderate or severe discomfort (0% vs 13.6%). In the missed cancer group a greater proportion of patients were on the emergency endoscopic bleed list (33% vs 7%). In both the missed cancer and the comparison group the proportion of endoscopies performed by Consultant Gastroenterologist was approximately 67%.
An analysis of the missed cancer cases found that in all 6 cases an abnormality had been noted in the area where the cancer was subsequently found. 3 of these cases had Barrett's oesophagus in all cases multiple biopsies were performed and interval repeat endoscopy was arranged. In one case the endoscopist described a benign oesophageal stricture and did not biopsy, repeat biopsy 8 month later demonstrated malignancy. In 2 cases inflammation was noted at the lower oesophagus and stomach; firstly in the form of a malignant 4cm GOJ polyp and secondly in the form a malignant gastric ulcer. In the oesophagitis case no biopsies were taken and in the gastritis case biopsies suspected Iron pill gastritis.
Conclusion: In a small but important number of patients we potentially miss cancer at OGD. In our analysis the performance of the OGD for acute haemorrhage and not taking a biopsy were associated with missing cancers. There did not seem to be a negative association with the use of sedation, the discomfort of the patient or seniority of endoscopists. We will be continuing to monitor our 'missed cancer' rate and promote quality OGD by emphasising the importance repeating endoscopies limited by bleeding and the sampling of abnormal sites.

Introduction: In the recent decades, the incidence of adenocarcinomas of the esophagogastric junction (AEGJ) has significantly increased. There are some disagreements regarding its pathogenesis, classification and approach. According to the Siewert classification, there are 3 types of AEGJ, depending if the lesion's epicenteris located 5cm above the esophagogastric junction (EGJ) (I), in the EGJ (II) or 5cm below it (III). The protocol of our institution establishes that AEGJ type I should be treated as esophageal cancer and the AEGJ II/III as gastric cancer, with similar treatment protocol.
Aims & Methods
Aim: To analyze the clinical characteristics and survival outcomes in AJEG II and AJG type III tumours.
Methods: Retrospective analysis of consecutive patients with EGJ II/III tumours referred from Mar/2009 to Jun/2014 followed by our institution's multidisciplinary team. Clinicopathological characteristics and survival were analyzed. Statistics: chi-square test (categorical data). Kaplan–Meier curves/log-rank test (survival outcome), and log-rank test (statistical significance).
Results: A total of 109 patients (EGJ II n = 50; EGJ III n = 59) were included , 75 men, with a mean age of 66 ± 13 years. Demographic features were comparable between the two groups.
Eighty five patients had intestinal type adenocarcinoma and 24 had poorly cohesive carcinoma. This last histologic pattern was more frequent in EGJ III tumors (p = 0.037). AEJG cancer staging: I (7/109), II (46/109), III (20/109) e IV (36/109). Eleven patients were submitted to surgery only, 26 underwent surgery plus perioperative chemotherapy, 16 completed neoadjuvant chemotherapy before the surgery and palliative treatment in 54 patients. There were no differences regarding staging and treatment between the two groups.
The degree of tumor regression induced by chemotherapy and evaluated in the surgical specimen was similar between the groups (p = 0.589). For EGJ II and EGJ III tumors, the 36 months overall survival rate was 28.9% versus 29.4 %, respectively (p = 0.733). In the subgroup of patients treated with curative intention, the 36 months overall survival rate was 46.7% versus 49.8 %, respectively (p = 0.90).
Conclusion: In our series, there were no differences in clinicopathological characteristics and survival outcomes in EGJ II and EGJ III tumors, except for histological pattern with poorly cohesive carcinoma being more frequently

found in EGJ III tumors. We consider that despite a possible distinct pathogenesis, these tumors have similar clinical behavior.

Introduction: 5-fluorouracil (5-FU) and platinum-based chemotherapy (CT) is considered as a standard of care in first line treatment of metastatic oesophageal squamous cell carcinoma (SCC). Few data, essentially with taxane regimens, are available on the efficacy and toxicity of a second-line treatment. We therefore conducted a study to assess the efficacy and toxicity of second-line CT in such patients after progression during first line CT with 5-FU plus platinum.
Aims & Methods: Between January 2003 and December 2013, every patient from eleven medical centers with a metastatic or unresectable locally advanced oesophageal SCC who received a second line therapy after progression while on 5-FU and platinum (Cisplatin or Oxaliplatin) CT were retrospectively included. We collected and compared the data on overall survival (OS), progression free survival (PFS) and toxicity, using the NCI classification, from the beginning of the second-line for all patients and specifically for patients treated with Taxane (Paclitaxel or Docetaxel) or Irinotecan-based regimens.
Results: 68 patients (OMS 0-1 : 87%) were included : 51 (75%) received a second line CT with a taxane-based (22) or irinotecan-based regimen (29), and 17 received another CT regimen. Among these 51 patients, the median OS was 7.9 months and median PFS were 4.9 months. The 22 patients treated with Taxane had an OS and PFS of 7.5 months and 3.9 months respectively. The patients treated with Irinotecan-based chemotherapy had an OS and PFS of 8.7 months and 5.4 months respectively. The difference was not statistically significant between the two groups of patients ($p = 0.28$). One year survival rates was 32% for all patients (41.3% for Irinotecan-based CT group and 14.4% for Taxane group). The rates of severe toxicity (grade 3-4) and discontinuation of treatment related to toxicity were similar in the two groups. No toxic death was observed.
Conclusion: In this study, patients treated with a second-line therapy after progression under 5-FU and platinum CT, achieved a median OS of 7.9 months. Irinotecan and taxane based regimens showed no major differences in terms of toxicity and efficacy. These two types of regimen could be used in patients with good performance status. Prospective studies are necessary to determine which treatment would be the most appropriate.

P1140 A COMPARATIVE STUDY COMPARING A NEW ANTI-REFLUX STENT TO A CONVENTIONAL OPEN STENT IN THE PALLIATION OF DISTAL OESOPHAGEAL CANCER

C. Kanagasundaram[1], J. Segal[2], A. Leahy[1]
[1]*Gastroenterology, Watford General Hospital, London,* [2]*Gastroenterology, Lister Hospital, Stevenage, United Kingdom*

Contact E-mail Address: cynthia_kanagasundaram@hotmail.com
Introduction: Oesophageal cancer is the sixth most common cause of death from cancer in the United Kingdom and worldwide. It accounts for 7,701 deaths in the UK in 2012.[1] Oesophageal cancer has a poor prognosis with a 5 year survival rate of 10-15%.[2,3] Unfortunately, greater than 50% of patients have unresectable cancers at presentation and most of these will go onto develop progressive dysphagia.[4]
There are various therapies to palliate dysphagia, oesophageal stenting has now become the main treatment option of choice for palliative oesophageal malignancy. Oesophageal intubation with a self-expanding stent is the treatment of choice for stenosing tumours, where rapid relief of dysphagia in a one stage procedure is desirable.[5] There have been various stent designs marketed that incorporate an anti-reflux valve stent with a view to reducing this complication. Currently the British Society of Gastroenterology concluded that anti-reflux stents confer no benefit above standard stents.[5]
Aims & Methods: To compare a new anti-reflux stent with a conventional open stent in the palliation of patients with distal oesophageal cancer. This is a prospective study involving 40 patients with cancer involving the gastro-oesophageal junction. All patients will have been deemed inoperable within the local multi-disciplinary team meeting. Patients will receive either an anti-reflux stent (cardia-valve stent, Premier endoscopy) or a conventional open stent (ultraflex, Boston Scientific). All stents will be partially covered and placed across the gastro-oesophageal junction.
Quality of life will be measured and analysed using the oesophageal module European Organisation into Research and Treatment of Cancer questionnaire (EORTC QLQ-OES18). The questionnaires will be recorded by the attending endoscopist/physician at weeks 0 and 1. Differences between groups will be statistically evaluated by the Mann-Whitney test.
Results: There were 15 Ultraflex stents and 8 Cardiovalve stents that were followed up. Baseline EORTC QLQ-OES18 showed no significant differences in baseline scores (the Z-Score is -0.7423, the p-value is 0.4593).
At week one follow up there was no significant differences in the EORTC QLQ-OES18 between the two groups. The Ultraflex group had a EORTC QLQ-OES18 increase score of 38 compared with a 0 increase in overall score in the Cardiovalve group (The Z-Score is -0.3151. The p-value is 0.74896).
Conclusion: There was no significant differences in EORTC QLQ-OES18 scores between the two groups at week one suggesting that the stents appeared have similar quality of life profiles at week one post insertion. This is a small study and longer time follow up data is currently ongoing with 3 month follow up data of 40 patients currently being analysed.

P1141 COMPARISON BETWEEN ARGON PLASMA COAGULATION AND SELF-EXPANDABLE METAL STENT PLACEMENT IN THE PALLIATIVE TREATMENT OF INOPERABLE OESOPHAGEAL CANCER

D. E. Sigounas[1], C. Krystalis[1], G. Couper[2], S. Paterson-Brown[2], J. N. Plevris[1]
[1]*Centre for Liver & Digestive Disorders,* [2]*University Department of Surgery, Royal Infirmary of Edinburgh, Edinburgh, United Kingdom*

Contact E-mail Address: J.Plevris@ed.ac.uk
Introduction: Self-expanding metal stents (SEMS) are the main palliative modality used in inoperable oesophageal cancer[1]. Other palliative options, including Argon plasma coagulation (APC), have been used and found effective[2]. Comparative studies between those modalities are scarce and the preference of SEMS as the palliation modality of choice is not based on solid evidence.
Aims & Methods: The aim of this study was to assess the relative efficacy of SEMS and APC in inoperable oesophageal cancer palliation, in terms of survival. This was a single centre, retrospective analysis of all patients ($n = 233$) with inoperable oesophageal cancer not receiving chemo-radiotherapy, treated with SEMS ($n = 163$) or APC ($n = 70$) as primary palliation modalities, between January 2000 and July 2014. Patient characteristics were retrieved from hospital records and Charlson Comorbidity Score (CCS) was calculated. Kaplan-Meier curves were created for each treatment modality and survival intervals were compared by the log-rank test separately for stage III and IV disease. A further analysis was performed after excluding patients surviving less than a month in order to minimize any potential selection bias.
Results: Patients having APC as primary treatment were older (median: 80 Vs 76 years, $p = 0.01$) and had a higher CCS (median 1 Vs 0, $p = 0.02$) compared to SEMS, but still had a significantly better survival. Median survival for patients treated with APC and SEMS was 257 (Interquartile range-IQR: 137, 414) and 151 (IQR: 61, 241) days respectively in stage III disease while it was 135 (IQR: 43, 238) and 70 (IQR: 32, 148) days respectively in stage IV disease. Both differences were statistically significant (0.02 and 0.05 respectively). After excluding patients not surviving more than a month, median survival in stage III patients was 257 (IQR:137,414) days for APC, compared to 162 (IQR: 100,285) for SEMS and in stage IV disease, median survival was 166 (IQR: 111,243) days for APC compared to 97 (IQR: 59,164) for SEMS. The difference was statistically significant in stage III ($p = 0.04$), whereas it was not in stage IV ($p = 0.07$).
Conclusion: Thsi study provides evidence that using APC as the primary palliation modality may significantly improve survival compared to SEMS in inoperable oesophageal cancer when patients are not candidates for chemo-radiotherapy. Further prospective studies to confirm those findings are needed.

P1142 LEARNING CURVE FOR DETECTING SUPERFICIAL HEAD AND NECK CANCER DURING SURVEILLANCE USING NARROW BAND IMAGING ENDOSCOPY

H. Morimoto[1], T. Yano[1], M. Imajoh[1], K. Tomohiro[1], S. Oosera[1], Y. Oono[1], I. Ikematsu[1], K. Kaneko[1]
[1]*Endoscopy Division, National Cancer Center Hospital East, Kashiwa, Japan, Chiba, Japan*

Contact E-mail Address: hmorimot@east.ncc.go.jp
Introduction: Narrow-band Imaging (NBI) is effective in detecting superficial head and neck squamous cell carcinoma (HNSCC) in patients with esophageal squamous cell carcinoma (ESCC), and we introduced the surveillance for HN region using NBI for all patients with ESCC before treatment. However, skilled endoscopic technique is necessary to survey pharyngo-laryngeal region and detect the superficial cancer during upper GI endoscopy, and detection rate of superficial cancer by beginner endoscopists is unknown. The aim of our study was to compare the performance in detecting HNSCC between beginner endoscopist and expert, and investigate detection leaning curves in beginner.
Aims & Methods: ESCC patients who fulfilled the following criteria, and underwent surveillance for pharyngo-laryngeal region using per oral endoscopy with NBI between January 2011 and March 2015 were recruited from our database, (1) initially diagnosed ESCC; (2) initial endoscopic examination with NBI in our hospital; (3) no history of any HNSCC; (4) no synchronously HNSCC was detected in previous hospital. All patients provided written informed consent before examination.
We compared the detection rate of HNSCC during initial endoscopic examination between beginner (less than 1 years' experience of surveillance) and expert (at least 3years' experience), and between the first 3 months of beginner 's first year (period A) and 3 to 12months (period B).
Results: 747 patients (median age 68) were enrolled, and total 36 endoscopists (26 beginners and 10 experts) performed the surveillance endoscopic examination. A total of 63 HNSCCs were detected in 47 patients (6.3%) and all of the lesions were superficial cancer. The lesions were located in hypopharynx ($n = 39$), oropharynx ($n = 19$), and larynx ($n = 5$). HNSCC detection rate was 4.4% in beginner and 7.1% in expert, ($p = 0.19$). No beginner could detect superficial HNSCC in the first 3 months (period A), but detection rate was 5.9% during period B ($p = 0.069$). In period A, detection rate of beginners was significantly lower than that of expert (0% vs 7.1%, $p = 0.040$), however, there was no significantly deference between beginners and experts during period B (5.9% vs 7.1%, $p = 0.73$).
Conclusion: Detection of superficial HNSCC during endoscopic surveillance with NBI might be difficult for novice endoscopists. However, detection rate was improved and almost as same as an expert after 3 months of intensive endoscopic training.

P1143 CLINICAL OUTCOMES OF PERORAL ENDOSCOPIC MYOTOMY FOR ACHALASIA DEPEND ON MANOMETRIC SUBTYPE

J. Y. Cho[1], W. H. Kim[1], K. B. Hahm[1], K. H. Ko[1], S. P. Hong[1]
[1]*Digestive Disease Center, CHA Bundang Medical Center, CHA University, Seongnam-si, Korea, Republic Of*

Contact E-mail Address: cjy6695@dreamwiz.com
Introduction: Peroral endoscopic myotomy (POEM) is known to be safe and effective endoscopic surgery compared with surgical myotomy for achalasia patients. A higher percentage of patients with type II achalasia successfully treated with laparoscopic Heller myotomy than patients with types I and III achalasia.
Aims & Methods: We evaluated whether manometric subtype was associated with response to treatment in a patients treated with POEM. Esophageal pre-treatment manometry data were collected from 53 cases that was performed POEM from November 2011 to August 2014 at two tertiary referral centers. Manometric tracings were classified according to the 3 Chicago subtypes.
Results: Among 53 cases, 35 type 1, 8 type 2 and 10 type 3 achalasia were included. There was no difference in pre-POEM Eckardt score, basal LES pressure, and integrated relaxation pressure (IRP) between type 1, type 2 and type 3 group (6.1 ± 3.9 vs. 8.4 ± 3.6 vs. 6.6 ± 3.4; $p = 0.215$, 27.3 ± 29.8 vs. 39.7 ± 12.3vs. 34.1 ± 32.8mmHg; $p = 0.089$, and 23.4 ± 29.6 vs. 30.1 ± 14.9vs. 19.2 ± 28.8mm Hg; $p = 0.709$). All patients showed a significant improvement in Eckardt score after POEM during median follow-up of 16 months (6.1 ± 3.9vs. 0.6 ± 2.4; $p < 0.001$, 8.4 ± 3.6 vs. 0.6 ± 1.4; $p = 0.008$, 6.6 ± 3.4vs1.0 ± 2.0; $p < 0.001$). But there was difference in decreased degree of Eckardt score between type 1, type 2 and type 3 group ($p = 0.637$), LES pressure was significant decrease only for type 2 group (23.5 ± 16.3 vs.16.1 ± 12.4; $p = 0.113$, 39.7 ± 12.3 vs. 19.5 ± 4.4;$p = 0.029$, 34.1 ± 32.8 vs. 16.8 ± 17.2; $p = 0.421$). IRP score was significant decrease only fortype 1 group (23.4 ± 18.3vs.11.0 ± 9.5;$p = 0.014$, 30.1 ± 14.9vs. 12.50 ± 7.5; $p = 0.057$, 19.0 ± 29.0vs. 11.6 ± 12.3; $p = 0.886$).
Conclusion: POEM showed good clinical outcomes in any manometric subtype. In the future, large prospective study is needed to confirm that POEM can be considered as standard treatment in any subtype of achalasia patients.

Introduction: Circumferential resection margin (CRM) involvement is universally regarded as a poor prognostic indicator in both oesophageal and rectal cancer surgery, but prediction of threatened CRM in the former is challenging. MRI accurately predicts CRM involvement in rectal cancer, but has proved technically difficult in oesophageal cancer.
Aims & Methods: The study aims to test the association between PET/CT defined tumour variables and CRM positivity. Prospectively collected data on 95 consecutive patients (median age 65 (range 24-82), 74 male, 85 adenocarcinoma, 9 SCC, 1 HGD) with FDG-avid oesophageal and junctional tumours, initially treated with surgical management +/- neo-adjuvant therapy were included. Five PET/CT defined variables; SUVmax, metabolic tumour length (MTL), metabolic tumour width (MTW), metabolic tumour volume (MTV) and total length of nodal disease (NLoD), were entered into a binary logistic regression model. Primary outcome was CRM positivity.
Results: Twenty-five patients had surgery alone, 65 received neo-adjuvant chemotherapy and 10 received neo-adjuvant chemo-radiotherapy. CRM was positive in 57.9%. A statistical trend was observed between MTW and CRM involvement in all patients (HR 0.68 (95% CI 0.44-1.04); $p = 0.07$). MTW was independently and significantly associated with CRM positivity in 60 patients treated with neo-adjuvant chemotherapy (HR 0.53, 95% CI 0.31-0.92, $p = 0.02$). There was a significant difference between the upper and lower quintiles in this group (mean MTW 0.97 vs 3.93cm, $p < 0.001$).
Conclusion: MTW of oesophageal tumours can predict CRM positivity. This knowledge further informs the MDT, suggesting neo-adjuvant chemo-radiotherapy should be given prior to surgery.
Disclosure of Interest: None declared

P1145 METFORMIN USE DURING TREATMENT OF RESECTABLE ESOPHAGEAL CANCER PATIENTS IS NOT ASSOCIATED WITH BETTER OUTCOMES

L. Spierings[1], H. van Laarhoven[1], S. Lagarde[2], M. van Oijen[1], S. Gisbertz[2], J. Wilmink[1], M. Hulshof[3], S. Meijer[4], M. Anderegg[2], M. van Berge Henegouwen[2]
[1]*Medical Oncology,* [2]*Surgery,* [3]*Radiotherapy,* [4]*Pathology, Academic Medical Center, Amsterdam, Netherlands*

Contact E-mail Address: h.vanlaarhoven@amc.nl
Introduction: Metformin use has been associated with a dose-dependent increased response to neo-adjuvant chemo(radio)therapy in esophageal cancer patients. However, no association between metformin use and overall survival (OS) has been reported yet. The aim of our study is to investigate the effect of metformin use on pathological response as well as OS and disease-free survival (DFS) in patients with resectable esophageal cancer.
Aims & Methods: Between March 1994 and September 2013 all patients undergoing an esophagectomy for esophageal and gastro-esophageal junction cancer after neo-adjuvant chemo(radio)therapy with curative intent were included in a prospective database. A complete pathological response was defined as ypT0N0M0, Mandard 1. Kaplan-Meier curves with log rank testing were performed for OS and DFS.
Results: Four hundred and sixty-one patients were included with a median follow-up of 24 months (range 1-228); 43 patients were diagnosed with diabetes mellitus type II (9.3%) of whom 31 patients used metformin (6.7%). A total of 95 (20.4%) patients had a complete pathological response, which did not differ between metformin users (19.4%) and non-metformin users (20.5%, $p = 0.14$). We observed neither a statistically significant difference between metformin users and non-metformin users for median OS (20.8 vs 24.4 months, $p = 0.840$), nor for median DFS (20.5 vs 20.3 months, $p = 0.845$). A subgroup analysis in patients with diabetes mellitus type II showed a non-significant increase in median OS for metformin users (43.6 months) compared to non-metformin users (21.4 months, $p = 0.237$). For median DFS a similar non-significant increase was observed for metformin users (36.1 months) compared to non-metformin users (20.2 months, $p = 0.163$).
Conclusion: The use of metformin did neither result in in higher pathological response rates nor in an improved OS or DFS compared to non-metformin use in patients receiving neo-adjuvant chemo(radio)therapy for resectable esophageal cancer. In contrast to what has been postulated for other tumor types, metformin may not have a beneficial effect in esophageal cancer.

P1146 CLINICAL COMORBIDITIES FOR ESOPHAGEAL CANCER IN THE LAST THREE DECADES IN ITALIAN PATIENTS

F. Cavallin[1], **M. Scarpa**[1], R. Alfieri[1], M. Cagol[1], E. Ancona[1], C. Castoro[1]
[1]*Oncological Surgery Unit, Veneto Institute of Oncology (IOV-IRCCS), Padova, Italy*

Contact E-mail Address: marcoscarpa73@yahoo.it
Introduction: The incidence of esophageal cancer (EC) has been increasing worldwide during the last few decades. The aim of this study was to investigate the variation in clinical comorbidities in a large cohort of Italian EC patients in the same period.
Aims & Methods: A retrospective cohort study was performed using a prospectively collected database. All patients presenting with a diagnosis of primary EC at the Center for Esophageal Diseases located in Padua between January 1, 1980, and December 31, 2011, were included in the study. Data on local comorbidities (reflux disease, Barrett esophagus, previous caustic ingestion, achalasia, peptic disease), previous regional neoplasms, radio-induced tumors, previous distant neoplasm and systemic comorbidities. Joinpoint regression analysis was performed to estimate annual percentage changes (APCs).
Results: A total of 4440 patients were included in the present study. Reflux rate increased until 1997 (APC 7.57%, $p < 0.01$) and then leveled (APC -3.18%, $p = 0.10$). The rate of patients presenting with Barrett esophagus increased from 1.4% in the first period to 6.3% in the last period (APC 6.95%, $p < 0.01$). Gastric ulcer rate started decreasing since 2004 (APC -18.93%). The rate of previous local neoplasm increased until 1995 (APC 8.47%) and then leveled (APC -3.11%). The rate of radio-induced tumors varied from 0% in the first period to 7.1% in the last period, without significant trend (APC 5.37%,). Few patients (less than 1% overall) had achalasia or previous caustic ingestion. The rate of patients presenting with a previous distant neoplasm increased from 3.0% in the first period to 7.8% in the last period (APC 2.97%, $p < 0.01$). Advanced liver disease and pulmonary disease decreased over time (APCs -2.94% and -1.94% , respectively; both $p < 0.01$), whereas hypertension, diabetes and cardiac disease increased (APCs 6.56% , 2.11% and 2.56%, respectively; $p < 0.01$).
Conclusion: In the last three decades patients with EC showed significant and clinically meaningful changes in their local and systemic comorbidities. These chages should be taken into account when dealing with such patients.

Introduction: Endoscopic treatment is a standard therapeutic option for patients with early esophageal cancer (EAC) with mucosal invasion (T1a). For patients with "high-risk" T1a cancer (e.g. advanced grading (G3/G4), invasion to lymphatic (L+) or blood vessels (A+), high degree of tumor cells dissociation (TCD 3) and for patients with T1b cancer (with any sm invasion)), surgery still remains a standard therapeutic approach.
Aims & Methods: To compare outcomes of endoscopic vs. surgical treatment in patients with high-risk EAC. High-risk cancer was defined as any cancer with submucosal (sm) invasion or mucosal cancer with at least one of the following: G3/G4 differentiation, invasion to blood (A+) and/or lymphatic (L+) vessels and high tumor cells dissociation (TCD3).
A single-center study. Patients with EAC underwent endoscopic resection (ER) or endoscopic submucosal dissection (ESD). Patients with high-risk EAC were referred for surgery if there were no contraindication such as advanced age, multiple co-morbidities, patient's refusal, etc. All other patients continued (if necessary) with endoscopic treatment which consisted of further sessions of ER (or ESD) and/or radiofrequency ablation (RFA). After treatment, all patients have been followed up for a median of 22 months (range 48-119).
Results: A total of 57 patients (50 men, 7 women, median age 63) underwent endoscopic treatment for EAC (47x adenocarcinoma, 9x squamous carcinoma, 1x duplicity (EAC + SCC)). Twenty-three patients (40%) had low-risk T1a cancer, and endoscopic treatment was considered curative. The remaining 34 patients (60%) had high-risk EAC (sm invasion: 56%; T1a cancers with "high-risk" features: 44%).
Eleven "high-risk" patients (32%) were referred for esophagectomy and 23 patients (68%) continued with endoscopic treatment. In one patient, the planned esophagectomy was finally not performed due to tumor generalization found during the operation. Among 10 patients who underwent esophagectomy, local residua of malignancy were present in only one (10%) patient and lymph node metastases have not been detected in any of these patients. During the follow-up, none of the patients who underwent esophagectomy has shown signs of generalization or a tumor relapse and no patient died.
In 23 "high risk" patients undergoing endoscopic treatment, local complete remission of neoplasia was achieved in all of them after a median of 2 treatment sessions. Neither local recurrence of neoplasia nor tumor generalisation have been observed so far, and there was no cancer related mortality.
Conclusion: Endoscopic therapy appears to be an effective alternative to esophagectomy in patients with "high-risk" early esophageal cancer.

P1148 INSTRUMENTAL PERFORATION IN ESOPHAGEAL CANCER : NONOPERATIVE TREATMENT WITH SELF-EXPANDABLE COVERED METAL STENTS

M. Anselmi[1], A. M. Gemmato[2], M. Figueroa[2]
[1]*Surgery, University of Concepcion. Chile,* [2]*Surgery, University of Concepcion, Concepcion, Chile*

Contact E-mail Address: manselmi@udec.cl
Introduction: The standard approach to esophageal perforations consists of conservative treatment or surgery. Recent studies have suggested that stent-grafting may improve the treatment outcome of patiens with oesophageal perforation. However in neoplastic disease there still lack of evidence.
Aims & Methods: To assess the efficacy of endoscopic management of instrumental esophageal perforations in patients with neoplastic oesophagus using selfexpandable covered metal stents.
This is a prospective single-center study of 16 consecutive oesophageal cancer patients with acute therapeutic endoscopy perforation suffered during a dilatation of a neoplastic stenosis.
The mean age was 78 years, 8 patients (50%) were female, in 14 (87.5%) the tumor was located in the thoracic oesophagus and 2 (12.5%) in the cardioesophageal region. The histological type was squamous cell carcinoma in 14 (87.5%) and adenocarcinoma in the remaining 2 (12.5%). In 15 patients the diagnosis was made inmediately after the dilatacion by routine endoscopic and radiological post procedure review and in one case (6.3%), the perforation was diagnosed 22 hrs later. In the first 10 patients a fully covered self-expanding 18 mm in diameter metallic stent was inserted. In the remaining 6, in order to prevent migration, a 22 mm in diameter partially covered prosthesis was used. The outcome of patients and immediate complications (up to 24 hrs post procedure), early (30 days) and late (over 30 days) were studied. Patients were monitored up to 90 after the perforation.
Results: The prosthesis insertion was successful in all patients. In 6 (37.6%) immediate morbidity associated with the perforation was found: 3 (18.8%) subcutaneous emphysema and 3 (18.8%) transient fever. The presence of early complications was found in 3 cases (18.8%), 2 of them developed a pleural effusion and a slight mediastinitis and one pleural fistula secondary to esophageal stent migration (18 mm completely covered). The prosthesis remained in place until the end of follow up in the remaining 15 patients (93.5%).
Oral intake was restarted by a mean of 3.6 ± 1.2 days (range 1 – 7) and mean duration from the stent insertion to discharge was 8.3 ± 2.4 days (range : 2 – 21). At the end of follow up, the 15 patients who survived had recovered the hability of oral feeding.
One patient died 19 days post procedure, as a result of pleural fistula secondary to a fully covered 18 mm esophageal stent migration, giving 30 day a mortality rate for this series of 6.3%.
Conclusion: The use of self-expanding metal stent for the treatment of esophageal instrumental perforations in patients with esophageal cancer is a safe and effective method, with low morbidity, adequate recovery of oral intake and short hospital stay.

P1149 RELATION BETWEEN THE LOCATION OF SUPERFICIAL BARRETT'S ESOPHAGEAL ADENOCARCINOMA (S-BEA) AND THE DIRECTION OF DUODENOGASTRIC REFLUX

M. Omae[1], J. Fujisaki[1], T. Shimizu[1]
[1]*Gastroenterology, Cancer Institute Hospital, Japanese Foundation for Cancer Research, Tokyo, Japan*

Contact E-mail Address: masami.nego@jfcr.or.jp
Introduction: s-BEAs in Barrett's esophagus are frequently found in the right wall of the esophagus.[1)] Why are they located on the right wall? Tongue-like SSBE was more frequent in the right anterior wall (in the 12 to 2 o'clock position) than at other locations ($^*P < 0.05$).[2)] Okita et al reported using pH monitoring with 8 channel sensors and patients with non-erosive reflux esophagitis (NERD) and reflux esophagitis had radial asymmetric acid exposure that was predominanton the right wall of the distal esophagus.[3)]
Aims & Methods: This study revealed the relation between the location of s-BEA and the direction of duodenogastric reflux.
33 s-BEA patients were enrolled in this study. 28 patients (28/77; 74.8%) had long segment Barrett's esophagus (LSBE), the others (5/33; 15.2%) had SSBE. The invasion depth in 18 s-BEAs was mucosal cancer (18/33; 54.5%), the remaining was submucosal cancer (15/33; 45.5%). We performed 24-h pH monitoring study before s-BEA was treated by ESD or operation. All patients took PPI. This catheter has 8 pH sensors circumferentialy arrayed at the same level of the device (developed by Shimane Medical University and Star-medical). The catheter was inserted transnasally into the esophagus and positioned 2cm above the squamo-columnar junction (SCJ). All 33 s-BEA patients took the position for 24 hours every day as same as possible and they didn't take special position by themselves. This device didn't rotate in their every position. We measured the maximal total duration of acid ($pH < 4.0$) and alkaline ($pH > 8.0$) reflux in all 33 s-BEA patients. We evaluated the relation between the location of s-BEA and the direction of the maximal total duration of acid and alkaline reflux.
Results: Regarding as maximal total duration of acid reflux, in 28 SSBE patients except for 4 patients without acid reflux, the rate of coincidence was 19/24 (79.2%). On the other hand, in 5 LSBE patients, the rate of coincidence was 4/5 (80.0%). Regarding as maximal total duration of alkaline reflux, in 28 SSBE patients except for 3 patients without alkaline reflux, the rate of coincidence was 20/25 (80.0%). On the other hand, in 5 LSBE patients, the rate of coincidence was 3/5 (80.0%). In all 33 s-BEA patients, the rate of coincidence for maximal total acid or alkaline reflux was 29/33 (87.9%).

Conclusion: The location of the s-BEA mostly corresponds with the direction of maximal total duration of acid and alkaline reflux. Measuring the direction of duodenogastric reflux by using pH monitoring with 8-channnel might be useful for early detection of the s-BEA in LSBE.

Introduction: Primary malignant melanoma of the esophagus (PMME) is a rare disease, and most of the PMME had been found in advanced stage. Treatment for PMME is basically esophagectomy, but treatment effect is poor and it's prognosis is extremely poor. In contrast, the early esophageal squamous cell carcinoma and early gastric carcinoma can be cured by the local treatment such as the endoscopic resection (ER;ESD/EMR). The early diagnosis and treatment is the best strategy to improve the patients' survival. Based on this fact, we supposed that the early PMME have low possibility of lymph nodes metastases, and we can get a good prognosis by the ER. Early detection is important in early treatment. But early PMME is more rarethan advanced PMME and is very difficult to find because we do not know collect endoscopic findings. To clarify the endoscopic findings of the early PMME will help to find early PMME.

Aims & Methods: The purpose of this study is to clarify the endoscopic findings of the early PMME. From Jan 2006 to Apr 2015, we experienced 4 cases of early PMME. For those 4 cases, we investigated their clinical and pathological and endoscopic findings.

Results: We have 2 female cases (57y.o and 71y.o) and 2 male cases (69y.o and 61y.o). There ware no symptoms in all cases, and all cases were found by screening endoscopy. Lesions were located in all part of esophagus. The lesion size was 3-40mm. In most of the lesions, the shape of lesion was flat type (0-IIb). Slight irregularities appeared when the cancer becomes thicker, and in 1 case, clear polypoid elevation can be seen. In benign melanosis, color of lesion is a thin black from pale gray, but in PMME the color of lesion was a very clear black and the lesion was composed of irregular large and small black-spots. The demarcation line was irregular, ill-defined and faded in color. Case1: A 57y.o female with 6 lesions. All lesions were 0-IIb. After the CT examination showing no metastasis, ER was performed, as the patient chose ER rather than operation. Pathological diagnosis was PMME, T1a-LPM,ly0,v0. We followed up every 6 months by endoscopy, and 8 times ER had been done for new lesions. 8.5 years has passed from the first ER, the patient is alive and free from disease. Case 2: A 69-year male with 2 lesions. All lesions were 0-IIb. After the informed consent, 2 lesions were removed by ER. The pathological diagnosis were PMME, T1a-LPM,ly0,v0. Case 3: A 71y.o female with 1 lesions. Type of lesion was 0-Ip + IIa + IIb, lesion size was 40mm and clear black polypoid elevation can be seen. Total esophagectomy with LN dissection was done. Pathological diagnosis was PMME, T1a-LPM,ly0,v0,n0. Case4: A 61-year male with 2 lesions. All lesions were 0-IIb. After the informed consent, 2 lesions were removed by ER. The pathological diagnosis was PMME, T1a-LPM,ly0,v0 in both lesions.

Conclusion: Next 4 Features are typical endoscopic findings of early PMME 1. Shape of lesion: flat(0-IIb)∼slight irregularities on surface 2. Color of lesion: very clear black 3. Structure of lesion: irregular large and small black-spots 4. Demarcation line: irregular, ill-defined and faded in color. Our cases indicate the possibility to cure early PMME by ER.

Introduction: Neoadjuvant chemotherapy (NAC) followed by surgery is one of the standard treatments for patients with resectable esophageal squamous cell carcinoma (ESCC). It was reported that surgery following NAC improved survival compared with surgery alone, especially in patients whose surgically resected specimens were assessed as pathological regression with chemotherapy. However, the clinical impact utilizing endoscopy for evaluating efficacy after NAC, especially for prediction of recurrence, is unknown.

Aims & Methods: The aim of this study was to clarify the correlation between recurrence-free survival (RFS) and the NAC therapeutic efficacy for primary tumors. The NAC therapeutic efficacy was evaluated with endoscopic evaluation and pathological tumor regression grade (TRG) of the superficial layer of the surgically resected tumor. We enrolled patients with clinical T2/3 ESCC who underwent NAC followed by definitive surgical resection in our institution between January 2008 and March 2013. We excluded any case that an endoscopic examination had not been performed after NAC. The NAC therapeutic effect was retrospectively estimated with each endoscopic image by 3 independent endoscopists, and patients were classified into 4 groups according to the degree of tumor regression (marked reduction [MR]: 90% or more reduction; half reduction [HR]: 50% or more reduction; insufficient reduction [IR]: less than 50% reduction; ineffective, resulting in growth [IG]: progression). In addition, we evaluated the therapeutic effect on the mucosal layer of resected specimens as grade 0–3 on the basis of TRG of the primary tumor. We evaluated RFS and clinicopathological factors, including endoscopic classification of the NAC therapeutic efficacy and superficial TRG. This study was approved by an institutional review board in our institution.

Results: We evaluated 129 patients (110 men, 19 women; median age 65 years, range 36-77) who were eligible. The numbers of patients with clinical stage IB/IIA/IIB/IIIA/IIIB/IIIC/IV were 9/28/6/50/25/2/9, respectively. The numbers of patients in group MR/HR/IR/IG were 44/35/44/6. In group MR, only 9 patients were regarded as complete remission. The numbers of patients with grade 0/1a/1b/2/3 superficial TRG score were 45/32/20/17/15. Most patients with grade 2-3 were evaluated as MR, and most patients with grade 0-1a were evaluated as IR or IG. The median follow-up period was 24 months, 56 patients had recurrence or death, and the median 3-year RFS was 56.3%. The median 3-year RFS of patients in group MR/HR/IR/IG was 85.3%/48.0%/39.3%/16.7%, respectively. A multivariate analysis demonstrated that cN factors and endoscopic classification for the NAC therapeutic efficacy were independent preoperative predictors of RFS, and ypT, ypN, ypR factors and superficial TRG were independent postoperative predictive factors.

Conclusion: In this study, there was a relationship between tumor recurrence and both of endoscopic evaluation for the NAC therapeutic efficacy and superficial TRG. These two factors could identify risk of recurrence.

P1152 OUTCOME OF ENDOSCOPIC SUBMUCOSAL DISSECTION FOR SUPERFICIAL PHARYNGEAL SQUAMOUS CELL CARCINOMA

T. Oyama[1], A. Takahashi[1]

[1]*Endoscopy, Saku Central Hospital Advanced Care Center, Saku, Japan*

Introduction: Recently, the detection of superficial pharyngeal squamous cell carcinoma has been increasing in Japan. However, the outcome and prognosis for endoscopic submucosal dissection (ESD) are unknown.

Aims & Methods: The aim of this study is to clarify the outcome and prognosis of pharyngeal Squamous cell carcinoma (SCC) treated by ESD.

86 pharyngeal SCC in 65 patients were treated by ESD from Jan. 2006 to Jul. Dec. 2014 in Saku Central Hospital. All ESD were performed using a Hook knife under general anesthesia with tracheal intubation. Clip with line or forceps was used to make traction during ESD.

Male/Female was 64/1. Median age was 67 (40-92) years old. Median tumor size was 5 (1 - 50) mm. Median observation duration was 71(1-127) months.

Results: 1) En bloc and R0 resection rate was 100% (86/86) and 93% (80/86), respectively. R0 resection was defined as En block resection, lateral and vertical margin was negative.

2) Complication: Perforation wasn't shown. Delayed bleeding rate was 1% (1/86). Dysphasia was shown in 2% (2/86).

3) Invasion depth: Epithelial (EP) and subepithelial (SEP) lesion was 69% (59/86) and 31% (27/86) respectively.

96% (51/53) of small lesions less than 10mm were EP. On the other hand, 76% (25/33) of large lesions 10mm or bigger were SEP.

4) Lymph-duct involvement

0/59 of EP and 4/27 of SEP had lymph duct involvement.

5) Local recurrence

One case had local recurrence. The case was SEP with lymph duct involvement. The local recurrent lesion was treated by re-ESD.

6) lymph-node metastasis (LNM)

LNM rate of EP and SEP was 0% and 11% (3/27), respectively. Two of three patients had lymph duct involvement. All of 3 patients were treated by lymph node dissection.

7) Prognosis

Two patient died of pharyngeal SCC. Both patients had SEP with lymph duct involvement, and refused additional treatment such as chemo-radio therapy.

Conclusion: ESD is a useful treatment method for superficial pharyngeal SCC. Additional therapy should be recommended for the patient who had lymph duct involvement.

Disclosure of Interest: None declared

P1153 LONG-TERM OUTCOMES OF ENDOSCOPIC SUBMUCOSAL DISSECTION (ESD) FOR EARLY ESOPHAGEAL SQUAMOUS CELL CARCINOMA (EESCC): A LARGE STUDY OF 344 CONSECUTIVE CASES

Y.-S. Zhong[1], I. Take[2]
[1]*Zhongshan Hospital of Fudan University,* [2]*Endoscopy Center, Shang hai, China*

Introduction: To evaluate the long-term outcomes of Endoscopic submucosal dissection (ESD) for early esophageal squamous cell carcinoma (EESCC) on a large patient cohort in China.
Aims & Methods: From January 2007 to November 2013, a total of 344 EESCC patients with high-grade dysplasia (HGD) and superficial squamous cell carcinoma of esophagus were included in the present retrospective study and all of the patients were treated by ESD. Demographic, pathological, clinical parameters and follow-up data were collected and analyzed.
Results: In this study, the mean age of patients was 61.8 ± 8.2 years. The ratio of male and female patients was 250:94. Among these patients, there were 78 HGD and 226 superficial squamous cell 72 epithelial or lamina propria (EP/LPM), 109 muscularis mucosa (MM) and 45 submucosal (SM1) cancer carcinoma. The median follow-up period was 34 months.
1) The complication rate was 30.5% (102/334), including 1 perforation, 1 pneumonia, 8 delayed bleeding and 92 (26.7%) postoperative stricture (defined as complaints of dysphagia). Balloon dilation under endoscopy were performed for 34 (9.9%) severe stricture patients who were suffering from aphagia.
2) Recurrence rate was 16.0%. The median time to recurrence were 18 (range 1-67) months. Longitudinal length > = 3cm ($p = 0.003$), Circumferential range > 3/4 ($p = 0.001$), lymph vascular involvement ($p = 0.004$), postoperative stricture ($p = 0.02$), and combined with other cancer ($p = 0.030$) were independent predictors of recurrence. The 5-year progression-free survival for high risk group and low risk group are 35% and 80%, respectively.
3) The 5-year progression-free survival rate was 72%, for HGD, EP/LPM, MM and SM1 were 82.5%, 67.1%, 74.6%, and 54.2%, respectively ($p = 0.003$). The median progression-free survival time was 72 months. Metastasis were observed in 10 (2.91%) patients, which were 7 lymph node, 3 lung, 2 laryngeal, 2 liver, and 1 stomach metastasis.
4) The 5-year overall survival rate was 95%, for HGD, EP/LPM, MM and SM1 were 97.40%, 87.30%, 92.62%, and 78.60%, respectively ($p = 0.008$). The median survival time was 84 months. There were 14 (4.1%) patients died. Death due to esophageal cancer occurred in 6 patients (1.74%), and 5 patients died owing to other cancer. The circumferential range > 3/4 ($p = 0.000$), combined with other cancer ($p = 0.000$), and infiltration depth of lesion ($p = 0.010$) were independent predictors of overall survivals.
Conclusion: ESD is efficient to treat EESCC. The risk of recurrence after ESD were mainly associated with longitudinal length > = 3cm, lymph vascular involvement, circumferential lesion > 3/4, combining with other cancer, and postoperative stricture. Overall survival appears to be affected by circumferential lesion > 3/4, combining with other cancer, and infiltration depth of lesion. These risk should be taken into account when considering the indications for ESD.

P1155 RELATION BETWEEN THE PROGNOSTIC NUTRITIONAL INDEX AND MORBI-MORTALITY POST R0 RESECTION IN THE GASTRIC CANCER

A. Borda[1], J. J. Vila[1], **I. Fernández-Urién**[1], J. Jiménez-Pérez[1], J. M. Zozaya[1], A. Guerra[1]
[1]*Gastroenterology, Complejo Hospitalario De Navarra, Pamplona, Spain*

Contact E-mail Address: abordamartin@yahoo.es
Introduction: A low prognostic nutritional index (PNI) has been related to a high complication rate after gastric cancer resection in Japanese reports, with no data in western countries.
Aims & Methods: To analyse in our media the relation between a pathologic PNI and the frequency and severity of post surgery gastric cancer complications.
This retrospective study included 124 cases of gastric carcinomas, consecutively operated in our centre, with R0 resection. The PNI was calculated with the form: [10 x serum albumin (g/dl) + 0.005 x total lymphocytes count/mm^2], being pathological a PNI < 40. Complication rates were compared between the group with normal and pathological PNI (Chi^2 test). A multivariate analysis of the complication rates according to PNI was performed [Cox model, stepwise, hazard ratio (HR) and 95% confidence interval (CI)] adjusting for: age > 68 years, preoperative ASA (ASA 1-2 vs ASA 3-4) and pTNM stage (I, II and III + IV). We determined the relation between PNI ≥ 40 and < 40 and the severity of the complications according to Martin and cols. classification (J Am Coll Surg. 2002; 194: 565-77), grouped in: no complications, mild, severe and exitus.
Results: Complication rate was: no complication: 95 (76.6%), mild complications: 14 (11.3%), severe: 12 (9.7%) and exitus: 3 (2.4%). 11.5% of cases presented a PNI < 40. Patients with pathological PNI registered a high frequency of complications: 24.1% vs 7.5% [p 0.021; OR = 3.91; CI95% = (1.09-14.17)], which was confirmed in the multivariate analysis [p 0.042; HR = 3.61; CI95% = (1.05-12.43)]. Furthermore, we registered complications with a higher severity in the group with pathological PNI: mild = 14.3% versus 11.1%; severe = 21.4% versus 8.3% and exitus = 14.3% versus 0.9% ($p = 0.005$).
Conclusion: 1. Patients with a pathological Prognostic nutritional Index (<40) show a three times higher risk of suffering complications after R0 resection in the gastric cancer. 2. This higher risk is independent of age, preoperative ASA and pTNM tumor stage. 3. Besides, cases with a PNI < 40 were associated with a significant higher rate of severe complications and postoperative exitus.

P1157 CLINICOPATHOLOGIC FEATURES OF SYNCHRONOUS MULTIPLE EARLY GASTRIC CANCERS

J. H. Kim[1], E. J. Kim[1], K. O. Kim[1], J.-W. Chung[1], Y. J. Kim[1], K. A. Kwon[1], W. K. Lee[2], D. K. Park[1]
[1]*Department of Internal Medicine,* [2]*Department of Surgery, Gachon University Gil Medical Center, Incheon, Korea, Republic Of*

Contact E-mail Address: junghokimm@gilhospital.com
Introduction: The multifocality rate of early gastric cancer (EGC) ranges from 4 to 21%, but there are few data regarding both lymph node metastasis and characteristics of synchronous multiple gastric cancers of patients with EGC.
Aims & Methods: We investigated the characteristics of synchronous multiple gastric cancers of patients with EGC after endoscopic or surgical treatment. We retrospectively reviewed the clinicopathological features from patients who were diagnosed with EGC after endoscopic resection or surgical treatment between February 2008 and May 2013. Of 999 EGC patients treated with endoscopic or surgical resection, 987 were included in the analysis.
Results: Of 987 patients, 578 (58.6%) were initially treated with surgical resection and 37 (9.5%) were diagnosed with synchronous multifocal EGC. The mean age at treatment of patients with solitary and synchronous multifocal EGC was 61.5 ± 11.7 and 64.3 ± 9.6 years, respectively ($p > 0.05$). The rates of lymph node metastasis were 4.6% (44/950) in solitary EGC and 5.4% (2/37) synchronous multifocal EGC ($p > 0.05$). In the multivariate analysis, synchronous multifocal EGC was associated with male and depth of invasion in main lesion compared solitary EGC ($p < 0.05$). In the subgroup analysis, 70.3% and 64.9% of patients with multiple synchronous EGC were found to have tumors located in same thirds and same aspect of the stomach, respectively.
Conclusion: Synchronous multifocal EGC does not increase the risk of lymph node metastasis compared with solitary EGC, and tumor location is an important determinant of occurrence in synchronous lesion. Clinician should pay special attention to detect synchronous lesion near the main tumor.

P1158 ENDOSCOPIC CLUE OF EN BLOC RESECTION IN GASTRIC INDEFINITE NEOPLASIA

R. Dae Gon[1], O. Sook Kyoung[1], K. Dae Hwan[1], K. Hyung Wook[1], C. Cheol Woong[1], P. Su Bum[1], **K. Su Jin**[1]
[1]*Pusan National University, Yangsan Hospital, Yangsan, Korea, Republic Of*

Contact E-mail Address: gon22gon@naver.com
Introduction: When gastric indefinite neoplasia (category 2 lesion) from endoscopic forceps biopsy is diagnosed, it is difficult to decide management. Especially, in some situations such as suspicious of early gastric cancer (EGC) macroscopically, it is hard to decide. The aim of this study was to discuss the results of final results of gastric indefinite neoplasia and associated clinical factors predictive of early gastric cancer.
Aims & Methods: This retrospective study enrolled 142 patients of gastric indefinite neoplasia on index forceps biopsy. We analyzed the initial endoscopic features of lesions and predictive factors of early gastric cancer (EGC).
Results:

Variable	Univariate analysis		Multivariate analysis		
P value	OR	P value	OR	95% CI	
Lesion size ≥ 10mm					
Nodular	**0.003**	12.500	0.021	11.401	1.432-90.759
Redness color	**0.002**	4.941	0.066	2.998	0.928-9.686
Pale color	**0.007**	4.048	0.014	3.777	1.306-10.923

After complete work-up, the final pathologic diagnoses were early gastric cancer (n = 34, 23.9 %), adenoma (n = 16, 11.3%), and non-neoplasm (n = 92, 64.8%). In the univariate analysis, lesion size more than 10 mm, surface nodularity and erythema were associated risk factors. In the multivariate analysis, lesions diameter (p = 0.019, OR 12.501, 95% CI 1.537-91.269) and surface redness (p = 0.015, OR 3.598, 95% CI 1.414-12.314) were significant risk factors.
Conclusion: Gastric indefinite neoplasia with larger size (≥ 10mm) and erythema might be need more definite diagnostic modalities rather than simple follow up endoscopy.
Disclosure of Interest: None declared

P1159 THE EFFICACY OF COLONOSCOPY IN PATIENTS WITH ENDOSCOPIC SUBMUCOSAL DISSECTION FOR EARLY GASTRIC CANCER

J. Joon Ho[1], K. Dae Hwan[1], K. Hyung Wook[1], C. Cheol Woong[1], P. Su Bum[1], **K. Su Jin**[1]

Introduction: Our goal is to study the risk of colorectal cancer in patients who underwent endoscopic submucosal dissection(ESD) with EGC as compared to controls. And We assessed the need for surveillance colonoscopy in patients with early gastric cancer.
Aims & Methods: The study group included a total of 180 patients with EGC that underwent ESD. As a control group, 430 sex and age-matched patients without gastric neoplasm were included. All of the patients underwent screening colonoscopy before or after 6months from gastric ESD between January 2010 and December 2013.
Results: High-risk colorectal neoplasm was diagnosed in 52/170 patients (30.5%) in EGC group and 12/420(2.8%) in controls ($p < 0.01$). Colorectal cancer was diagnosed in 22/170 patients (12.9%) in EGC group and 3/220 (1.3%) in controls ($p < 0.01$). Univariate analysis demonstrated that high-risk colorectal neoplasm was associated with presence of EGC, age, DM, and colorectal cancer was associated with presence of EGC, colorectal cancer family history. Multivariate analysis demonstrated that age (OR 6.19, 95% CI 3.5-11.5), EGC (OR 7.50, 95% CI 4.41-18.10) were risk factors for high-risk colorectal neoplasm. And the presence of age (OR 3.58, 95% CI 1.57-10.92), EGC (OR 6.47, 95% CI 2.87-15.10), colorectal cancer family history (OR 3.07, 95% CI 1.92-9.34) were risk factors for colorectal cancer.
Conclusion: The incidence of colorectal cancer who underwent an ESD for EGC group was higher than the control group. Therefore, we believe that screening colonoscopy should be considered in patients with ESD because of early gastric cancer.

Introduction: Lymph node metastasis is important to evaluate the indication of the submucosal dissection (ESD). Submucosal invasion and lymphovascular invasion is considered to be an independent risk factor for lymph node metastasis in early gastric cancer. Accurate diagnosis of the invasion depth in the previous ESD remains a challenge and can only be confirmed by final pathologic report following ESD. The purpose of the study is to identify risk factors for SM/LV invasion in early gastric cancer.
Aims & Methods: We studied retrospectively pathological data of patients treated ESD from Jan 2010 to May 2014 and presenting EGC of differentiated-type adenocarcinoma, 2.0 cm or smaller in size and no ulceration.
Results: Among 390 lesions consecutively resected by ESD, 297 lesions in 277 patients were included in this study. Submucosal and lymphovascular invasions were detected in 32 lesions. Multivariate analysis revealed two independent risk factors for SM/LV invasions: Histology of moderate-differentiated (odds ratio (OR) 4.082; 95% CI 1.925-8.616; $P = 0.008$), location of upper and middle third (U/M) of stomach (OR 2.917, 95% CI 1.410-6.048;$P = 0.008$).
Conclusion: Histology of moderate-differentiated adenocarcinoma, and location of U/M were identified as independent risk factors of SM/LV invasion in EGC meeting absolute criteria for ESD.

Introduction: Gastric cancer with enteroblastic differentiation (GCED), which is a histologic type of alpha-fetoprotein (AFP)-producing gastric cancer, is very rare and its clinicopathological features have not been well investigated. Additionally, there is no report that focused on an early stage of GCED.
Aims & Methods: This study aimed to clarify the clinicopathological features of early stage of GCED by comparisons with conventional early gastric cancer (CGC: well to moderately differentiated carcinoma). We analysed 191 cases (143 males, 48 females; mean age 72.8 y; 214 lesions) of early gastric cancer that underwent endoscopic resection from September 2011 to February 2015 in our hospital. Five of 191 cases were GCED (2.6%). We evaluated the comparison between 5 cases (4 males, 1 female; mean age 75.8 y; 5 lesions) of early gastric cancer with a GCED component and 186 cases (139 males, 47 females; mean age 73.7 y; 209 lesions) of conventional early gastric cancer, clinicopathologically.
Results: No significant difference was observed in tumour locations (U/M/L = 1/2/2 and 23/91/95 in GCED and CGC, respectively), mean of tumour size (15.0 and 15.2 mm in GCED and CGC, respectively) and macroscopic types (flat or depressed type/ elevated type = 4/1 and 92/117 in GCED and CGC, respectively). Endoscopically, we could not find specific findings for GCED, and we did not anticipate deep submucosal invasion. No lesion was diagnosed as GCED by examination of biopsy specimens. Regarding depth of tumour invasion, total submucosal invasion rates were significantly higher in GCEDs than CGCs (60.0% vs. 11.4%, $P < 0.001$). Furthermore, positive rates of lymphatic and venous invasion were significantly higher in GCEDs than CGCs (40.0 vs. 2.3%; and 60.0 vs. 0.4%, $P < 0.001$). In 2 of 5 GCED cases, additional surgery was performed (A: T1N0M0, stage IA; B: T1N1M0, stage IIA). Histological examination demonstrated the presence of tubulopapillary carcinoma with clear cytoplasm at the deeper part of the mucosa. In all cases of GCED, the superficial mucosal layer was covered with a conventional tubular adenocarcinoma. Immunohistochemically, positive findings were as follows: AFP: 1/5(20%), PAS: 3/5(60%), glypican 3: 3/5(60%), SALL 4: 2/5(40%).
Conclusion: To our knowledge, this is the first report on multiple cases of early stage of GCED. Since GCED exists only in the deeper part of the mucosa in early stage cancer, preoperative diagnosis by biopsy is thought to be difficult. Additionally, ratio of lymphovascular invasion in GCED was significantly higher than CGC, which indicates that GCED has high malignant potential. Further investigations are needed to establish optimal treatment approaches for GCED.

Introduction: A gastrointestinal stromal tumor (GIST) with malignant potential typically requires surgery. Differentiating GISTs from other submucosal tumors (SMTs), especially leiomyoma, is therefore important in daily practice. Although GISTs express specific proteins, such as c-kit and CD34, serum biomarkers for GISTs have not yet been established.
Aims & Methods: The aim of this study was to identify candidate microRNAs (miRNAs) for serum biomarkers of GIST through the investigation of miRNA expression patterns in human cases of GIST and leiomyoma. MiRNA expression was examined in 9 GIST samples and 6 leiomyoma samples that were diagnosed histopathologically and acquired by a novel sampling method, submucosal tunneling biopsy (STB). STB offers the advantage of sufficient tumor specimen acquisition without contamination under direct vision. Total RNA was extracted from these tissues and analyzed for miRNA expression patterns by microarray. Subsequently, reverse transcription and real-time qPCR were used to confirm specific miRNA overexpression in the microarray analysis, comparing GISTs with leiomyomas.
Results: Microarray analysis revealed the upregulation of 10 miRNAs and the downregulation of 22 miRNAs in GISTs compared to leiomyomas; in particular, the miR-140 families and miR-181a-5p were upregulated, whereas the miR-378 family was downregulated. MiRNAs extracted from tumor tissues clustered differentially between GISTs and leiomyomas. Real-time qPCR revealed that the expression level of miR-140-5p in GISTs was 28.5 times higher than that in leiomyomas, and the expression level of miR-140-3p was also 23.2 times higher in GISTs compared to leiomyomas.
Conclusion: The STB method provided suitable SMT samples for miRNA analysis. As shown by real-time qPCR, miR-140 family members may serve as serum biomarkers of GIST compared to leiomyoma, which could lead to the development of a non-invasive diagnostic tool.

Contact E-mail Address: moribata@wakayama-med.ac.jp
Introduction: Endoscopic submucosal dissection(ESD) is the standard therapy for early gastric cancer. Several studies reported successful *Helicobacter pylori*(HP) eradication reduced metachronous gastric cancer after ESD. In contrast, some other studies showed the HP eradication was not effective for reducing gastric cancer.

Aims & Methods: The aim of this study is to reveal the predictive factors for metachronous recurrence of gastric cancer after HP eradication in the post-ESD status.
370 patients with early gasric cancer received first ESD at our hospital between October 2004 and December 2012. Exclusion criteria were histories of gastric surgery, gastrectomy, and eradication, serologically HP negative, rejection of eradication, unsuccessful eradication, no recept of endoscopy after eradication. Of the 98 patients in the final analysis, we retrospectively evaluated endoscopic features associated with histopathological findings related to HP infection in the pre-ESD and post-eradication. A endoscopic examination in the post-eradication was carried out one year or more after eradication treatment. Outcome measures were the following endoscopic findings: fundic gland polyp, regular arrangement of collecting venules (RAC), flat erosion, severity of atrophy, intestinal metaplasia, rugal hyperplasia, nodularity, mucosal edema, spotty redness, xanthoma, and Map-like redness. These findings were analyzed to identify the predictive factor for recurrence.
Results: The subjects comprised 73 males and 25 females with a mean age (SD) of 68.0 (±8.9) years. There was no significant difference in age, gender, endoscopic findings except for map-like redness. Map-like redness after HP eradication was the only predictive factor showing a significant difference by univariate analyses. The cumulative recurrence-free survival was significantly lower in patients with map-like redness after HP eradication than in those without the finding since the time of successful HP eradication ($p = 0.003$, Log-rank test).
Conclusion: Map-like redness after HP eradication is a vital factor for metachronous gastric cancer after HP eradication in the post-ESD status.

Introduction: Gastric outlet obstruction (GOO) is a clinical syndrome characterized by epigastric abdominal pain and postprandial vomiting due to mechanical obstruction. In past, treatment of malignant gastric outlet obstruction was palliative surgery including bypass through a gastro-jejunostomy. There have been significant technical advances in stent development and endoscopic technology over recent years. Self-expandable metal stents (SEMS) can be used to palliate patients with malignant gastric or duodenal obstruction and to restore the ability of oral feeding with the recent advances in endoscopic technology.
Aims & Methods: In this study, we tried to assess the feasibility and efficacy of SEMS which were inserted through the scope method for the palliation of malignant obstruction of gastric or duodenal obstruction. During January 2011 to April 2014, 220 patients with gastric or duodenal obstruction due to malignancy underwent endoscopic SEMS insertion at Asan Medical Center. We analyzed technical/clinical outcomes and complications according to the type of stent and the location of obstruction.
Results: Among 220 patients (median age was 63 years, men were 125), full covered SEMS was inserted in 16 patients, partial covered SEMS in 77 patients, and uncovered SEMS in 120 patients. %). The median width of stent was 20 mm (IQR, 20-20mm) and the median length of stent was 80 mm (IQR, 60-100mm). The location of obstruction was shown in gastric outlet including duodenal bulb ($n = 106$), in duodenal 2nd and 3rd portion ($n = 114$). Technical success was found in 213 of 220 cases (96.8%) and clinical success was in 184 of 213 (86.4%). According to the type of stent and site of obstruction, clinical success was shown in like these; full covered SEMS (15/16, 93.8%), partial covered SEMS (68/77, 88.3%), and uncovered SEMS (101/120, 84.2%) ($p = 0.476$); gastric outlet obstruction (95/104, 91.3%) and duodenal obstruction (89/109, 81.7%) ($p = 0.039$). Of total, migration was happened in 20 cases (9.1%) and obstruction was in 51 cases (23.2%). According to type and site, migration was shown in like these; full covered SEMS (6/16, 37.5%), partial covered SEMS (7/77, 9.1%), and uncovered SEMS (7/120, 5.8%) ($p < 0.001$); gastric outlet obstruction (16/104, 15.4%) and duodenal obstruction (4/109, 1.2%) ($p = 0.003$). According to type and site, obstruction was shown in like these; full covered SEMS (2/16, 12.5%), partial covered SEMS (17/77, 22.1%), and uncovered SEMS (32/120, 26.7%) ($p = 0.409$); gastric outlet obstruction (26/104, 25.0%) and duodenal obstruction (25/109, 22.9%) ($p = 0.724$). Early complications were observed in 10 patients and late complications were observed in 64 patients. The obstruction complication was occurred mainly (45 cases) in late complication patients. The median stent patency period was 84 days (IQR, 34.5-165.5 days) and median survival was 124 days (IQR 55.5-224.0 days).
Conclusion: In malignant GOO, We should carefully decide what type of stent to use according to the obstruction site. Especially, migration risk should be considered when fully covered stent is inserted at the peri-pyloric area.

P1165 EPSTEIN-BARR VIRUS ASSOCIATED GASTRIC CARCINOMA IN SOLID-ORGAN TRANSPLANT RECIPIENTS

K. Jung[1], H.-Y. Jung[1], H. K. Na[1], J. Y. Ahn[1], D. H. Kim[1], K. W. Jung[1], J. H. Lee[1], K. D. Choi[1], H. J. Song[1], G. H. Lee[1], J.-H. Kim[1]
[1]*Department of Gastroenterology, University of Ulsan College of Medicine, Asan Medical Center, Seoul, Korea, Republic Of*

Contact E-mail Address: forjkw@gmail.com
Introduction: Epstein-Barr virus (EBV), as well as *Helicobacter pylori*, has been accepted as an infective agent causing gastric cancer (GC). In conventional gastric adenocarcinoma of the diffuse and intestinal types, EBV is found in 7% > 14% of cases. Moreover, EBV associated GC (EBVaGC) occur more frequently in male and in young age group, in the proximal stomach. However, the incidence of EBV associated GC (EBVaGC) in patients that received solid organ transplantation (SOT) and immunosuppression therapy is still unknown.
Aims & Methods: The aims of this study were to evaluate the pathological characteristics and clinical outcomes of EBVaGC in patients who had performed SOT. Between January 1994 and December 2011, total 29 gastric carcinomas on 28 consecutive were confirmed and treated with endoscopic resection or operation in patients undergone SOT at Asan Medical Center, Seoul, Korea. Formalin-fixed paraffin-embedded tissue from these resection specimens were re-assessed for EBV by in situ hybridization and data from medical record were also reviewed retrospectively.
Results: Of the 6,491 patients who underwent SOT during the study periods, 30 patients (0.46%) with 31 lesions were diagnosed with gastric cancer. Among them, 28 patients with 29 lesions were treated by endoscopic resection or operation. The median age of patients was 59 years (IQR, 54-64 years) and men were 23. The median duration between transplantation and diagnosis of GC was 45 months (IQR, 34.5-80.5 months). Of total 29 GCs, 8 were found as EBVaGCs (27.5%) (6/23 males and 2/6 females). The location of tumor, histologic differentiation, initial stage[l1] and organ of transplantation showed no differences between EBVaGC and GC. The *Helicobacter pylori* was infected in 12.5% of EBVaGC and 23.8% in GC ($p = 0.615$).[l2] The survival rate was 62.5% (5/8) in EBVaGC and 81.0% (17/21) in GC ($p = 0.299$).
Conclusion: Although the incidence of EBVaGC was higher in SOT recipients than well-known incidence of EBVaGC in non-transplant patients, the pathological characteristics and clinical outcomes were not different according to the infection of EBV.
Disclosure of Interest: None declared

P1166 CLINICAL OUTCOMES OF ENDOSCOPIC RESECTION OF GASTRIC GASTROINTESTINAL STROMAL TUMOR

K. Jung[1], D. H. Kim[1], E. J. Gong[1], J. Y. Ahn[1], H. K. Na[1], J. H. Lee[1], K. W. Jung[1], K. D. Choi[1], H. J. Song[1], G. H. Lee[1], H.-Y. Jung[1], J.-H. Kim[1]
[1]*Department of Gastroenterology, University of Ulsan College of Medicine, Asan Medical Center, Seoul, Korea, Republic Of*

Contact E-mail Address: forjkw@gmail.com
Introduction: Gastrointestinal stromal tumors (GIST) are the most common mesenchymal tumors of the gastrointestinal tract. Up to date, total surgical resection still constitutes the only standard treatment for non-metastatic GISTs and a wide surgical margin is not necessary for total resection as long as the premise of negative margins is respected in comparison with that of other GI malignant tumors. With the recent advances in endoscopic technology, endoscopic resection (ER) has been attempted for the curative treatment of gastric GIST.
Aims & Methods: Here we aim to investigate the feasibility and safety of ER of gastric GIST. Subjects who underwent ER for gastric GIST at the Asan Medical Center from May 2005 to April 2014 were eligible. Patient factors, tumor factors, procedure factors, and clinical outcomes were evaluated using medical record.
Results: A total of 25 patients underwent ER for GIST. The median age was 58 years (42-72 years), and the male to female ratio was 1.5:1. The location of tumors were upper third of the stomach in 11 patients (44%), middle third in 5(20%), and lower third in 9(36%). The median size of tumors was 24.1 mm (range: 10-40 mm). The median procedure time was 37.5 minutes (range:10-80minutes). All lesions were divided into three groups according to the size and mitotic index; very low risk (16/25, 64%), low risk (7/25, 28%, and intermediate risk (2/25, 8%). Complications occurred in 5 patients (20%) including microperforation ($n = 4$, 16%) and delayed bleeding ($n = 1$, 5%). Five patients underwent sequential wedge resection of stomach because of microperforation and noncurative resection, and the pathologic evaluation revealed residual tumors in 2 patients. There was no recurrence or metastasis occurred during the median follow-up period of 49.9 months(range: 2-108 months).
Conclusion: ER of gastric GIST may be a feasible and safe method, on the basis of favorable clinical outcomes.
Disclosure of Interest: None declared

P1168 CLINICOPATHOLOGICAL REVIEW OF PIT DYSPLASIA AFTER ENDOSCOPIC RESECTION OF GASTRIC EPITHELIAL NEOPLASMS : THE FEATURES AND IMPORTANCE OF PIT DYSPLASIA

Contact E-mail Address: dhbeak@hanmail.net

Introduction: Endoscopic resection (ER) is widely accepted as appropriate treatment modalities for gastric epithelial neoplasms. However, issues regarding discrepancy between forceps biopsy and ER specimens or negative pathologic diagnosis (NPD) after ER have been rising. Recently pit dysplasia (PD) is suggested as one of subtypes of gastric dysplasia.

Aims & Methods: We aimed to review clinicopathologic features of cases with NPD after ER for early gastric neoplasms, and to evaluate the role of PD in these cases. From January 2006 to September 2013, 29 NPD lesions after ER, which had 1) available pretreatment forceps biopsy specimen, 2) correct targeting during ER, 3) no cautery artifact on resection specimen, were included in this study. Pretreatment forceps biopsy and ER slides were reviewed by 2 expert pathologists in gastrointestinal pathology.

Results: Review of 29 NPD lesions after ER showed PD in 16 lesions and no neoplastic pathology in 13 lesions. Initial pretreatment forceps biopsy diagnoses of 29 NPD lesions were low-grade dysplasia (LGD) in 17 lesions, high-grade dysplasia (HGD) in 7 lesions, and adenocarcinoma in 5 lesions. Reviewed diagnoses of initial pretreatment forceps biopsy were PD in 19 lesions, LGD in 4 lesions, adenocarcinoma in 2 lesions and no neoplastic pathology in 4 lesions. Taken together, of 29 NPD lesions after ER, 9 lesions (31%) were removed by forceps biopsy due to small size of the lesion, 4 NPL lesions (14%) were initially misinterpretated as neoplastic lesions, and 16 PD lesions (55%) were misinterpretated as NPD lesions in ER slides.

Conclusion: In about half of lesions initially interpreted as NPD after ER, they were diagnosed as LGD or HGD on initial biopsy specimen, and their final diagnoses were changed into PD. Therefore, the use of PD as a subtype of gastric dysplasia could narrow diagnostic discrepancy between initial forceps biopsy and ER and could lessen the frequency of NPD.

P1169 CLINICAL FACTORS ASSOCIATED WITH DUODENAL TUMOR: DIFFERENCE BETWEEN THE 2ND PORTION AND THE BULB

M. Ueda[1], J. Matsuzaki[1], H. Suzuki[1], T. Masaoka[2], S. Fukuhara[1], S. Miyoshi[1], H. Mori[1], Y. Iwao[2], Y. Sugino[2], T. Kanai[1]
[1]*Internal medicine, Keio University School of medicine,* [2]*Center for Preventive Medicine, Keio University Hospital, Tokyo, Japan*

Introduction: Primary duodenal adenocarcinoma is a rare malignant neoplasm among all gastrointestinal malignancies which poor prognosis is likely to be associated with delayed diagnosis. Lee et al reported the characteristics and prognosis of 53 cases with duodenal adenocarcinoma [1]. According to this report, 14 of 60 cancers (23%) found in the 2nd portion and 8 of 12 cancers (67%) in the bulb were unresectable at diagnosis. This suggests that the duodenal tumors in the bulb would be rare but show poorer prognosis than those in the 2nd portion. The present case-control study was designed to evaluate the characteristics of patients with duodenal adenoma or adenocarcinoma. In addition, the characteristics between the tumor in the bulb and the 2nd portion were compared.

Aims & Methods: Patients who made a histological diagnosis of duodenal adenoma or duodenal adenocarcinoma at Keio University Hospital between January 2010 and June 2014 were enrolled as cases. On the other hand, two age- and gender- matched control subjects for each case were randomly extracted from individuals who underwent esophagogastroduodenoscopy for medical checkup in the same period and did not have duodenal tumors. Individuals with familial adenomatous polyposis or the Peutz-Jeghers syndrome were also excluded. Lifestyle characteristics, comorbidities, and endoscopic findings were compared between cases and controls.

Results: 157 cases (123 with duodenal adenoma and 34 with duodenal adenocarcinoma) and 314 age- and gender- matched healthy controls were investigated. Multivariable logistic regression analysis revealed that current smoking (odds ratio [OR], 2.5; 95% confidence interval [CI], 1.3 - 4.6]), the presence of Barrett's esophagus (OR, 4.7; 95% CI, 2.5 - 8.8), the presence of fundic gland polyps (OR, 2.5; 95% CI, 1.5 - 4.4) and a history of malignant diseases (OR, 3.0; 95% CI, 1.8 - 5.2) were independently associated with the presence of duodenal tumor. The presence of duodenal tumor in the 2nd portion ($n = 137$) was associated with current smoking (9% vs. 17%; $p = 0.03$), Barrett's esophagus (7% vs. 20%; $p < 0.01$), reflux esophagitis (7% vs. 13%; $p = 0.045$), fundic gland polyps (15% vs. 29%; $p = 0.002$) and a history of malignant diseases (13% vs. 24%; $p = 0.006$). On the other hand, the presence of duodenal tumor in the bulb ($n = 20$) was associated with the presence of Barrett's esophagus (3% vs. 25%; $p = 0.01$) and a history of malignant diseases (10% vs. 40%; $p = 0.01$). The presence of open-type atrophy was inversely correlated with the presence of duodenal tumor in the 2nd portion (25% vs. 15%; $p = 0.02$), whereas the presence of open-type atrophy was more frequently observed in individuals with duodenal tumor in the bulb (28% vs. 40%; $p = 0.38$).

Conclusion: Clinical characteristics were different between individuals with the duodenal tumors in the 2nd portion and those in the bulb. These results suggest the differences of the etiology of tumor development between the locations of primary duodenal tumor.

P1170 CLINICAL OUTCOME OF ENDOSCOPIC SUBMUCOSAL DISSECTION FOR EARLY GASTRIC CANCER BEYOND THE EXPANDED CRITERIA

N. Shibukawa[1], N. Tatsumi[1], A. Kaneko[1]
[1]*Gastroenterology, NTT West Osaka Hospital, Osaka, Japan*

Contact E-mail Address: n_shibukawa@yahoo.co.jp

Introduction: Endoscopic submucosal dissection (ESD) has been widely undertaken for the treatment of early gastric cancer. However, the long-term outcome of ESD beyond the expanded criteria remains uncertain.

Aims & Methods: From July 2006 to February 2015, ESD for early gastric cancer was performed in 302 patients in our hospital, and 53 patients met beyond the expanded criteria. We retrospectively studied their clinical course after ESD.

Results: En bloc resection rate and complete resection rate were 90.6 % and 60.4 %, respectively. Both rates of postoperative bleeding and perforation after ESD were 3.8 %. Among the 53 patients beyond the expanded criteria, 16 (30.2 %) underwent additional gastrectomy (surgical group) and 37 (69.8 %) did not (non-surgical group). Local recurrence rate was 0 % in the surgical group and 2.7 % in the non-surgical group. Lymph node metastasis was observed in 18.8 % and 0 %, respectively. Distant metastasis was not observed in both groups. Three-year overall survival rate was 93.8 % and 78.4 %, respectively. Death due to gastric cancer was observed only one patient in the non-surgical group.

Conclusion: Beyond the expanded criteria does not always lead to cancer recurrence or metastasis. Thus, if additional gastrectomy cannot be underwent because of patient's underlying condition or refusal, a close follow-up might be considered.

P1171 DETERMINANTS OF PATIENT'S AND DOCTOR'S DELAY IN DIAGNOSIS OF GASTRIC CANCER IN THE NETHERLANDS; A ROUTINE CARE DATA ANALYSIS

N. F. Van Erp[1], Y. Arik[1], C. W. Helsper[1], N. J. de Wit[1]
[1]*Julius Center for Health Sciences and Primary Care, UMC Utrecht, Utrecht, Netherlands*

Contact E-mail Address: nfvanerp@gmail.com

Introduction: An efficient diagnostic process is important to reduce burden of disease for gastric cancer patients. Duration of this diagnostic process and determinants of relatively long duration are unknown for the Netherlands.

Aims & Methods: The aim of the present study was to determine the duration of the different phases of the diagnostic process of gastric cancer patients in the Netherlands and to identify determinants of relatively long duration ('delay'). A retrospective observational study was performed, using routine care data of 51 eligible gastric cancer patients diagnosed between 2008 and 2013, whose anonymized patient files were retracted from the Primary Care Network Utrecht (PCNU) database. Three phases in the diagnostic process were defined (T1 to T3): T1 – from onset of symptom(s) to first gastric cancer related consultation with general practitioner (GP); T2 – from first GP consultation to referral for diagnosis; T3 – from referral to final diagnosis. Based on manual exploration of free-text and coded data, the duration of these phases was determined. Median duration and interquartile ranges (IQR) were calculated in days. 'Delay' was defined as the longest quartile of phase duration. To find determinants of 'delay', the association between patient-, disease- and consultation related variables and 'delay' was assessed using univariate χ^2 and multivariate logistic regression analyses.

Results: The median time from onset of symptoms to final diagnosis was 128 days (IQR 61 - 213). Median duration of the different time periods was: T1: 17 days

(IQR 3 - 42); T2: 22 days (IQR 4 - 66); T3: 34 days (IQR 15 - 56). The only variable for which a suspicion of an association with 'delay' was found was psychiatric co-morbidity in T2 (OR 2.27, 95%CI 0.93 - 5.57).
Conclusion: Dutch gastric cancer patients face a modest 'delay' in the diagnostic process in primary and secondary care. No clear determinants of long duration could be identified. The variation in duration of each phase, particularly in time from first consultation to referral by the GP, is substantial. Since the time from referral by the GP to final diagnosis was relatively long, increasing efficiency of the secondary care diagnostic process is likely to be the most effective intervention to reduce 'delay'.

P1172 DEVELOPMENT OF AN E-LEARNING SYSTEM FOR THE ENDOSCOPIC DIAGNOSIS OF EARLY GASTRIC CANCER: AN INTERNATIONAL MULTICENTER RANDOMIZED CONTROLLED TRIAL

N. Uedo[1], K. Yao[2], M. Muto[3], H. Ishikawa[4], on behalf of Global
[1]*Department of Gastrointestinal Oncology, Osaka Medical Center for Cancer and Cardiovascular Diseases, Osaka,* [2]*Endoscopy, Fukuoka University Chikushi Hospital, Chikushino,* [3]*Therapeutic Oncology, Kyoto University Graduate School of Medicine,* [4]*Graduate School of Medical Science, Kyoto Prefectural University, Kyoto, Japan*

Contact E-mail Address: uedou-no@mc.pref.osaka.jp
Introduction: Gastric cancer ranks the third highest cause of cancer deaths worldwide. Except Japan and Korea where screening program is implemented, most of the gastric cancers were diagnosed at advanced stage. We suspect one of the reason why gastric cancers around the world were detected late is because of limited knowledge and experience of endoscopists. Accordingly, the authors have developed an Internet-based e-learning system to teach medical practitioners how to detect early gastric cancer using standard white light endoscopy.
Aims & Methods: The aim of this study was to evaluate effectiveness of the e-learning system on teaching good practice for endoscopic screening of gastric cancer. The study was designed as a randomized controlled trial. Medical practitioners around the world participated in this study with a signed consent form. The participants first undertook a pre-test via Internet, and then they were randomly allocated into two groups (e-learning and non-e-learning groups). Pre-adjustment strata were the pre-test score, experience of endoscopy, a nurse endoscopist or a medical doctor, and medical institution and country. The participants only in the e-learning group were allowed to access to the e-learning system that consisted of video lectures to learn basic knowledge and self-exercise tests to accumulate experience. A post-test was conducted in the both groups two months after the pre-test. The pre-determined primary endpoint was the difference in improvement rate of the test result (post-test score/pre-test score) between the two groups. After completion of the post-test, the e-learning system was opened for all participants.
Results: Five-hundred fifteen medical practitioners from 35 countries were assessed eligibility for this study. Finally, 322 participants who met inclusion criteria completed the pre-test and enrolled in this study. One-hundred sixty-six were allocated to the e-learning group and 166 were allocated to the non-e-learning. Among them, 151 participants in the e-learning group and 144 in the non-e-learning group had completed the post-test, and were included into the analysis. The mean improvement rates (standard deviation) of the test result in the e-learning and the non-e-learning groups were 1.24 (0.26) vs. 1.00 (0.16), respectively ($P < 0.001$). Namely, our e-learning system yielded substantial improvement to medical practitioners in the e-learning group, while there was no improvement for those in the non-e-learning group.
Conclusion: This global study demonstrated efficacy of our e-learning system to improve ability for endoscopic detection of early gastric cancer among medical practitioners worldwide. The effectiveness will be evaluated on improvement of early gastric cancer detection rate of all participants in actual clinical practice. (UMIN: R000012039)

Introduction: Compared to Asian countries, ESD is rarely performed for gastric lesions in the West. The aim of our study was to report our experience and results in absolute and expanded indications for endoscopic resection of early gastric cancer (EGC).
Aims & Methods: All patient files, included in a prospective register, treated for gastric lesions by endoscopic submucosal dissection between January 2005 and December 2014 were analysed focusing on pre-ER histology, curative resection rates, and clinical outcomes based on pathology specimen and follow-up. Patients were classified following the Japanese guidelines as standard (SC) and expanded criteria (EC). All patients not fulfilling these criteria were considered as "out of criteria" (OOC).
Results: The data for 118 consecutive gastric lesions resected by ESD in 106 patients were reviewed (mean follow-up 50 months), mean age 69 years, 71 (67%) men. Lesions were 70 EGCs, 23 HGD, 9 LGD adenomas, 4 neuroendocrine tumors, 10 benign various lesions. Mean lesion size was 25 mm (5-60). Perforation were observed in 2 pts (endoscopic management). R0 resection rate in EGC were 93% in SC (14/15 pts), 89% in EC (17/19 pts), and 42% (15/36 pts) in OOC. Significantly better resection rates were observed during the second period of ESD experience (2011-2014 vs 2005-2010: 100 vs. 86%, 90 vs 87% and 61% vs 22%, respectively. OOC classification was usually due to a combination of factors including lymphatic permeation (4), undifferentiated cancer foci (19), ulceration (12), and sm1 or 2 invasion (24). 13 pts with R1 resections and OOC underwent gastrectomy: 50% had no residual disease, all three intramucosal EGCs were staged pN0 whereas 2/10 of the ten EGCs reaching the submucosa were staged pN+ (20%).
Conclusion: In the Western world, a significant proportion of EGC treated by ESD are either expanded criteria indications or even out of criteria due to G3 foci, lymphatic permeation or a combination of factors. Most of these factors could not be detected before endoscopic resection. Excellent curative resection rates of more than 90% could be offered to patients with expanded indications. More than 2/3 of patients with R1 resection and OOC specimens were also effectively cured by ESD, as proven by subsequent gastrectomy. This treatment could therefore still be considered as a curative option in frail patients.

Contact E-mail Address: rcannizzaro@cro.it
Introduction: Loss of cadherin 1 (CDH1) expression, which is normally involved in cell adhesion and maintenance of tissue architecture, is a hallmark of Hereditary Diffuse Gastric Cancer (HDGC).
The frequency of CDH1 germline mutations in families with HDGC is 25-30% but the real frequency and characterization of germline variants for CDH1 in sporadic Gastric Cancer (GC) patients is not known. Moreover, recently CDH1 mutations have been demonstrated to have a prognostic role in overall GC. It is important to determine the prevalence of germline CDH1 mutations in overall patients with GC.
Aims & Methods: To this end, we tested CDH1 for germline mutations in a population of patients with non-Hereditary GC.
Peripheral blood from 142 patients with a histopathological confirmed GC diagnosis was investigated for CDH1 mutations. Patients attend from a single center (CRO, Centro di Riferimento Oncologico) at the Gastroenterology Unit. CDH1 mutations of all 16 exons and their flanking non coding regions were analyzed by using PCR followed by direct sequencing.
The frequency of CDH1 germline mutations in families with HDGC is 25-30% but the real frequency and characterization of germline variants for CDH1 in sporadic Gastric Cancer (GC) patients is not known. Moreover, recently CDH1 mutations have been demonstrated to have a prognostic role in overall GC. It is important to determine the prevalence of germline CDH1 mutations in overall patients with GC. To this end, we tested CDH1 for germline mutations in a population of patients with non-hereditary GC.
Results: Within the 142 samples screened a number of 20 mutations were found, including five which load to aminoacid replacement (non synonymous), nine synonymous variants, four intronic variants and two variant in the 5' untranslated region (UTR). More specifically, the five non synonymous variants were: G54R, G274S, A298T, T470I and A592T, with the last present in two patients. The G54R mutation is a new variant of exon 2 and studies are going to test the pathogenicity of the mutation.
Conclusion: The frequency of non synonymous CDH1 mutations in our series was 5 out of 142 cases (3.5 %). The pathogenesis and prognostic effect of these mutations in patients with GC are in course.). More specifically, the five non synonymous variants were: G54R, G274S, A298T, T470I and A592T, with the last present in two patients. The G54R mutation is a new variant of exon 2 and studies are going to test the pathogenicity of the mutation.

Contact E-mail Address: gon22gon@naver.com
Introduction: There are several reports of superiority of self expandable metal stent (SEMS) placement over surgery in symptom relief and shorter hospital stay in malignant gastric outlet obstruction (GOO). However, there is significant difference between technical and clinical success rate of placement of

SEMS placement. So, we investigated factors associated with clinical success on the placement of SEMS.
Aims & Methods: We analyzed retrospectively medical records of 124 patient who received endoscpoic placement of SEMS due to malignant GOO from February 2009 to June 2014 in Pusan national university Yangsan Hospital. The change of the Gastric Outlet Obstruction Scoring System (GOOSS) before and after the procedure was investigated. Then we analyzed some factors associated with the improvement of GOOS.
Results: The rate of techinical success of placement of SEMS was 98%(122/124). Clinical success of placement of SEMS was defined as improvement of GOOSS within 7 days after stent placement and it was 81.1% (99/122). Causes of stenosis were stomach cancer 39 (32%), pancreatic cacer 37 (30.3%), cholangiocarcinoma 20 (16.4%), ampulla of vater cancer 8(6.6%), gall bladder cancer 18 (14.7%). We reviewd variables related to improvement of GOOSS and identified some factors such as ECOG ≥ 3 (Adjusted OR 9.9, $p = 0.001$), gall bladder cancer (Adjusted OR 9.201, $p = 0.011$), carcinomatosis peritonei (Adjusted OR 33.11, $p < 0.001$) and impossibility of passing the endoscope through obstructive site (Adjusted OR 6.743, $p = 0.037$).
Conclusion: We realized some factors of clinical success in placement of self expandable metal stent in malignant GOO. Physician should take into account of these factor.

Introduction: The gastrointestinal tract is the most frequent site for neuroendocrine tumors (NETs). Duodenal NET is rare and occurs less frequently than gastric and rectal NETs. The surgical resection is a standard treatment for T2 duodenal NET invading into muscle layer or indicating more than 1cm in size. However, the endoscopic resection (ER) has the possibility to cure T1 duodenal NET invading within submucosal layer (SM) and 1cm or less in size because of a low frequency of lymph node and distant metastasis.
Aims & Methods: The aim of this study was to analyze the clinical outcomes of patients with duodenal NET and to assess the indication for ER as a curative procedure in selected cases. We included 47 consecutive patients with 49 lesions who were diagnosed to have nonampullary duodenal NETs as G1 and G2 categories of WHO classification between May 1997 and June 2014 in our hospital. Patients who underwent only chemotherapy were excluded from this study as well as patients diagnosed with ampullary NET. We analyzed patient characteristics, endoscopic findings, treatment methods, complications, pathological results and long-term outcomes.
Results: Male/female, 32/15; mean age, 65.2; 1st/2nd/3rd part, 42/6/1; single/multiple, 45/2; median tumor size in cases of ER/surgery, 5mm (range, 3-10)/10mm (1-40). 38 lesions were recognized as an elevation in the submucosal tumors and the finding of the delle was positive in 17 lesions endoscopically. Twenty-one patients with 22 lesions underwent ER including 7 endoscopic submucosal dissections and 15 endoscopic mucosal resections. The tumor depth was limited to SM in all lesions histopathologically. The proportions of positive lesions for vertical margin were 13% (5/7) for 5mm in size or less and 71% (2/15) for 6mm or more, and 2 patients received the additional surgery after ER. Twenty patients with 21 lesions, involving 2 cases with additional surgical resection, underwent surgery including local excision of the duodenum for 8 patients, distal gastrectomy for 8, total gastrectomy for 3, and pylorus preserving pancreaticoduodenectomy for 2. Eight lesions were incidentally detected in the surgical specimen. Eight patients were carefully followed up for various reasons. Lymph node metastasis (LNM) were positive histopathologically among 6 out of 20 surgical patients and all the lesions had the finding of the delle. Three lesions that invaded into muscle layer or deeper were 12-40mm in size and were diagnosed as G2 category with Ki-67 labeling index 3% or more. The remaining 3 limited into SM were 10mm or less in size and were diagnosed as G1 category with Ki-67 labeling index less than 3%. In the group of 39 patients treated endoscopically or surgically, there were no LMN (0/23) in T1 cases negative for the finding of the delle, 8.6% (3/35) in cases of G1 category and 9.7% (3/31) in T1 cases regardless of the finding of the delle. In 1 patient, second surgery was performed for the metachronous LNM 47 months after the initial operation. There were no death from duodenal NET and no recurrence of liver metastasis during 42 months of the median follow-up.
Conclusion: Surgical resection is basically recommended for nonampullary duodenal NET, however ER can be considered for T1 lesions without the finding of the delle and 5mm or less in size.

Contact E-mail Address: anam_vaz@hotmail.com
Introduction: The estimated prevalence of *Helicobacter Pylori* (H.P.) in the Portuguese population is about 80%. Due to its ulcerogenic and carcinogenic potential, the screening and eradication of this bacteria before bariatric surgery has become common practice. Recently, the relation between H.P and multiple metabolic disorders has been deserving attention from the scientific community.
Aims & Methods: Our aim was to evaluate the prevalence of H.P. and its relation with metabolic comorbidities in obese patients. We did a retrospective study of patients who performed upper endoscopy before being submitted to bariatric surgery between January 2012 and December 2014.
Results: A total of 200 patients were included, 90% females with a mean age of 44.2 ± 11.2 years, weight 109.6 ± 18.2 Kg and Body Mass Index (BMI) 42.2 ± 4.9 Kg/m^2. As for metabolic comorbidities, Hypertension was present in 58% of patients, Hypercholesterolemia in 57.5%, Hypertriglyceridemia in 23.5% and type 2 Diabetes Mellitus in 28%. The prevalence of H.P in this population was 58%, with diagnosis made by endoscopic biopsy (histology or rapid urease test) in 109 patients (94%) and in the remaining through fecal antigen test. There was no significant correlation between the presence of dyspeptic symptoms, endoscopic or histologic findings, weight, BMI or age and testing positive for H.P. Concerning the metabolic comorbidities previously referred, there was a significant relation between altered cholesterol values and infection with H.P ($p < 0.05$). Twelve patients (6%) had postoperative complications, but there was no statistical association with H.P infection.
Conclusion: We have verified a lower prevalence of H.P. infection in obese patients when compared to the general population, as well as a statistical relation between hypercholesterolemia and the presance of infection. The eradication of this pathogen in obese patuients may therefore play a role in improving these patients' lipid profile.

Contact E-mail Address: limz00@gmail.com
Introduction: Recent studies suggested that *Helicobacter pylori* could prevent allergic disease, especially in the children. However, there are debates in the adults.
Aims & Methods: The aim of this study is to clarify the true association between *H. pylori* infection and asthma in a population with high prevalence of *H. pylori* in the age over 16 years. Medical records of subjects who received health surveillance checkup between January 2005 and December 2011 were reviewed. Their serum *H. pylori* IgG status, *H. pylori* eradication history, and history of asthma or other allergic conditions, such as allergic rhinitis, atopic dermatitis, chronic urticarial, food/drug allergy, and others were analyzed. Those who had *H. pylori* IgG or *H. pylori* eradication history were considered to have *H. pylori* infection. Information about patients' history of asthma or other allergic conditions was obtained from their questionnaire and medical records.
Results: Out of the total 15,999 patients, 9,662 had history of *H. pylori* infection, 376 had asthma, and 3,530 had other allergic conditions than asthma. *H. pylori* infection was positively related with age (OR 1.052, 95% CI: 1.049-1.055, $p < 0.001$). Among the total, *H. pylori* infection and asthma demonstrated no significant association (OR 1.031, 95% CI: 0.829-1.282, $p = 0.783$). However, among those under 50 years old, *H. pylori* was inversely associated with asthma with statistical significance (OR 0.649, 95% CI: 0.453-0.931, $p = 0.018$). Other allergic conditions than asthma also showed inverse relationship with *H. pylori* infection among the total (OR 0.923, 95% CI: 0.854-0.999, $p = 0.047$).
Conclusion: The inverse association between *H. pylori* infection with asthma or other allergic conditions in young population suggests underlying immune mechanism by *H. pylori* infection inhibits some allergic reaction in the adults.

P1179 GASTRIC JUICE POLYMERASE CHAIN REACTION (PCR) FOR THE DIAGNOSIS OF *HELICOBACTER PYLORI* INFECTION IN PATIENTS WITH UPPER GASTROINTESTINAL BLEEDING: COMPARISON WITH OTHER CLASSICAL DIAGNOSTIC METHODS

A. Sirinawasatien[1], S. Chandrasakha[1], P. Hansombun[1]
[1]*Department of Medicine, Rajavithi Hospital, Bangkok, Thailand*

Contact E-mail Address: sui_apichet@yahoo.com
Introduction: The prevalence of *H. pylori* infection is approximately 70% in patients with peptic disease.[1] Many studies have demonstrated that rapid urease test and histology lack sensitivity for a bleeding peptic ulcer.[2,3] Gastric juice PCR has better accuracy for diagnosis of *H. pylori* infection than histology

in a non-bleeding peptic ulcer.[4] However, there is a lack of data for patients with UGIB.

Aims & Methods: To determine the diagnostic efficacy of gastric juice PCR for the detection of *H. pylori* infection compared to histology, rapid urease test and culture in patients with UGIB. Sixty-four patients who presented with UGIB and were undergoing upper GI endoscopy between 1 January, 2015 and 31 March, 2015 were enrolled consequetively. Gastric biopsy specimens from the corpus and antrum were taken for rapid urease test, histology (hematoxylin and eosin) and culture. Five milliliters of gastric juice was aspirated by a sterile ERCP catheter via the endoscope working channel. The sample was evaluated by agarose gel electrophoresis and Southern blot hybridization for the 23S rRNA gene of *H. pylori*. Sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV), accuracy, positive and negative likelihood ratio for gastric juice *H. pylori* PCR were compared to histology, rapid urease test and culture.

Results: Of 64 patients, 41 were male and 23 were female. The mean age was 59 years. There were 53.1% of patients who presented with melena, 26.6% with hematemesis, and 20.3% with both melena and hematemesis. The means of Rockall and Blatchford scores were 2.52 and 11.23, respectively. Endoscopic findings showed lesion at stomach in 51 patients, duodenum in 6 patients and in both stomach and duodenum in 7 patients. The most common cause was peptic ulcer (60%). The prevalence of *H. pylori* infection, either positive culture or positive rapid urease test plus histology, was 43.8%**.** The sensitivity of gastric juice PCR for *H. pylori* was significantly higher than histology (92.9% vs 25%, $P < 0.001$) but equal to rapid urease test (92.9%) and culture (96.4%). Further analysis showed a non-significant difference in the sensitivity of rapid urease test, culture and gastric juice PCR for *H. pylori* between patients with and without blood in the stomach (47% and 53%, respectively).

Conclusion: Gastric juice PCR for *H. pylori* is highly sensitive for diagnosing *H. pylori* infection in patients with upper gastrointestinal bleeding. It is non-invasive, non-biopsy-based test.

Contact E-mail Address: haimsh@asaf.health.gov.il

Introduction: Among available tests to detect *H. pylori*, histopathology is the most accurate when performed correctly with unknown validity in daily practice clinic settings.

Aims & Methods: To determine the rate of potentially false negative *H. pylori* results that might be due to continued use of PPIs in routine endoscopy practice. We also aimed to establish whether gastroenterologists recommend routine cessation of PPIs before EGD and whether they regularly document that biopsies for *H. pylori* testing have been taken while the patients are on PPI treatment.

Detailed information about three known factors (PPIs, antibiotics or bismuth and prior *H. pylori* eradication treatment), which may cause histology or rapid urease test (RUT) to be unreliable, had been prospectively collected through interviews using a questionnaire before each test. The site and the number of the gastric biopsies that were obtained from each patient during esophagogastroduodenoscopy (EGD) were according to the local recommendations in each center. Gastric biopsies were stained with H&E for histological analysis.

Results: A total of 409 subjects at three academic Gastroenterology Institutions were tested 200 times with histology. Fifty six percent (68 of 122) of all negative tests fell in the category, of continuing PPI use, which had the potential to make the histology and RUT results unreliable.

Conclusion: These data demonstrate a clear and important gap between current guidelines and real-world practice with regards to the diagnosis of *H. pylori* during EGD. A negative histology or RUT should be considered false negative until potential protocol violations are excluded. In all patients documentation of PPI use during the EGD should be an integral part of the EGD report. The current practice of taking biopsies for *H. pylori* testing in patients under PPI, should be reevaluated.

P1181 USEFULNESS OF LINKED COLOR IMAGING (LCI) FOR DIAGNOSIS OF *HELICOBACTER PYLORI* (H. PYLORI) INFECTION

H. Kitae[1], N. Yagi[1], A. Tomie[1], Y. Oshima[1], A. Obora[1], T. Kojima[1]
[1]*Gastroenterology, Murakami Memorial Hospital, Asahi University, Gifu-shi, Japan*

Contact E-mail Address: hkitae@koto.kpu-m.ac.jp

Introduction: LCI is a novel image-enhanced endoscopy with a laser light source to enhance the slight difference in mucosal color. That is, LCI performs expansion and reduction of color information simultaneously so that a reddish color become redder, and a whitish color become whiter. Approximately half of the world's population is infected with *H. pylori*. It is now well known that *H. pylori* infection induce duodenal and gastric ulcer disease and gastric cancer. Diffuse redness of fundic mucosa was one of the most important endoscopic features of *H. pylori* infection. We expected LCI to enhance the diffuse redness in *H. pylori*-positive patient, and to facilitate the endoscopic diagnosis of *H. pylori* infection.

Aims & Methods: The aim of this study is to evaluate the usefulness of LCI for diagnosis of *H. pylori* infection compared to the conventional endoscopy with white-light image (WLI). We retrospectively analyzed 134 patients with *H. pylori* infection and 126 patients with negative *H. pylori* infection those were examined with WLI and LCI at Murakami Memorial Hospital Asahi University from July 2014 to April 2015. We performed the definitive diagnosis of *H. pylori* infection using several methods. Two endoscopists (A: an expert involved in the development of LCI, B: a senior resident) evaluating all of the endoscopic WLI and LCI images, divided patients into *H. pylori*-positive group and *H. pylori*-negative group. Additionally we divided patients in each groups into highly-suggestive (HS) and lower-suggestive (LS) sub-groups.

Results: The levels of accuracy / sensitivity / specificity of diagnosis of *H. pylori* infection by A using WLI, and LCI were 75.8% / 68.7% / 83.3%, and 83.8% / 83.6% / 84.1%, respectively. On the other hands, those of diagnosis by B using WLI, and LCI were 73.5% / 86.6% / 55.1%, and 81.5% / 95.5% / 77.7%, respectively. The accuracy and sensitivity of diagnosis with LCI was significantly higher than those of WLI by two endoscopists ($p < 0.05$). There were no difference between the specificity of diagnosis by WLI and LCI. The kappa value of variability between A and B for LCI (kappa value = 0.635) was higher than that for WLI (kappa value = 0.488). The ratio of HS group to LS group among patients correctly diagnosed using LCI is significantly greater than when it is diagnosed using WLI ($p < 0.01$).

Conclusion: LCI is valuable tool for diagnosis of *H. pylori* infection compared to WLI. LCI has the high accuracy and sensitivity of diagnosis of *H. pylori* infection. When it is suspected *H. pylori* infection using LCI, it needs to be carefully diagnosed using appropriate methods, because the consensus is that it should be eradicated as soon as possible and best before pre-cancerous lesions are present.

P1182 A SIGNIFICANT INCREASE OF PEPSINOGEN I/II RATIO IS A RELIABLE BIOMARKER FOR SUCCESSFUL *HELICOBACTER PYLORI* ERADICATION; A SINGLE INSTITUTE EXPERIENCE IN JAPAN

H. Osumi[1], J. Fujisaki[1], T. Suganuma[2], M. Igarashi[1], K. Miki[1]

Introduction: Heretofore, there were many reports about the evaluation criteria of eradication therapy for *Helicobacter pylori (H.pylori)* using pepsinogen. Almost all reports were based on the percentage changes in serum PG before and after eradication therapy. In addition, the evaluation criteria using multi cut-off level was higher accuracy than the evaluation criteria using mono cut-off revel. If we could evaluate *H.pylori* eradication using serum PG, it is convenient and cost-effective compared to ^{13}C-urea breath test.

Aims & Methods: The aim of this study was to evaluated usefulness as the evaluation criteria using the percentage changes in serum PGI/II ratios of eradication therapy for *H.pylori*. A total of 650 patients received eradication therapy from October 2008 to March 2013 and we could measure serum pepsinogen I (PGI) and pepsinogen II (PGII) levels in 562 cases with *H.pylori* infection before and after eradication therapy. We also determined percentage changes in serum PGI: PGII ratios before and 3 months after the treatment by CLEIA (FUJIREBIO Inc, Tokyo, Japan) and established cut-off values for them to distinguish success from failure of *H.pylori* eradication. Cut-off values for percentage changes in serum PGI: PGII ratios were set as +40%, +25%, and + 10% when the serum PGI:PGII ratios before treatment were less than 3.0, not les than 3.0 but less than 5.0 and not less than 5.0, respectively. The percentage change in values were calculated as follows: percentage change = {(value 3 months after end of the treatment) –(value before treatment)}/(value before treatment)$\times 100^{2)}$. Gold standard of *H. pylori* eradication was defined as a negative by the use of a ^{13}C-urea breath test performed 3 months after completion of the eradication treatment. The statistical significance of serum levels of PGI, PGIIand PGI:PGIIratios as function of the eradication status was determined by Student's *t* test. Findings of $p < 0.05$ were taken to indicate statistical significance.

Results: Patients characteristics were as follows: 562 patients (226 males 40.3%, 336 females 59.7%) with a mean age of 62 ± 10 yr. The ratios of first, second, third line eradication treatment were 77.9% (438/562), 19.9% (112/562), 2.2% (12/562), respectively. Eradication of *H. Pylori* was achieved in 433 cases (77.0%). There were no significant differences serum level of PGI, PGII, and

PGI:PGIIratios before eradication treatment between the eradication success group and failure group. (PGI:55.0 ± 30.6 vs 57.9 ± 30.2, PGII: 24.7 ± 12.1 vs 24.9 ± 12.8, PGI/II: 2.3 ± 1.0 vs 2.4 ± 0.9, p = n.s) On the other hand, there was were significant differences of each factors after eradication treatment.(PGI: 33.6 ± 19.6 vs 54.2 ± 26.7, PGII: 7.5 ± 3.5 vs 23.3 ± 12.2, PGI/II: 4.5 ± 1.6 vs 2.5 ± 1.1, $p < 0.05$) Increasing percentage in serum levels of PGI:PGIIratios after treatment compared with the values before treatment clearly distinguished success from failure of eradication. (108.2 ± 57.2 vs 6.8 ± 30.7, $p < 0.05$) Using above cut-off values, the sensitivity (non-eradication: *H.pylori*+), specificity (eradication: *H.pylori* -), and validity for determination of *H.pylori* were 93.1, 93.8 and 93.2%, respectively.

Conclusion: In conclusion, our findings suggested that the percentage changes in serum PGI/II ratios are useful as the evaluation criteria of eradication therapy for *H. pylori*.

P1183 THE HELICOBACTER ERADICATION ASPIRIN TRIAL (HEAT): A LARGE SIMPLE RANDOMISED CONTROLLED TRIAL USING NOVEL METHODOLOGY IN PRIMARY CARE

J. S. Dumbleton[1], A. Avery[2], C. Coupland[2], F. D. R. Hobbs[3], D. Kendrick[2], M. V. Moore[4], C. Morris[5], G. P. Rubin[6], M. D. Smith[7], C. J. Hawkey[1]

Contact E-mail Address: jennifer.dumbleton@nottingham.ac.uk

Introduction: Clinical trials measuring the effect of an intervention on clinical outcomes are more influential than those investigating surrogate measures but are costly. We developed methods to reduce costs substantially by using existing data in primary and secondary care systems, to ask whether *Helicobacter pylori* eradication would reduce the incidence of hospitalisation for ulcer bleeding in aspirin users.

Aims & Methods: The Helicobacter Eradication Aspirin Trial (HEAT) is a HTA-funded, CRN-supported, double-blind placebo controlled randomised trial of the effects of *H. pylori* eradication on subsequent ulcer bleeding in infected individuals taking aspirin daily, conducted in practices across the whole of England, Wales and Northern Ireland. A bespoke web-based trial management system developed for the trial (and housed within the secure NHS N3 Data Network) communicates directly with the HEAT Toolkit software downloaded at participating practices, which issues MIQUEST queries searching entry criteria (≥60 years, on chronic aspirin ≤325mg daily, not on anti-ulcer therapy or non-steroidal anti-inflammatory drugs) for GP review of eligibility. Trial participation is invited using a highly secure automated on-line mail management system that ensures patients receive an invitation within 48 hours. Interested patients are seen once for consent and breath testing. Those with a positive test are randomised to eradication treatment (lansoprazole, clarithromycin, metronidazole) or placebo with drug sent by post. Events are tracked by upload of accumulating information in the GP database, patient contact, review of national Hospital Episode Statistics and ONS data.

Results: HEAT is the largest CRN CTIMP trial, with 105,276 invitation letters sent from 772 practices, 20,509 volunteers, and 2,847 H. pylori positive patients randomised to active or placebo treatment after 2.5 years of recruitment. 178 practices have performed their first follow-up MIQUEST search to identify 21 potential endpoints to date.

Conclusion: HEAT is important medically, because aspirin is so widely used, and methodologically, as a successful trial would show that large-scale studies of important clinical outcomes can be conducted at a fraction of the cost of those conducted by industry, which in turn will help to ensure that trials of primarily medical rather than commercial interest can be conducted successfully in the UK.

P1184 COMPARISON OF NON-INVASIVE TESTS; STOOL HPSA ELISA AND C13UREA BREATH TEST IN THE DIAGNOSIS OF *HELICOBACTER PYLORI* INFECTION IN A LOW PREVALENCE COHORT

J. A. Omorogbe[1], D. Brennan[1], S. Smith[1], M. Alsaffar[2], D. Mcnamara[1], on behalf of Trinity Academic Gastroenterology Group
[1]*Clinical Medicine,* [2]*Trinity College Dublin, Dublin, Ireland*

Contact E-mail Address: joeamaen@gmail.com

Introduction: Non-invasive testing for *H. pylori* infection has allowed for cost effective and safer ways to diagnose infection in both primary care and hospital settings. The reduced prevalence of *H. pylori* infection in the Irish population in keeping with other developed nations, can negatively impact on the diagnostic accuracy of a given test. Frequent evaluation and comparison of commercially available tests has been recommended and should be performed to ensure that the most sensitive and specific are used in clinical practice.

Aims & Methods: To evaluate and compare two non-invasive *H. pylori* tests; premier platinum HpSA and C^{13}UBT in an Irish cohort**.** Adult patients referred for a C^{13}UBT at the Adelaide and Meath Hospital were prospectively recruited. Patients on recent antibiotics, regular PPI or who had previously received a course of eradication therapy were excluded. Following informed consent patients were asked to collect and bring in a stool sample on the day of their C^{13}UBT testing. HpSA ELISA testing was carried out in accordance with manufacturer's instructions (Meridian Biosciences, Germany). An absorbance cut off of ≥0.140 (at 450nm) was considered positive. C^{13} UBT was considered as the gold standard and a delta value of ≥4% was deemed positive.

Results: To date 124 patients mean age 41 years, male gender 87(30%) have been recruited. In all 45(36%) percent where *H. pylori* positive on C^{13}UBT. Overall the performance of HpSA was disappointing with only 29(23%) positive tests. In all there were 17 false negative and 1 false positive HpSA test. As such the sensitivity, specificity, positive and negative predictive values for HpSA compared with C^{13}UBT were 62%, 99%, 97% and 82% respectively. Overall correlation between these two non-invasive tests was poor 0.13, 95% CI 0.016 – 0.242. The low sensitivity may reflect specific collection and storage requirements which are a common problem for many faecal tests.

Conclusion: HpSA performance in this study does not meet international guidelines for a diagnostic test for *H. pylori* infection and cannot be recommended for regular clinical use. The accuracy of UBT appears to be less affected by the relatively low prevalence of *H. pylori* infection in our community, however formal comparison with invasive modalities should be undertaken to assess its accuracy. C^{13}UBT testing continues to remain the first line non-invasive diagnostic tool in detection of *H.pylori* infection.

Abstract number: P1185

	Hp positive	Hp eradicated	Total	Sensitivity	Specificity	PPV	NPV	ROC/AUC
	446	297	743					95% CI
RAC +	34	21	55	92.9%	6.6%	60.0%	38.2%	75.4%
RAC-	412	276	688					0.707-0.800
Atrophic change +	405	270	675	90.8%	9.1%	60.0%	39.7%	49.8%
Atrophic change -	41	27	68					0.456-0.540
Diffuse redness +	440	1	441	98.7%	99.7%	99.8%	98.0%	99.0%
Diffuse redness -	6	296	302					0.983-0.998
Spotty redness +	226	42	268	50.7%	85.9%	84.3%	53.7%	68.3%
Spotty redness -	220	255	475					0.645-7.721
Rugal hyperplasia +	204	217	421	45.7%	26.9%	48.5%	24.8%	35.9%
Rugal hyperplasia -	242	80	322					0.319-0.399
Mucosal swelling +	56	24	80	12.6%	91.9%	70.0%	41.2%	51.7%
Mucosal swelling -	390	273	663					0.475-0.559
Exudation +	229	3	232	51.3%	99.0%	98.7%	57.5%	75.1%
Exudation -	217	294	511					0.717-0.785
	Hp eradicated	Hp positive						
Map-like redness +	207	8	215	69.7%	98.2%	96.3%	83.0%	84.0%
Map-like redness -	90	438	528					0.806-0.873

Diffuse redness, which had been generally observed in patients with *Hp* positive cases, was almost totally disappeared after *Hp* eradication. In contrast, map-like redness appeared in approximately 70% of patients with *Hp* eradicated status.

Introduction: Little has been reported on endoscopic findings related to *Helicobacter pylori* (*Hp*) eradicated case while several findings have been revealed to be useful in diagnosing *Hp* positive status.
Aims & Methods: To clarify the characteristic endoscopic appearance of *Hp* eradicated status upper GI endoscopy was performed in 446 patients with *Hp* positive and 297 patients proved to be negative 12 months after its treatment (women, 380; mean age, 62.4 years). Serum *Hp* IgG antibody level or rapid urease test were adopted to confirm *Hp* infection in all the cases and at least 2-site biopsy specimens were examined for histology and ^{13}C UBT was performed in all the *Hp* treated cases. The presence or absence of the following 8 endoscopic findings were evaluated: regular arrangement of collecting venules (RAC), atrophic change, diffuse redness, spotty redness, rugal hyperplasia, mucosal swelling, exudation, map- like redness. Five well-trained endoscopists who were blinded to clinical information assessed the findings.
Results: See table.
Conclusion: Disappearance of diffuse redness is the most important and decisive finding and map-like redness appearance is also beneficial to diagnose *Hp* eradicated status.

Contact E-mail Address: tafuruta@fd6.so-net.ne.jp
Introduction: Serum pepsinogens (PGs) reflect the atrophy and inflammation of gastritis induced by *H. pylori* infection. Recently, Kyoto-classification of gastritis has been developed and used widely.
Aims & Methods: The aim of the study was to investigate the relationship between Kyoto-classification of gastritis and serum PGs.
A total of 283 patients who underwent gastroscopy were enrolled. Serum levels of PG I and PG II were measured. Of the parameters of Kyoto-classification of gastritis, atrophy (C0-CII:A0, CII-C-III:A1, and OI-OIII:A2), intestinal metaplasia (None:I0, within antrum:I1 and up to corpus:I2), hypertrophy of gastric fold (-:H0, +: H1), nodular gastritis (-:N0, +:N1) and diffuse redness (-:DR0, mild: DR1, severe:DR2) were scored based on endoscopic findings.
Results: Mean PGI levels of A1, A2 and A3 groups were 67.7, 68.9 and 50.0 (ng/ml), respectively ($P < 0.001$). Those of PG II were 15.2, 26.1 and 23.8 (ng/ml), respectively ($P < 0.001$). Therefore, the expansion of gastric atrophy can be estimated by PGI and PG II. The PG I/PG II ratios in I0 and I1 gorups were 3.0 and 2.2, respectively ($P < 0.001$). Therefore, presence of intestinal metaplasia can be estimated by measurements of PG I/PG II ratios. In H0 and H1 groups, mean PG I levels were 56.8 and 65.2 (ng/ml), respectively, those of PG II were 21.1 and 32.1 (ng/ml), respectively and those for PG I/PG II were 3.0 and 2.2, respectively ($P < 0.001$), suggestion that hypertrophy of gastric folds are related to severe inflammation of gastric mucosa. Nodular gastritis were observed more often in females. Means of PG I, PG II and PG I/PG II in patients with nodular gastritis were 66.2 (ng/ml), 24.4 (ng/ml) and 2.9, respectively, suggesting that nodular gastritis is tempted to be induced in female patients with severe gastric inflammation but mild atrophy. The total score was significantly correlated with PG I/PG II. After eradication of *H. pylori*, the mean of PG I decreased from 61.1 to 37.2 ($P < 0.001$), that of PG II decreased from 25.0 to 9.0 ($P < 0.001$) and PG I/PG II ratios increased from 2.7 to 4.5 ($P < 0.001$). The mean of total gastritis score also decreased from 4.6 to 2.5 ($P < 0.001$).
Conclusion: We confirmed that serum PGs reflects the gastric atrophy as well as inflammation. Kyoto classification of gastritis is implicated with not only atrophy but also inflammation and is well correlated with serum PGs.
Disclosure of Interest: None declared

P1187 THE EFFECTS OF *HELICOBACTER PYLORI* ERADICATION THERAPY FOR CHRONIC IDIOPATHIC THROMBOCYTOPENIC PURPURA

J. J. Hwang[1], D. H. Lee[1], H. Yoon[1], C. M. Shin[1], Y. S. Park[1], N. Kim[1]
[1]*Department of Internal medicine, Seoul National University Bundang Hospital, Seongnam, Korea, Republic Of*

Contact E-mail Address: frontierassa@hanmail.net
Introduction: The aim of this study was to evaluate the ability of *Helicobacter pylori* eradication treatment for increasing platelet counts in patients in Korea with chronic idiopathic thrombocytopenic purpura (ITP).
Aims & Methods: The medical records of patients diagnosed with chronic ITP were retrospectively reviewed between January 2003 and December 2013. All patients were assessed for *H. pylori* infection using a 13C-urea breath test, and those with a positive result received standard triple therapy. A total of 102 patients were evaluated against two criteria. First, those diagnosed with *H. pylori* infection in whom eradication was successful were assigned to the *H. pylori*-positive and -eradicated group ($n = 39$), while those diagnosed with *H. pylori* infection in whom eradication failed were assigned to the *H. pylori*-positive and -non-eradicated group ($n = 3$) and those without *H. pylori* infection were assigned to the *H. pylori*–negative group ($n = 60$). Second, those with complete remission in whom the platelet recovery effect was maintained over the average follow-up period of 6 months after eradication therapy were defined as the responder group ($n = 58$), while those with partial or no response were defined as the non-responder group ($n = 44$).
Results: Platelet counts of the *H. pylori-positive* and -eradicated group increased significantly 6 months after eradication therapy compared to those of the *H. pylori-positive* and -non-eradicated group and *H. pylori-negative* group (43.2 ± 29.1 to $155.3 \pm 68.7 \times 103/\mu L$ vs. 42.5 ± 28.1 to $79.8 \pm 59.7 \times 103/\mu L$ vs. 43.1 ± 28.9 to $81.2 \pm 62.2 \times 103/\mu L$, $p = 0.041$). The eradication therapy success rate in the responder group was 100.0% (39/39) versus that of the non-responder group (0.0%; 0/3) ($p < 0.001$).
Conclusion: Platelet counts of the *H. pylori-positive* and -eradicated group increased significantly 6 months after eradication therapy compared to those of the *H. pylori-positive* and -non-eradicated group and *H. pylori-negative* group. *H. pylori* eradication therapy was related to increasing platelet count, and successful eradication affected the increased platelet count in patients in Korea with chronic ITP.
Disclosure of Interest: None declared

P1188 COMPARISON OF EFFICACY OF MOXIFLOXACIN-BASED SEQUENTIAL THERAPY AND HYBRID THERAPY AS FIRST-LINE ERADICATION REGIMEN FOR *HELICOBACTER PYLORI* INFECTION

J. J. Hwang[1], D. H. Lee[1], H. Yoon[1], C. M. Shin[1], Y. S. Park[1], N. Kim[1]
[1]*Department of Internal medicine, Seoul National University Bundang Hospital, Seongnam, Korea, Republic Of*

Contact E-mail Address: frontierassa@hanmail.net
Introduction: The aim of this study was to evaluate the efficacy of 14-day moxifloxacin-based sequential therapy compared with 14-day hybrid therapy as a first-line eradication treatment of *Helicobacter pylori* infection.
Aims & Methods: From August 2014 to January 2015, 284 patients with confirmed *H. pylori* infection randomly received 14days of moxifloxacin-based sequential (MSQT group, $n = 140$) or hybrid (Hybrid group, $n = 144$) therapy. Successful eradication therapy for H. pylori infection was defined as a negative 13C-urea breath test 4 weeks after the end of eradication treatment.
Results: The eradication rates by intention-to-treat (ITT) analysis were 91.4% (128/140; 95% confidence interval [CI]: 90.2-92.9%) and 79.2% (114/144; 95% CI: 77.3-80.7%) in the MSQT and Hybrid groups, respectively ($p = 0.013$). The eradication rates by per-protocol (PP) analysis were 94.1% (128/136; 95% CI: 92.9-95.6%) and 82.6% (114/138; 95% CI: 80.6-84.1%) in the MSQT and Hybrid groups, respectively ($p = 0.003$). Compliance was good in both groups (MSQT/ Hybrid group: 100%/100%). The adverse event rates were 11.8% (16/136) and 19.6% (27/138) in the MSQT and Hybrid group, respectively. ($p = 0.019$).
Conclusion: The eradication rates were 91.4% and 79.2% in the MSQT and Hybrid groups by intention-to-treat (ITT) analysis. The eradication rates by per-protocol (PP) analysis were 94.1% and 82.6% in the MSQT and Hybrid groups. The 14-day moxifloxacin-based sequential therapy is effective and, moreover, shows excellent compliance and safety compared with the 14-day hybrid therapy.

P1189 1-WEEK AND 2-WEEK MOXIFLOXACIN-CONTAINING TRIPLE THERAPIES FOR SECOND-LINE ERADICATION OF *HELICOBACTER PYLORI* INFECTION AFTER NON BISMUTH QUADRUPLE SEQUENTIAL AND CONCOMITANT TREATMENT FAILURE

J. H. Lim[1], D. H. Lee[2]
[1]*Internal Medicine, Incheon Sarang Hospital, Incheon,* [2]*Internal Medicine, Seoul National University Bundang Hospital, Seongnam, Korea, Republic Of*

Contact E-mail Address: medfd@naver.com
Introduction: PPI-based standard triple therapy for *Helicobacter pylori* infection has fallen considerably. To increase the eradication rate, non-bismuth quadruple sequential and concomitant therapies were introduced recently. Nevertheless, not inconsiderable patients fail to achieve eradication and need second-line treatment.
Aims & Methods: We tried to know the efficacy of moxifloxacin-containing triple therapy after non-bismuth quadruple therapy failure. A total of 98 patients who were not eradicated with non-bismuth quadruple therapy received 1-week or 2-week moxifloxacin-containing triple therapy (400 mg of moxifloxacin once daily, and 20 mg of rabeprazole and 1 g of amoxicillin twice daily). *H. pylori* status was evaluated 4 weeks later, after completion of treatment by ^{13}C-urea breath test.
Results: 60 patients and 38 patients received 1-week and 2-week moxifloxacin-containing triple therapy, respectively. The intention-to-treat and per-protocol eradication rates were 56.7% (95% CI, 45.0-70.0) and 59.6% (95% CI, 46.6-71.7) in 1-week group, and 76.3% (95% CI, 63.2-89.5) and 80.6% (95% CI, 66.7-91.9) in 2-week group ($p = 0.048$, 0.036). There were no significant between-group differences, in regard to the compliance and side effects.
Conclusion: 2-week moxifloxacin-containing triple therapy showed a better efficacy than 1-week regimen after non-bismuth quadruple therapy failure. More large sample sized prospective study will be needed.

Introduction: *Helicobacter pylori (H. pylori)* resistant strains to amoxicillin, clarithromycin or metronidazole have been increasing rapidly owing to widespread use of antibiotics with proton pump inhibitors (PPI) for eradication. The standard therapy includes the use of an antibiotic with a PPI. Rebamipide, one of the gastro-protective agents in common use, has been shown to exhibit preventive or healing effects in gastric mucosa or mucosal lesion by increasing endogenous prostaglandin or by suppressing oxygen-free radicals.

Aims & Methods: A meta-analysis of randomized control trials (RCTs) was conducted to determine if the use of Rebamipide in combination with a PPI and antibiotic can augment the eradication rate of *H. pylori*-associated gastric inflammation in adult patients diagnosed to have peptic ulcer disease.

A literature search was performed on the PubMed database and resulted in six articles, of which four were selected. Allocation concealment, intention-to-treat analysis, completeness of follow-up and blinding of investigators, participants and outcome assessors were independently analyzed by three authors and was critically appraised with regards to methods of minimizing selection bias, performance bias, exclusion bias and detection bias. Trial results were combined under a random-effects model. Dichotomous data were analyzed by calculating the risk ratio with 95% confidence interval (CI) and a significant p value of 0.05. Subgroup analyses were performed to statistically compare subgroups. Cochrane Review Manager Software version 5.0 statistical software was used for all analyses.

Results: The primary outcome of the meta-analysis was the eradication rate of *H. pylori*-positive peptic ulcer disease. Across all four trials, 209 of 293 patients (71.3%) had successful eradication of *H. pylori*-associated peptic ulcer disease using Rebamide in combination with an antibiotic and PPI compared with 179 of 271 control group patients (66.0%). The risk ratio for the eradication rate of *H. pylori*-associated peptic ulcer disease in all four trials were highly consistent ranging narrowly from 0.98 – 1.31. The pooled risk ratio was 1.07 with 95% CI of 0.98-1.17.

Conclusion: There is no significant difference in the eradication of *H. pylori* associated peptic ulcer disease with the use of Rebamipide in addition to antibiotic and PPI compared to the standard therapy alone. However, due to the rise in resistant strains of *H. pylori*, there may be an increasing need to add Rebamipide to the standard therapy as it has protective effects shown to augment ulcer healing. As such, Rebamipide may still be used in peptic ulcer disease as per the discretion of the clinician.

Introduction: Increased resistance of *Helicobacter pylori* (*H. pylori*) to antibiotics has increased the need to develop new treatments for *H. pylori*. Thus, there is clearly an urgent need to develop new drugs that are effective against resistant strains.

Aims & Methods: The aim of our study is to develop new substance that have an anti-*H. pylori* activity by using high-throughput screening assay. Chemical library composed of 1200 chemical compounds were obtained from high-throughput screening core laboratory. Antimicrobial susceptibility test was performed using the broth microdilution technique. A 96-well microtiter plates were prepared for 82 chemical compounds which showed anti-*H. pylori* activity in high-throughput screening assay. Among chemical compounds which showed growth inhibitory potential, potent chemical compounds for practical application were selected.

Results: Diphenyleneiodonium chloride (DPI) and parthenolide (PTL) were selected and measured minimal inhibitory concentrations (MICs) against reference and resistant strains of *H. pylori*. Furthermore, DPI and PTL was further evaluated to validate susceptibility against resistant *H. pylori* strains. The MIC value of parthenolide (PTL) and diphenyleneiodonium chloride (DPI) showed MIC value of 2.0-8.0 μg/ml and lower than 0.03 μg/ml. DPI also show antibacterial activity against common aerobic bacteria showing MICs ranges from 0.5 to 2 μg/ml.

Conclusion: This study shows that DPI could be a powerful new class of drugs against *H. pylori*. Further in vivo study is needed to develop this substance as anti-*H. pylori* drug.

Introduction: Levofloxacin triple therapy (LT) has been recommended as one of the second line eradication regimen for *Helicobacter pylori (H. pylori)* according to the Maastricht Consensus Report. However, recent studies showed unsatisfactory efficacy (<80%) of this regimen. Our previous pilot study showed that the eradication rate of modified sequential therapy containing levofloxacin (MS) was higher than 90%.

Aims & Methods: Therefore, we further conducted this randomized trial to compare the efficacy and tolerability of the two regimens. This open-label, randomized, multicenter trial was conducted in 9 hospitals and one community in Taiwan between 2012 and 2015. *H. pylori* infected subjects who failed from clarithromycin-based regimens (N ± 600) were randomized (1:1) to receive MS ((lansoprazole and amoxicillin for the first 5 days, followed by lansoprazole, levofloxacin, and metronidazole for another 5 days) or LT (lansoprazole, amoxicillin, and levofloxacin for 10 days). Successful eradication was defined as negative ^{13}C-urea breath test at least 6 weeks after treatment. Our primary outcome was the eradication rate by intention-to-treat (ITT) and per-protocol (PP) analyses. Antibiotic resistance was determined by agar dilution test. (ClinicalTrials.gov NCT01537055)

Results: The prevalence of clarithromycin, levofloxacin, and metronidazole resistance in this study population were 60%, 17.6%, and 36.9%, respectively. The eradication rates of MS and LT were 84.4% (249/295) and 76.3% (225/295) in the ITT analysis ($p = 0.013$), respectively, and 86.5% (249/288) and 79.2% (225/284) in the PP analysis ($p = 0.022$), respectively. There were no differences in the compliance. The efficacies in strains susceptible and resistant to levofloxacin were 92.7% (76/82) and 47.2% (9/19) for MS ($p < 0.001$), respectively, and were 76.4% (55/72) and 19.2% (5/26) for LT, respectively ($p < 0.001$). The efficacies in strains susceptible and resistant to metronidazole were 92.3% (55/59) and 83.3% (30/36) for MS, respectively.

Conclusion: Modified sequential therapy containing levofloxacin was more effective than levofloxacin triple therapy in the second line treatment for *H. pylori* in populations with high clarithromycin resistance.

Contact E-mail Address: pedro.n.carvalho@gmail.com

Introduction: *Helicobacter pylori* (HP) is the most prevalent infectious agent in the world adult population, and its eradication has become increasingly difficult as resistances to several commonly used antibiotics develop. The most adequate first-line eradication regimen for HP in Portugal has not yet been determined.

Aims & Methods: We aimed to compare HP eradication rates between triple therapy (TT) and sequential therapy (ST) in a naive Portuguese population.

Prospective randomized trial including consecutive patients with HP infection referred for first-line eradication treatment. Exclusion criteria for enrollment included previous gastric surgery or neoplasia, pregnancy or lactancy, allergy

to any of the drugs. The compared eradication regimens were TT (pantoprazol 40 mg, amoxicillin 1000 mg and clarithromycin 500 mg 12/12h for 14 days) and ST (pantoprazol 40 mg 12/12h for 10 days, amoxicillin 1000 mg 12/12h during days 1-5 and clarithromycin 500 mg 12/12h, metronidazol 500 mg 12/12h during days 6-10). Eradication success was confirmed with urea breath test, and side-effects as well as the need to stop treatment were registered. Statistical analysis was performed with SPSS v21.0 and a p value < 0.05 was considered statistically significant.

Results: Of the 63 randomized patients, 3 were lost to follow-up, resulting in the inclusion of 60 patients, 39 (65%) female with mean age 52 years (SD± 14.3). Chief indications for HP eradication were functional dyspepsia (42%), premalignant gastric lesions (23%) and peptic ulcer disease (13%). TT (n = 31) and ST (n = 29) groups were homogeneous for gender, age and indication for treatment.

No statistical differences were encountered between ST and TT eradication rates (86.2% versus 77.4%, p = 0.379), global eradication rate was 82%.

Side-effects were reported in 10 (16.7%) patients (5 in each treatment arm), most commonly dyspepsia, diarrhea and dysgeusia. In only 2 patients, both in the ST group, treatment adhesion was irregular because of moderate dyspepsia, but in both cases, HP eradication was proven successful.

Conclusion: In this randomized controlled trial in a naive Portuguese population, we found a satisfactory global *Helicobacter pylori* eradication rate of 82%, with no statistical differences observed in the efficacy of the treatment between triple and sequential regiments. These results support the use of either therapy for the first-line eradication of *Helicobacter pylori*.

Contact E-mail Address: rdas@amity.edu

Introduction: Antibiotic resistance to commonly used antibiotics against *H. pylori* is increasing very rapidly. Resistance of *Helicobacter pylori* to clarithromycin is associated with single base substitution in the 23S rRNA gene.

Aims & Methods: To determine antimicrobial susceptibility pattern of *H. pylori* strains against commonly used antibiotics in *H. pylori* treatment and to analyze the mechanism of clarithromycin resistanc in India.

H. pylori were cultured from 68 patients suffering from different gastro-duodenal diseases. Minimum Inhibitory concentration to different antibiotics was determined by agar dilution method. The point mutation in clarithromycin resistant strains were recognized by PCR- Restriction Fragment Length Polymorphism (RFLP) and DNA sequencing.

Results: The clinical diagnosis of 68 patients who were *H. pylori* culture positive were Gastro Esophageal Reflux Disease (GERD) (n = 23), Nonerosive reflux Disease (NERD) (n = 22), Non Ulcer Dyspepsia (NUD) (n = 13), Antral Gastritis (n = 3), Duodenal ulcer (n = 2) and others (n = 5). Of the 68 *H. pylori* isolates, 29.4 % (20/68) had no resistance, the prevalence of total drug resistance was 70.6% (48/68) which includes the resistance against Metronidazole (48.5%), Furazolidone (22.1%), Amoxicillin (17.6%), Tetracycline (16.2%) and Clarithromycin (11.8%). Dual and multiple drug resistance were found in 26.5 % (18/68) and 8.9% (6/68) of cases.

In our study, A2143G point mutation in 23S rRNA gene was found in 87.5% (7/8) clarithromycin resistant strains. Another most common mutation A2142G and T2182C was found in 12.5% (1/8) clarithromycin resistant strain.

Conclusion: We conclude that more than two- third of the isolated *H. pylori* strains showed resistance to at least one of the antibiotics for *H. pylori* treatment. Metronidazole showed the maximum resistance. Emergence of dual and multi-drug resistance is of great concern and there is an urgent need for regular antibiotic resistance surveillance studies. Amoxicillin and clarithromycin based anti- *H. pylori* regimens commonly prescribed for triple therapy in India shows least resistance and hence appropriate for anti *H. pylori* management in India. To our knowledge this is the first study in India to report that the point mutation at position A2143G, A2142G and T2182C is associated with clarithromycin resistance which confirms the reports available from other parts of the world.

P1195 A COMPARISON OF SEQUENTIAL THERAPY WITH STANDARD TRIPLE THERAPY FOR HELICOBACTER PYLORI ERADICATION IN AN IRISH COHORT

R. B. Haider[1], S. Smith[1], J. Omorogbe[1], D. Brennan[1], B. Hall[1], G. Holleran[1], C. O'Morain[1], H. O'Connor[1], D. McNamara[1]
[1]*Departments of Gastroenterology & Clinical Medicine Tallaght & Naas Hospital, TAGG (Trinity Academic Gastroenterology Group), Dublin, Ireland*

Contact E-mail Address: bhrana@hotmail.com

Introduction: Eradication rates for the standard first line triple therapy for *H. pylori* infection have fallen to an unacceptably low level. Sequential therapy has been suggested as a treatment option to replace standard triple therapy. The efficacy of sequential therapy has not been assessed to date in an Irish population.

Aims & Methods: To compare the efficacy of standard triple therapy with sequential therapy for *H. pylori* eradication. A prospective, multicentre, randomised controlled study was conducted after ethical approval in all participating hospitals. Treatment-naïve *H. pylori*-infected patients (>18 years), as assessed by a positive urea breath test (UBT), were invited to participate and informed consent was obtained. Patients were randomised to receive either standard triple therapy (20 mg omeprazole, 1 g amoxicillin and 500 mg clarithromycin twice daily for 7 days) or sequential therapy (20 mg omeprazole and 1 g amoxicillin twice daily for 5 days, followed by 20 mg omeprazole, 500 mg clarithromycin and 500 mg metronidazole twice daily for 5 days). A follow-up UBT was performed 6-8 weeks post-treatment to assess treatment success.

Results: To date, 86 eligible patients (mean age: 41.7 ± 11.8 years; 64% female) who tested positive for *H. pylori* infection by the UBT have been recruited to the study. 90% (N ± 77) were referred for dyspepsia. A smoking habit was reported by 22% (N ± 19) of the patients. 51% (N ± 44) patients (mean age: 43.2 ± 12.6 years; 75% female) received standard triple therapy and 49% (N ± 42) patients (40.1 ± 11 years; 52% female) received sequential therapy. The eradication efficacy by intention-to-treat analysis was 56.8% (95% CI: 42.2-71.4%) for standard triple therapy and 69% (95% CI: 55.0-83.0%) for sequential therapy. In the standard triple therapy group, 2 patients did not attend for follow-up and one patient did not complete their medication due to side effects. All patients in the sequential therapy group attended for follow-up and were compliant. The eradication rates by per-protocol analysis for standard triple therapy and sequential therapy were 61% (95% CI: 46.1-76.0%) and 69% (95% CI: 95% CI 55.0-83.0%) respectively. The differences in eradication rates by either intention-to-treat or per-protocol analysis were not statistically significant. The most common adverse event reported was mild nausea at 15% (95% CI: 7.5-22.6%). Incidence in adverse events was not significantly different between the study groups.

Conclusion: Sequential therapy has a non-statistically significant advantage over standard triple therapy in our patient cohort. However, eradication rates for both standard triple therapy and sequential therapy fall considerably short of the 80% intention-to treat-rate. Further studies are required to identify potential alternatives to standard first line triple therapy.

P1196 CUMULATIVE HELICOBACTER PYLORI ERADICATION THERAPY IN OBESE PATIENTS UNDERGOING GASTRIC BY-PASS SURGERY

R. Cerqueira[1], M. Correia[1], H. Vilar[1], M. C. Manso[2]
[1]*Centro Hospitalar entre Douro e Vouga, Santa Maria Feira,* [2]*University Fernando Pessoa & LAQV@REQUIMTE-UP, Porto, Portugal*

Contact E-mail Address: rute.cerqueira@chedv.min-saude.pt

Introduction: The Maastricht IV Consensus Report has recently updated guidelines for the management of *Helicobacter Pylori* (HP) infection with special emphasis in high clarithromycin (CLT) resistance geographical areas. However, in Portugal, there are some limitations with HP eradication treatments as bismuth is not available. In line with the recommendations of the European Guidelines on surgery of severe obesity (1) and with the recommendations of the American Society of Gastrointestinal Endoscopy on endoscopy of the bariatric patient (2) we perform HP eradication in obese patients undergoing Roux-en Y gastric by-pass (RYGB) surgery.

Aims & Methods: Over a 4-year period (2011-2014), our aim was, in obese patients undergoing RY GB surgery to assess the cumulative HP eradication rates by adopting a 14 days quadruple concomitant therapy in first line treatment as proposed by the Maastricht IV consensus – proton pump inhibitor (PPI) bid, CLT 500mg bid, metronidazole (MTX) 500 bid and amoxicillin (AMX) 1000mg bid – and a 14 days second line levofloxacin based regimen – PPI bid, AMX 1000 mg bid and levofloxacin 500mg od. HP infection status was determined by histology or urea breath test and post treatment HP status was assessed by urea breath test 4-6 weeks after the end of therapy.

Results: Six hundred twenty consecutive HP-positive patients completed concomitant first-line treatment: 511 (82.4%) female, age 40.8 (±10.3) years, median age of 41 years, age range of 18-64 years. HP was eradicated in 458 patients – 73.9% (95%CI: 70.3-77.2%). In the remaining 162 patients, second-line levofloxacin based regimen eradicated HP in 95 patients – 58.6% (95%CI: 50.9 - 65.9%). These results give 89.2% (95% CI: 86.5-91.4%) cumulative eradication rates. Eradication rates were not significantly different by gender, age and smoking habits.

Conclusion: By adopting IV Maastricht guideline quadruple concomitant first-line treatment and second-line levofloxacin-based therapy high cumulative HP eradication rates are achieved but still leaves around 11% of obese patients undergoing RYGB in need of the culture and susceptibility testing prior to third-line treatment.

P1197 TREATMENT TRIAL RESULTS FROM COMMUNITY H. PYLORI PROJECTS IN THE CANADIAN ARCTIC

S. Veldhuyzen Van Zanten[1], A. Morse[1], K. Fagan-Garcia[1], L. Aplin[1], M. Keelan[1], S. Girgis[1], K. Goodman[1], on behalf of CANHelp Working Group
[1]*University of Alberta, Edmonton, Canada*

Contact E-mail Address: vanzanten@ualberta.ca

Introduction: The Canadian North *Helicobacter pylori* (CAN*Help*) Working Group links northern community leaders and health officials with scientists to conduct research focused on community concerns about health risks from *H.pylori* infection. To date, we have initiated four community *H.pylori* projects: in 2007 in Aklavik, Northwest Territories (NT) (population~600); in 2010 in Old Crow, Yukon, YT (population~250); in 2011 in Tuktoyaktuk, NT (population~850); and in 2012 in Fort McPherson, NT (population~800).

Aims & Methods: The design of each community project was guided by a local planning committee. Projects components include: surveys of health and socio-environmental factors, urea breath test (UBT) screening for *H. pylori* infection, upper gastrointestinal endoscopy, treatment, knowledge exchange, and policy development.

We invited all *H.pylori*–positive participants ≥15 years to enrol in a treatment trial that randomly assigned alternate 10-day *H.pylori* therapies: 1) PPI-CA - the Canadian standard 3-drug therapy with a proton pump inhibitor (PPI), amoxicillin, and clarithromycin; 2) ST - sequential therapy with a PPI and amoxicillin for days 1-5, followed by a PPI, clarithromycin and metronidazole for days 6-10; 3) QT - quadruple therapy with a PPI, bismuth, metronidazole, and tetracycline. Only treatment naive participants not known to have clarithromycin-resistant *H.pylori* could be assigned PPI-CA, which was discontinued after initial results showed poor effectiveness. To assess infection status after treatment, we offered UBT at > = 10 weeks post treatment. Each participant's treatment outcome was classified as successful or failed according to a negative or positive UBT result, respectively.

Results: Of 921 community *H.pylori* project participants to date, 832 had results from *H.pylori* screening by UBT (positivity = 60%), 323 had endoscopy with gastric biopsy, 267 enrolled in the treatment trial, and 179 had a post-treatment UBT.

Of trial participants with a follow-up UBT, treatment was successful in: 62% (29/47; 95%CI 46-75%) of those randomized to PPI-CA; 73% (65/89; 95%CI 63-82%) of those randomized to ST; 95% (39/41; 95%CI 83-99%) of those randomized to QT. If non randomized patients are also included (PPI-CA 11, ST 10 and QT 12) the cumulative success rates are: PPI-CA 62%, ST 71 % and QT 92%.

Of 205 *H.pylori* isolates tested for antibiotic susceptibility, 43% (88) were resistant to > = 1 antibiotic: 35% (71) to metronidazole, 16% (33) to clarithromycin, 4% (8) to ciprofloxacin, 1% (2) to nitrofurantoin, 1.5% (3) to rifampicin; 0 to tetracycline or amoxicillin.

Conclusion: Treatment success estimates from this Canadian Arctic community treatment trial are imprecise due to small group sizes; however preliminary results show that QT is superior to ST and PPI-CA across communities.

Contact E-mail Address: manolis.pyleris@gmail.com

Introduction: Current knowledge suggests that small intestinal bacterial overgrowth (SIBO) participates in the pathogenesis of irritable bowel syndrome (IBS). It is questionable is this association is modulated by intake of proton pump inhibitors (PPIs). We aimed to provide a clear-cut answer analyzing a big prospective cohort of patients undergoing small intestinal quantitative aerobe culture.

Aims & Methods: Duodenal aspirates were collected from 897 outpatients subjected to upper GI endoscopy and quantitatively cultured under aerobic conditions. SIBO was diagnosed as the isolation of at least one coliform $\geq 10^3$ cfu/ml. Results were correlated with history of IBS, PPI intake, type of PPI and duration of treatment, age, body mass index (BMI) and endoscopic findings. Odds ratios (OR) and 95% confidence intervals (CIs) were measured according to Mantel and Haenzel. Comparison between OR were done by the Tarone's test. Factors independently linked with SIBO were found after forward logistic regression analysis providing ORs. Definition of a cut-off for a continuous variable to enter regression analysis was done after Receiver Operator Characteristics curve analysis with specificity greater than 90%.

Results: 158 had SIBO and 739 did not have SIBO; 20.2% and 22.2% respectively had a history of PPI intake (p: 0.558). Among patients without history of PPI intake, 123 had SIBO and 590 did not have SIBO; 56.9% and 19.0% respectively had IBS (OR: 5.63, 95%CIs: 3.76-8.5, $p < 0.0001$). Among patients with history of PPI intake, 35 had SIBO and 149 did not have SIBO; 65.7% and 31.5% respectively had IBS (OR: 4.16, 95%CIs: 1.91-9.06, $p < 0.0001$; p: 0.498 between ORs). Factors independently linked with SIBO were age ≥60 years (OR: 2.36, p: 0.001), body mass index ≥22 kg/m^2 (OR: 0.60, p: 0.049), presence of IBS (OR: 6.29, $p < 0.0001$), type 2 diabetes mellitus (OR: 1.59, p: 0.032) and endoscopic gastritis (OR: 0.47, $p < 0.0001$). Among patients with IBS predominant-diarrhea (IBS-D), 22.1% had history of PPI intake of more than 9 months; this was 10.1% among patients without IBS (p: 0.004). This effect was pronounced among patients reporting esomeprazole consumption (OR: 3.59, $p < 0.0001$).

Conclusion: The association between IBS and SIBO was completely independent from PPI intake. Long-term treatment with PPI of more than 9 months was associated with IBS-D; this was mainly an effect of esomeprazole. Although gastritis was protective against SIBO, results show that modulation of gastric pH with PPI cannot prime SIBO.

P1199 FECAL MICROBIOTA TRANSPLANTATION FOR TREATMENT OF SLOW TRANSIT CONSTIPATION: A PROSPECTIVE OPEN-LABEL STUDY

C. Ding[1], **H. Tian**[1], J. Gong[1], N. Li[1]
[1]*Research Institute of General Surgery, Jinling Hospital, Nanjing University School of Medicine, Nanjing, China*

Contact E-mail Address: dingchao19910521@126.com

Introduction: Fecal microbiota transplantation (FMT) has been proposed as a therapeutic approach for functional gastrointestinal disease (FGID). Previous studies suggested dysbiosis is frequently complicated in constipation and gut microbiota can affect gastrointestinal transit.

Aims & Methods: We launched a clinical study (NCT02301221) to examine the safety and efficacy of FMT for slow-transit constipation (STC). Twenty patients with STC, aged 20 to 74, were enrolled in this prospective open-label study. Patients received FMT on three consecutive days via nasojejunal tube with follow-up at 1, 2, 4 and 8 weeks after treatment. Bowel movements per week, Wexner Constipation Scores, Patient Assessment of Constipation Quality of Life (PAC-QOL) and adverse events were evaluated at each study visit.

Results: The rate of clinical improvement and remission based on clinical symptoms at 8 weeks postoperatively was 60% (12/20) and 35% (7/20) respectively. The patients' spontaneous complete bowel movements (SCBMs) increased from a mean of 1.75 ± 1.27 per week pre-FMT to 4.54 ± 1.36 at 8 weeks without laxative-use ($p < 0.01$). Over 8 weeks, Wexner constipation scores, scored 9.75 ± 4.88 at 1 week, 7.50 ± 2.57 at 2 weeks, 7.43 ± 3.65 at 4 weeks and 7.48 ± 1.57 at 8 weeks, showed a significant reduction as compared with 14.1 ± 3.29 at pre-FMT ($p < 0.01$ for all comparisons). Compared with baseline, significant overall improvements were also seen in PAC-QOL scores at 1, 2, 4 and 8 weeks of follow-up ($p < 0.01$). Meanwhile, there were no severe treatment-related adverse events during the whole FMT procedure follow-up except for venting, abdominal pain, bloating and diarrhea.

Conclusion: This is the first study to demonstrate that FMT has the potential to be somehow of help in managing patients with slow-transit constipation, but considerable further efforts are necessary to maintain a long-term effect.

P1200 PERINATAL ANTIBIOTIC TREATMENT ALTERS OFFSPRING'S GUT MICROBIAL PROFILE PREDISPOSING THEM TO EXPERIMENTAL COLITIS

P. Munyaka[1], A. Khafipour[1], H. Wang[1], N. Eissa[1], E. Khafipour[2], **J.-E. Ghia**[3]
[1]*Immunology,* [2]*Animal Sciences,* [3]*Immunology / Internal Medicine, Univeristy of Manitoba, Winnipeg, Canada*

Introduction: The use of antibiotics in the perinatal period is associated with delayed microbial colonization. Postnatal maturation of the immune system is largely driven by exposure to microbes, and thus the nature of the intestinal colonization may be associated with the development of childhood diseases that may persist into adulthood, including inflammatory bowel diseases.

Aims & Methods: Therefore, we have explored whether prenatal antibiotic therapy can increase offspring susceptibility of experimental colitis through an alteration of the gut microbiota.

Pregnant C57Bl/6 mice were treated with cefazolin at 160 mg/kg body weight (bw) or with saline starting six days before the due date. At 7 weeks, male offspring from the two groups received 4% dextran sulfate sodium (DSS) in the drinking water for 5 days. Disease activity index (DAI), histology, colonic interleukin (IL)-6, IL-1β and serum C-reactive protein (CRP) were determined. From colon and fecal samples, the V3-V4 region of bacterial 16S rRNA was amplified

and subjected to Illumina sequencing. Alpha-diversity was calculated using Chao 1 and beta-diversity was determined using QIIME. Differences at the genus level were determined using partial least squares discriminant analysis (PLS-DA), and phylogenetic investigation of communities by reconstruction of unobserved states (PICRUSt) was used for bacterial functional predictions.
Results: Prenatal ATB increased the onset of clinical disease as assessed by stool consistency, weight loss and rectal bleeding. On day 5, macroscopic and histologic scores were significantly increased. Colonic IL-6 was increased, but IL-1β levels were not changed. Conversely, in the ATB-DSS group, the CRP level was significantly decreased. In colitic mice compared to the control group, ATB significantly decreased the richness of the bacterial species in fecal samples but not in the colon, and bacterial community composition differed between the groups in both sample types, although this was further influenced by the mother. PLS-DA analysis revealed an association of specific taxa with ATB-DSS or control-DSS at lower taxonomic levels. Also, there were differences in microbial functional pathways in both fecal and colonic samples.
Conclusion: These results support the hypothesis that prenatal antibiotics modulates offspring intestinal bacterial colonization and susceptibility to develop colonic inflammation in a murine model of colitis. Furthering our understanding of the impact of prenatal antibiotics on gut bacterial colonization and susceptibility to colitis may guide future interventions to restore physiologic intestinal colonization in offspring born to antibiotic-exposed mothers.

P1201 SMALL INTESTINAL BACTERIAL OVERGROWTH AS A CAUSE OF SECONDARY LACTASE DEFICIENCY

N. Fadeeva[1], I. Ruchkina[1], A. Parfenov[2], P. Shcherbakov[3], O. Knyazev[1]
[1]*Department of Inflammatory Bowel Disease,* [2]*Department of Inflammatory Disease,* [3]*Department of Endoscopy, Moscow Clinical Research Center, Moscow, Russian Federation*

Contact E-mail Address: chuevana@mail.ru
Introduction: Human microflora is a stable genetically determined system. Most bacteria are in the colon with their concentration reaching up to 10^{10}–10^{11} CFU/ml and more. The concentration of microorganisms in the small intestine fluctuates from 10^1 to10^4 CFU/ml of the intestinal content.
Secondary lactase deficiency (SLD) is inability to digest lactose, the predominant sugar of milk. This inability results from decrease of lactase enzyme activity, which is produced in the small intestine. **Purpose:** to define the influence of SIBO in patients with SLD in adult patients.
Aims & Methods: : In this study, 386 patients (the mean age – 33.9 ± 9.09; F/M - 249/137) with postinfectious irritable bowel syndrome (IBS) were analyzed concerning lactase deficiency. All patients underwent intestinal endoscopy with biopsies from the mucosa of the descending duodenum in order to determine lactase deficiency. The biopsies were taken in order to determine lactase deficiency (normal, mild and severe) by means of lactose quick test (LQT). To diagnose small intestinal bacterial overgrowth (SIBO) all patients underwent lactulose breath test during 2 hours.
Results: SLD was detected in 36.5% of patients with postinfectious IBS. Mild SLD was determined in 25.6% of patients, and severe SLD – in 10.9% of patients. The specific clinical symptoms of mild SLD were moderate flatulence with abdominal pain (80.7%); the majority of patients (73.7 %) had normal stool consistency, one time a day; the other patients had semi-liquid faeces, 2-3 times a day (26.3%). The clinical symptoms of severe SLD were diarrhea (stool > 4 times a day) in 85.7% of patients, abdominal pain and flatulence (90.5%). SLD in all cases was accompanied by SIBO (the average level of lactulose breath test was 80.3 ± 28.3ppm, N < 20ppm). It turned out that the degree of lactase deficiency depends on the severity of SIBO in the lumen of the small intestine. Thus, when mild SLD average value SIBO was 72.4 ± 25.1ppm, whereas severe SLD average indicators of SIBO achieved higher values, 99.3 ± 26.9ppm (N < 20ppm). To establish the degree of dependence of SIBO in the small intestine and the degree of deficiency of lactase in the small intestine biopsies performed a statistical analysis of the results by calculating the Spearman rank correlation coefficient in order to study a statistically significant link between the various phenomena. In this study, an inverse correlation between the degree of lactase deficiency in patients with the SLD and the severity of SIBO in the small intestine, i.e. the higher the hydrogen concentration in the exhaled air, the less activity of the enzyme lactase in the small intestine biopsy specimens ($r = -0.49$, $p < 0.001$).
Conclusion: SIBO in all cases was accompanied by SLD. Thus, the high frequency of the SLD associated with SIBO in the small intestine in patients postinfectious IBS can be explained by the growth of pathogenic microflora in the small intestine.

P1202 SMALL INTESTINAL BACTERIA OVERGROWTH AND USE OF PPI AS A PREDISPOSING FACTORS FOR NSAID-ENTEROPATHY

S. Tkach[1], L. Onischuk[1], A. Balabanceva[2]
[1]*Internal Medicine #1, National Medical University, Kyiv, Ukraine,* [2]*Therapy@family medicine, Crimea Medical University, Simferopol, Russian Federation*

Contact E-mail Address: tkachsergio@yahoo.com
Introduction: There is good evidence from animal studies that gut bacteria play an important role in the pathogenesis of NSAID-induced small bowel damage. Other studies demonstrated alterations in the composition of small bowel bacteria in human, often with increases in gram-negative bacteria, after the administration of NSAIDs. In a prospective study of chronic NSAID users, 50-60% were found to have severe small bowel damage by video capsule endoscopy, associated with small intestinal bacteria overgrowth (SIBO). There is ample evidence that proton pump inhibitors (PPIs) can induce alteration of intestinal flora and SIBO too.
Aims & Methods: Our aim was to evaluate the frequency of SIBO by using a hydrogen glucose breath test (H_2-GBT) and frequency of small bowel lesions in chronic PPIs (standard doses of omeprasole) and NSAIDs (diclofenac) users. We investigated 34 pts with NSAIDs-gastropathy (20 male, mean age – 45 years) with H_2-GBT (EC60 Gastrolyzer 2, Bedfont Scientific Ltd, Rochester, UK). All patients with positive results of H_2-GBT were examined with video capsule endoscopy (Given, Israel) and were treated with rifaximine (1200 mg/day during 10 days). The efficacy of treatment was controlled with repeated H_2-GBT.
Results: Overall, 20 pts (58.8%) had demonstrated positive results of H_2-GBT and presence of SIBO. Among this patients the small bowel lesions were found in 16 pts (80%) by using a video capsule endoscopy. After use of rifaximine (1200 mg/day during 10 days) negative H_2-GBT was found only in 2 (10%) patients with initially diagnosed SIBO.
Conclusion: High prevalence of SIBO in patients with NSAID- induced gastric damage treated with PPIs may confirm its important role in pathogenesis of NSAID-enteropathy. PPIs may exacerbate small bowel damage induced by NSAIDs through alteration of gut microbiota. Rifaximine is highly effective for treatment of SIBO.

P1203 SACCHAROMYCES BOULARDII STRAIN CNCM I-745 SHOWS PROTECTIVE EFFECTS AGAINST B. ANTHRACIS LT TOXIN

D. Czerucka[1], R. Pontier-Bres[1], P. Rampal[2], J.-F. Peyron[1], E. Lemichez[1]
[1]*C3M, INSERM U1065, Nice, France,* [2]*CSM, Monaco, Monaco*

Introduction: Anthrax disease is a severe bacterial infection often characterized by both septicemia and toxemia. Toxemia depends on a tripartite toxin secretion. LT toxin, composed of the PA binding sub-units and LF catalytic unit, has been directly implicated in epithelia and endothelia barrier dysfunction observed in the gastrointestinal form of the disease. Massive reorganization of the actin cytoskeleton promoted by LT through MEK inhibition is a great system to study inhibitors of the intoxication process. The probiotic yeast *Saccharomyces boulardii* CNCM I-745 (*S.b*) is prescribed worldwide for prophylaxis and treatment of diarrheal diseases caused by bacteria, virus or antibiotics. Several studies have shown that *S. b*. exerts a proteolytic effect on several bacterial toxins while maintaining the barrier function of intestinal epithelium.
Aims & Methods
Aim: In this study we tested whether *S.b* might confer protective effect on cell intoxication by *B. anthracis* LT-toxin.
Material and Methods: The study was performed on filter grown polarized T84 cells or non-polarized HUVEC cells. Permeability was measured by trans-epithelial resistance (TER). The modifications in the distribution of the tight junctions associated protein ZO-1, and reorganization of actin cytoskeleton were monitored by confocal microscopy. MEK-2 cleavage, PA and LF degradation were detected by western-blot.
Results: After 15 and 24 hours incubation, LT toxin affected epithelial integrity which was visualized by a significant drop of TER in polarized T84 cells. In parallel we observed that LT toxin caused modification of tight junctions morphology with a diffuse staining of ZO-1. It induced as well formation of actin stress fibers in both cell lines. LT toxin is known to target mitogen-activated protein kinase kinases (MEK); kinetics studies on MEK-2 cleavage reveals in our study that it occurs at 2 hours of incubation in HUVEC cells and is delayed to 6 hours of incubation in T84 cells.
An overnight treatment with *S. b* before LT toxin incubation maintained the integrity of the monolayers, prevented morphological modification of tight junctions, restricted LT effects on actin remodeling and delayed LT-induced MEK -2 cleavage. Finally, to unravel the molecular mechanism by which *S.b* protects cells, the yeast was incubated with the LT subunits (PA and LF) for 2, 6, and 24 hours. After centrifugation, we determined that cleaved forms of PA were detected in the supernatant after 24 hours of incubation. A small quantity of PA and LF were also founded in the pellet containing *S.b* corresponding probably to yeast-bound toxins fraction. These results could explain the anti-toxin activity of *S. b*.
Conclusion: Our study highlights the therapeutic potential of *S.b* strain CNCM I-745 to be used as prophylactic agent against the gastrointestinal form of *B. anthracis* infection.

P1204 EFFECT OF SACCHAROMYCES BOULARDII STRAIN CNCM I-745 ON DENDRITIC CELLS POPULATIONS IN THE LAMINA PROPRIA OF MICE FOLLOWING SALMONELLA TYPHIMURIUM INFECTION

D. Czerucka[1], R. Pontier-Bres[1], G. Michel[1], P. Rampal[2], J.-F. Peyron[1]
[1]*C3M, INSERM U1065, Nice, France,* [2]*CSM, Monaco, Monaco*

Introduction: Recent studies characterized, in the lamina propria, two DCs populations that include: $MHCII^+CD11c^{hi}CD103^+CD11b^+$(referred as $CD103^+CD11b^+$DCs) and MHC^{hi} $CD11C^{hi}CD103^-CD11b^+$(referred as $CD103^-CD11b^+$DCs). Buganovic M et al. (*Immunity* 2009) have previously

established a difference of involvement of both populations of DC during infection of streptomycin-pretreated mice with *Salmonella typhimurium* (ST). The transport of pathogenic *Salmonella* from the intestinal tract to the mesenteric lymph nodes involves $CD103^+CD11b^+$DCs, whereas intracellular bacteria in the lamina propria reside in $CD103^-CD11b^+$ DCs. The probiotic yeast *Saccharomyces boulardii* CNCM I-745 (*S.b*) is prescribed worldwide for prophylaxis and treatment of diarrheal diseases caused by bacteria, virus or antibiotics. In the streptomycin-pretreated model, we demonstrated that *S.b* modifies ST propagation along the intestinal tract and ST translocation (Plos One 9 e103069).

Aims & Methods

Aim: Investigate the effect of *S. b* on the different DCs populations in the intestine of mice after *Salmonella* infection.

Material and Method: Bioluminescent imaging (BLI) was used to evaluate the effect of *S.b* on the progression of luminescent ST (ST-lux) in the GIT of mice pretreated with streptomycin. The intestine was sampled in three parts and the photon emission reflecting ST-*lux* progression was recorded in i) the site of maximum photon emission ("I°"), ii) the ileum, which showed no photon emission ("I^-"), and iii) the duodenum, which had already been in contact with the bacteria ("I^+"). The different DCs populations extracted from the Inflammatory cells were characterized by FACS. *In vitro* studies were performed on RAW264.7 cells exposed or not to *S.b* before infection. GM-CSF was detected in the supernatant by array.

Results: FACS analysis of DCs extracted from ST-*lux* alone infected mice revealed that the "I°" sample presented a population expressing $CD103^+CD11b^+$DCs and $CD103^-CD11b^+$DCs that was absent in the other part of the intestine: "I^-" and "I^+". The "I°" sample obtained from *S.b* pretreated mice before infection presented a significantly reduced population expressing $CD103^+CD11^+$DCs and $CD103^-CD11b^+$ DCs when compared to "I°" portion of ST alone infected mice. Interestingly the "I^-" portion of *S.b* treated mice (portion of intestine that has not been in contact with ST but has been in contact with yeast) contained a population expressing $CD103^-CD11b^+$ DCs. GM-CSF was required for the development of CD103 + CD11b + DCs. *S.b* abolished secretion of GM-CSF in RAW 264.7 infected by ST.

Conclusion: Altogether these data demonstrate that *in vivo,* shortly after ST administration, *S.boulardii* CNCM I-745 modulates the DCs composition of lamina propria by inducing the $CD103^-$DCs and reducing the $CD103^+$ DCs populations.

P1205 WHEN GASTRIC INHIBITION IMPLIES INTESTINAL BACTERIAL ALTERATION. A CONFIRMATION FROM A FOLLOW-UP STUDY

L. Lombardo[1], M. Schembri[2]

[1]*Gastroenterology Service, Poliambulatorio Statuto,* [2]*Gastroenterology, Mauriziano Hospital, Turin, Italy*

Contact E-mail Address: manuelaprinzio@yahoo.it

Introduction: The causative role of PPIs on small intestinal bacterial overgrowth (SIBO) is still controversial. However, the incidence of SIBO is increasing, probably because of the increase of pharmacological risk factors (1). Although SIBO can satisfactorily be eradicated by Rifaximin (2), its recurrence and retreatment are so far poorly investigated and may pose clinical challenges. Here we investigated the effect of PPIs, on a follow-up study, after the first successful eradication of SIBO by Rifaximin.

Aims & Methods: One hundred and forty four patients (pts) treated with long-term PPIs for gastro-esophageal reflux disease (GERD), successfully eradicated from SIBO with high dose Rifaximin were followed-up for 1 year for relapse investigation. A group of pts continued full dosage PPIs therapy (A group) while another stopped it (B group). An additional group of pts with IBS, eradicated from SIBO, not taking PPIs, was also followed-up, as control (C group). At the end of follow-up, or before if symptoms suggested it, glucose hydrogen breath test (GHBT) (Quintron, Milwaukee, WI, USA) was performed to each patient and symptoms were recorded. All relapsed pts were retreated with Rifaximin 1200 mg/die for 2 weeks, as in the first course. The outcome of therapy was assessed both clinically and by means of GHBT, 2 months after the completion of Rifaximin course.

Results: Out of a cohort of 144 pts (M 84; mean age 46 ± 14) successfully eradicated from SIBO with Rifaximin, 97 pts continued treatment with PPIs (M 52, mean age 45 ± 13) and 47 (M 31, mean age 44± 14) discontinued it. An additional series of 20 pts with IBS (M11, mean age 43 ± 17), eradicated from SIBO, PPIs-free, were followed-up for 1 year. Forty-nine out of 97 pts of A group (50%), 3 out of forty-seven of B group (6%) and 1 out of 20 of C group (5%) had a SIBO relapse , with a statistically significant difference between the first group and the others ($p < 0.001$). Forty-seven out of 52 pts retreated with Rifaximin showed negative GHBT along-side symptoms remission (90%), indicating a successful eradication from SIBO. No relevant side effect was registered.

Conclusion: 1) Relapse rate of SIBO within 1 year is high if treatment with PPIs is not discontinued (90%). 2) Retreatment with Rifaximin 1200 mg/die for 2 weeks results to be effective and safe.

Contact E-mail Address: marjorie.walker@newcastle.edu.au

Introduction: Small intestinal bacterial overgrowth (SIBO) is characterized by a variety of clinical features thought to result from alteration of the microbiota within the upper gastrointestinal (GI) tract and commonly defined as the presence of $> 10^5$ colony forming units/ml of bacteria in an aspirate of fluid collected from the upper small intestine[1]. SIBO can be diagnosed with the lactulose H2 breath test, which is a non-invasive, low cost, simple test[2]. Symptoms related to SIBO are heterogeneous and may mimic functional GI disorders, including functional dyspepsia (FD).

Aims & Methods: This study aimed to define whether abnormal duodenal pathology previously related to dyspeptic symptoms (increased duodenal eosinophilia) occurs in patients with dyspepsia and SIBO.

This was a prospective case-control study, 9 patients with normal upper endoscopy, upper abdominal ultrasonography, and symptoms of functional dyspepsia (FD; 8 females, mean age 37 years, range 19-63,) were compared to 9 patients with SIBO (defined by lactulose H2 breath test) and functional dyspepsia (7 females, mean age 46 years, range 31-72). Biopsies were taken from the gastric antrum and duodenum, and examined for routine pathologies by haematoxylin and eosin staining, plus additionally eosinophil counts/ mm^2 and mast cells by immunocytochemistry (CD117). Symptoms of FD and the presence of postprandial distress syndrome (PDS), and epigastric pain syndrome (EPS) were recorded. Effect sizes are reported as Cohen's d (> 0.5 moderate, > 0.8 is large effect size) and comparisons between SIBO and non-SIBO FD was undertaken using the Mann-Whitney test for immune cell counts and Chi-Square for categorical measures.

Results: All patients were non-smokers, with no allergies and no parasitic ova on stool microscopy. SIBO patients were more likely to have postprandial distress symptoms (PDS) (77% v 44%, p = 0.1) or PDS alone (33% v 11%, p = 0.3). SIBO patients showed evidence of reduced duodenal eosinophils (d = -0.76, p = 0.08), elevated duodenal intraepithelial lymphocytes (d = +0.50, p = 0.3) and reduced duodenal mast cells (d = -0.57, p = 0.5) compared to those with FD alone. Failure to reach statistical significance despite moderate to large effect sizes is likely due to low sample size with statistical power 0.3 or less for all comparisons. In contrast there was minimal evidence of difference between SIBO and non-SIBO FD patients with respect to gastric eosinophils (d = -0.14, $p > 0.9$) or gastric intraepithelial lymphocytes (d = -0.37, p = 0.7).

Conclusion: SIBO in patients with functional dyspepsia appears to be associated with alteration in duodenal but not gastric innate immune response and may be associated with the PDS rather than EPS FD subtype. Larger studies are required to improve the statistical certainty of these findings.

P1207 SMALL INTESTINAL BACTERIAL OVERGROWTH MAY INCREASE THE LIKELIHOOD OF LACTOSE, FRUCTOSE AND SORBITOL INTOLERANCE FALSE POSITIVE DIAGNOSIS

T. T. Perets[1], D. Hamouda[1], E. Shporn[1], Y. Niv[2], R. Dickman[2]
[1]*Gastroenterology Laboratory,* [2]*Gastroenterology Department, Rabin Medical Center - Beilinson Hospital, Petah Tikva, Israel*

Contact E-mail Address: kaiser1974@gmail.com

Introduction: Small intestinal bacterial overgrowth (SIBO) is defined by the presence of an excessive concentration of bacteria in the small intestine. Lactose intolerance (LI), fructose intolerance (FI) and sorbitol intolerance (SI) and SIBO share many gastro-intestinal (GI) symptoms usually attributed to patients diagnosed with irritable bowel syndrome (IBS).

Aims & Methods: To evaluate the role and effect of SIBO in the formation of LI, FI and SI symptoms in affected patients. A total of 348 patients with suspected IBS underwent SIBO and LI, FI and SI diagnosis by hydrogen breath test (HBT). 15 gr of lactulose dissolved in 50 ml of water and 50 gr of lactose, 25 grams of fructose and 15 grams of sorbitol dissolved in 250 ml of water were used for SIBO and LI, FI and SI HBT respectively. The test results were considered positive when hydrogen concentration acceded 10 PPM for SIBO and 20 PPM for LI, FI or SI above baseline.

Results: Out of the 348 patients tested for SIBO and LI, 101 (29%) were positive for both tests. Out of the 197 patients tested for SIBO and FI, 17 were positive for both tests. And finally, out of the 196 patients tested for SIBO and SI, 45 were positive for both tests. Out of the 101 SIBO and LI, 17 SIBO and FI and 45 SIBO and SI positive patients, 82 (81%), 14 (82%) and 23 (53%) respectively had an increase of hydrogen measurement above threshold between 30-90 minutes during their LI/FI/SI-HBT, implying SIBO.

Conclusion: The fermentation of lactose, fructose or sorbitol in the small bowel due to SIBO may increase the likelihood of LI, FI and SI incorrect diagnosis. We suggest that all symptomatic patients will undergo SIBO testing and eradication if diagnosed positive, prior to LI, FI or SI HBT evaluation.

P1208 A PROSPECTIVE APPLICATION OF THE ESPGHAN GUIDELINES IN A SYMPTOMATIC ADULT POPULATION

K. Efthymakis[1], M. Serio[1], D. D'Amato[1], A. Milano[1], F. Laterza[1], A. Bonitatibus[1], M. Neri[1]
[1]*Medicine and Ageing Sciences and CESI, Università "G. D'Annunzio", Chieti, Italy*

Contact E-mail Address: efkn78@gmail.com

Introduction: Current adult guidelines require histological confirmation of celiac disease (CD)[1]. However, recent pediatric guidelines have proposed algorithms to reduce the need for biopsy in genetically susceptible symptomatic children[2].

Aims & Methods: To explore the applicability of the current ESPGHAN criteria and assess the accuracy of serology in detecting mucosal abnormalities in a prospective cohort of symptomatic adults. We recruited 234 consecutive symptomatic adults (mean age = 33.9ys) referred to our tertiary center, showing EMA positivity and genetic susceptibility. All patients underwent upper endoscopy with multiple biopsy sampling in the duodenum. Histological lesions were graded according to the Corazza-Villanacci classification and considered diagnostic for grades $\geq$ B. Anti-tTG titers were assessed with 12 different assays; one ELISA kit (specified Upper Limit of Normal = 3.5U/ml) was used in 141 subjects (60.3%), while a second one in 59 (25.2%, ULN $\pm$ 9.9U/ml). Accuracy of anti-tTG testing and optimal cut-off levels were determined by means of a ROC curve. Performance was also calculated for a cut-off 10 times ULN.

Results: Mean anti-tTG levels at inclusion were 71.1 $\pm$ 4.4U/ml, while mean adjusted levels (anti-tTG/ULN) were 14.8 $\pm$ 0.9 times ULN (mean $\pm$ SE). Among the 234 patients, 21 (9%) showed no atrophy; partial and total atrophy were present in 85 (36.3%) and 128 (54.7%) respectively. Anti-tTG levels significantly correlated to the degree of villous atrophy (ANOVA $p < 0.001$; $\rho_s = 0.397$, $p < 0.001$). AUC proved a fair diagnostic accuracy both for the unadjusted and adjusted anti-tTG levels (respectively 0.803, 0.807; $p < 0.01$). For the ESPGHAN criterion of anti-tTG $\geq$ 10 times ULN, a positive predictive value (PPV) of 97.7% was calculated (sensitivity = 59.2%, specificity = 86.9%). The optimal cut-off for adjusted anti-tTG levels was $\geq$16 times ULN, with a PPV of 98.9% (sensitivity = 41.2%, specificity = 95.7%). Considering different assays, results were puzzling; although in the first one PPV(= 97.14%) seemed to peak at around 50U/ml (14.3 times ULN), the second assay proved considerably more predictive: for a cut-off = 37.3U/ml (3.7 times ULN) it showed a superior PPV = 100% (sensitivity 53.1%, specificity 100%). Age and sex did not correlate with histology or serology.

Conclusion: In an adult population of symptomatic patients showing EMA positivity and genetic susceptibility, anti-tTG titers correlate with the degree of villous atrophy. The ESPGHAN criteria showed a PPV similar to that of symptomatic children[3]. However, PPV was higher for a cut-off 16 times ULN and peaked when considering a single ELISA assay, indicating a possible kit-specific variability. Further studies are required to determine if optimal cut-off levels are dependent on patient or assay characteristics. The findings of this study could prove useful when assessing equivocal histological cases of CD, and could help in guiding patient follow-up.

P1209 THE DIAGNOSTIC DELAY IN CELIAC DISEASE IS SIGNIFICANTLY INCREASED IN WOMEN DUE TO DOCTOR'S BUT NOT PATIENT'S DELAY

S. Vavricka[1], A. Schoepfer[2], P. Frei[3], G. Rogler[4], **L. Biedermann**[4]

Contact E-mail Address: luc.biedermann@usz.ch

Introduction: The majority of celiac disease (CD) cases are associated with a considerable diagnostic delay or even remain undiagnosed due to a variety of reasons, such as silent disease, unspecific symptoms with overlap to other diseases and insufficient awareness in both patients as well as physicians. The total diagnostic delay can be subdivided into patient's (gap between beginning of symptoms and first medical consultation) and doctor's (gap between first medical consultation and definitive diagnosis of CD) delay. There is insufficient data on diagnostic delay, its comprising two components and associated factors in CD. In addition, it remains to be clarified, whether its extent has an impact on the course of the disease.

Aims & Methods: We performed a large systematic, nation-wide patient survey study among unselected CD patients in Switzerland.

Results: A total of 1689 patients (76% female; mean age 41.3 y, range 0-92y, mean age at diagnosis 31.1y, range 0-83y) were analysed. We found a mean total diagnostic delay of 72.3 months (median 18, IQR 4-72), with an enormous range from 0 up to 780 months and roughly equal fractions of patient's and doctor's delay with a mean/median of 39.9/4 (IQR 0-28) and 39.4/3 (IQR 0-24) months, respectively. While the mean age of diagnosis was not different in female vs. male patients (31.2 vs. 31 years), both, mean/median total (76.2/21 vs. 56.9/12, $p = 0.008$) and doctor's (43.8/5 vs. 25.6/2, $p < 0.001$) diagnostic delay was significantly higher in female vs. male patients, whereas patient's delay was similar (39.4/3 vs. 37.8/2, not significant).

A total of 15.3% of patients reported that IBS was diagnosed or suspected by their treating physician(s), prior to establishing the diagnosis of, significantly more women than men (16.7 vs. 10.5%, $p = 0.004$). Notably, a significantly higher doctor's delay in women was equally observed if patients with antecedent IBS diagnoses were excluded (mean/median total, patient's and doctor's delay of 67.1/16 vs. 45.5/11, $p = 0.015$; 37.8/3 vs. 33/2, n.s.; 36/4 vs. 22.5/2, $p = 0.004$ in non-IBS women vs. men).

Treatment of any nutritional deficiencies states was significantly more often required in patients with a delay $\geq$24 vs. $<$24 months (74.6 vs. 58.4%, $p < 0.001$). The same was observed for need of steroids and/or immunosuppressants to treat CD with 4.4 vs. 2.0%, corresponding to a relative risk of 0.48 (CI 0.26-0.87, $p = 0.016$).

In addition, total, patient's and doctor's diagnostic delay was significantly higher in patients diagnosed after vs. up to the age of 30 (mean/median 106.3/32, 59.5/4 and 58.5/6 vs. 35.7/12, 18.9/2 and 19.3/3 months, respectively, for all $p < 0.001$).

Conclusion: There is a substantial diagnostic delay in CD, which is significantly longer in patients with older age at diagnosis and in female patients. The increased diagnostic delay in women is due to doctor's but not patient's delay. This increase in doctor's delay cannot be explained by antecedent symptoms or diagnosis of IBS prior to establishing the diagnosis of CD. Our findings point to an insufficient awareness for CD in physicians especially in women and older patients. In addition, a longer diagnostic delay is associated with more frequent need of immonusuppressants to treat CD and a lower chance of clinical remission after diagnosis.

P1210 THE SELECTED PARAMETERS OF OXIDATIVE STRESS, ANTIOXIDANT CAPACITY AND INFLAMMATORY MEDIATORS IN TREATED AND UNTREATED ADULT PATIENTS WITH COELIAC DISEASE - A PRELIMINARY REPORT

M. Zwolinska-Wcislo[1], A. Piatek-Guziewicz[1], P. Paśko[2], P. Zagrodzki[2], M. Krośniak[2], M. Przybylska-Feluś[1], A. Ptak-Belowska[3], T. Mach[1]
[1]*Gastroenterology,* [2]*Department of Food Chemistry and Nutrition,* [3]*Department of Physiology, Jagiellonian University Collegium Medicum, Krakow, Poland*

Contact E-mail Address: mzwcislo@su.krakow.pl

Introduction: It has been assumed that oxidative stress is one of the mechanism that can play a role in gluten toxicity although its role in patients with celiac disease (CD) is not fully elucidated.

Aims & Methods: To evaluate the cytotoxic effect of gluten by determining the selected parameters of oxidative stress, antioxidant capacity and inflammatory mediators in treated and untreated adult patients with CD The study has enrolled 98 patients, including 72 patients with CD. The subjects were divided into 3 groups: 1) patients with untreated CD (N = 35), including patients with newly diagnosed CD (N = 10) and patients not adhering to a gluten-free diet (GFD) (N = 25), 2) patients with CD on GFD for at least two years (n = 37), 3) healthy control group (N = 26). A standard blood test, the level of anti-tissue transglutaminase antibodies and /or endomysial antibodies and

histopathological study of duodenal biopsy were evaluated. The serum concentration of nitric oxide (NOx), IL-15, FRAP (Ferric Reducing Antioxidant Power), reduced glutathione (GSH) and glutathione peroxidase (GPx) were detected.
Results: There were no differences between the groups in serum concentrations of Il-15. The concentration of GSH in untreated patients was lower than in patients on GFD and control group. GPx activity was lower in treated and untreated CD group than in controls. FRAP level was reduced in patients with CD compared to the controls. The serum level of nitrate in patients with CD without GFD were significantly higher than those of controls ($p < 0.001$). Patients who were on a gluten-containing diet had also significantly lower values of RBC, HGB and HCT in comparison to control group. Patients who did not obey GFD had significantly higher serum level of nitrate and the level of coeliac antibodies ($p < 0.001$) and lower level of MCV in comparison to the patients who used recommended diet. It was observed that ferritin concentration was positively correlated with iron concentration (CW = 0.402), AST (CW = 0.542), bilirubin (CW = 0.501), and with GGTP (CW = 0.824). The latter parameter was also correlated with AST (CW = 0.551), bilirubin (CW = 0.493) and with total cholesterol level (0.417). Two parameters, nitrate level and ALT were also highly positively correlated (CW = 0.503).
Conclusion: Oxidative/antioxidative balance is shifted toward oxidative side by gluten-containing diet in patients with CD. GFD, especially enriched in antioxidants may decrease oxidative stress in this group. Results of study suggested the role of serum NO as an indicator of diet compliance. Strong correlation between NO level and ALT may suggest the role of NO in the pathogenesis of gluten-induced hepatitis. Further research are needed.

Introduction: Even though coeliac disease (CD) is considered to be the most common lymphocyte T helper-1 (Th-1) mediated enteropathy in Western countries, it seems that Th1- and lymphocyte T helper-2 (Th-2)-mediated diseases could co-exist in CD patients.
Aims & Methods: The aims of the study were: 1) to establish the prevalence of immune-mediated disorders at time and after CD diagnosis; 2) to evaluate a possible change in immune response after starting gluten-free diet (GFD); 3) to investigate the potential role of GFD in reducing and/or preventing immune-mediated disorders in adult CD patients.
Methods: We carried out a database-driven study including all consecutive adult CD patients followed-up at our Gastrointestinal Unit. CD diagnosis was made in accordance with the Oslo classification. The main demographic, clinical, serological, endoscopic and histological features were recorded for all CD patients. All patients were investigated for the presence of Th1 and/or Th2-mediated disorders at time of CD diagnosis. The search for Th1 and/or Th2 diseases were reassessed after a 5-years follow-up period. Statistical analysis included chi-square (χ^2) test, Mann-Whitney U test, ANOVA and odds ratio (OR) when indicated. All results were considered significant with a $p < 0.05$.
Results: Finally, 1255 CD were enrolled (M/F 258/997). 257 patients out of 1255 (20.5%) suffered from immune-mediated diseases at time of CD diagnosis, with 150 of them (58.4%) presenting a Th1-predominant disease vs 107 (41.6%) with Th2-mediated diseases ($p = 0.7$). After a 5-years follow-up period, 682 out of 1255 patients (54.3%) showed an immune-mediated disease even if following a restrict GFD; among them, 391 subjects (57.3%) presented a Th1-related condition vs 291 (42.7%) with a Th2-mediated disease ($p = 0.8$). When comparing the prevalence of immune-mediated diseases before and after CD diagnosis, no significant ''switch'' from Th1- to Th2-response or vice versa was seen (58.4% and 41.6% before CD vs 57.3% and 42.7% after CD diagnosis, respectively; p = ns). The number of patients with a Th1- and/or a Th2-merdiated disease increased during the GFD period (20.5% vs 54.3%; $p < 0.01$; OR 1.9). The most frequent CD-related immune-mediated diseases were: Hashimoto's thyroiditis (8.2% before vs 24% after CD diagnosis; $p < 0.01$; OR 1.6); psoriasis (0.7% before and 2.7% after CD diagnosis; $p < 0.01$; OR 1.5), type 1 diabetes mellitus (1.8% before vs 0.2% after CD diagnosis; $p < 0.01$; OR 0.08). No correlation was found between the developed immune-mediated diseases and age at the time of CD diagnosis, clinical symptoms, a-tTG serum levels and Marsh grade.
Conclusion: The prevalence of immune-mediated diseases at time of CD diagnosis, particularly as regards with Hashimoto's thyroiditis, psoriasis and type 1 diabetes mellitus, is high and it seems to increase in the follow-up period despite GFD. GFD does not influence and/or reduce the prevalence, the occurrence and the Th1/Th2 nature of immune-mediated diseases in CD.

P1212 THE PREVALENCE OF COELIAC DISEASE AT THE INTERSECTION OF EUROPE AND ASIA: A POPULATION-BASED CROSS-SECTIONAL STUDY FROM MERSIN, TURKEY

O. Sezgin[1], B. Sarıtaş[2], I. Aydın[3], T. Şaşmaz[4], E. Serinsöz Linke[5]
[1]*Gastroenterology,* [2]*Mersin University School of Medicine,* [3]*70. Yıl Family Health Center,* [4]*Public Health,* [5]*Pathology, Mersin University School of Medicine, Mersin, Turkey*

Contact E-mail Address: drorhansezgin@gmail.com
Introduction: Coeliac Disease (CD) has emerged as a public health problem, and the disease prevalence varies among different races and nations. In Turkey, which stands at an important transition point at the junction of Europe and Asia where the races mix, an adult community-based prevalence study has not been conducted as yet. Thus, the present study was designed to investigate the prevalence of undiagnosed CD in Turkish adult population in Mersin and to detect the characteristics of these pts.
Aims & Methods: This study was undertaken during the June 2011–January 2013. Mersin is a cosmopolitan city in the South of Turkey, which has 10 different districts. Adults aged 18 and older living within the Mersin formed the target population of the study. According to 2009 population census results, there are 1133935 people in this age group living in Mersin. The minimum sample size has been calculated as 1519. It was planned to include 1600 people in the study group. The study group was sorted based on age, gender and district via stratified sampling method. Family physicians were selected district-wide through random sampling method. Respondents to be sampled were chosen from those registered to each family physician by using stratified sampling method. Participants were evaluated for demographic features, and gastrointestinal symptoms, and were tested for anti-tissue transglutaminase (tTG) and anti-Deaminated Gliadin Peptid (DGP) immunoglobulin (Ig) A and IgG using an ELISA assay. Small intestinal biopsies were obtained from the seropositive pts, and they were examined according to the Marsh classification. HLA-DQ2 and DQ8 genotyping and blood tests were done.
Results: 1554 people participated in this study and the participation rate was 97.1%. The mean age was 42 years and 50.4% were female. 12 of the participants showed anti-tTG/DGP IgA or IgG positivity. Thus, the total seropositivity was 0.77%. The mean age of seropositive participants was 41 years, and 83% of them were female. All seropositive participants were either HLA-DQ2 or DQ8 positive. 5 pts had Marsh type 3 pathology, 1 had Marsh type 2. The other 6 pts had Marsh type 0. Endoscopic findings concordant with celiac disease observed in only 5 pts with Marsh type 3 pathology. All pts were asymptomatic; but 5 pts had iron deficiency anemia, 1 had deficiency of vitamin B12 and premenopausal osteoporosis and her daughter was diagnosed with CD earlier. One had the IgA deficiency. 1 pt had been diagnosed Hashimato tiroiditis before. The niece of 1 pt was diagnosed with CD. The son of a male pt, who had diagnosis of irritabl bowel syndrome earlier, was diagnosed with CD after reevaluation.
Conclusion: This study is the first population-based prevalence study of CD in Turkish adults. We found that seroprevalence of CD is 0.77%. All pts were asymptomatic. Iron deficiency anemia was the most common finding and positive family history stood out. The importance of serology for diagnosis should not be disregarded and it should be kept in mind that histologic and endoscopic findings were negative in half of the cases.

P1213 INNATE AND ADAPTIVE CYTOKINES AND CHEMOKINES IN THE DUODENAL MUCOSA OF SUBJECTS WITH NONCELIAC GLUTEN SENSITIVITY VERSUS CELIAC DISEASE

P. Giuffrida[1], C. Salvatore[1], A. Vanoli[2], D. Bagordo[1], G. R. Corazza[1], A. Di Sabatino[1]
[1]*First Department of Medicine,* [2]*Department of Molecular Medicine, St Matteo Hospital, University of Pavia, Pavia, Italy*

Contact E-mail Address: paolo.giuffrida01@gmail.com
Introduction: Immune mechanisms have been implicated in the pathogenesis of nonceliac gluten sensitivity (NCGS), a condition characterized by intestinal and/or extraintestinal symptoms caused by the ingestion of gluten in nonceliac/non-wheat allergic individuals.
Aims & Methods: We here investigated both innate and adaptive cytokines and chemokines in the duodenal mucosa of subjects with NCGS. Duodenal biopsies from 14 NCGS subjects, nine patients with untreated celiac disease (CD) and 12 control individuals were cultured ex vivo for 24h, and in the culture supernatants we detected by ELISA interleukin (IL)-15, and by cytokine array a number of innate cytokines, including tumor necrosis factor-a, IL-1b, IL-6, IL-12p70, IL-23, IL-27 and IL-32a, adaptive cytokines, including interferon (IFN)-g, IL-17A, IL-4, IL-5, IL-10 and IL-13, chemokines, including CCL1, CCL2, CCL3, CCL4, CCL5 and CXCL1, and growth factors, including granulocyte colony stimulating factor (G-CSF) and granulocyte-macrophage colony stimulating factor (GM-CSF). Eleven out of 14 NCGS subjects underwent a double-blind, placebo-controlled crossover trial, over which their intestinal and extraintestinal symptoms were scored.
Results: Both innate and adaptive cytokines, chemokines and growth factors did not differ between NCGS subjects and control individuals. On the contrary, mucosal levels of IL-6, IL-15, IL-27, IFN-g, IL-17A, IL-23, G-CSF, GM-CSF, CCL1 and CCL4 were significantly higher in patients with untreated CD in comparison to NCGS subjects and control individuals. No statistical significant correlation was found between innate/adaptive cytokines, chemokines or growth factors and clinical response to gluten or placebo.
Conclusion: Abnormalities of the mucosal immune response in terms of either innate/adaptive cytokines or chemokines do not seem to be implicated in the pathogenesis of NCGS.
Disclosure of Interest: None declared

P1214 A CROSS-SECTIONAL STUDY OF THE CLINICAL PHENOTYPE IN COELIAC DISEASE IN A LARGE COHORT OF IRISH PATIENTS

P. Dominguez Castro[1], C. Kiat[2], J. L. Chin[1], G. Harkin[2], V. Trimble[1], T. Martin[3], D. Kevans[1], P. MacMathuna[3], N. Mahmud[1], V. Byrnes[2], N. Kennedy[1], R. McManus[1]
[1]*Institute of Molecular Medicine & Department of Clinical Medicine, Trinity College Dublin, Dublin,* [2]*Department of Clinical Medicine, University College Hospital Galway, Galway,* [3]*Gastrointestinal Unit, Mater Misericordiae University Hospital, Dublin, Ireland*

Contact E-mail Address: domingup@tcd.ie
Introduction: Coeliac disease (CD) occurs both in adults and children at a rate of approximately 1% in most populations [(1)]. There has been a considerable increase in CD positive serology over time. CD has a wide spectrum in its clinical presentation [(1-4)]. The co-existence of CD with other disorders has been well reported [(5, 6)]. Few studies have addressed the clinical phenotype of CD in Ireland, and those available consist of small samples with little information on associated disorders [(7-9)].
Aims & Methods: The aim of this study is to explore the clinical phenotype of a large cohort (n = 443) of Irish CD patients (310 females, median age 57 years, range 16-87 years) through the retrospective analysis of medical charts.
Results: The median age of diagnosis was 45 years (range 0.5-86 years). Onset of CD was symptomatic in 383 patients (93%), while 29 presented with a subclinical phenotype (7%). 305 (68.8%) patients reported having ever suffered from common disorders associated with CD (i.e. osteoporosis, iron deficiency, depression). These patients were diagnosed later in life (Median = 48 years) than those who did not report having had any of these conditions (Median = 39 years) ($p = 0.001$). 145 patients (32.7%) had a coexistent autoimmune disorder, the most prevalent being thyroid disease (19.6%).
Conclusion: CD patients commonly present with other autoimmune and non-autoimmune conditions. Diagnosis later in life appears to be associated to the development of co-existent non-autoimmune disorders.

P1215 PREDICTING HISTOLOGICAL REMISSION IN PATIENTS WITH CELIAC DISEASE ON A GLUTEN-FREE DIET

P. D. Mooney[1], M. Kurien[1], M. Burden[1], S. Wong[1], D. Sanders[1]
[1]*Academic Department of Gastroenterology, Royal Hallamshire Hospital, Sheffield, United Kingdom*

Contact E-mail Address: p_d_mooney@hotmail.com
Introduction: Up to 30% of patients with celiac disease (CD) will have persistent symptoms despite the introduction of a gluten-free diet (GFD). Assessment of adherence in celiac disease can involve any combination of patient self-reporting adherence, dietetic assessment, serology and biopsy with histology. Histology is considered to be the 'gold standard' but this requires a repeat endoscopic examination with its associated risks and problems with tolerance. As a result surrogate markers of persistent gluten exposure and histological changes such as serology are frequently used but the relationship between serology and persistent histological changes is not linear. A structured interview with a dietician has been shown to be the most accurate method of assessing GFD adherence however this is time consuming and requires extra clinic visits. The aim of this study was to assess the usefulness of two novel options. Firstly a previously internally validated scoring system for assessing GFD adherence[1] (which has never been externally validated) and secondly a rapid deamidated gliadin peptide based point of care test (POCT, Simtomax) for the prediction of persistent villous atrophy (VA).
Aims & Methods: All patients with known CD and persistent symptoms coming to a specialist CD endoscopy list for the re-assessment of histology were invited to take part. All patients were tested for Endomysial Antibody (EMA), tissue transglutaminase (tTG), immunoglobulins and the POCT. They were also asked to complete a questionnaire to calculate a 5 point score (0 – 4) with a high score representative of improved adherence to a gluten-free diet. All patients underwent gastroscopy with at least 4 biopsies from the second part of the duodenum and 1 to 2 biopsies from the bulb.
Results: 94 patients (77% female, mean age 52.6) were recruited between April 2013 and December 2014. Median duration of GFD was 84 months (range 6-768). 36 (38.3%) patients had persistent VA on duodenal biopsy. The POCT was the most sensitive marker with 63.4% of patients with VA having a positive test. EMA was the most specific surrogate marker at 82.8% although it was highly insensitive with only 33.0% of patients with VA having a positive EMA. The adherence score could not be reliably used to predict VA with a sensitivity of only 30.6%.

Measure	Sensitivity (%)	Specificity (%)	PPV (%)	NPV (%)
Adherence Score	30.6	79.3	47.8	64.8
tTG	50.0	75.9	56.3	37.9
EMA	33.0	82.8	54.5	66.7
POCT	63.4	60.3	50.0	72.9

Conclusion: An accurate surrogate marker for VA could reduce the number of endoscopies required. In this cohort the POCT had the best sensitivity, detecting 23/36 (63.4%) cases of villous atrophy, however this is pilot data and further work is required. It may be that additive methods for assessing adherence could achieve 100% sensitivity.

P1216 HEART RATE VARIABILITY (HRV) – PREDICTOR OF MESENTERIC ISCHEMIA IN CARDIAC PATIENTS

A. I. Suceveanu[1], A. P. Suceveanu[1], F. Voinea[1], I. Parepa[2], D. Catrinoiu[3], L. Mazilu[3]
[1]*Gastroenterology,* [2]*Cardiology,* [3]*Internal Medicine, St Apostle Andrew Emergency Hospital, Constanta, Romania*

Contact E-mail Address: andrasuceveanu@yahoo.com
Introduction: Reduced HRV is proved to be a predictor of mortality after myocardial infarction and other medical conditions, including congestive heart failure, diabetic neuropathy, depression or post-cardiac transplant status. Mesenteric ischemia (MI) is a medical condition in which inflammation and injury of the small intestine result from inadequate blood supply.
Aims & Methods: We aimed to identify if the decrease-frequency component of HRV may be used as a predictor for the mesenteric ischemia (MI) occurrence in cardiac patients before the onset of digestive symptoms. Using ECG recordings, we measured the HRV in 170 patients admitted in Cardiac Care Unit (CCU) of St. Apostle Andrew Emergency Hospital of Constanta County. The study was done in collaboration with Gastroenterology Department of the same medical institute. We created a model of prediction for occurrence of MI in patients with cardiac diseases using correlations between the type of HRV and MI.
Results: From the total of 170 patients hospitalized in CCU in 3 months (January - March' 15), 24 (14.11%) patients developed MI. From the total of 36 patients with decreased high-frequency HRV, 18 patients (50%) developed the MI. In contrast, only 6 patients (4%) of those with high-frequency value of HRV get the disease. Our results fixed a positive correlation between reduced high-frequency of HRV and MI occurrence ($r = 0.98$).
Conclusion: Identifying the HRV in cardiac patients and making interventions to improve the parasympathetic nervous system activity we can simply avoid the occurrence of a high risk mortality disease that can worsen the prognosis of cardiac patients.

Introduction: The superior mesenteric artery (SMA) syndrome is a rare entity presenting with upper gastrointestinal tract obstruction and weight loss, due to the compression of the third part of duodenum between the aorta and the SMA. Studies to determine the optimal methods of diagnosis and treatment are essential.

Aims & Methods: This study aims to analyze the clinical presentation, the diagnosis and the management of SMA syndrome. Over a 2-year period (2013-2014), 10 cases of SMA syndrome (out of 2074 esophagogastroduodenoscopies (EGDS)) were initially suspected through EGDS. Therefore, these patients performed computed tomography (CT) scan to confirm the diagnosis. Once the diagnosis was confirmed, the patients were referred to a gastroenterologist and to a nutritionist to discuss a personalized approach of therapy; furthermore, for each patient a surgical consultation was proposed.
Results: In our series we evaluated retrospectively 10 cases of SMA (8 females), with a prevalence of 0.005%. Median age was 23.5 years (range 14-40), and the median body mass index was 21.5 kilos/m2. Symptoms developed between 6 to 24 months (median 18). Premorbid conditions were present in four patients (Anorexia nervosa in two patients, and Spina bifida and Crohn's disease in two patients). Only 2 of 10 patients were hospitalized, due to severe malnutrition. Median aorto-mesenteric angle was 22°, and median aorta-SMA distance was 6 mm. Interestingly, all the patients improved on conservative treatment.
Conclusion: o date, SMA syndrome represents a diagnostic and therapeutic challenge. With regard to previous series published, our results show: the importance of the endoscopic suspicion of SMA syndrome, confirmed by CT scan; the preponderance of a longstanding and chronic onset; a female preponderance; the importance of the nutritional counseling in the therapeutic approach; the absence of need for surgical intervention; the better diagnostic accuracy of the narrowing of the aorta-SMA distance, rather than the narrowing of the aortomesenteric angle. Further prospective studies, with a larger number of patients, are needed to clarify the best way to diagnose and manage the SMA syndrome.

P1218 HIGH VARIATION IN TREATMENT STRATEGIES FOR GASTROINTESTINAL ANGIODYSPLASIAS: A NATIONWIDE SURVEY IN THE NETHERLANDS

K. Grooteman[1], E. van Geenen[1], J. Drenth[1]
[1]*Gastroenterology and Hepatology, Radboud University Medical Center, Nijmegen, Netherlands*

Contact E-mail Address: karina.grooteman@radboudumc.nl
Introduction: Gastrointestinal angiodysplasias are the second leading cause of gastrointestinal bleeding in the elderly. On the other hand, angiodysplasias can be a coincidental finding on endoscopy and asymptomatic. Guidelines assisting in a treatment strategy in patients with symptomatic angiodysplasias are lacking.
Aims & Methods: Our aim was to assess current practice of the treatment of gastrointestinal angiodysplasias and attitudes concerning these practices among Dutch gastroenterologists.
To achieve this aim, a 19-item web-based survey covering current practices in the treatment of gastrointestinal angiodysplasias was administered between February and April of 2015 to gastroenterologists in the Netherlands.
Results: Of the 395 e-mailed questionnaires, a total of 111 (28%) gastroenterologists completed the survey (mean age = 47 years; 24% women), and the sample is representative for the profession in the Netherlands. Respondents correctly identified Von Willebrand disease (17%), chronic kidney disease (21%) and aortic stenosis (86%) as risk factors for the development of angiodysplasias. Colonoscopy (54%) and esophagogastroduodenoscopy (43%) were the preferred first tools to screen for angiodysplasias. The favoured (77%) first treatment option is endoscopic argon plasma coagulation, while 20% starts iron supplementation or blood transfusions. This decision on treatment strategy is mostly (65%) based on the location of the angiodysplasia. Thirteen percent of the gastroenterologists would treat angiodysplasias as a coincident finding during endoscopy for another indication than anaemia. Of the pharmacological therapies, thalidomide (40%) is preferred over octreotide (19%). In case octreotide is prescribed, 20 mg monthly is mostly (52%) given after a test period with short-acting octreotide (86%).
Conclusion: Identification of risk factors, the diagnostic tools used and treatment strategies varies widely between gastroenterologists in the Netherlands. Moreover, a considerable proportion of gastroenterologists would treat angiodysplasias found by coincidence, which is not according to endoscopic guidelines. A guideline for the treatment of angiodysplasias might be helpful to create a more uniform and evidence-based practice.

P1219 PROSPECTIVE, QUANTITATIVE ASSESSMENT OF PAIN REDUCTION AND QUALITY OF LIFE IMPROVEMENT FOLLOWING VASCULAR INTERVENTION IN CHRONIC MESENTERIC ISCHEMIA; A PILOT STUDY

L. Everlo[1], J. Kolkman[1,2], P. Mensink[1], M. Brusse-Keizer[3], B. Geelkerken[4], E. Stassen[5]
[1]*Gastroenterology, Medisch Spectrum Twente, Enschede, Enschede,* [2]*Gastroenterology, University Medical Centre Groningen, Groningen,* [3]*Medical School Twente,* [4]*Vascular Surgery,* [5]*Interventional Radiology, Medisch Spectrum Twente, Enschede, Enschede, Netherlands*

Contact E-mail Address: l.everlo@mst.nl
Introduction: There is a lack of knowledge of the quantitative effects of treatment of chronic mesenteric ischemia (CMI) on pain and health-related quality of life (HRQOL). This prospective pilot-study was designed to determine the mid-term change of pain intensity and HRQOL in CMI treatment.
Aims & Methods: Patients with mesenteric ischemia, treated with endovascular intervention for luminal stenosis or endoscopic release of the diaphragm crux in celiac artery compression syndrome between August and December 2013 were enrolled. For pain we used the visual analogue scale for pain intensity (VAS-PI, graded 0-100 mm). For HRQOL we used the 36-item Short Form Health Survey (SF-36). All parameters were obtained before and three months after the intervention.
Results: We included 29 patients; mean age 55.9 years (SD 20.0), 79.3 % female. Single-vessel (n = 7), multi-vessel (n = 15) atherosclerosis and celiac artery compression syndrome (n = 7). The VAS for pain improved following treatment: for the average pain from median 60 (IQR: 48 – 72) to 2 (IQR: 0 – 40, $p < .001$), for postprandial pain from median 74 (IQR: 63–84) to 2 (IQR: 0–40, $p < .001$), and for post-exercise pain from median 63 (IQR: 50–80) to 4 (IQR: 0–30, $p < .001$). The number of painful days per week decreased from median 7 days (IQR: 5–7) to 1 day (IQR 0–6.8 days, $p < .001$). The HRQOL measured with SF-36 improved for five of eight dimensions (role physical (p.005), bodily pain (p.001), vitality (p.004), social functioning (p.001) and mental health (p.001)) and the both component summary scores (physical (p.008) and mental (p.009)).
Conclusion: This pilot study showed that three months after vascular intervention for CMI the pain is significantly reduced and quality of life for patients improved. The magnitude of effects exceeded our expectations, but larger studies with longer follow-up are needed to confirm this observation.

P1220 EFFECTS OF GUT MICROBIOTA MANIPULATION BY ANTIBIOTICS ON PLASMA AMINO ACID LEVELS IN OBESE HUMANS

E. Neis[1], D. Reijnders[2], G. Goossens[2], E. Blaak[2], C. Dejong[3], S. Rensen[1], on behalf of NUTRIM School for Nutrition, Translational Research in Metabolism
[1]*Surgery,* [2]*Human Biology, Maastricht University,* [3]*Surgery, Maastricht University Medical Center+, Maastricht, Netherlands*

Contact E-mail Address: e.neis@maastrichtuniversity.nl
Introduction: Gut bacteria can alter the bioavailability of amino acids and have been implicated in the pathogenesis of metabolic disease. Obesity and type 2 diabetes are associated with elevated systemic concentrations of aromatic and branched-chain amino acids (BCAA).
Aims & Methods: We aimed to investigate the effects of gut microbiota knockdown on arterial amino acid levels in humans. For this, 38 obese male subjects (BMI $31.2 \pm 2.6 kg/m^2$, age $59 \pm 7y$, HOMA-IR 4.5 ± 0.2) with impaired fasting glucose and/or impaired glucose tolerance participated in a randomized double-blind placebo-controlled trial. Subjects were orally treated with 1500mg/day amoxicillin (AMOX; broad-spectrum antibiotic), vancomycin (VANCO; aimed at Gram-positive bacteria), or placebo (PLA; microcrystalline cellulose) for 7 days. Before and after treatment, arterial concentrations of 21 amino acids were measured using liquid chromatography.
Results: Baseline BCAA concentrations were high but did not differ between groups: 445.0 ± 35.9µmol/L (VANCO), 423.3 ± 42.7µmol/L (AMOX), and 440.6 ± 44.7µmol/L (PLA), $P = 0.406$. AMOX treatment specifically increased BCAA levels in comparison to PLA (464.3 ± 60.7µmol/L vs. 434.6 ± 66.5µmol/L; $P = 0.042$), whilst VANCO treatment did not (441.9 ± 30.3µmol/L; $P = 0.867$). Within treatment groups, isoleucine (one of the BCAA) concentrations increased significantly upon both AMOX (from 68.4 ± 8.1µmol/L to 79.3 ± 10.9µmol/L; $P = 0.003$) and VANCO treatment (from 70.3 ± 7.7µmol/L to 78.3 ± 9.6µmol/L; $P = 0.001$), but not in the PLA group (from 75.6 ± 10.5µmol/L to 78.1 ± 12.3µmol/L; $P = 0.305$). Besides, arginine concentrations increased significantly only upon AMOX treatment (from 89.9 ± 20.1µmol/L to 101.5 ± 21.2µmol/L; $P = 0.025$). Other amino acids were not affected by any treatment.
Conclusion: The broad-spectrum antibiotic AMOX increases plasma BCAA concentrations. Current ongoing analyses will shed light on the nature of the gut microbiota alterations provoked by AMOX in relation to specific amino acid aberrations, parameters of insulin sensitivity, and substrate metabolism in obese subjects with impaired glucose tolerance.

P1221 ADIPOCYTE HYPERTROPHY AND INFLAMMATION COULD AFFECT LIVER INJURY IN NAFLD BY ALTERNATIVE MECHANISMS

J.-P. Sowa[1], M. Schlattjan[1], G. Gerken[1], A. Canbay[1]
[1]*Department for Gastroenterology and Hepatology, University Hospital, University Duisburg-essen, Essen, Germany*

Contact E-mail Address: ali.canbay@uni-due.de
Introduction: Lifestyle changes and obesity have spread over the world, leading to an obesity epidemic. Metabolic syndrome (MS) induced by obesity is similarly common in industrialized countries and accordingly non-alcoholic fatty liver disease (NAFLD) and the more severe form non-alcoholic steatohepatitis (NASH) are the most common liver diseases in industrialized countries.
Aims & Methods: Aim of the present study was to investigate if changes in adipose tissue affect development or severity of NAFLD and NASH in MS. To this end visceral adipose tissue, liver tissue samples and blood were obtained from 145 morbidly obese patients (age median = $49 \pm 10y$; 114w/30m; mean BMI: $53 \pm 8.7 kg/m^2$) undergoing bariatric surgery. Biopsies were scored with NAFLD activity score (NAS; median 3/range 1-7) and patients were grouped as NAFL ($NAS \leq 4$) or NASH ($NAS > 4$). Blood samples taken before surgery were analyzed for parameters of liver injury M30 (Apoptosis) and M65 (Overall cell death) and adiponectin. Visceral adipose tissue and hepatic mRNA levels of genes for inflammasome activity and fatty acid metabolism were assessed by qRT PCR.

Results: NASH patients showed significantly higher concentration of markers for cell death (M65), HbA1c, classic liver parameters (ALT, AST), and CRP in serum. Adiponectin serum concentration was significantly lower in NASH. Expressions of analyzed genes did not differ between the groups. Though, NAS was significantly correlated to visceral adipocyte cell size, classic liver parameters, fasting blood glucose and HbA1c, M65, and to liver mRNA expression of MCP1 and NLRP. Cell size of visceral adipocytes was correlated to serum leptin and liver mRNA expression of ATG12 and was inversely correlated to mRNA expression of FASN and CGI-58 in the liver. Moreover MCP1 mRNA expression in adipose tissue correlated with mRNA expression of MCP1, autophagy genes (ATG5, ATG12, LC3), and PPARγ2 in the liver. Expression of the FAS-Receptor in adipose tissue correlated with mRNA expressions of CGI-58 and PPARγ2 in liver tissue.
Conclusion: These results suggest that visceral adipocyte hypertrophy affects hepatic regulation of fatty acid metabolism by downregulation of genes involved in triglyceride breakdown. This may lead to accumulation of lipotoxic compounds and increased liver injury. In contrast high HbA1c might be associated to increased inflammation in the adipose tissue which seems connected to inflammatory gene expression and autophagy in the liver, affecting liver metabolism by other mechanisms.

P1222 ACTIVATORS OF THE TRANSCRIPTION FACTOR NRF-2 AS NEW REGULATORS OF HEPCIDIN EXPRESSION

J. Martin[1], S. Ulrich-Rückert[1], J. Stein[2]
[1]*Pharmaceutical Chemistry, Goethe University Frankfurt,* [2]*Hospital of Sachsenhausen, Frankfurt a.M., Germany*

Contact E-mail Address: martin.julia@gmx.de
Introduction: Hepcidin, an acute phase protein, is regarded as central mediator of the cytokine-induced anaemia of chronic inflammation (ACI), one of the most common causes of iron deficiency anaemia in patients with inflammatory bowel disease and obesity. Identified as primary trigger is the STAT-3 mediated induction of hepcidin synthesis in the liver and macrophages by cytokines of the IL-6 family (IL-6, oncostatin M).
Aims & Methods: The current study aimed to determine additional signal transduction paths of cytokine-induced hepcidine synthesis, with particular focus on a possible role of the transcription factor NF-E2-related factor 2 (Nrf2). HepG2 and Huh7 cells were cultivated in standard conditions and treated for 6 or 16 h with either IL-6 (10 ng/ml) or OSM (10 ng/ml) alone, or in combination with STAT-3 inhibitor (50 μM), sulforaphane (SFN) (10 μM), dimethylfumarat (DMF) (100 μM), 15-Deoxy-Delta-12-14-prostaglandin J2 (15d-PGJ2) (10 μM). For the reporter gene assay, the cells were transfected by lipofectamine with hepcidin promoter plasmid, and the luciferase activity was measured luminometrically. Quantitative real time PCR was performed for quantitative determination of mRNA. Proteins were analysed using western blot.
Results: Both IL-6 (10 ng/ml) and OSM (10 ng/ml) trigger significant hepcidin promotor activation (***$p < 0.001$), which could be significantly reduced (***$p < 0.001$) by coincubation with the STAT3 inhibitor (VI, S3I-201). Coincubation of OSM and IL-6 with the Nrf-2 activators SFN (***$p < 0.001$), DMF (**$p < 0.01$) and 15d-PGJ2 (*$p < 0.05$) led not only to significant inhibition of hepcidin promotor activity, but also to a significant reduction of intracellular hepcidin mRNA levels (mind. *$p < 0.05$). No reduction of the pSTAT/STAT ratio was observed after 8 and 16h incubation with SFN.
Conclusion: The results indicate the transcription factor Nrf-2 to play a role in the expression of the iron regulator hepcidin, with possible involvement of STAT-3 independent signal transduction pathways.

P1223 IRREGULAR BOWEL HABIT INCREASES THE RISK OF OBESITY

K. A. Shemerovskii[1,2], V. I. Ovsiannikov[2], V. P. Mitreikin[1]
[1]*Pathophysiology, Pavlov I P University,* [2]*Physiology of visceral system, Institute Experimental Medicine, St-Petersburg, Russian Federation*

Contact E-mail Address: constshem@yandex.ru
Introduction: Bowel habit in accordance with chronobiology is one of the fundamental circadian rhythms with the regular frequency of at least 7 times a week. The slowing of the rhythm in the form of constipation is a risk factor for colorectal cancer [1,2], the risk of which is increased in obesity [3,4]. However, the impact of the slowdown of the rhythm on the risk of obesity remains poorly studied.
Aims & Methods: The aim of this study was to elucidate the relation between irregular bowel habit and the risk of obesity.
Methods: Validated questionnaires were used for weekly monitoring of circadian rhythm of defecation at 2501 persons, who consider themselves healthy. Regular bowel habit was detected in 1399. Irregular bowel habit was diagnosed in 1102. To diagnose the risk of obesity we randomized two groups of 200 persons with regular and irregular rhythm of defecation. The first group of 100 people (86 women) 23-85 years demonstrated regular bowel habit (daily morning bowel movement with a frequency of 7 times per week). The second group of 100 persons (90 women) 25-79 years demonstrated irregular bowel habit (not daily defecation, frequency 1-6 times per week). The analyzed groups did not significantly differ by gender and age. We calculated the body mass Index (BMI), according to which each group was divided into three subgroups: I – BMI 20-25 kg/ml — normal, II — BMI 25-30 kg/ml— overweight, III — BMI above 30 kg/ml is obesity.
Results: There were identified 53 persons with normal BMI, 37 persons with overweight and 10 subjects with obesity among 100 individuals of the first group with regular bowel habit (RBH). Consequently, in a group of persons with regular bowel habit the risk of obesity was 10%. There were 36 persons with normal BMI, another 36 persons - with overweight, and 28 subjects with obesity among 100 persons of the second group with the irregular bowel habit (IBH). Consequently, in the group of persons with a broken, irregular bowel habit the risk of obesity was 28%. Thus, the risk of obesity among patients with IBH was almost three times (2.8 times) higher than among persons with RBH.
Conclusion: Among individuals with regular bowel habit the probability of normal body mass index (53%) was almost 1,5 times higher than in patients with irregular bowel habit (36%). Among those with irregular bowel habit the risk of obesity (28%) was almost 3 times higher than in those with regular bowel habit (10%). The lack of regular bowel habit predominantly in women of different age significantly (almost 3 times) increases the risk of obesity.

P1224 PRELIMINARY RESULTS OF AN ONGOING MULTI-CENTER, PROSPECTIVE, CONTROLLED TRIAL OF THE DUODENAL-JEJUNAL BYPASS LINER FOR THE TREATMENT OF TYPE 2 DIABETES MELLITUS IN OBESE PATIENTS: EFFICACY AND FACTORS PREDICTING A SUB-OPTIMAL EFFECT

M. Benes[1], T. Hucl[1], P. Drastich[1], P. Stirand[1], J. Spicak[1]
[1]*Hepatology and Gastroenterology, Institute of Clinical and Experimental Medicine, Prague, Czech Republic*

Contact E-mail Address: marek.benes@ikem.cz
Introduction: The global increase in obesity incidence results in an increase of type 2 diabetes mellitus (T2DM) incidence. Surgical treatment has proven to be effective, however it carries a high risk of complications. The duodenal-jejunal bypass liner (EndoBarrier®, GI Dynamics, DJBL) is an endoscopic implant that mimics the intestinal bypass portion of the Roux-en-Y Bystric Bypass. It results in weight loss and improvements in glucose control in obese patients with T2 diabetes mellitus (T2DM).
Aims & Methods: This is an interim report of an ongoing three years study. The aim of this prospective, controlled, multicentre study is to determine the effectiveness of DJBL and to identify clinical factors associated with a sub-optimal outcome of DJBL.
Results: Fifty seven subjects (32 with an implant, 25 controls) were included in the study. The groups were comparable with respect to age, gender, BMI (mean 40.7 vs. 38.5 kg/m2), T2DM duration (7.3 vs. 8.1 years), HbA1c level (89 vs 83 mmol/mol) and T2DM treatment. In the DJBL group, all devices were successfully implanted. Only four devices had to be explanted prior to the end of the 10 months study period (bleeding, dislocation and need for ERCP because of choledocholithiasis). The mean procedure time was 19.2 minutes for an implantation and 18.5 minutes for an explantation. At 10 months there was significantly greater weight loss and %EWL (21% vs. 8% and 44 vs. 14) and significantly improved long term compensation of T2DM marker HbA1c (decreased by 25 vs. 11 mmol/mol) in the DJBL group. T2DM medicinal treatment could be reduced in more device subjects than controls. There was no serious adverse event. Mild abdominal pain and nausea after implantation were experienced by 72% of patients during first 14 days after implantation, 33% of patients during the first month and 10% of patiens after one month. Lower initial BMI, distal position of the anchor and lower body height were identified as negative prognostic factors for pain.
Conclusion: The DJBL is safe when implanted for 10 months, and results in significant weight loss and HbA1c reduction. This suggests that this novel device is a candidate for the primary therapy of morbid obesity and T2DM. Lower initial BMI, distal position of the anchor and lower body height could be negative prognostic factor for pain.

P1225 CD24 POLYMORPHISMS ARE ASSOCIATED WITH OBESITY RISK

N. Shemesh[1], **I. Naboichtchikov**[1], S. Shapira[1], D. Kazanov[1], S. Zigdon[1], L. Galazan[1], A. Leshno[1], S. Kraus[1], A.-A. Subhi[2], N. Arber[1]
[1]*Integrated Cancer Prevention Center,* [2]*Department of Surgery, Tel Aviv Sourasky Medical Center, Tel Aviv, Israel*

Contact E-mail Address: nadira@tlvmc.gov.il
Introduction: Background: Obesity is a global epidemic and major risk factor for various health conditions. It is a multifactorial condition and has genetic and environmental etiology. Several studies have suggested candidate genes that may predispose to obesity. CD24 is a small, mucin-like glycoprotein that is expressed in almost all tumors. We have recently found that *CD24* knockout male (but not female) mice are overweight and display greater insulin sensitivity than their wild-type (WT) littermates. Several single nucleotide polymorphisms (SNPs) in the *CD24* gene are known to be associated with various cancers and autoimmune diseases.
Aims & Methods
Aim: Evaluate whether *CD24* SNPs are associated with risk of obesity.
Methods: Genomic DNA was obtained from peripheral blood leukocytes of 63 obese Israeli patients (BMI ≥ 35; 27 males, 36 females) and 53 age- and gender-matched healthy controls (BMI ≤ 27; 30 males, 23 females). Samples were genotyped for the *CD24* SNPs: C170T (rs8734), TG1527del (rs3838646), A1626G (rs1058881) and A1056G (rs1058818) by real-time PCR using Custom TaqMan® SNP allelic discrimination assays. χ^2 test was used to examine whether the *CD24* gene polymorphisms are associated with obesity. An association was considered statistically significant if $p < 0.05$. Odds ratio (OR) and 95% confidence interval (CI) were estimated by logistic regression models.
Results: A1056G and A1626G SNPs were found to be more prevalent in obese patients than in normal weight subjects (OR = 2.973, 95% CI: 1.155-7.6527, p = 0.0234 and OR = 4.7212, 95% CI: 2.1408-10.412, p = 0.0001, respectively). Moreover, all four CD24 SNPs carriers were more predominant in the obese group, although the correlations were not statistically significant. In addition, gender adjustment revealed a significant association between A1626G and obese male patients. The prevalence of the WT variant was 0% in the obese males and 76.7% control males (p = 0.0001). A similar trend was found for A1056G, although the correlation was not statistically significant (OR = 4, 95% CI:0.9667 -16.551, p = 0.0613).
Conclusion: CD24 may play a role in male obesity
Carriers of A1056G and A1626G *CD24* SNPs may be more prone to develop obesity, and in particular male A1626G carriers.
No correlation was found between age-dependency and genetic variant distribution in obese patients.

Contact E-mail Address: ovirchenko@gmail.com
Introduction: Childhood obesity is a predisposing factor for poor health in adolescence and also in adulthood. The number of overweight has more than doubled in children and quadrupled in adolescents in the past 30 years. Today the correction of lifestyle and diet remain the most effective way of obesity treatment. Despite of this a lot of obese people do not improve their health and the search of nontoxic antiobesity drugs is still urgent.
Aims & Methods: So, the aim of the study was to investigate the influence of cerium dioxide nanoparticles ($nCeO_2$) intermittent administration on the obesity in rats induced with neonatal injection of monosodium glutamate (MSG).
The study was carried out on 3 groups of rats: control, MSG- and MSG + $nCeO_2$, 10 animals in each. Just after the born they were injected with saline (control) or MSG (4 mg/g, 3M) at 2^{nd}–10^{th} day of life subcutaneously. A month after born MSG-rats had been treated with water in a volume of 2.9 ml/kg, MSG + CeO_2 groups – with 1 mM solution of CeO_2 (1 mg/kg) intragastrically (i.g.). Introduction had been performed intermittently (two-week courses alternated with two-week breaks) for 3 months. In 4-month rats visceral adipose tissue (VAT) mass was measured, content of lipid peroxidation products in serum and enzymatic activity of superoxide dismutase (SOD) and catalase was estimated by standard biochemical methods. The content of proinflammatory cytokines (interleukin (IL)-1β, IL-12Bp40, interferon-γ (INF-γ)) and anti-inflammatory cytokines (IL-4, IL-10, tumor growth factor-β (TGF-β)) were measured by ELISA kits.
Results: In 4-month MSG-rats it was observed the development of visceral obesity in rats that was confirmed by the increase of the VAT mass, alteration of body mass index, index Lee, malfunction of cytokine system and shift to prooxidative processes. In MSG + $nCeO_2$ we established the decrease of visceral obesity (the VAT mass in MSG-group *vs.* MSG + $nCeO_2$ group 19.0 ± 2.0 g *vs.* 8.3 ± 1.4 g., $p < 0.05$). $nCeO_2$ significantly reduced the conjugated dienes content by 27% ($p < 0.05$), TBA-products – by 43% ($p < 0.05$) and Schiff bases – by 21% ($p < 0.05$) compared to MSG-group. Nanoparticles reduce the content of proinflammatory cytokines (IL-1β, IL-12Bp40, INF-γ) in rat serum. We have also performed the preclinical study of $nCeO_2$ on rat and showed its very low toxicity ($LD_{50} > 2000$ mg/kg i.g., V toxicity class).
Conclusion: Thus, it was revealed the antiobesity properties of intermittent administration of $nCeO_2$. The reduction of visceral adiposity in rats by $nCeO_2$ was associated with its antioxidant and anti-inflammatory properties. Discovered properties and low toxicity of $nCeO_2$ allow to recommend it for clinical investigation.

Contact E-mail Address: azpiroz.fernando@gmail.com
Introduction: The metabolic activity of colonic microbiota is influenced by diet and meals, but their effect on colonic biomass is not known. Our aim was to determine whether and to what extent meals and diet influence colonic content.
Aims & Methods: In 10 healthy subjects 2 abdominal MRI scans were acquired during fasting one week apart after 3 days on low- and high-residue diets, respectively. On each diet, daily fecal output and the number of the daytime anal gas evacuations were measured. On the first study day, a second scan was acquired 4 h after a test meal (n = 6) or after 4 h without ingesting anything (n = 4). On the second study day, a scan after a spontaneous bowel movement was also acquired.
Results: On the low-residue diet, daily fecal output averaged 145 ± 17 mL, subjects passed 11 ± 2 anal gas evacuations during daytime and by the third day colonic content was 622 ± 44 mL. The high-residue diet increased the 3 parameters up to 223 ± 19 mL fecal output, 17 ± 3 anal gas evacuations and 821 ± 59 mL colonic content ($p < 0.05$ vs low-residue diet for all). On the low-residue diet, 4 hours after the test meal colonic content increased up to 732 ± 51 mL ($p < 0.05$ vs first fasting scan), whereas no significant change was observed after 4 hours fast. Defecation significantly reduced colonic content in distal colonic segments (by $29 \pm 5\%$; p = 0.002).
Conclusion: Meals and diet influence microbiota metabolic activity and colonic biomass as well.

P1228 THE INTERACTIONS BETWEEN DIET, MUCOSAL PROLIFERATION AND GI CANCER RISK IN RURAL AFRICANS AND AFRICAN AMERICANS

H. Kaseb[1], K. Mohamed[1], J. Ou[1], S. O Keefe[1]
[1]*Department of Gastroenterology, University of Pittsburgh, Pittsburgh, United States*

Contact E-mail Address: phys.hatemosama@inbox.com
Introduction: Based on the analysis of worldwide epidemiological studies, it has been estimated that >90% of GI cancers are diet-related. African Americans have an extremely high risk of colon cancer (~65:100,000) while rural Africans rarely get the disease. On the other hand, rural Africans have an extremely high risk of squamous cell carcinomas of the esophagus (125/100,000 in men) while African Americans have a low risk.
Aims & Methods: We investigated the usual diets and performed upper and lower endoscopies to obtain mucosal biopsies for the measurement of mucosal biomarkers of cancer risk form the esophagus, stomach, and colon (Ki67 staining of proliferative epithelial cells) in matched groups (n = 20, age 50-65, BMI 18.5-35 kg/m2) from each population.
Results: Dietary analyses based on 3-day recalls have shown that there are major differences in the diets of rural Africans when compared to African Americans. Our measurements show that the Ki67 staining of esophageal epithelial proliferative cells was higher in rural Africans than African Americans. The glandular gastric ki67 cell staining was also higher in the rural Africans compared to African Americans. On the other hand, African Americans had higher proportions of Ki 67 staining cells in the colonic mucosal crypts.
Conclusion: Based on our measurements of epithelial proliferation rates by Ki67 immunohistochemistry as a biomarker of cancer risk, our results support the view that the high fiber, low meat and fat African diet suppresses colon cancer risk, but that its lower vitamin and antioxidant content may increase the risk of upper GI cancers as compared to African Americans. The high prevalence of *H pylori* infections in Africans (i.e. 80%) was associated with higher antral proliferative rates, but not with cancer rates in the population as a whole.

P1229 INTAKE OF NATURALLY-OCCURRING OLIGOSACCHARIDES WITH POTENTIAL PREBIOTIC ACTIONS: VALUABLE DATA FOR FUTURE PREBIOTIC RESEARCH

J. Barrett[1], J. Muir[1], P. Gibson[1]
[1]*Gastroenterology, Monash University, Melbourne, Australia*

Contact E-mail Address: jacqueline.barrett@monash.edu

Introduction: Reducing intake of indigestible, fermentable, short chain carbohydrates (low FODMAP diet) has recently been shown to reduce absolute and relative abundance of 'beneficial' bacterial in the faeces. Furthermore, mildly increasing FODMAP intake over that in the habitual diet had prebiotic effects [1]. These variations are likely to be due to alteration in dietary fructo-oligosaccharides (fructans) and galacto-oligosaccharides (GOS), which, when given as pure supplements at doses of 5-10 g/d can be prebiotic. However, the impact in clinical trials of such prebiotics on clinical outcomes has been in general disappointing. Dietary prebiotic intake has never been taken into account in such studies.

Aims & Methods: The aim of this study is to define the potential influence of normal dietary intake of oligosaccharides by quantifying dietary fructan and GOS intake and examining variance across individuals.

Data obtained during the validation of a food frequency questionnaire in 72 healthy Australians [2] was reanalysed using an updated FODMAP database that included recent publications [3] and unpublished addition. Intakes of fructans and GOS were calculated and expressed as g/d, presented as mean, range and quartiles.

Results: Mean (SD) of fructan and GOS intake was 3.8 (1.1) and 1.2 (0.9) g/d, respectively. Combined prebiotic fructan and GOS intake ranged from 1.4 – 10.3 g/d. Common foods contributing to the higher fructan intake were wheat and rye breads, pasta, onion, garlic and shallots and the most common sources of GOS were legumes and nuts.

Table 1: Prebiotic Fructan and GOS consumption data from the CNAQ validation study

FODMAP type	Mean (SD) g	Range (g)	1st Quartile (g)	2nd Quartile (g)	3rd Quartile (g)	4th Quartile (g)
Fructan	3.8 (1.1)	1.1-7.3	<2.9	2.9-3.7	3.8-4.6	>4.6
GOS	1.2 (0.9)	0.2-4.3	<0.6	0.6-0.9	1.0-1.4	>1.4
Fructan + GOS	5.0 (1.6)	1.4-10.3	<3.7	3.7-4.8	4.9-6.2	>6.2

Conclusion: Dietary intake of potentially-prebiotic oligosaccharides varies widely from minimal (where effects of supplemented prebiotics may be high) to high (where additional prebiotic effects of supplements are less likely). These findings imply that the highly variable inter-individual effect of supplemental prebiotics in clinical trials might reflect habitual dietary intake, which should be assessed in any prebiotic trial. Such an approach might assist in defining the value or otherwise of prebiotic supplementation.

P1230 THE ROLE OF FODMAPS IN GASTRIC ACCOMMODATION AND UPPER GASTROINTESTINAL MOTOR ACTIVITY

I. Masuy[1], J. Tack[1], J. Biesiekierski[1]
[1]*TARGID, KU Leuven, Leuven, Belgium*

Contact E-mail Address: Jessica.Biesiekierski@med.kuleuven.be

Introduction: There is accumulating evidence for the benefit of a diet low in fermentable oligosaccharides, disaccharides, monosaccharides and polyols (FODMAPs) for the management of irritable bowel syndrome (IBS) symptoms. Whether FODMAPs alter the upper GI response to nutrients, including gastric accommodation (GA), remains to be assessed.

Aims & Methods: The objectives were to assess the role of different FODMAPs in the intragastric pressure (IGP) response to nutrient ingestion (which reflects GA), upper GI motility, meal-induced satiation and symptom generation. A high resolution manometry and infusion catheter were positioned in the proximal stomach of healthy volunteers. After a stabilisation period and when the subjects were in late phase II of the migrating motor complex (MMC), one of four solutions (Table 1) were intragastrically infused at 60 mL/min, three days to one week apart in a single-blind randomised cross-over order. The infusion ended when subjects scored maximum satiation (0-5 scale). IGP was recorded for the duration of the drink infusion and for the following 3 hours. IGP was presented as change from baseline (mean ± SEM). Intensity of epigastric and GI symptoms were rated before the infusion, and then every 15 minutes using a 100 mm VAS. Results were compared using a repeated measures ANOVA.

Results: 15 healthy volunteers (19-32 y, 7 men, 18-30 BMI) were randomised. All were non-smokers with no GI symptoms or history of GI disease. Total ingested volumes at maximal satiation did not differ significantly between solutions (fructan 1376 ± 248 mL; fructose 1080 ± 147 mL, FODMAP mix 1252 ± 154 mL, glucose 1092 ± 126; p = NS). In all subjects and with each infusion, the IGP decreased initially to gradually recover thereafter. The mean IGP drop during infusion was significantly less for fructans (4.71 ± 0.59 mmHg), when compared to all other solutions ($p < 0.001$; fructose -5.86 ± 0.75 mmHg, FODMAP mix -5.38 ± 0.64 mmHg and glucose -5.69 ± 0.70 mmHg). After recovery of the IGP drop, although all solutions remained constantly high in their pressure across the three hours post infusion, the fructans maintained a significantly higher intra-gastric pressure (3.8 ± 0.16 mmHg) compared to the fructose, FODMAP mix and glucose (2.6 ± 0.16, 2.1 ± 0.15 and 1.9 ± 0.1 mmHg, respectively) ($p < 0.0001$). In comparison to the glucose, differences in symptoms were reported for bloating following the fructose, for wind following the fructans, fructose and FODMAP mix and for cramps following the fructose and FODMAP mix solutions ($p < 0.05$).

Table 1: Composition of challenge solutions (in 500 ml water)

		FODMAP total
1. Fructans		19 g
2. Fructose		50 g
3. FODMAP mix	10 g fructans + 5 g galacto-oligosaccharides + 15 g fructose + 5 g sorbitol + 5 g mannitol	40 g
4. Glucose (control)		50 g

Conclusion: This study indicates that fructans induce a significantly lower IGP response in the healthy state, when compared to the other FODMAPs and glucose. Unraveling the sensory, neural and/or hormonal pathways involved in the effect of fructans on gastric physiology require further mechanistic studies. The findings also offer opportunities to identify whether ingestion of fructans contribute to symptoms associated with impaired GA seen in functional GI patients, including IBS.

P1231 EXOGENOUS SALSOLINOL TARGETS REGULATORY MECHANISMS CONCERNED WITH ENERGY BALANCE

M. Kurnik[1], K. Gil[1], A. Bugajski[1], P. Thor[1]
[1]*Pathophysiology, Jagiellonian University Medical College, Krakow, Poland*

Contact E-mail Address: magdalena.kurnik@uj.edu.pl

Introduction: The digestive system produces a number of hormones to aid energy metabolism, digestion and nutrient uptake into the circulation. Some of them influence gut function, neuronal metabolism, appetite and peripheral energy metabolism, and some of them may be linked with the process of neurodegeneration. Salsolinol (1-methyl-6,7-dihydroxy-1,2,3,4-tetrahydroisoquinoline), which structurally resembles MPTP (1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine), may be involved in this process, especially if several scientists have been pointing its regulatory role in the central and peripheral neurohormonal circuits.

Aims & Methods: The aim of this study was to evaluate the influence of subchronic intraperitoneal salsolinol administration on body weight, food intake, adipose tissue accumulation, gastric emptying and postprandial serum levels of GIP (glucose-dependent insulinotropic polypeptide) and GLP-1 (glucagon-like peptide-1).

Male Wistar rats were subjected to continuous intraperitoneal low dosing of salsolinol (200 mg/kg in total) with osmotic mini-pumps for two and four weeks with either normal (S1, S2) or high-fat diet (SF1, SF2). Appropriate groups served as the controls (C1, C2, CF1, CF2). Blood samples were collected and gastric emptying was assessed by determination of residual solid food in the stomach at the end of the experiment. Both epididymal fat pads were dissected from each rat and weighted. Serum samples were assayed for GIP and GLP-1 by ELISA method.

Results: Salsolinol significantly reduced animals total body weight, however there were no differences in the cumulative food intake between the groups. The epididymal fat pad/body weight ratio was significantly different between control rats on high-fat diet (CF1 = 15.97 mg/g ± 0.6, CF2 = 21.65 mg/g ± 2.6) and salsolinol-treated rats on high-fat diet (SF1 = 13.09 mg/g ± 0.8, SF2 = 14.54 mg/g ± 2.6). The percentage of mean residual solid food in the stomachs of the S1 group rats (80.24% ± 6.06; $p < 0.05$) was significantly higher than in the C1 group (68.40% ± 6.13). GIP levels were elevated in salsolinol-treated rats in comparison with their controls, especially in groups S2 = 0.42 ng/ml ± 0.12 (C2 = 0.04 ng/ml ± 0.04) and SF2 = 0.36 ng/ml ± 0.19 (CF2 = 0.18ng/ml ± 0.14). GLP-1 levels were lower in salsolinol-treated rats in comparison with their controls, especially in the group SF2 = 0.007 ng/ml ± 0.004 (CF2 = 0.039 ng/ml ± 0.014).

Conclusion: Salsolinol might influence regulatory mechanisms concerned with body weight and fat content through neurohormonal pathways. Our results might suggest that salsolinol targets at least some incretin regulatory circuits.

P1232 XYLOGLUCAN FOR THE TREATMENT OF ACUTE DIARRHEA: RESULTS OF A RANDOMIZED, CONTROLLED, OPEN-LABEL, PARALLEL GROUP, MULTICENTRE, NATIONAL CLINICAL TRIAL

L. Gnessi[1], **X. Llop**[2], N. Piqué[3]
[1]*University of Rome, Rome, Italy,* [2]*Novintethical Pharma, SA, Pambio-Noranco, Switzerland,* [3]*Universitat de Barcelona, Barcelona, Spain*

Contact E-mail Address: xllop@novintethical.com

Introduction: There is a strong rationale for the use of agents with film-forming protective properties, like xyloglucan, for the treatment of acute diarrhea. However, few data from clinical trials are available.

Aims & Methods: To assess the efficacy, safety and time of onset of the antidiarrheal effect of xyloglucan (Xilaplus®), in comparison with two widely used antidiarrheal agents, the yeast probiotic *Saccharomyces boulardii* (Ultra-Levura®), and diosmectite (Smecta®), an absorbent activated natural aluminosilicate clay. This randomized, controlled, open-label, parallel group, multicentre, clinical trial included adult patients with acute diarrhea due to different causes.

Patients were randomized to receive a 3-day treatment (4 capsules/6 h of Xilaplus®, 3 sachets/day of Smecta® and 2 capsules/day of Ultra-Levura®), being the first dose administered at visit 1. Presence of symptoms (stools type 6 and 7 on Bristol Scale, nausea, vomiting, abdominal pain and flatulence) was assessed by a self-administered *ad-hoc* questionnaire at 1, 3, 6, 12, 24, 48 and 72 h after the first dose administration. Adverse events were recorded.

Results: 150 patients (69.3% women, mean age 47.3 ± 14.7 years) were included ($n = 50$ in each group). A faster onset of action was observed in the xyloglucan group compared with diosmectite group, in terms of absolute and mean number of stools ($p < 0.05$) during the first 24 h. In the xyloglucan group the highest reduction of the number of type 6 and 7 stools was observed at 6 h with an effect that was statistically significant compared with diosmectite ($p = 0.031$). A higher efficacy was also observed with xyloglucan compared to *S. bouliardii* at 12 and 24 h.

Xyloglucan was the most efficient treatment in reducing nausea throughout the study, particularly during the first hours (from 26% at baseline to 4% after 6 and 12 h).

An important improvement of vomiting was observed in all three treatment groups, with null percentages at 6 and 12 h.

Xyloglucan was more effective than diosmectite and *S. bouliardii* in reducing abdominal pain, with a constant improvement observed throughout the study. At visit 2, the lowest percentage of patients with abdominal pain was recorded in the xyloglucan group (10%), in comparison with diosmectite (22%) and *S. bouliardii* (12%).

The clinical evolution of flatulence followed similar patterns in the 3 groups, with continuous improvement of the symptom. The greatest improvement was shown in the xyloglucan group, with 10% of patients with flatulence at visit 2, compared with diosmectite (30%) and *S. bouliardii* (18%).

All 3 treatments were well tolerated, without adverse events.

Conclusion: Xyloglucan is a fast, efficacious and safe option for the treatment of acute diarrhea, with a rapid onset of action in reducing diarrheal symptoms.

P1233 LOW RATES OF FEEDING GASTROSTOMY ASSOCIATED MORBIDITY AND MORTALITY IN THE COMMUNITY

E. Clarke[1], V. Chudleigh[1], N. Pitts[1], A. Latchford[2], S. Cochrane[1], S. Lewis[1]
[1]*Gastroenterology, Derriford Hospital, Plymouth,* [2]*Gastroenterology, St Mark's Hospital, London, United Kingdom*

Contact E-mail Address: emilyclarke2@nhs.net

Introduction: Morbidity after 30 days and morbidity after 1 year from gastrostomy placement is poorly characterised as patients are discharged into the community. We prospectively recorded morbidity and mortality associated with gastrostomy placement over a five-year period.

Aims & Methods: Community dietitians regularly reviewed all patients with a gastrostomy after hospital discharge, prospectively recording morbidity and mortality between 2008-2012. In addition hospital databases and case notes were examined. Recorded morbidity included insertion site infection, leakage, over granulation, haemorrhage and buried bumper.

Results: There were no deaths and few complications directly related to gastrostomy insertion in 350 patients. We collected a total of 571 years of gastrostomy data. Mortality within 10 days was predominantly from a respiratory cause. 30 day, 3 and 21 month cumulative mortality (and morbidity) were 8% (2%), 16% (10%) and 35% (15%) respectively. 38% of patients required treatment for an insertion site infection with 70% of these having further infections. Overall there was a site infection every 2.1 years a gastrostomy was in situ. Complications such as buried bumpers, persistent fistulas and overgranulation were rare. Few gastrostomies required replacement (11%).

Mortality after gastrostomy placement during study period, median (IQ range) or N (%)

	Time to death after PEG placement				
	< 30 days	1-3 months	3-6 months	6-12 months	> 12 months
Mortality (% of total population)	28 (8%)	29 (8%)	29 (8%)	37 (11%)	66 (19%)
Accumulative mortality	28 (8%)	57 (16%)	86 (25%)	123 (35%)	189 (54%)

Conclusion: This is the first prospective study of morbidity and mortality in a large number of patients undergoing gastrostomy placement over an extended period of time. We have demonstrated reassuringly low rates of gastrostomy-associated morbidity and mortality. There was no direct mortality. The greatest morbidity resulted from gastrostomy-site infection.

P1234 INCREASING SERUM ALBUMIN LEVEL SHORTLY AFTER GASTROSTOMY INSERTION PREDICTS LONGER SURVIVAL IN ELDERLY DEMENTED PATIENTS

R. Gingold-Belfer[1,2], A. Weiss[3], A. Geller[2], B. Sapojnikov[1], N. Morag-Koren[4], Y. Niv[2], Y. Ringel[2], H. S. Weiss[1]

Contact E-mail Address: rachelgingoldbelfer@gmail.com

Introduction: A growing proportion of elderly demented patients are now surviving. Thus, at the advanced stages of their illness, swallowing problems are being developed. There is insufficient evidence whether percutaneous endoscopic gastrostomy (PEG) is beneficial in this population (1).

Aims & Methods

Aim: We aimed to evaluate the outcomes of PEG in elderly patients with an advanced dementia.

Methods: Included 194 demented patients who underwent PEG insertion in our unit during 2002-2011. Data regarding their background diseases, age, gender, survival by December 2014, and the level of albumin, hemoglobin, lymphocytes and cholesterol performed 14 days prior the procedure and 90 days after it, were retrieved. Univariate analysis using Cox proportional hazard model was performed to find predicting factors for mortality. Multivariate analysis using Cox regression model for time to death was performed with significant risk factors from the univariate analysis.

Results: Out of 194 demented patients 70% were women. Mean age was 83.28 ± 7.6, range 64-106 years. The median survival rate was 13 months (range 0-105).

32 patients died within 30 days of PEG insertion. Those who died within 1 month of the procedure were older (87 ± 8.6 vs. 83 ± 7.2 years, $p = 0.003$) and had a lower hemoglobin level (10.8 ± 1.5 vs. 11.6 ± 1.5, $p = 0.013$). In addition they had a lower mean baseline albumin as compared to those who survived more than 30 days (2.5 ± 0.6 vs. 3.3 ± 0.5, $p < 0.001$). In 95 patients, a significant increase in serum albumin level was noted within 90 days of PEG insertion. Those patients survived significantly longer than those who failed to improve their baseline albumin levels (24.5 ± 2.5 vs.18.2 ± 2.2, $p = 0.063$). Failure to improve albumin level was a risk factor for mortality (HR: 1.416, 95% CI: 1.029-1.948, $p < 0.001$). Each increment of 1gr/dL of serum albumin, decreased mortality risk by HR = 0.54 (95%CI: 0.41-0.71, $p < 0.001$). An older age and lower hemoglobin level were risk factors for mortality too (HR: 1.17, 95% CI: 1.05-1.31, $p = 0.004$; HR: 0.84, 95% CI: 0.77-0.93, $p < 0.001$). Gender and the absolute count of lymphocytes didn't affect mortality. When we performed multivariable analysis by cox regression, age and albumin level remained the only risk factors for mortality.

Conclusion: Elderly demented patients benefit PEG if their baseline serum albumin is within the normal range or if their albumin level is improved within 3 months after PEG insertion. We believe that when eating problems are developed in demented patients, there is a "window of opportunity" in which PEG should be inserted. Therefore, physicians should follow especially the albumin level of the demented patients and offer them PEG when a decreased level would have noticed. Thus, an improvement of the albumin level will eventually prolong their survival.

P1235 PERCUTANEOUS ENDOSCOPIC GASTROSTOMY IN PATIENTS WITH AMYOTROPHIC LATERAL SCLEROSIS: A CASE SERIES

R. Coelho[1], M. Silva[1], A. Peixoto[1], R. Gaspar[1], M. Gonçalves[2], R. Ramalho[1], G. Macedo[1]
[1]*Gastrenterology,* [2]*Pneumology, Centro Hospitalar São João, Oporto, Portugal*

Contact E-mail Address: rosacoelhoabrantes@hotmail.com
Introduction: Patients with amyotrophic lateral sclerosis (ALS) and severe bulbar muscle impairment may be at risk of respiratory failure during percutaneous endoscopic gastrostomy (PEG). Non-invasive ventilation (NIV) might reduce the risk of respiratory complications in patients with severe ventilatory impairment (SVI).
Aims & Methods: Our aim was to evaluate the outcomes of PEG placement with NIV in patients with ALS with SVI. It was a retrospective study including ALS patients with dysphagia due to severe bulbar muscle impairment proposed for PEG placement, in the last 5 years. Pre-PEG pulmonary data was analyzed. All the PEG were placed using the pull method and the procedure was performed with the patient under nasal NIV with portable home ventilator in spontaneous timed bi-level mode.
Results: Included 38 patients (63% female) with a mean age of 61 ± 25 years and a mean duration of the disease of 4 ± 3 years. Most patients (92%) performed NIV at home prior to PEG placement, for a median period of 5 months (IQR: 0-15), with an average IPAP: 20 ± 3 mmH2O, EPAP: 6 ± 1 mmH2O and volume current: 887 ± 504 mL. Fifty-three percent of patients had SVI for 24 hours/day. The median time between the onset of bulbar symptoms and the placement of PEG was 7 months (IQR: 2-16). In most of the patients (90%) the procedure was performed without general anesthesia, and in 53% midazolam was given. In 68% of the patients PEG was performed due to dysphagia and in the rest of the patients due to severe ventilator impairment during feeding. There were no complications from PEG placement and the mortality rate at 3, 6 and 12 months was 27%, 42%, 54% respectively.
Conclusion: The placement of PEG with NIV seems to be safe in patients with ALS with SVI. In this cohort no patients complicated or required tracheal intubation. Our results encourage PEG placement even in high-risk patients.

Introduction: The percutaneous endoscopic gastrostomy (PEG) is currently considered the best option for enteral feeding in patients requiring enteral nutrition for long periods.
Aims & Methods: This study aimed to evaluate the current indications, technical success, complications and need to repeat procedures.
Methods: Retrospective study of patients referred for our endoscopy unit for PEG placement for a period of 3 years (2012-2014). We reviewed clinical reports in order to evaluate the long term outcome of patients after placement of PEG by the pull method.
Results: Summaries of the results: included 223 patients (60% males) with a mean age of 63 ± 17 years, followed for a median of 18 months (IQR: 8-28). The indications for PEG placement were: cancer (26% of which 80% were head and neck cancers), cerebral vascular accident (23%) and neurological causes (22%). During the analyzed period of time, from the first to the third year, there was an increased rate of PEG placement of 41%. Minor complications occurred in 29 patients (13%) including: inadvertent PEG removal (7%), leakage of the food content (4%) and infection stoma (2%). Five patients had major complications including buried bumper syndrome ($n = 4$) and hemorrhage ($n = 1$). Only 2% of the patients removed the PEG due to complications. There were no deaths related to the procedure and the mortality rate at 30 days 4%. Twenty-two percent of patients replaced the PEG in a median of 10 months (IQR: 5-16). Oral feeding was resumed in 6% of patients at a median of 6 months (IQR: 2-15) after PEG placement.
Conclusion: There was a significant increase in the number of PEGs placed in the last 3 years. This is a safe procedure associated with a low complication rate.

P1237 HIGH SERUM MANGANESE LEVELS IN PATIENTS RECEIVING LONG TERM TOTAL PARENTERAL NUTRITION

S. Nair[1], C. Jeffray[1], C. Mountford[1], N. P. Thompson[1]
[1]*Freeman Hospital, Newcastle Upon Tyne, United Kingdom*

Contact E-mail Address: shelleynair@doctors.net.uk
Introduction: In patients receiving long-term parenteral nutrition (TPN), high manganese levels have been associated with cholestatic liver disease and nervous system disorders including parkinsonism. Case reports have shown patients on long-term TPN with high manganese levels developing parkinsonism with psychiatric effects. T1-weighted magnetic resonance imaging in these patients demonstrates high-intensity signals in the globus pallidus which regresses on discontinuation of the manganese supplementation. NICE guideline (CG32) recommends checking manganese levels in patients on long-term TPN every 3-6 months.
Aims & Methods: The aim of the study was to assess serum manganese levels in patients on long term TPN and to establish if removing manganese supplements results in normalisation of serum manganese levels.
Serum manganese levels were measured in all patients receiving long-term TPN in the North East of England and Cumbria during the study period from Nov 2013 to Jan 2015. Of those with a high serum manganese, manganese supplementation was withdrawn and the levels were rechecked within 12 months of withdrawal.
Results: In the North East of England and Cumbria, 77 patients were receiving long-term TPN during the study period. Of these, 48 were female and 29 were male. The age range of patients was from 19 to 84 years. The indication for TPN in these patients included; 23 ischaemia, 21 inflammatory bowel disease, 10 intra-abdominal malignancy, 9 post-surgical complication, 5 enteric dysmotility, 4 radiation enteritis, 3 visceral myopathy, 1 connective tissue disorder and 1 congenital abdominal defect. Of the 77 patients, 46 had high serum manganese levels at initial measurement (mean 288nmol/l; range 90-1620). Serum manganese levels were rechecked in these patients within 12 months of manganese withdrawal. When rechecked; 26 patients had normal serum manganese levels and 11 patients had manganese levels reduced but not above the normal limits. 9 patients did not undergo a repeat manganese level due to either acute illness, discontinuation of TPN or death. No patients reported any neurological symptoms or were noted to have cholestatic liver function tests to suggest toxicity.
Conclusion: The study demonstrated that high levels of manganese are found in 60% of all patients receiving long-term TPN. Withdrawing manganese supplementation in these patients results in a normalisation of manganese in levels in 57% and a reduction in manganese level in 20% within 12 months. Although no patients in the study showed signs of manganese toxicity, studies have shown a potential risk of toxicity resulting in neurological disorders. This study highlights the importance of checking manganese levels in keeping with NICE guidance every 3-6 months and adjusting manganese supplementation for those with high levels to avoid potential toxicity. Manganese is supplemented in combination with other trace elements some of which may not be replaced individually including molybdenum, iodine and chromium. Further studies are required to determine the clinical significance of withdrawing these trace elements.

Introduction: Despite creating an enteric route for administration of food and drugs, the real benefit of a gastrostomy is still matter of debate. We aimed to evaluate the global impact of percutaneous endoscopic gastrostomy (PEG) in patients followed at a specialized multidisciplinary consultation.
Aims & Methods: From the 201 patients submitted to PEG between May/2011 and September/2014, 60 were included in a prospective unicentric study. Age, gender, indication for PEG, Charlson index and mortality were analysed. Number of emergency department (ED) visits or hospitalizations, presence of pressure ulcers, and changes in laboratorial values were collected and compared before and after PEG.
Results: From the 60 analysed patients, 33 (55%) were women and the median age was 79 years (range from 19 to 92). The main indications for PEG were dementia (43.3%), post-stroke dysphagia (30%) and post-traumatic brain injury (8.3%). Mean Charlson Index was 6 and mortality rate during follow-up was 27%. A decrease in the mean number of hospitalizations (1.4 vs. 0.3; $p < 0.001$) and visits to ED (2.2 vs. 1.1; $p = 0.003$) were noted in the next 6 months after PEG, when compared to the previous semester. In 53.8% of patients with pressure ulcers, complete ulcer healing was observed after PEG; however, the number of patients with pressure ulcers before and after PEG did not differ significantly ($p = 0.203$). PEG was associated with significant increases in haemoglobin ($p = 0.024$), lymphocytes ($p = 0.041$), total cholesterol ($p = 0.008$), transferrin ($p < 0.001$), albumin ($p < 0.001$) and total proteins ($p < 0.001$), and significant decrease in serum sodium ($p = 0.001$), which were recognized 4 months after PEG. No significant changes were found on urea ($p = 0.682$), creatinine ($p = 0.146$) or triglycerides ($p = 0.398$).
Conclusion: Percutaneous endoscopic gastrostomy has an early impact in patients. It reduces the need of hospital health care services, facilitates healing of pressure ulcers, and induces metabolic changes that reflect a better nutrition and hydration.

P1239 APPROPRIATE RISK STRATIFICATION FOR PERCUTANEOUS ENDOSCOPIC GASTROSTOMY INSERTION MAKES PLACEMENT SAFE AND FEASIBLE IN LATE-STAGE MOTOR NEURONE DISEASE

V. Blackwell[1], R. Marsden[2], A. Thompson[3], C. Lawson[4], J. Brooks[4], A. Nickol[5], J. East[1], K. Talbot[3], M. R. Turner[3], P. Allan[1]

Introduction: Weight loss and malnutrition may aggravate muscle weakness, and independently predict survival in Motor Neurone Disease (MND) (1). Gastrostomy placement improves body mass index and offers a small survival benefit (2), but 30-day mortality following PEG insertion has previously been quoted as 10% (3,4) with most risk observed in patients with a forced vital capacity < 50% predicted. Since 2011 we routinely undertook PEG placement in patients with MND. In September 2012 we introduced a risk stratification system prior to PEG placement to guide suitable precautions for those deemed at high risk. These were: a reduction in sedative dose, 30° head-up bed tilt, gently held paediatric mouthguard, and with only experienced operators placing PEGs in the highest-risk patients.
Aims & Methods: Our objective was to evaluate the risk of PEG placement in patients with MND and to evaluate whether risk stratification might reduce complications. We undertook a retrospective systematic search and analysis of a prospectively maintained database of all patients with MND who underwent placement of a PEG between 1/2/11 and 31/3/15. 30-day complication and mortality rate, and dose of sedation given were analysed for the whole cohort and for the pre- and post-risk stratification groups
Results: Data was collected for 90 patients. Overall 30- day mortality was 4/90 (4.4%). None of the deaths were directly related to PEG insertion. 2 patients had complications within 30 days of the procedure (2.2%). The mean (± standard error) midazolam dose was 3.3mg (±0.3) and fentanyl dose was 54.7mcg (±5.8). 39 patients (43%) had PEGs placed prior to the introduction of a risk stratification system and 51 (57%) afterwards. There was a reduction in mortality from 2/39 (5.1%) to 2/51 (3.9%) and a reduction in complications from 1/39 (2.6%) to 1/51 (2%) following introduction of the risk stratification system. Mean sedation rates reduced for midazolam from 4.3mg (±0.6) to 2.6mg (±0.2) ($p < 0.01$) and for fentanyl from 62.2mcg (±5.3) to 49.0mcg (±3.5) ($p < 0.05$).
Conclusion: We have shown a significantly lower 30 day mortality of 4.4% compared to previously quoted mortality of 10% for both PEG and RIG insertion. This suggests that PEG is a suitable and safe choice of feeding tube for patients with MND. We have also demonstrated that with risk stratification, lower doses of sedation and standard precautions taken for all patients with MND the overall mortality rate and complication rate can be reduced to an acceptable level and allows PEGs to be placed in those previously considered unsuitable. Further work needs to be undertaken looking at longer follow-up data and determining the optimal timing of gastrostomy. We would recommend PEG insertion with multi-disciplinary team participation as a safe and effective method of nutritional support in MND.

P1240 PROTON-PUMP INHIBITORS AND SPONTANEOUS BACTERIAL PERITONITIS IN LIVER CIRRHOSIS: ANY ASSOCIATION?

M. Gravito-Soares[1], E. Gravito-Soares[1], S. Lopes[1], C. Sofia[1]
[1]*Gastroenterology, Centro Hospitalar e Universitário Coimbra, Coimbra, Portugal*

Contact E-mail Address: ms18498@gmail.com

Introduction: Proton-pump inhibitors (PPI) are one of the most commonly prescribed pharmacologic classes, leading to their overuse in clinical practice. They were associated to a high susceptibility for enteric infections. The association between PPI and Spontaneous bacterial Peritonitis (SBP) remains unclear.
Aims & Methods: Retrospective case-control study of 143 consecutive episodes of SBP between 2009-2014, compared with cirrhotic patients without SBP (ratio 1:1). They were divided in 4 groups, according with PPI chronic therapeutic and indications: PPI and approved indication (G1), PPI and non-approved indication (G2), without PPI and approved indication (G3) and without PPI and non-approved indication (G4). The appropriate use is considered for G1 + G4. Patients with primary/second prophylaxis for SBP, previous antibiotic therapy (< 3 months), immunosuppression or recent gastrointestinal bleeding (< 1 month) were excluded.
Results: PPI were prescribed in 45.1% of cirrhotic patients, with non-appropriate indication in 45.1%. In SBP patients, PPI use was superior (53.1% vs 37.2%;$p = 0.016$), with non-appropriate indication in 54.0% (vs 36.3%; $p = 0.008$). In patients with SBP and PPI, the main approved indications were recent endoscopic oesophageal variceal ligation/sclerotherapy (42.8%), Peptic Ulcer Disease (PUD) and Erosive Esophagitis (EE) (28.6%). There is no identification of prescription PPI reason in 50.9% of patients. Some cirrhotic patients without PPI had indication for their prescription (SBP: 7.1% and without SBP: 8.0%), being the most common indication in SBP patients the EE (37.5%), followed by PUD and NSAID use with risk factors (25.0%). After multivariate analysis, PPI use (OR3.395; $p = 0.002$) was the only factor associated with SBP development.
Conclusion: Despite of common PPI use in cirrhotic patients, PPI are inappropriately prescribed in almost half of cases. PPI use is associated with three-fold increased risk for developing SBP. It is necessary new recommendations for a rational prescription of that pharmacologic class in liver cirrhosis.

P1241 CAN LIVER STIFFNESS MEASUREMENT BY FIBROSCAN® PREDICT THE PRESENCE AND SIZE OF ESOPHAGEAL VARICES IN HEPATITIS C RELATED CIRRHOTIC PATIENTS?

M. Bakkar[1], L. Amrani[1], H. El Bacha[1], N. Amrani[1], N. Kabbaj[1]
[1]*EFD Hepato Gastroenterology Unit , Ibn Sina Hospital, Rabat, Morocco*

Contact E-mail Address: meriem55@hotmail.com

Introduction: Liver cirrhosis is the final stage of all chronic hepatopathies. Esophageal varices (EV) and variceal bleeding are feared complications. EV diagnosis is established by periodical upper digestive endoscopy. Gastroscopy in all cirrhotic patients is very expensive, and repeated endoscopies are poorly accepted by patients. The Aim is to predict EV's presence and grading by fibroscan® s in Hepatitis C virus (HCV) related cirrhotic patients.
Aims & Methods: Forty six HCV related cirrhotic patients were recruited in our unit. Inclusion criteria were: age > 18 years, Body Mass Index (BMI) < 35, HCV infection and no history of upper gastro intestinal bleeding. Patients underwent clinical examination, laboratory investigations, abdominal ultrasonography, upper endoscopy and liver measurement with fibroscan®.
Results: There were 25 women (54.3%), mean age was 63.71 years old. Body mass index was 26, 58 kg/m^2, Clinical examination was normal in 80% of patients. Mean HVC viral load was 5.66 log UI/ml, and the most frequent genotype was genotype 2 in 48% of cases. Thirteen patients (28%) had EV. Mean liver stiffness was 23.65 KPa, with a mean Interquartile Range of 4, 26% and a success rate of 93.3%. Mean liver stiffness for patients for patients with small EV (grade I) was 16.54 KPa and for patients with large EV and therefore a risk of variceal bleeding was 22, 86 KPa. The area under the curve ROC was 0.82 with high sensibility and specificity.
Conclusion: Liver stiffness measurement by fibroscan® in our current study is valuable in predicting the presence of large esophageal varices in patients with liver HCV cirrhosis. It may help to select patients for endoscopic screening. A study including a greater number of patients is necessary to confirm those results.

Introduction: Treatment of patients with refractory ascites should focus on symptom relief and quality of life (QoL). No patient reported outcome that assesses symptom relief after treatment for ascites resulting from cirrhosis is validated in US patients.
Aims & Methods: We identified ascites-specific symptoms based on literature, patient interviews (n = 8) and a clinician survey (n = 8) to develop an ascites-specific questionnaire (Ascites-Q). Twelve symptoms were selected; fullness, lack of appetite, early satiety, nausea, abdominal pain, back pain, shortness of breath, limited mobility, tiredness, sleep problems, dissatisfaction with size of abdomen and problems with sexual intimacy. Subsequently, we administered the Ascites-Q, Japanese Ascites Symptom Inventory-7 (ASI-7), FACIT-ascites index for malignant ascites and an overall QoL VAS-scale in cirrhotic patients with refractory ascites scheduled for therapeutic paracentesis; before paracentesis (baseline) and 7 days after paracentesis (target sample size n = 90). Scores are transformed to a 0-100 scale with a higher score indicating more symptoms. We compared baseline scores of patients with refractory ascites with cirrhotic patients without refractory ascites (Mann Whitney U test) recruited at the Mayo liver transplant clinic from January - May 2015. Spearman correlation coefficients of the overall QoL VAS-scale and ascites questionnaires were calculated to assess validity of the questionnaires. Responsiveness of questionnaires to detect changes in ascites-specific symptoms was assessed by comparing questionnaire scores at baseline and 7 days after paracentesis with a paired T-test.
Results: We included 32 patients with refractory ascites (59% male, 61 ± 10 year, MELD-score 15 ± 6 and median tapped volume 3600 mL (IQR 2725 – 6525)) and 61 patients without refractory ascites (controls) (76% male, 57 ± 9 year, MELD-score 11 ± 4). Patients with refractory ascites scored higher than controls on all symptoms of the Ascites-Q and ASI-7, except for back pain ($p = 0.096$) and tiredness ($p = 0.228$). There was no difference between patients and controls in 6/13 FACIT-ascites index symptoms (sleep problems, mobility, nausea, vomiting, frequent urination and emotional distress, $p > 0.05$). Overall QoL correlated with the Ascites-Q and ASI-7 ($r = .497$, $p = 0.008$ and 0.471, $p = 0.013$), but not with the FACIT-ascites index ($r = 0.332$, $p = 0.090$). Symptom scores of the Ascites-Q, (-11.53 ± 18.874, $p = 0.013$), ASI-7 (-35.46, ± 29.22, $p < 0.001$) and FACIT-ascites index (-9.46 ± 10.60, $p = 0.001$) changed significantly 7 days after paracentesis.
Conclusion: The Ascites-Q and the ASI-7 are most sensitive for ascites-specific symptoms in patients with cirrhosis. We will investigate which symptoms are most responsive to treatment to further refine the Ascites-Q.

Contact E-mail Address: nic.weiss@wanadoo.fr

Introduction: The protein S-100 beta (PS-100) is a small dimeric cytosolic protein synthetized in astrocytes and Schwann cells. High serum levels of PS-100 are associated with brain lesions and altered blood-brain barrier permeability in traumatic brain injury, ischemic stroke, cerebral tumors and subarachnoid hemorrhage. Early brain damage has been detected in patients with cirrhosis. We hypothesized that those insults could be detected by the PS-100 serum levels (normal values < 0.10 µg/L).

Aims & Methods: Hence, the aim of the present study was to assess PS-100 levels in cirrhotic patients, and compare them to PS-100 levels in non-cirrhotic patients followed up in the same department for initial workup of elevated liver enzymes (controls).

We prospectively included a population of cirrhotic patients admitted for complication of cirrhosis in ICU and controls. Baseline data were recorded and levels of ammonemia and PS-100 determined at admission. Overt HE was diagnosed as a West-Haven score ranging between 2 and 4.

Results: Between October 2013 and October 2014, 124 cirrhotic patients (mean age: 63 years, male gender: 73%, etiology of cirrhosis: alcoholic 51%, viral 25%, other 24%, Child-Pugh 11 [8-12], MELD score 21 [14-26]) and 79 non-cirrhotic patients (mean age: 63 years, male 59%, etiology of elevated liver enzymes: alcoholic 5%, viral 44%, NASH 38%, other 13%, mean Fibroscan: 5.3 kPa, mean FibroTest: 0.15) were included. Among cirrhotic patients, 40 patients (33%) displayed HE at admission and 50 (41%) had an infection. Mean PS-100 level were 0.15 ± 0.01 for cirrhotic patients and 0.07 ± 0.01 for non-cirrhotic patients ($p < 0.0001$). In cirrhotic patients, PS-100 was correlated to AST ($p = 0.0027$), bilirubin ($p = 0.0001$), Child-Pugh score ($p = 0.001$) and MELD ($p = 0.0004$) and inversely correlated to albumin ($p = 0.04$), sodium ($p = 0.01$), PTT ($p = 0.001$), and FV ($p = 0.011$). PS-100 levels were not correlated to the presence of overt HE nor to infection. In multivariate analysis, levels of PS-100 were independently associated with MELD score ($p = 0.0006$), whereas overt HE was associated to hyperammonemia ($p = 0.002$) and the presence of infection ($p = 0.008$) but not to PS-100 levels.

Conclusion: Patients with cirrhosis in ICU display neurological insult or blood-brain barrier dysfunction even in the absence of overt HE. Brain damage is more frequent in patients with advanced liver disease.

P1244 THE PREVALENCE AND CLINICAL IMPACT OF MULTIDRUG-RESISTANT SPONTANEOUS BACTERIAL PERITONITIS IN CIRRHOTIC PATIENTS

P. Magalhães-Costa[1], S. Santos[1], C. Chagas[1]
[1]*Gastrenterology, Hospital Egas Moniz - Centro Hospitalar Lisboa Ocidental, Lisboa, Portugal*

Contact E-mail Address: pmagalhaescosta@gmail.com

Introduction: International guidelines recommend third-generation cephalosporins as the empirical therapy of choice in spontaneous bacterial peritonitis (SBP), however, recent studies have challanged this recommendation due to high rates of third-generation cephalosporin-resistant infections and a consequent higher mortality among this patients due to inappropriate empirical antibiotic choice. We present a single-center cohort study analyzing the prevalence, risk factors and the short-term clinical impact of multidrug-resistant (MDR) SBP.

Aims & Methods: Retrospective analysis (Jan 2008 and Dec 2013) of 54 SBP episodies in cirrhotic inpatients. Studied variables: demographics, laboratorial, microbiological and known risk factors for MDR acquisition.

Results: Among a total of fifty-four SBP episodes, 39% ($n = 21$) were aquired in the nosocomial setting. In 43% ($n = 23$) of the SBP, at least one bacteria was isolated and, among those culture-positive SBP, 39% ($n = 9$) were MDR bacteria. Almost 2/3 (67%; $n = 6$) of MDR-SBP were aquired in the nosocomial setting, on the other hand, 2/3 of the non-MDR-SBP were aquired in the community or healthcare-associated. The bacteria most frequently isolated were: *Escherichia coli* non-MDR (30%), Streptococcus non-*viridans* (22%) and vancomycin-sensitive *Enterococcus* (22%). The rate of acute kidney injury (AKI) was higher among MDR-SBP patients (67% vs 49%). Among all study population thirty-day mortality was 35%, higher among MDR-SBP group (67% vs 29%). On a multivariate analysis we found no independent predictors for MDR-SBP acquisition. After multivariate analysis, MDR-SBP, AKI and diabetes mellitus were independent predictors of 30-day mortality.

Conclusion: In this study, we have found an high prevalence of MDR-SBP (39%). Also, the acquisition of this type of infection was independently associated with a very high 30-day mortality rate (67%). Althought independent predictors for MDR-SBP acquisition were not found in our study, it is important to implement preventive strategies in order to minimize the risk of MDR acquisition.

Contact E-mail Address: pconway@norgine.com

Introduction: The value for money of drugs varies by country mainly due to changes in treatment patterns and related costs. Hepatic encephalopathy (HE) is associated with high morbidity and mortality. Rifaximin-α 550 mg (XIFAXAN) is effective in reducing the recurrence of episodes of overt HE, and reduces hospital utilisation. Our aim was to characterise the cost effectiveness of rifaximin-α 550 mg versus standard care (lactulose) in patients with liver cirrhosis in Sweden.

Aims & Methods: This economic evaluation used a Markov state transition model. The outcome metric was the incremental cost effectiveness ratio (ICER), derived from estimates of the cost/quality adjusted life years (QALYs). The payer perspective was that of the Swedish healthcare system. Outcome data were from two trials of rifaximin-α 550 mg. Population outcome data were from a complementary study of patients with liver cirrhosis treated in Sweden. Swedish Costs data (2012) were derived from published sources. Health-related utility was estimated indirectly from disease-specific quality of life RCT data. The time horizon was five years. Costs and benefits were discounted at 3.5%. Extensive sensitivity analyses were carried out. Real-world data were also applied into the model for length of stay in hospital and the number of admissions.

Results: The average cost of the included elements of care was SEK302,520 (€32,667) in the rifaximin-α 550 mg arm and SEK393,777 (€42,522) in the lactulose arm, a difference of -SEK91,257 (-€9,854). The corresponding values for benefit was 2.38 QALYs and 1.83 QALYs per person, respectively, a difference of 0.55 QALYs over the five-year period. This translated into a dominant base-case ICER at five-years, meaning that rifaximin-α 550 mg was both less costly and more beneficial. Key parameters that impacted the ICER included length of stay in hospital and the number of admissions to hospital. Evaluation to 10 years also resulted in a dominant ICER, although the lifetime ICER was SEK5,918 (€639) per QALY.

Conclusion: In Sweden, treatment with rifaximin-α 550 mg in patients with recurrent HE in the context of liver cirrhosis was cost effective compared to standard care, by reducing episodes of overt HE.

Contact E-mail Address: pconway@norgine.com

Introduction: Hepatic encephalopathy (HE) is associated with high morbidity and mortality. Rifaximin-α 550 mg (XIFAXAN/TARGAXAN) is effective in reducing the recurrence of episodes of overt HE. Our aim was to determine the cost effectiveness of rifaximin-α 550 mg versus standard care (lactulose) in patients with cirrhosis in the UK.

Aims & Methods: This economic evaluation used a Markov state transition model. The outcome metric was the incremental cost effectiveness ratio (ICER), derived from estimates of the cost/quality adjusted life years (QALYs). The payer perspective was that of UK National Health Service. Outcome data were from two trials of rifaximin-α 550 mg. Population outcome data were from a complementary study of patients with liver cirrhosis treated within the NHS. UK Costs data (2012) were derived from published sources. Health-related utility was estimated indirectly from disease-specific quality of life RCT data. The time horizon was five years. Costs and benefits were discounted at 3.5%. Extensive sensitivity analyses were carried out. Real world data describing the use of rifaximin-α 550 mg in the UK NHS were also applied into the model for length of stay in hospital and the number of admissions.

Results: The average cost for the included elements of care was £22,971 in the rifaximin-α 550 mg arm and £23,545 in the lactulose arm, a difference of -£573. The corresponding values for benefit were 2.56 QALYs and 1.75 QALYs per person, respectively, a difference of 0.81 QALYs. This translated into a dominant base-case ICER. Key parameters that impacted the ICER included length of stay in hospital and the number of admissions to hospital. Evaluation to 10 years and lifetime resulted in ICERs of £3,024/QALY and £5,068/QALY, respectively.

Conclusion: Rifaximin-α 550 mg in patients with recurrent HE in the context of liver cirrhosis represented good value for money compared to standard care, by reducing episodes of overt HE, the likelihood of hospital admission and hospital length of stay.

Contact E-mail Address: doctorw@poczta.onet.pl

Introduction: Liver cirrhosis is associated with profound disturbances in coagulation system. Portal vein thrombosis (PVT) is being increasingly recognized in patients with advanced cirrhosis and in those undergoing liver transplantation with 10-25% reported prevalence. The presence of PVT is associated with the long-term mortality. Although the pathogenesis of PVT is poorly understood, a reduced flow in the portal vein, portal endotoxemia and hypercoagulability are most often incriminated for the development of PVT.

Aims & Methods: We aimed to investigate several biochemical markers characterizing the coagulation system, platelets aggregation and permeability of the intestinal barrier to determine the high-risk individuals for PVT attending our center.

In total, 49 consecutive patients with cirrhosis (15 in Child-Pugh class A and 34 in class B&C) aged 27-81years were included to the study. They were divided into two groups: those without PVT (n = 33) and those with partial or complete PVT (n = 16) diagnosed by spiral computed tomography. Routine laboratory and coagulation parameters, as concentration/activity of vonWillebrand factor (vWF), factor VIII, D-dimers, protein C, prothrombin and tissue factor (TF) were measured in the serum. Platelets aggregation was tested by Multiplate Analyzer using adenosine diphosphate (ADP, 6.4 μM), arachidonic acid (ASPI, 0.5 mM), ristocetin (Risto, 0.2 mg/ml and 0.77 mg/ml) and thrombin receptor-activating peptide (TRAP, 32 μM). Permeability of gut barrier was assessed by serum levels of lipopolysaccharides (LPS) and zonulin.

Results: In patients with PVT endoscopic banding of esophageal varices was more common (81.2% vs 42.4%; p = 0.02), and these patients had significantly larger size of splenic and superior mesenteric vein, lower count of leukocytes (3.9 ± 1.4 vs 5.5 ± 2.7 G/l; p = 0.01), lower bilirubin level (2.1 ± 1.0 vs 4.0 ± 3.4 mg/dl; p = 0.02), and higher levels of D-dimer (4.45 ± 2.59 vs 3.04 ± 2.97 pg/ml; p = 0.04) and prothrombin (175 ± 98.8 vs 115 ± 72.9 μg/ml; p = 0.01) in comparison with those without PVT. Protein C, vWF, factor VIII and TF showed no significant differences in both groups. There was no significant difference in the concentration of LPS and zonulin between PVT positive and negative patients. Generally, the platelets aggregation activity in patients with PVT was lower compared to those without thrombosis (statistically different in ADP and TRAP tests). D-dimer levels showed 90% negative prediction value for diagnosis of PVT (cut-off 1.82 pg/ml) and in stepwise logistic regression model the D-dimers, bilirubin and TRAP test were independent risk factors for PVT.

Conclusion: 1) Low count of leukocytes as well as high D-dimer level indicate PVT in cirrhotic patients. 2) D-dimer level below 1.82 pg/ml excludes with high probability PVT. 3) The platelets aggregation in patients with PVT is reduced that may be either adaptive response to a decrease in liver perfusion and increase of portal hypertension. 4) Endotoxemia does not seem to play a major role in the development of PVT.

P1248 CLIF-AD SCORE VALIDATION FOR PREDICTING MORTALITY IN PATIENTS WITH ACUTE DECOMPENSATED CIRRHOSIS WITHOUT ACUTE-ON-CHRONIC LIVER FAILURE

R. Barosa[1], G. Nunes[1], M. Patita[1], L. R. Ramos[1], C. Fonseca[1], J. Freitas[1]
[1]*Hospital Garcia de Orta, Almada, Portugal, Almada, Portugal*

Contact E-mail Address: a.rita.b@gmail.com

Introduction: Recently EASL-CLIF Consortium defined a new prognostic score (CLIF-AD) for patients with acute decompensated cirrhosis without acute-on-chronic liver failure (ACLF).[1]

Aims & Methods: We sought to validate the CLIF-AD score and compare it with the existing scoring systems Model for End-Stage Liver Disease (MELD), MELD-Sodium and Child-Turcotte-Pugh (CTP). Retrospective analysis of demographic, clinical and laboratorial data of patients admitted for acute decompensation of cirrhosis without ACLF criteria between January 2013 and September 2014. Twenty eight (M28), 90-day (M90), 180-day (M180) and 365-day (M365) mortality were evaluated. CLIF-AD performance in predicting mortality in each time-point was compared with MELD, MELD-Sodium and CTP performances.

Results: 90 patients were included (male sex:72.2%, mean age:59 ± 11 years). 82% had alcoholic cirrhosis (with or without viral infection) and 32.2% had active alcoholism. Mean CLIF-AD was 51.8 ± 8.4 and was significantly higher in patients who died at M28, M90 and M180 time-points versus survivors (63.3 ± 7.6 vs. 50.9 ± 7.7, p = 0.001; 56.2 ± 10.3 vs. 50.7 ± 7.4, p = 0.05; 57.2 ± 10.2 vs. 50.3 ± 7.1, p = 0.008, respectively). CLIF-AD ≥ 60 was associated with significantly higher M28, M90, M180 and M365 (60.0 vs. 8.1%, p = 0.006; 80.0 vs. 20.9%, p = 0.008; 80.0 vs. 22.1%, p = 0.01 and 80.0 vs. 32.6%, p = 0.041, respectively). The AUROC of CLIF-AD in predicting M28 (0.891 ± 0.43), M180 (0.723 ± 0.74) and M365 (0.636 ± 0.065) was significantly superior to CTP, MELD and MELD-Sodium.

Conclusion: The application of the new CLIF-AD identifies patients with high mortality (CLIF-AD ≥60). The CLIF-AD score accurately predicts short and long-term mortality and is superior to the existing scoring systems.

P1249 VALIDATION OF THE EASL-CLIF CONSORTIUM DEFINITION OF ACUTE-ON-CHRONIC LIVER FAILURE AND THE CLIF-SOFA SCORE FOR PREDICTION OF MORTALITY IN A WARD

R. Barosa[1], M. Patita[1], L. R. Ramos[1], J. Freitas[1]
[1]*Hospital Garcia de Orta, Almada, Portugal, Almada, Portugal*

Contact E-mail Address: a.rita.b@gmail.com

Introduction: Recently, the EASL-CLIF Consortium defined diagnostic criteria for acute-on-chronic liver failure (ACLF), a frequent syndrome characterized by acute decompensation of cirrhosis, organ failure(s) and high mortality.[1]

Aims & Methods: We sought to validate the ACLF definition and the Chronic Liver Failure-Sequential Organ Failure Assessment (CLIF-SOFA) score in patients admitted in a Gastroenterology ward and compare it with the existing scoring systems Model for End-Stage Liver Disease (MELD) and Child-Turcotte-Pugh (CTP). Retrospective analysis of demographic, clinical and laboratorial data of patients admitted for acute decompensation of cirrhosis between January and September 2014. Twenty eight (M28) and 90-day (M90) mortality were evaluated. Patients with and without ACLF were compared. CLIF-SOFA performance was compared with MELD and CTP.

Results: 82 patients were included (male sex:78%, mean age:63 ± 13 years). 82% had alcoholic cirrhosis (with or without viral infection) and previous episodes of acute decompensation were absent in 27%. At admission 27.1% fulfilled criteria for ACLF (Grade 1 17.6%, Grade 2 9.5%) and 9.8% developed it during hospitalization. M28 e M90 were, respectively, 1.9% and 15% in patients without ACLF and 46.4% and 64.3% in patients with ACLF (p = 0.01). Mortality was > 70% in patients with ACLF grade 2 and 3; 44.4% of ACLF grade 2 patients had median arterial pressure < 65mmHg. Patients with ACLF were older (70 ± 13 vs. 60 ± 12 years, p = 0.038), had more infections (61% vs. 23%, p = 0.001) and higher C-reactive protein, independently of the presence of infection (1.3 vs. 4.1 mg/dL, p = 0.01). The AUROC of CLIF-SOFA in predicting M28 was 0.907 ± 0.0461 (95%CI 0.820-0.961) and M90 was 0.820 ± 0.0504 (95%CI 0.717820-0.897), which was significantly superior to CTP but not significantly superior to MELD.

Conclusion: The application of ACLF criteria in the ward identifies patients with high mortality. The CLIF-SOFA score accurately predicts short-term mortality but was not significantly superior to MELD; this might be related to absence of CLIF-SOFA circulatory and ventilatory failure criteria in the ward setting, leaving only parameters common to other hepatospecific scores.

Introduction: Minimal hepatic encephalopathy (MHE) has been associated with increased mortality risk and impaired quality of life. Its detection using the Psychometric Hepatic Encephalopathy Score (PHES) is recommended in the treatment algorithm of cirrhotic patients.

Aims & Methods: The aim was to evaluate the applicability in clinical practice of the calculation of the PHES in patients with liver cirrhosis. It was a prospective cohort of consecutive patients with liver cirrhosis without clinical encephalopathy, followed as Hepatology outpatients. Any conditions impeding the completion of the test were registered. When applicable, 5 psychometric tests were performed to calculate the PHE:Trail Making Test A and B, the Digit Symbol Test, the Serial Dotting Test and the Line Drawing Test.

Results: A total of 69 patients were included (78% male). Twenty nine percent of patients proposed to determine the PHES did not perform the tasks due to the following causes: neurological disease/dementia (40%), alcohol consumption >40 g alcohol/day (35%), visual disturbances (15%) and illiteracy (10%). Twenty nine percent of the patirents that completed the psychometric test had MHE. The Trail Making test (Part B) was the test that separately detected more patients with MHE (54%). Four tests (Trail Making Test, the Serial Dotting Test and the Line Drawing Test) detected all cases of MHE diagnosed in this cohort. The mean time to perform the 5 tasks was 13 ± 6 minutes. The time to determine the PHES was statistically significant higher in patients with MHE compared to patients without such cognitive dysfunction (20 ± 1 vs. 11 ± 7 minutes, $p < 0.001$).
Conclusion: A significant proportion of patients were not eligible to determine the PHES due to several limitations to complete the psychometric tests. Despite of being relatively easy to apply, these 5 tasks were time consuming in the presence of MHE.

P1251 DETERMINATION OF PREDICTIVE FACTORS FOR MINIMAL HEPATIC ENCEPHALOPATHY WITH PSYCHOMETRIC TESTS

R. Coelho[1], M. Silva[1], R. Gaspar[1], R. Gonçalves[1], S. Rodrigues[1], H. Cardoso[1], G. Macedo[1]
[1]*Gastrenterology, Centro Hospitalar São João, Porto., Portugal*

Contact E-mail Address: rosacoelhoabrantes@hotmail.com
Introduction: Minimal hepatic encephalopathy (MHE) encompasses several neuropsychiatric abnormalities in patients with liver cirrhosis (LC). The detection of MHE requires specialized testing as it is not diagnosed on standard clinical examination. The Psychometric Hepatic Encephalopathy Score (PHES) calculated using 5 psychometric tests, shows high sensitivity and specificity for MHE diagnosis. The aims were to determine the prevalence and predictor factors for MHE.
Aims & Methods: It was a prospective study with consecutive patients with LC followed as Hepatology outpatients. Five psychometric tasks were performed: Trail Making Test A and B, the Digit Symbol Test, the Serial Dotting Test and the Line Drawing Test. Patients with clinical encephalopathy and neurological diseases were excluded. PHES normality tables validated for the Portuguese population were used and the final score was calculated for each patient, the total score of -4 points defined MHE.
Results: We included 49 patients (69% men) with a mean age of 57 ± 10 years. The most frequent aetiology of LC was hepatitis C (50%) and 62% had Child-Pugh score A (64%). Eighteen percent of patients were under treatment with lactulose and 3% with rifaximin. The proportion of EHM was 29% and 63% of them were still driving. The presence of MHE was associated with:diuretic therapy ($p = 0.004$), use of benzodiazepines ($p = 0.015$), score Child-Pugh B/C ($p = 0.018$), previous hospital admissions due to cirrhosis descompensatio ($p = 0.015$) and the presence of esophageal varices ($p = 0.002$). Previous episodes of hepatic encephalopathy, INR and albumin levels, MELD score and thrombocytopenia were not significantly different in the group of patients with EHM. In logistic regression, the use of benzodiazepines [OR: 7.812 95% CI (1.242 to 45.287)] was independently related with the presence of EHM.
Conclusion: The presence of EHM was associates with: diuretic therapy, score Child-Pugh B/C, prior hospitalization due to decompensation of LC and esophageal varices. Benzodiazepines therapy was an independent risk factor for EHM.

P1252 ALFA PUMP FOR THE TREATMENT OF REFRACTORY ASCITES: A "REAL-WORLD" EXPERIENCE FROM THE UK

S. Nair[1], E. Robinson[1], F. Smith[2], S. Macdonald[3], H. Mergental[4], D. Talbot[1], D. Tripathi[4], B. Griffiths[2], R. Jalan[3], S. Mcpherson[1]

Contact E-mail Address: shelleynair@doctors.net.uk
Introduction: Up to 10% of cirrhotic patients with ascites become refractory to diuretic therapy requiring either large volume paracenteses (LVP), transcutaneous intrahepatic portosystemic shunt (TIPSS) or liver transplantation (LT). In patients where TIPSS or LT is contraindicated, repeated LVP is the only option. LVP is an uncomfortable procedure requiring hospital visits and has risk of complications. The ALFA pump is a surgically implanted automated low flow pump system that transports fluid from the peritoneal cavity to the bladder and is an alternative treatment option for patients with refractory ascites. Our aim was to evaluate the early "real world" experience of the ALFA pump for the treatment of refractory ascites from centres in the UK.
Aims & Methods: Retrospective case note review of the outcomes of patients who had an ALFA pump implanted for refractory ascites outside trials at 4 NHS hospitals since Sept 2013.
Results: ALFA pumps were implanted in 9 patients (6 male, 3 female; median age 74, range 41-81) at four centres (4 NCL, 2 UCL, 2 CAM, 1 QEHB). 7 patients had ascites related to cirrhosis (4 Child-Pugh B, 3 Child-Pugh C), 1 due to congestive cardiac failure and 1 with portal hypertension due to arteriovenous malformation. Prior to insertion of the ALFA pump the median frequency of paracenteses was every 10 days (range 7 – 20) and the median volume of ascites drained was 9 litres (range 8 to 12). ALFA pumps were successfully implanted in all patients. Requirement for paracenteses was substantially reduced post ALFA pump implantation with 7 patients no longer requiring any paracenteses. In one patient the pump blocked after 3 weeks and required reimplantation with a second pump that also blocked and the patient has returned to LVP. In another patient the pump blocked after 8 months and a second ALFA pump was successfully implanted. All 9 patients had ALFA pump related complications including 4 post-operative seromas, 3 bladder catheter migrations/occlusions, 5 site related infections, 6 acute kidney injury/electrolyte disturbance and 1 urinary incontinence. 5 of the 9 patients were alive with a functioning pump 6 months after implantation.
Conclusion: The ALFA pump offers an alternative option for patients who have refractory ascites in whom TIPSS and LT are contraindicated. ALFA pump implantation substantially reduces the need for paracenteses in a cohort of patients who had previously required a significant number of LVP. ALFA pump related complications were frequent suggesting the need for careful patient selection in this high risk group. Outcomes of a randomized controlled trial are eagerly awaited.

P1254 THE RISK OF HEPATIC ENCEPHALOPATHY FOR ALCOHOL VERSUS VIRAL CIRRHOTIC PATIENTS

S. Chiriac[1], A. Trifan[1], I. Girleanu[1], O. Stoica[1], R. Maxim[1], T. Cuciureanu[1], C. Stanciu[2]
[1]*University of Medicine and Pharmacy "Gr. T. Popa",* [2]*Institute of Gastroenterology and Hepatology, "St. Spiridon" Hospital, iasi, Romania*

Contact E-mail Address: stefannchiriac@yahoo.com
Introduction: Hepatic encephalopathy (HE) is found frequently in the setting of liver cirrhosis (LC). HE worsens the prognostic and impairs the quality of life for patients with LC. The current accepted classification comprises covert (CHE) and overt (OHE) encephalopathy. Alcohol determines changes in the frontal cortex, therefore cognitive function and treatment may be different between alcoholic and viral liver cirrhosis. In this retrospective study, we evaluated the risk of OHE and CHE, in viral versus alcoholic LC.
Aims & Methods: We retrospectively evaluated 642 patients that were hospitalized in our service of gastroenterology from January 2014 to December 2014 (viral: 338 and alcohol: 304) with compensated and decompensated LC. The patients were followed for six months. The diagnosis of CHE and OHE was made according to the West Haven classification.
Results: The mean age of patients with alcoholic and viral LC was 56.45 (10.59) and 55.24 (11.4) years, respectively. The patients with alcoholic etiology of the liver disease had a risk of developing HE that was 1,48 fold higher than the ones with viral etiology ($P < 0.0001$, OR 1.48, CI 1,254-1,747). The patients that were diagnosed with OHE had a higher risk of death than the ones that were diagnosed with CHE ($P < 0.046$, CI 0.938-2,384).
Conclusion: The risk of developing hepatic encephalopathy is higher for the cirrhotic patients with alcoholic etiology than for the ones with viral etiology, therefore the cirrhotics that associate alcohol disease may benefit from a closer monitoring for the diagnostic of HE than the ones with viral etiology.

Contact E-mail Address: tamara.alempijevic@med.bg.ac.rs
Introduction: Acute on chronic liver failure (ACLF) is defined as progressive deterioration of hepatic function after an acute insult on an underlying diagnosed or undiagnosed chronic liver disease. It is associated with high short-term mortality due to multiorgan system failure. Therefore ACLF is one of the most clinical challenging health problem. Liver transplantation is the only therapeutical option to improve survival, but a large proportion of patients succumb while waiting on the transplanta list. So other therapeutical options are tried as use of erythropoietin (Epo). Epo is a pleiotropic cytokine known for its role in stimulation of erythropoiesis, but also rise levels of calcium in the blood vesels endothelium, stimulates acting of angiotensin II, whis activate sinthesis of NO with pressor efect. Elevation of blood pressure leads to better perfusion and healing. Epos has an antiinflammatory and cytoprotective effect as well.
Aims & Methods: In this study 54 patients were included, mean age 58.2 ± 1.3 years. The liver disease in majority of patients (83.3%) was caused by alcohol abuse. All patients underwent a complete biochemical workup, including measuring of Epo values. Relevant scores for assing liver functions and outcome in ACLF were measured (Child, MELD, MELD Na, SOFA, APACHE II). We analyzed the values of Epo in correlation to acute insult and outcome.
Results: We devided the patients into two groups according to the acute insult-bleeding due portal hypertension (A-13 pts) and other-icterus, encephalopathy etc. (B-41 pts). The mean Epo, Child, MELD, MELD Na, SOFA, APACHE and CLIF score values were presented in table , and as presented, the Epo values are significantly higher in patients who presented initialy as gastrointestinal bleeding.

	Group A	Group B	p values
Epo (mIU/mL)	327.27 ± 244.19	201.43 ± 200.87	0.03
Child	10.38 ± 2.29	11.2 ± 2.0	0.14
MELD	19.31 ± 4.11	22.71 ± 7.51	0.06
MELD Na	21.23 ± 4.87	22.76 ± 9.75	0.29
SOFA	8 ± 2.71	9.22 ± 3.24	0.11
APACHE II	14.15 ± 4.61	14.93 ± 4.86	0.31

In group A, 6 (78%) patients had lethal outcome, and in group B ,16 (39%) respectively. Further, we analyzed the values of Epo according to outcome. In group A, patients with lethal outcome had statistically significant higher ($p = 0.007$) values of Epo (493.5 ± 242.86 and 184.79 ± 137.07, respectively), while in group B, the Epo values were statistically significant lower ($p = 0.002$) in patients who succumb (89.09 ± 84.32 and 273 ± 221.37, respectively).
Conclusion: Patients suffering from ACLF without bleeding as an initial insult have significantly lower values of Epo. Taking into account benefits of Epo treatment by stimulating hepatic regeneration and improvement of hepatic function, further studies are necessary in order to define which patients will have the optimal benefit of using Epo in treatment of ACLF.

Introduction: The diagnosis of spontaneous bacterial peritonitis (SBP) based on the presence of ascitic fluid absolute polymorphonuclear leukocyte (PMN) count equal or greater than 250 cells/mm^3 without an evident intra-abdominal, surgically treatable source of infection. Neutrophil-lymphocytic ratio (NLR) may be considered as a simple and inexpensive indicator of inflammation in some diseases.
Aims & Methods: The aim of this study was to evaluate clinical utility of NLR as a noninvasive marker for diagnosis of SBP.126 Consecutive cirrhotic ascitic patients who were diagnosed with SBP and 54 cirrhotic ascitic patients without SBP were enrolled in this study. NLR was calculated and high-sensitive CRP (hsCRP) values were determined for all patients. The ability of NLR values as a marker for diagnoses of SBP in ascitic patients was analyzed using receiver operator characteristic (ROC) curvature analysis.
Results: NLR and hsCRP were significantly higher among cirrhotic ascitic patients with SBP versus non SBP patients ($p < 0.001$) for each one. ROC was computed between blood NLR and hsCRP in patients with SBP. At the cut of blood NLR (>2.89) in patients with SBP the sensitivity was (80.3%) and specificity (88.9), whereas hsCRP (>11.3) had a sensitivity of (88.9) and specificity (92.6). In logistic regression analysis model combining both NLR and hsCRP, the sensitivity was (95.1) and specificity (96.3).
Conclusion: The findings indicate that the combination of NLR and hsCRP could be used as a novel noninvasive marker for the diagnosis SBP.

P1257 POTENTIAL RISK FACTORS IN PATIENTS WITH PRIMARY BILIARY CIRRHOSIS: A FIVE-YEAR SINGLE CENTER EXPERIENCE

Z. Straume[1,2], V. Skuja[1,2], R. Aleksejeva[3], B. Janicka[3], D. Pētersone[3], J. Sekretarjovs[3], **A. Derovs**[2,4]
[1]*Department of Internal Medicine, Riga Stradins University,* [2]*Gastroenterology, Hepatology and Nutrition Clinic, Riga East Clinical University Hospital,* [3]*Faculty of Medicine,* [4]*Riga Stradins University, Riga, Latvia*

Contact E-mail Address: zanestraume@gmail.com
Introduction: Aetiology of primary biliary cirrhosis (PBC) is unknown, but it is associated with frequent bacterial and viral infections, autoimmune conditions, reproductive hormone replacement therapy, cigarette smoking and use of nail polish.
Aims & Methods: To analyse potential risk factors in patients with confirmed PBC diagnosis in Latvia. Retrospective medical documentation study of all PBC patients admitted to Riga East Clinical University Hospital – the biggest, 2270-bed medical centre in Latvia, from 2010 to 2015. An originally created study protocol, containing more than 35 parameters, including the most likely risk factors as infection diseases, autoimmune conditions and exogenous agents, was completed for each patient and data was entered into database with consecutive statistical analysis using SPSS 20.0.
Results: 34 patients, 33 (97%) female and 1 (3%) male patient, were admitted 54 times. 19 (55.88%) of all 34 patients had no identified potential PBC risk factors in the past. 5 (14.71%) of all patients have been diagnosed with urinary tract infection. 12 (35.29%) of all patients have had other bacterial infections. 11 (32.35%) of all patients have had viral infections in the past and 2 (5.88%) patients have had contact with chemical agents and previous reproductive hormone replacement therapy. No data about pesticides, food additives, use of certain cosmetics, including nail polish, no data about genetic variants of HLA class II, IL12A, and IL12RB2 loci and no data about family history was found during the study. Statistically significant differences were not found between patients who had bacterial or viral infection in the past and patients who did not have any potential PBC risk factors in the past, when comparing MELD, CTP and length of the hospitalization period.
Conclusion: 1. Bacterial infections, viral infections, urinary tract infections, contact with chemical agents and reproductive hormone replacement therapy are the most frequently found risk factors that are consistent with the literature data. 2. Additional study, including more detailed lifestyle and environmental factor analysis in combination with genetic analysis should be performed to analyse PBC risk factors more profoundly. 3. Statistically significant differences were not found between patients who had and patients who did not have any bacterial or viral infections in the past.

Contact E-mail Address: maasaber@yahoo.com
Introduction: Host genetic factors have a role in the clearance of HCV infection in patients under treatment with PEG/RBV. Several studies have reported that interferon Lambda (IFNL) gene polymorphism is the best baseline predictor of response to interferon alfa(IFNα)-based antiviral therapies in chronic hepatitis C. Recently, a new IFN-L4 polymorphism was identified as first potential functional variant for induction of IFNL4 expression. Myxovirus resistance gene A (MxA) expression is induced by IFNs and Ribavirin (RBV) treatment.
Aims & Methods: In this study polymorphism of interferon lambda 3 (IFNL3) and IFNL4 and their association with MxA RNA expression have been evaluated in respect to sustained virological response (SVR) in IFNα/RVB treated hepatitis C-4 patients. A Total of 442 hepatitis C-4 Egyptian patients (male/female = 272/170; mean age: 45 [20-65] y) were investigated. Liver fibrosis was assessed by liver biopsy. Treatment was standard pegIFNα/RBV for 48 Weeks. SNPs rs12979860, rs8099917, rs12980275 were analyzed by Real time-PCR system and and ss469415590 mutations was analyzed by DNA sequencing. Relative Expression of MxA RNA was evaluated by qPCR. Fifty healthy people were served as a control.
Results: Distribution of variants of INFL3 (rs12979860) was: CC (27%), CT (46.5%) and TT (26.5%) variant. For rs8099917: GG (4.5%), GT (35.7%) and TT (59.8%) variant. For rs12980275: AA (29.2%), AG (56.4%) and GG (15.4%) variant. For ss469415590: ΔG/ ΔG (6.5%), ΔG/TT (54.4%) and TT/TT (39.1%) variant. Highly significant higher percentage of SVR rates was found among cases with CC subtype of rs12979860 ($p = 0.0001$) and cases with AA subtype of rs12980275 ($p = 0.001$), while SNPs rs8099917 and ss469415590 had no significant impacted on SVR ($p = 0.6$, 0.2 respectively). Expression of MxA (thatenhance IFN-α anti-viral activity against HCV) was highly significant ($p = 001$) in SVR cases than non-responders.
Conclusion: Polymorphisms in IFNL3/4 genes and expression of MxA gene have a different impact effects on response to IFNα/RBV treatment in HCV-4 infected patients. Although there are significant correlation between some subypes of polymorphisms and MxA expression and prediction of response to treatment, but on indivedual levels, there is no absolute predictor factor for response to IFNα/RBV therapy.

P1259 DEPLETION OF CD4+CD25+REGULATORY T CELLS ATTENUATE THE DEVELOPMENT OF CCL4-INDUCED LIVER FIBROSIS IN HCV NONSTRUCTURAL PROTEIN 3/4A TRANSGENIC MICE

R. Bansal[1,2], L. Frelin[1], M. Sallberg[1]
[1]*Department of Laboratory Medicine, Division of Clinical Microbiology, Karolinska Institute, Stockholm, Sweden,* [2]*Targeted Therapeutics, Department of Biomaterials Science and Technology, University of Twente, Enschede, Netherlands*

Introduction: Regulatory $CD4^+CD25^+$ T cells (Tregs) are considered to affect the disease outcomes of Hepatitis C virus (HCV) infection and appear to play a crucial role in viral persistence by suppressing HCV-specific T cell responses. But the role of Tregs in HCV infection, particularly in inflammation and fibrogenesis is still debated.
Aims & Methods: In this study, we aimed to understand the role of $CD4^+CD25^+$ Tregs in CCl_4-induced fibrosis progression in HCV (NS3/4A) transgenic mice. We used transgenic (Tg) mice with hepatic-specific expression of the HCV non-structural NS3/4A protein complex. Tregs were depleted for 4 weeks using anti-CD25 and anti-GITR antibodies and control group received isotype control antibodies. After 2 weeks of antibodies administration, mice were treated either with olive oil or CCl_4 (1ml/kg) for 2 weeks to induce liver fibrosis. Liver damage, HSC markers, inflammatory markers (M1 and M2 macrophages) and Th1/Th2/Th17 responses were examined using immune-histological stainings and quantitative gene expression PCR analysis.
Results: Hepatic expression of NS3/4A did not induce spontaneous liver disease. Following Treg depletion, NS3/4A-Tg mice exhibited significantly reduced Collagen I protein and mRNA expression showing reduced fibrogenesis in comparison to non-depleted NS3/4A-Tg mice. Furthermore, in Treg-depleted mice, significant inhibition of hepatic stellate cells proliferation (desmin) and activation (a-SMA) was observed. No significant differences in intra-hepatic macrophages was found as determined by F4/80 staining. Strikingly, YM1-positive macrophages and MMP-13 levels were drastically increased in Treg-depleted mice as compared to isotype (non-depleted) control mice. IL-1b and IL-6 gene expression was also significantly reduced suggesting inhibition in inflammation in Treg-depleted animals. Furthermore, in Treg-depleted NS3/4A-Tg mice, strong bias towards Th2 was observed as compared to Th1 response together with reduced Th17 response.
Conclusion: In conclusion, these results suggests that $CD4^+CD25^+$ Tregs depletion in chronic HCV infection attenuates hepatic fibrogenesis by inhibiting HSC activation, suppressing liver inflammation and modulates Th1/Th2 balance toward a Th2 dominant response.

P1260 QUANTITATIVE ANALYSIS OF HEPATITIS B SURFACE ANTIGEN AFTER TWO YEARS OF ENTECAVIR TREATMENT IN PATIENTS WITH CHRONIC HEPATITIS B

A. Fujimura[1], T. Ichikawa[1]
[1]*Gastroenterology, Itabashi Chuo Medical Center, Itabashi, Japan*

Contact E-mail Address: korochan0305@yahoo.co.jp
Introduction: Anti-hepatitis B e antigen (anti-HBe) seroconversion and hepatitis B surface antigen (HBsAg) loss are important therapeutic endpoints in patients with hepatitis B virus (HBV) infection. Quantitative measures of HBsAg have been identified as potentially useful indicators of therapeutic response in HBV monoinfection. A rapid HBsAg decline during nucleoside/nucleotide analogue therapy may identify patients who will show clearance of HBsAg. In the present study, we examined HBsAg levels in patients who received entecavir for chronic HBV in our hospital.
Aims & Methods: A total of 54 patients who received entecavir for chronic HBV, were screened for study inclusion and 25 patients were excluded due to inadequate data. In 29 patients (14 males and 15 females), biochemical values and HBV-DNA and HBsAg levels were determined at the start, six months, and 1 and 2 years after the start of entecavir treatment.
Results: At the start, the patients' mean age was 55.7 ± 15.6 years, HBV-DNA levels were 6.6 ± 1.6 log copies/mL, median alanine aminotransferase (ALT) level was 268 IU/L, and median HBsAg level was 11,123 IU/L. No patient became negative for HBsAg at two years. After two years of entecavir treatment, HBsAg levels showed no significant difference (>0.5 log) in 20 patients (69%), but decreased in 7 patients (24%) and increased in 2 patients (7%). HBeAg-positive patients showed significantly decreased HBsAg levels compared with HBeAg-negative patients (35.7 vs. 14.3%, respectively, $P = 0.002$). High levels of HBV-DNA (7.98 vs. 6.17 log copies/mL, respectively, $P = 0.01$), ALT (289 vs. 126 IU/L, respectively, $P = 0.026$), and prothrombin time (PT) (113 vs. 86%, respectively, $P = 0.002$) at baseline were found in patients with significantly decreased HBsAg, compared with patients with no significant decrease in HBsAg. At two years, 27 of the 29 patients (93.1%) became negative for HBV-DNA, and 6 of 14 patients (42.9%) showed HBeAg seroconversion. In those with seroconversion, there was no significant correlation among ALT, HBsAg, and HBV-DNA levels at baseline. In addition, there was no significant difference in the seroconversion rates between patients with or without significantly decreased HBsAg levels at six months (40.0 vs. 33.3%, respectively, $P = 0.297$).
Conclusion: HBV-DNA proliferation was inhibited by entecavir treatment, and most of the patients became negative for HBV-DNA. However, most patients showed no significant decrease in HBsAg levels. Patients with significant HBsAg reduction after two years of entecavir treatment had higher HBV-DNA levels, ALT levels, and PT levels at baseline. The significantly decreased HBsAg levels at six months were not correlated with the seroconversion rates at two years.

P1261 PREVALENCE AND RISK FACTORS OF HEPATITIS B INFECTION IN PREGNANT WOMEN AT THE PRENATAL CLINIC OF THE UNIVERSITY OF THE PHILIPPINES- PHILIPPINE GENERAL HOSPITAL

A. Q. Taguba[1,*], G. C. Carpio[1], L. C. Tan[2], J. Ong[1], M. L. O. Daez[1]
[1]*Department of Medicine, Section of Gastroenterology,* [2]*Department of Obstetrics and Gynecology, University of the Philippines - Philippine General Hospital, Manila, Philippines*

Contact E-mail Address: aubreytaguba@gmail.com
Introduction: Perinatal transmission remains to be the leading cause of spread of hepatitis B virus in the Philippines. This study assessed the prevalence and associated factors for hepatitis B surface antigen (HBsAg) and hepatitis B e antigen (HBeAg) in pregnant subjects seeking prenatal care at the Philippine General Hospital (PGH).
Aims & Methods: Outpatient charts of consecutive pregnant subjects at the prenatal clinic of PGH from January to July 2014 were reviewed. Information on age, marital and employment status, educational attainment, residence, gravidity, history of abortion or stillbirth, number of sexual partners, history of surgery and sexually transmitted infection, and results of screening test for syphilis were recorded. STATA SE version12 for Windows was used for statistical analyses. Univariate analysis and simple logistic regression were used to determine independent predictors of HBsAg positivity. A p-value of < 0.05 was considered as statistically significant.
Results: A total of 768 outpatient charts were reviewed. The prevalence of HBsAg seropositivity was 9.6%. HBeAg positivivity was 15.9%. HBsAg positive subjects compared with HBsAg negative subjects, tend to be older ($p = 0.016$), married ($p = 0.0032$), have multiple (≤ 3) pregnancies ($p = 0.0157$), and have history of spontaneous abortion ($p = 0.0458$). The odds of having hepatitis B infection was 1.05 times higher in older subjects; 2.22 times higher among married; 1.83 times higher among those with history of abortion; and 2.00 times higher among those with multiple pregnancies.
Conclusion: Prevalence of HBsAg seropositivity in pregnant women in PGH remains to be high despite screening guidelines and nationwide HBV vaccination.

Contact E-mail Address: catia.f.leitao@gmail.com
Introduction: Reactivation of hepatitis B virus (HBV) infection is a well-recognized complication of systemic chemotherapy, including chemotherapy regimens with corticosteroids and/or rituximab. Traditionally, hepatitis B surface antibody (anti-HBs) is considered a protective antibody. The effect of rituximab on these antibodies has not been established.
Aims & Methods
Aim: To ascertain the clinical features of patients who lost anti-HBs during treatment of lymphoma.
Methods: Four non-Hodgkin's lymphoma (NHL) patients previously vaccinated for HBV and became negative for anti-HBs after treatment were analyzed, regarding their clinical and demographic data. Serological HBV tests (HBsAg, anti-HBs and anti-HBc) were performed at the initial screening and throughout NHL treatment. It was considered loss of immunity when anti-HBs was less than 10 IU/mL.
Results: Four patients were included, 1 man, with a mean age of 47 ± 28 years (15-75 years). Two patients were diagnosed with a diffuse large B cells NHL, one had a mantle cell lymphoma and one had a lymphoma with intermediate features of Burkitt lymphoma/Diffuse B Large cells NHL. All patients were treated with chemotherapy (3 RCHOP and 1 protocol LMB-95). Two patients underwent further treatment: R-ESHAP followed by bone marrow transplantation (1) and radiotherapy (1). All patients received steroids and rituximab. The median pre-treatment anti-HBs titer was 19.17mIU / ml (11.9-25.8mIU / mL). The median interval between the beginning of treatment and the loss of anti-HBs was 5 months (range, 2–9 months). No patient was infected by HBV.
Conclusion: Chemotherapy for NHL has an important role in reducing the anti-HBs titers and loss of immunity, which my lead to an increased risk of developing a new HBV infection. In vaccinated patients it seems reasonable to perform a systematic determination of anti-HBs while under immunosuppressive therapy and to consider re-vaccination if immunity is lost.

[2]*Department of Translational Medical Science, University of Naples "Federico II", Naples, Italy*

Contact E-mail Address: maria.guarino86@gmail.com
Introduction: Serum HBsAg loss is the recommended stopping rule in NUC responders, yet this event occurs rarely. Decreasing serum HBsAg levels, preceeding HBsAg seroclearance, has not been investigated sufficiently and the predictive value of baseline and on-treatment quantitative serum HBsAg levels in the therapeutic response to NUC in chronic hepatitis B (CHB) patients remains unclear. We aimed to investigate the kinetics of HBsAg levels during NUC therapy to predict the treatment period to achieve HBsAg seroconversion.
Aims & Methods: Patients with CHB, receiving NUC antiviral therapy with stable viral suppression (HBV-DNA < 20 UI/ml), were recruited at the Gastroenterology Unit of the University of Naples ''Federico II''. Sequential serum samples from these patients were tested for HBsAg with the ''HBsAg II quantitative immunoassay''(Roche). HBsAg levels were determined at baseline, where possible, and during antiviral therapy every 12 months.
Results: A total of 63 patients (male/female: 50/13, median age 58yrs, range 35-80yrs,27% cirrhosis) with CHB, HBeAg-negative, responder to different NUC therapies, were enrolled. Currently, 38 patients were in therapy with Tenofovir, 11 with Entecavir, 14 with Lamivudine. The median treatment duration was 110 months, range 48-183 months. There was a significant decrease of the HBsAg levels during at least 4 years of monitoring (p value < 0.05); in particular, at time of enrollment, the HBsAg baseline mean value was 3372 UI/ml (26.6-28948 UI/ml), while the mean value of the last determination of HBsAg was 1496 UI/ml (<20-9700 UI/ml). The statistically significant decrease of HBsAg levels was also maintained in different patient'subgroups in relation to different antiviral therapy and presence/absence of cirrhosis. HBsAg seroclearance, with HBsAb seroconversion, occurred in 12.6% of patients. Undetectable HBsAg was evidenced at least two years before the HBsAb seroclearance.
Conclusion: The results of this study suggest a role of on-treatment HBsAg quantification in the management of NUC-treated patients. If validated, prospectively in a larger patient cohort, HBsAg measurements would be a useful parameter to optimize antiviral treatment schedule.

P1264 PREVALENCE OF FAMILIAL AGGREGATION IN CHRONIC HEPATITIS B AND CORRELATION WITH CLINICAL CHARACTERISTICS AND INFLUENCE ON PATHOGENESIS OF OFFSPRING: A CROSS-SECTION STUDY FROM A HIGH EPIDEMIC AREA IN CHINA

J. Ye[1], Y. Wu[1], B. Zhong[1], on behalf of yes
[1]*Gastroenterology Department, the First Affiliated Hospital of Sun Yat-sen University, Guangzhou, China*

Contact E-mail Address: sophiazhong@hotmail.com
Introduction: Family infection is one of the most remarkable characteristics in pathogenesis pattern of hepatitis B in China. Family aggregation of hepatitis B varies from geographic distribution and the impact on disease remains controversial.
Aims & Methods
Aims: To investigate the prevalence of familial aggregation in Guangzhou area of which population prevalence rate of Chronic hepatitis B (CHB) is 12.45%[1] and study the relationship between clinical characteristics, influence on pathogenesis of offspring and family assemble chronic hepatitis B.
Methods: We conducted a cross-sectional survey in the First Affiliated Hospital of Sun Yat-sen University from January 2009 to January 2015. 853 consecutive subjects with established CHB were investigated at our out-patients clinic. Information of their core family members on status of HBV infection was collected with specific designed questionnaires and from the treating doctor. HBV serologic indicators, HBV DNA levels, liver function, blood cells count and imaging examination were assessed. Univariate logistic regression model were used to analyze the risk of HBV transmission.
Results: Of 668 patients with available family member data, 441 (66.0%) patients were male and the median age was 38.5 (26~68) years. Positive HBV family history was found in 331 patients (49.5%); Negative family history in 337 patients (66.02%). Two group patients were stratified according to age, as young subgroup (16~30y), middle age subgroup (31~45y), older subgroup (>45y). A significant difference was observed in the rate of diagnose with cirrhosis decompensated in HBV family history positive patients with 6.89%, 41.38%, 51.73% in young subgroup, middle age subgroup, older subgroup respectively, compared with 6.25%, 15.63%, 78.3% in HBV family history negative patients ($P = 0.046$). The rate of middle age subgroup with family history was significantly greater than that of control group ($p = 0.027$), while the differences in the other 2 subgroups were not significantly ($p > 0.05$). The groups did not differ in gender, estimated duration of infection, HBV serologic indicators, liver function and PLT ($P > 0.05$). In HBV family history positive group, children with HBsAg positive brothers was the most common aggregation pattern(30.51%), followed by children with HBsAg positive mothers (29.60%) and children with HBsAg positive fathers (23.56%). Adjusted odds ratios (OR) of risk of HBV transmission to offspring were elevated for father infected alone with HBV compared with for mother alone (OR = 2.92, 95%CI = 2.38~3.96, p = 0.009), parents both (OR = 9.54, 95% CI = 4.12~13.62, p = 0.0062).
Conclusion: Patients with HBV family history may develop cirrhosis decompensated earlier than those without. CHB children with HBsAg positive brothers is the predominant pattern in familial CHB. Mother alone or parents both infected with HBV may be at higher risk of HBV transmission to offspring than father alone.

Contact E-mail Address: ray.shidrawi@homerton.nhs.uk
Introduction: Hepatitis B virus (HBV) infection is a global health problem with significant morbidity and mortality. Mother-to-child transmission is a major mode of transmission, against which immunoprophylaxis confers protection. The United Kingdom's (UK) public health strategy to prevent HBV transmission has hitherto been to offer babies born to HBV carriers immunoprophylaxis, as opposed to universal vaccination. More recently, recommendations have been proposed to introduce direct acting antiviral therapy in the third trimester of pregnancy in highly replicating mothers as an additional strategy to reduce vertical transmission. We set out to observe the effectiveness of the UK immunisation strategy, in order to quantify the risk of mother-to-child transmission despite immunoprophylaxis and introduce this into the debate on the use of direct acting antivirals in pregnancy.
Aims & Methods
Aims: To evaluate the effectiveness of our current HBV vaccination protocol in preventing mother-to-child transmission and identify risk factors for vaccination failure.
Methods: An HBV perianatal vaccination programme at a single UK London district general hospital within an area of high HBV endemicity. Children born to HBV carriers identified by universal screening were offered an accelerated immunisation schedule with 0.5ml Engerix B (GSK Pharma, UK) at birth, one month and two months of age, with a booster at 12 months of age and assessment of HBV immunity. Children born to HBV e antigen positive mothers were in addition offered HBV Immunoglobulin (HBIG, 20 IU, Colindale, UK) at birth. A dedicated HBV post-natal screening programme ensured a high patient compliance rate.
The serological records of all ante-natal patients registering within our hospital were retrospectively examined and HBV carriers identified. The serological records of children born to these carriers were used to identify vaccination failures. The case records of case failures were studied to identify risk factors for vaccination failure.
Results: Of 37,662 women registering in the Antenatal Clinic for the period 2008-2012, 805 (2.12%) patients were found to be HBV carriers, giving a much higher prevalence than the national average (0.54%). Seventy women (8.7%) were HBV e antigen (HBeAg) positive carriers. 98% compliance rates were recorded for the post-natal immunisation clinics. Two infants born to HBeAg positive mothers with high viral titres (above 6 $\log_{10}$ IU/ml) were deemed as vaccination failures (0.24% of the total born to HBV carriers and 2.86% of those born to HBeAg positive carriers) despite both passive and active immunisation. The numbers needed to treat (NNT) with direct acting antivirals in the third trimester of pregnancy in patients with high viral titres is 55 (95% CI, 45.1 – 67.9).
Conclusion: There are areas of high HBV endemicity within London (2.12%) which merit special public health attention. Current strategies to prevent HBV mother-to-child transmission are not without a significant failure rate (2.86%). The health economic debate can now take place to convince the medical community of the cost-effectiveness of the use of direct acting antivirals in the third trimester of pregnancy.

P1266 OUTCOMES OF THERAPEUTIC RESPONSE TO TENOFOVIR DIPIVOXIL FUMARATE (TDF) IN CHRONIC HEPATITIS B PREGNANT PATIENTS

M. Gill[1], S. Gill[1], A. Nawaz[1], N. Yousaf[1], M. Malik[1], F. Irfan[1]
[1]*Gastroenterology, Maroof International Hospital, Islamabad, Pakistan*

Contact E-mail Address: gill95@yahoo.com
Introduction: Antiviral therapy may be required during pregnancy to control maternal disease and to prevent vertical transmission at third trimester. We prospectively studied the efficacy and safety of TDF in managing these patients.
Aims & Methods: Chronic Hepatitis B mothers who required antiviral treatment during pregnancy were screened. Those with ALT 50 and above and HBDNA more than 10,000 IU were treated with TDF until 52 weeks postpartum.
Primary endpoints in mother were HBV DNA < 5log10 copies/mL at delivery and the percentage of patients with HBV DNA undetectable at postpartum week 52.
Primary end points in infants were incidence of Hep B surface antigen positivity. Secondary endpoints were safety, tolerability of the drug.

Results: During 3/2012-3/2013, 30 consecutive chronic hepatitis B mothers were enrolled. All subjects received TDF 300 mg daily with a mean (range) duration of 17.1 (9-39) weeks prior to delivery. At delivery, a significant reduction of HBV DNA was observed when compared to those at the baseline (2.8 vs. 7.1 log10 copies/mL, $p < 0.001$), all mothers achieved HBV DNA reduction to the levels below 5log10 copies/mL. The treatment was well tolerated with no viral breakthrough. At postpartum week 4, four patients self-discontinued TDF without severe ALT flares. At postpartum week 52, 57% of mothers had undetectable HBV DNA levels; 64.3% of patients achieved normalization of alanine aminotrans-ferase; The adverse events were mild in severity.
Conclusion: In our cohort, mothers with chronic hepatitis B had excellent response to TDF during pregnancy. The therapy was well tolerated with no safety concerns. TDF treatment is effective not only in managing maternal disease, but also in preventing vertical transmission in mothers with high level of viremia. Further large multicenter studies are needed to verify our findings.

Contact E-mail Address: sandrocferreira@terra.com.br
Introduction: The clinical relevance of single nucleotide polymorphisms (SNPs) of the IL28B gene (interferon [IFNλ3]) is controversial in patients with hepatitis B virus (HBV) infection. Our objective was to evaluate the role of viral and host factors, including IL28B polymorphism (rs12979860), in the outcome of HBV infection in HBV patients followed up at the Hepatitis Outpatient Clinic of the University Hospital, Faculty of Medicine of Ribeirão Preto, University of São Paulo, Brazil, from 2001 to 2013.
Aims & Methods: SNPs of IL28B were determined by polymerase chain reaction in 224 chronic HBV patients, 178 males and 87 females, aged 12-69 years (128 chronic hepatitis B HBeAg (-), 52 chronic hepatitis B HBeAg (+) and 44 inactive carriers) and 41 patients with spontaneous HBsAg seroconversion. All patients were submitted to serial blood tests (the results used for analysis are given in brackets): HBV-DNA (average of 3 measurements/year) [$\leq 2x10^3$ IU/ml and $>2\ x10^3$ IU/ml], ALT (average of 4 determinations/year) [elevated ALT (ALT $\geq$ 1.5 x LSN) and normal/elevated ALT ($<$1.5 x LSN)] and HBV serology (once a year) [HBsAg, HBeAg and Anti-HBeAg].
Results: The distribution of the different genotypes of IL-18 was: chronic hepatitis B infection(C/C: 95 patients; C/T: 94 patients and T/T: 35 patients) and spontaneous HBsAg seroconversion (C/C: 13 patients; C/T: 25 patients and T/T: 3 patients). The frequency of the IL28B C/T genotype was significantly higher in patients with spontaneous HBsAg seroconversion than in patients with chronic hepatitis B infection ($p = 0.027$; OR = 0.462; 95%CI = 0.234 to 0.914). No association was observed between the IL28B genotypes (C/C, C/T, T/T) and ALT levels, viral load and HBeAg status. Spontaneous HBsAg seroconversion was associated to inactive carrier status (67.5% inactive carriers vs 32.5% chronic hepatitis, $p<0.0001$; OR: 0.24; 95%CI: 0.123 to 0.455) and age higher than 40 years ($p = 0.0007$).
Conclusion: IL28B C/T genotype appears to be associated with spontaneous HBsAg seroconversion. Additional studies are needed to understand the mechanisms of IL28B polymorphisms in the evolution of HBV infection.

P1268 AUDIT ON ANTE NATAL CARE OF PATIENTS WITH HEPATITIS B IN A MULTI-PROFESSIONAL CLINIC IN A NON-REGIONAL CENTRE

S. Chandrapalan[1], C. Smyth[1], J. Lau[2], S. Lahiri[2], C. Kirkham[2], A. Brind[1], A. Ramakrishnan[1]
[1]*Gastroenterology,* [2]*Obstetrics, University Hospital of North Midlands Nhs Trust, Newcastle Under Lyme, United Kingdom*

Contact E-mail Address: arulraas@yahoo.com
Introduction: Vertical Hepatitis B (HBV) transmission is the commonest mode of transmission. Antenatal screening for HBV was introduced in the UK in 2000[1]. Our hospital serves half a million population with predominantly Caucasian population. Prior to establishing antenatal Hepatitis B service, the service was haphazard due to a combination of non-referral to Hepatologist by GP and maternal non-attendance. Henceforth multi-professional antenatal HBV clinic for screen detected patients during their ante-natal visits was established in 2009 with Obstetrician, Hepatologist, Midwife in attendance. Antenatal Hepatitis B services are available at regional centres in UK but 25% rate of non-attendance are barriers to the delivery of high-quality service[2, 3].
Aims & Methods: We aimed to determine the prevalence of active HBV disease that requires treatment and to review the management of mothers during pregnancy by comparison of our attendance rate to regional centres. We did a retrospective database review of 5 years from 2009-2014 of all HBV-infected pregnant women who attended the multi-professional clinic. Demographics, clinical information, vaccination and immunoprophylaxis were reviewed electronically.
Results: 81 patients were screen detected: 3 patients' records not retrievable; 5 had miscarriages; 4 patients did not attend hospital ante-natal clinic and 3 did not see Hepatologist. We reviewed the records of 62 patients. Mean age was 29. Only 3% of mothers were white British, rest were ethnic minority with Chinese being the majority (35%). 97% (60/62) were surface antigen positive, 89% (55/62) were HBe Ag negative, 15% (9/62) were HBe Ab negative, 16% had viral DNA $> 10^6$ (10/62, 7 HBe Ag positive and 3 HBe Ag negative). 19% infants (12/62, 2 infants born to mother with HBe Ab negative state and 10 infants born to mother with viral load $> 10^6$ in 3rd trimester), received Immunoglobulin and vaccination as per DOH guidelines[3, 4]. 16% (10/62) mothers with viral load more than 10^6 received anti-viral treatment in the 3rd trimester. Vaccination uptake was complete in all infants.
Conclusion: 16% mothers having active Hepatitis B requiring treatment and 19% infants requiring immunoglobulin does validate the need for a specialist service. The non-attendance rate of 9% substantiates the need for locally established multi-professional clinic to prevent vertical transmission compared to nearly 25% rate of non-attendance in regional service.

P1269 REACTIVATION OF OCCULT OR PAST HEPATITIS B VIRUS INFECTION IN A NON-HODGKIN B CELL LYMPHOMA POPULATION

V. Costa Santos[1], J. Castela[1], C. Leitão[1], P. Sousa[1], S. Mão de Ferro[1], S. Ferreira[1], M. Cunha[1], M. Silva[1], A. Dias Pereira[1]

Introduction: Reactivation of hepatitis B virus (HBV) infection is a life-threatening complication in patients undergoing systemic chemotherapy. Rituximab is a risk factor for reactivation of occult or past HBV infection (antibody to hepatitis B core antigen [anti-HBc] positive and hepatitis B surface antigen [HBsAg] negative) in patients with B cell non-Hodgkin lymphoma (NHL-B). Recently published guidelines recommend HBV prophylaxis in these subgroup of patients.
Aims & Methods: We aim to characterize clinical and demographically anti-HBc positive/HBsAg negative NHL-B population and determine the HBV reactivation rate. All patients with the diagnosis of NHL-B are routinely tested for HBsAg, anti-HBc and antibody to HBsAg (anti-HBs). We performed an observational, retrospective, single-center study of anti-HBc positive/HBsAg negative NHL-B patients, diagnosed between 2003 and 2014. Clinical data, demographic characteristics and HBV reactivation were analysed. HBV reactivation was defined as seroconversion to HBsAg with or without detection of HBV-DNA.
Results: We included 202 patients, 120 male, mean age 73.0 ± 14.7 years. Seventy-sixt percent (n = 154) were anti-HBs positive and 30.2% were tested for HBV-DNA level (all negative). Seventy percent (n = 141) underwent chemotherapy, which included rituximab in 84.3% and corticosteroids in 97% of the cases. During chemotherapy, 10 patients performed antiviral prophylaxis with lamivudine (n = 6) or entecavir (n = 4), with suspension 5.5 ± 4.5 months after chemotherapy discontinuation. Two patients (1%), one with diffuse large B cell lymphoma and other with chronic lymphocytic leukemia, had HBV reactivation during follow-up. Both were anti-HBs negative before chemotherapy, were treated with rituximab, and none performed antiviral prophylaxis. Reactivation was detected 2.8 and 5.4 months after discontinuation of rituximab. These patients were managed with entecavir, one of them successfully (sustained virological response); the other one died of variceal bleeding.
Conclusion: This is one of the largest series evaluating anti-HBc positive/HBsAg negative B cell lymphoma population. In this study, patients with occult or past HBV infection had a small (1%) but potentially fatal risk of HBV reactivation after rituximab therapy if no antiviral prophylaxis was performed. With the implementation of the new guidelines, prospective studies are expected to validate antiviral prophylaxis in these high-risk patients.

Introduction: Quantification of serum hepatitis B antigen (HBsAg) is an important test that marks active infection with hepatitis B and helps in the prediction of the clinical outcome and management of hepatitis B virus (HBV) infection.

Correlation with HBV DNA quantitative levels may help in developing strategies for antiviral treatment.

Aims & Methods: The study was to evaluate HBsAg titres in various phase of HBV-infection in HBsAg-positive patients. 976 HBV related patients were analyzed in this retrospective cross-sectional study. Patients were categorized based on the phase of HBV infection: immune tolerant phase (IT, n = 123), immune clearance phase (IC, n = 192), low-replicative phase (LR, n = 476), and HBeAg-negative hepatitis (ENH, n = 185). HBsAg titers were quantified and correlated with HBV-DNA levels and clinical parameters.

Results: Median HBsAg titres were different between each phases of HBV infection ($p < 0.001$): (4.62 log10 IU/ml), IC (3.88 log10 IU/ml), LR (2.76 log10 IU/ml) and ENH (2.94 log10 IU/ml). HBsAg and HBV DNA levels showed significant correlation in the whole group ($r = 0.694$, $p < 0.001$), and this was also observed in different phases of HBV infection. Strong correlation in IT phase ($r = 0.603$, $p < 0.001$) and IC phase ($r = 0.523$, $p < 0.001$), moderate in LR phase ($r = 0.362$, $p < 0.001$) and week in ENH ($r = 0.110$, $p = 0.04$). No correlation was observed between serum HBsAg levels and biochemical parameters.

Conclusion: The study demonstrated significant difference in the median baseline values of serum HBsAg titres in different phases of HBV infection. These results may provide additional information in understanding the natural history of HBV-infection.

Introduction: Information about co-morbidities of patients (pts) currently treated for chronic HCV genotype 1 (G1) infection in real-life is scarce. The present interim analysis of the NOVUS observational study was therefore aimed to investigate the frequency of preexisting and ongoing co-morbidities of pts treated for chronic HCV G1 infection in German real-life and to determine the frequency of co-medications.

Aims & Methods: From April 2012 until January 2014, 536 pts with HCV G1 infection were recruited in the ongoing NOVUS study by 97 practices and hospitals in Germany. Until now, pre-existing co-morbidities before triple therapy of HCV G1 infection with boceprevir were documented for 469 pts (treatment-naïve N ± 306, pretreated N ± 154).

Results: Ongoing co-morbidities were reported for 329 of 469 pts (70%) before treatment of HCV G1 infection. Overall, 599 ongoing co-morbidities (multiple answers allowed) were documented. The most frequently reported co-morbidities were obesity (BMI > 30 kg/m^2) (19 %), cardiovascular diseases (18%), psychiatric disorders (14%), opiate substitution (13%), gastrointestinal diseases (11%), metabolic disorders (8%), thyroid gland diseases (7%), bone and joint diseases (6%), skin diseases (5%), HIV-co-infection (4%) and kidney diseases (2%). When co-morbidities were analyzed by gender (female vs. male), thyroid diseases occurred more frequently in females (13% vs. 3%, $P < 0.0001$), while opiate substitution (9% vs. 15%, $P < 0.04$) and HIV- co-infection (1% vs. 6%, $P < 0.01$) occurred less frequently in female pts. Regarding age (≤ 50 vs. > 50 years), cardiovascular (9% vs 28%, $P < 0.0001$), thyroid (3% vs. 12%, $P = 0.0002$) and kidney diseases (0.4% vs. 5%, $P = 0.0025$) were more frequently reported in pts older than 50 years, while opiate dependence (20% vs. 4%, $P < 0.0001$) and HIV-co-infections (6% vs 1%) were less frequently reported in elder pts. In contrast, obesity, psychiatric disorders and diseases of skin and bone/joints showed no association with gender and age. Co-medications were documented for 233 of 469 pts (50%). According to the frequency of co-morbidities, 39% of overall 564 co-medications were related to treatment of neuropsychiatric disorders including opiate dependency, 19% were cardiovascular drugs, 14% were agents for gastrointestinal and metabolic diseases and 6% for thyroid diseases.

Conclusion: The present analysis demonstrates that preexisting co-morbidities are a frequent problem in pts undergoing treatment of HCV G1 infection in German real-life and that several co-morbidities are related to gender or age. As a consequence, there is a high frequency of co-medications which needs attention with regard to possible interactions between co-medications and direct-acting antivirals.

Introduction: Since 2011, triple therapy with the HCV protease inhibitor boceprevir (BOC) is widely used as standard of care for patients (pts) with chronic HCV G1 infection. The present interim analysis of the German NOVUS observational study was aimed to compare the efficacy of BOC triple therapy in previously untreated and previously treated patients in German real-world and, in particular, to compare the virologic outcome of pts who achieve an early virologic response (EVR) at treatment week (TW) 8.

Aims & Methods: From April 2012 until January 2014, 536 pts with genotype 1 infection were recruited in the ongoing NOVUS study by 97 practices and hospitals in Germany. Pts were treated with pegylated interferons (PegIFN) and ribavirin (RBV) together with BOC up to 44 weeks after a 4 weeks lead-in period with PegIFN/RBV. The present interim analysis was restricted to 275 treatment-naïve pts and 140 previously treated pts who started triple therapy at least 12 months ago.

Results: Overall 275 previously untreated pts were compared with 140 previously treated pts (37% relapsers, 14% partial responders, 19% null-responders, 6% breakthrough and 21% with unknown previous response to dual therapy) who showed the following characteristics (untreated vs. treated): Mean age: 45 vs. 51 years ($P < 0.0001$); male gender: 59% vs. 60%; baseline viral load > 400,000 IU/mL: 68% vs. 72%; G1b: 50% vs. 49%; liver cirrhosis: 5% vs. 11% (not significant, ns); co-infection with HIV: 4% vs. 4%; opioid substitution: 12% vs. 10%. Previously untreated pts achieved more frequently undetectable HCV-RNA levels at TW8 (72% vs 59%, $P = 0.014$), at TW12 (87% vs. 77%, $p = 0.020$) and at end of treatment (88% vs. 77%, $P = 0.009$) than pretreated pts. Until now, follow-up data available from 199 untreated and 108 pretreated pts indicated significantly higher SVR rates in treatment-naïve pts (76% vs. 57%, $P = 0.0008$). Notably, comparable high/low SVR rates were observed in untreated and pretreated pts with EVR (87% vs. 86%, ns) or without EVR (46% vs 34%, ns). Regarding EVR together with the virologic response to PegIFN/RBV lead-in at the end of TW4, untreated pts showed more frequently a HCV-RNA decline > 1log$_{10}$ than previously treated pts (79% vs. 67%, $P = 0.0143$), while no difference in HCV-RNA decline > 1log$_{10}$ at TW4 was observed when untreated or pretreated pts achieved EVR (84% vs. 89%, ns).

Conclusion: Untreated and previously treated pts undergoing BOC triple therapy for HCV G1 infection in German real-world attain SVR rates of 76% and 57%. When pts achieve an EVR, SVR rates are comparably high in untreated (87%) and pretreated pts (86%). Sensitivity to PegIFN/RBV as assessed by HCV-RNA decline at the end of lead-in seems to be higher in untreated pts but comparable in previously untreated and previously treated pts who achieve an EVR.

Introduction: Direct acting antivirals (DAA) have revolutionized treatment of chronic hepatitis C. Septua- and octogenarians were not included in clinical studies and therefore data on efficacy and safety of IFN-free treatments in elderly are missing. Elderly patients may have a decrease of renal and hepatic function and are at risk for drug-drug interactions with DAA with drugs required for long-term treatment for other medical conditions.

Aims & Methods: The aim of this study was to investigate safety and efficacy of inferferon (IFN) and ribavirin (RBV)-free treatments in patients > 70 years with advanced chronic hepatitis C.

44 otherwise healthy patients > 70 years (cirrhosis: 32, F3:12, mean age: 74.6, range 70-88, m/f: 19/26, median HCV RNA $1.18x10^6$ IU/ml, HCV-genotype: GT-1a:6; 1b:35; 3:1; 4:2; missing:1; treatment experienced: 25; median platelet count: 137 G/l; median albumin: 39.5 g/l; median bilirubin: 0.86 mg/dl; median GFR using Cockroft-Gault formula: 66.6 ml/min) were enrolled. The patients were treated with sofosbuvir (SOF) 400mg/day combined either with daclatasvir (DCV) 60mg/day, simeprevir (SMV) 150mg/day, or ledipasvir (LDV) 90 mg/day. HCV RNA quantification was carried out with Abbott RealTime HCV (ART) assay (LLOQ < 12IU/mL). Treatment duration was 12 weeks, and was prolonged to up to 24 weeks in patients with detectable HCV-RNA at week 8.

Results:

	N	Completed treatment N	Completed Follow Up N	SVR	On treatment N	TND*	<12**
SOF/SMV	**21**	**18**	**8**	**7**	**3**	**2**	**0**
SOF/DCV	**17**	**13**	**6**	**6**	**4**	**0**	**1**
SOF/LDV	**6**	**3**	**2**	**2**	**3**	**3**	**0**
Total (%)	**100**	**77.2**	**36.0**	**34.0**	**22.7**	**11.3**	**2.2**

*HCV-RNA: TND = Target not detected. ** HCV-RNA at least 4 weeks of treatment (IU/ml)

Currently, 34 patients completed treatment of which 15 reached end of follow up. No severe adverse events were observed. The most frequent adverse events (AE) were fatigue (27.2%), cephalea and pruritus (6.8% and 13.6). Other less common side effects observed were insomnia (11.4%), mood changes (4.5%), but also dyspnoe, arthralgia, nausea and cough (< 5%). No dose modifications were required. One patient treated with SOF/SIM had a relapse after reaching end of treatment.

Conclusion: IFN/RBV-free treatment regimens are safe and effective in elderly chronic hepatitis C patients with advanced liver disease.

P1274 DECOMPENSATION, HEPATOCELLULAR CARCINOMA, LIVER RELATED HOSPITAL ADMISSION AND LIVER RELATED MORTALITY AFTER ANTIVIRAL TREATMENT; A POSTSCRIPT AT THE END OF ERA OF CONVENTIONAL DUAL THERAPY FOR CHRONIC HEPATITS C

R. B. Thandassery[1], S. Al Kaabi[1], A. K. John[1], S. S. Nairat[1], M. E. Soofi[1]
[1]*Gastroenterology, Hamad General Hospital, Doha, Qatar*

Contact E-mail Address: doc.ragesh@gmail.com

Introduction: There are only limited large-scale data to show the impact of conventional dual antiviral therapy with pegylated interferon and ribavirin (CDAVT) on natural history of chronic hepatitis C (CHC).

Aims & Methods: We aim to evaluate development of decompensation, hepatocellular carcinoma (HCC), liver related hospital admission (LRA) and liver related mortality (LRM) in patients who had received CDAVT.

Methods: 1605 patients (from January 2002 to December 2013) with CHC who underwent liver-biopsy (LB) and received CDAVT were retrospectively analyzed for development of decompensation, HCC, LRA and LRM.

Results: Mean age of patients was 41.9 ± 9.7 years (85% males), predominantly genotype 4(65%) and genotype 1(11%). Pre treatment LB showed (Scheuer classification) stage-0 fibrosis in 1.9%, stage-1 in 32.9%, stage-2 in 39.5%, stage-3 in19% and stage-4 in 6.6% patients. Median follow-up was 3.5 years (5617.5 patient-years). There were 1079 (67.6 %) responders, 482 (30.2%) non-responders and 34 (2.1%) relapsers. Among responders, 1017 (63.3%) patients had persistent sustained virologic response (SVR) and 62 (3.8%) had recurrence (non persistent SVR) on quantitative PCR assay. 86 (5.3%) patients developed decompensation [bleed (n = 16), ascites (n = 55), jaundice (n = 28), hepaticencephalopathy (n = 2), spontaneous bacterial peritonitis (n = 1) and hepatorenal syndrome (n = 1)]. Esophageal varices developed in 47(2.9%) patients, gastric varices in 1 and both in 1. 15(0.9%) patients developed HCC,28 (1.7) had LRA and 4 (0.2%) had LRM. Non liver related hospital admissions (n = 131, 8.1%) was significantly higher than LRA($p = 0.04$). Non liver related mortality (n = 5, 0.3%) and LRM were comparable ($p = 0.30$). The development of all outcome measures were significantly lower in patients who had persistent SVR compared to non persistent SVR, relapsers and non-responders (Table 1). On comparing patients with persistent SVR and the rest of the patients, the risk of overall decompensation (2% v/s 11.6% $p < 0.001$), bleed (0.2 v/s 2.4%, $p < 0.001$) ascites (1% v/s 7.8%, $p < 0.001$), jaundice (0.6% v/s 3.8%, $p < 0.001$), development of HCC (0.1 v/s 2.4%, $p < 0.001$) and LRA (0.4% v/s 4.2% $p < 0.001$) were significantly lower in the former. LRM showed a similar trend (0.1% v/s 0.5%, $p = 0.06$).

Conclusion: In chronic hepatitis C decompensation, development of HCC, LRA and LRM occur despite treatment and attainment of SVR. However, patients with loss of SVR on follow up, nonresponders and relapsers are at higher risk of these complications.

P1275 METABOLIC FACTORS ASSOCIATED WITH HEPATIC STEATOSIS AND FIBROSIS IN CHRONIC HEPATITIS C PATIENTS

R. M. Elsharkawy[1,2], G. Galal[1], M. AbdelFattah[1], E. Salah[3]
[1]*Tropical medicine and Gastroenterology, Sohag University Hospital-Egypt,*
[2]*Hepatology and Gastroenterology, Sohag Specialized Liver Institute,*
[3]*Pathology, Sohag University Hospital-Egypt, Sohag, Egypt*

Contact E-mail Address: ramitropic@hotmail.com

Introduction: Liver steatosis is a common finding in patients infected with hepatitis C virus (HCV)[(1)]. HCV steatosis was recently identified as a risk factor for progression to extensive fibrosis[(2)]. Chronic HCV infection is closely related to the metabolic syndrome (MS). Accordingly, CHC should be classified into CHC with and CHC without MS. Insulin resistance (IR) is the main feature of the MS. In CHC, there is a close association between IR, hepatic steatosis[(3)], and progression of fibrosis[(4)].

Aims & Methods: Evaluate metabolic factors associated with hepatic steatosis and fibrosis in patients infected with CHC, and to assess the impact of insulin resistance (as measured by HOMA-IR score) and serum adipocytokines levels on hepatic steatosis and fibrosis relative to other factors. Finally, to evaluate the relationship between CHC and metabolic syndrome.

Results: Significant steatosis (> 33%) was detected in 54% of the patients, while 21.12% of the patients had stage 3/4 fibrosis. Higher degree of steatosis was significantly associated with higher BMI, serum insulin, HOMA index and TNF-α ($P < 0.0001$, $P < 0.0006$, $P < 0.0001$, and $P < 0.01$ respectively). Higher stages of fibrosis were significantly associated with higher BMI and serum triglycerides ($P < 0.04$, $P < 0.02$ respectively). Multivariate analysis of the metabolic factors showed that HOMA index ($P < 0.001$) and TNF-α ($P < 0.03$) were the factors mostly predicting higher degree of steatosis. While, BMI index ($P < 0.01$) and serum triglycerides ($P < 0.03$) were the factors mostly predicting higher stage of fibrosis. We also found that CHC is closely related to MS, and we recognized that olderage ($P < 0.011$), higher BMI ($p < 0.0001$), lower, serum adiponectin ($P < 0.0001$), higher TNF-α ($p < 0.0001$) and higher steatosis degree ($p < 0.04$) are significantly associated with MS in these patients.

Conclusion: In patients with CHC, steatosis is of metabolic origin as it is closely associated with the presence of metabolic syndrome. Higher BMI, HOMA-IR, lower serum adiponectin and higher serum TNF-α and triglycerides were associated with HCV hepatic steatosis and metabolic syndrome, while higher BMI and serum triglycerides are the predictors of more advanced fibrosis stage in CHC patients.

Abstract number: P1274. Table 1: Development of decompensation, hepatocellular carcinoma liver-related hospital admission and liver-related mortality in patients with CHC after CDAVT

	Decompensation, (total N ± 86) N (%)	Bleed, (total N ± 16) N(%)	Ascites, (total N ± 55) N(%)	Jaundice, (total N ± 28) N(%)	Hepatocellular carcinoma, (total N ± 15) N(%)	Liver-related hospital admission, (total N ± 28) N(%)	Liver-related mortality, (total N ± 4) N(%)

Introduction: Several interferon-free treatments of chronic hepatitis C have recently become available. Due to their high cost, reimbursement by health insurance has been mostly restricted to patients with severe fibrosis (F3) and cirrhosis (F4). Transient elastography (Fibroscan®) has been widely used to detect ≥F3 using a cut-off of 9.5 kPa, but reliable measurements can be obtained in only 80% of patients approximately. Simple fibrosis tests including FIB-4, APRI and platelet count are readily available and have been found useful to detect significant fibrosis (F2) and cirrhosis (F4) but data on detection of severe fibrosis (F3) are scarce.

Aims & Methods: Consecutive patients with chronic hepatitis C (n = 614) who underwent liver biopsy prior to antiviral treatment were included in two Austrian centers. Exclusion criteria were prior antiviral treatment, presence of hepatocellular carcinoma, previous liver transplantation, and lack of a representative biopsy specimen. METAVIR fibrosis stage was used as reference. Routine laboratory values including AST, ALT, and platelet count (PLT) were collected at the time of liver biopsy; APRI and FIB-4 were calculated using published formulas. Diagnostic accuracy of APRI, FIB-4, and PLT for detection of METAVIR ≥F3 was assessed by ROC analysis and best cut-offs were determined by Youden index.

Results: In our cohort, METAVIR fibrosis stage was distributed as follows: F0: n = 17 (3%), F1: n = 204 (33%), F2: n = 202 (33%), F3: n = 58 (9%), F4: n = 133 (22%). APRI and FIB-4 progressively rose and PLT progressively declined with increasing fibrosis stage. ROC analysis revealed high diagnostic accuracies (AUC, 95% CI) of FIB-4 (0.84, 0.81-0.88), APRI (0.81, 0.77-0.85), and PLT (0.83, 0.79-0.86) for detection of METAVIR ≥F3. Youden index revealed an optimal FIB-4 cut-off of ≥1.77 (sensitivity 77%, specificity 83%, PPV 67%, NPV 89%) for detection of METAVIR ≥F3.

Conclusion: In treatment-naive patients with chronic hepatitis C, severe fibrosis or cirrhosis (METAVIR ≥F3) may be accurately detected by simple fibrosis tests based on routine laboratory values. Highest diagnostic accuracy was found for FIB-4.

Contact E-mail Address: salemyousefmohamed@gmail.com

Introduction: The Egyptian Ministry of Health initiated a nationwide HCV treatment program with the newly developed oral antiviral therapies and formulated national guidelines for treatment allocation which gives favor for patients with advanced fibrosis and early cirrhosis. One of the prerequisites for treatment was upper Gastro-intestinal (GIT) endoscopy.

Aims & Methods: This study aimed at judging the validity of the national recommendation of upper GIT endoscopic screening before enrollment in HCV antiviral therapy and to assess the work load on the endoscopic units met by this recommendation. This study was carried out at gastrointestinal endoscopy units, Zagazig University Hospitals starting in January 1st and followed to December 31st 2014. The epidemiologic and clinical features of patients undergoing preparation for HCV therapy were examined. Endoscopic findings were analyzed and were compared to other cirrhotic HCV patients on regular endoscopic follow up. Endoscopic classification of esophageal varices was carried out after the Italian liver cirrhosis project while gastric varices were classified according to Sarin classification.

Results: A total of 1143 patients sought upper GIT endoscopy at our units in preparation for HCV treatment during the study peroid. This comprised 22% of all patients undergoing upper GIT endoscopy over that year. There was a four-fold rise in percentage of patients undergoing endoscopy for therapy in this year (22%) after starting enrollment for sofosbuvir-based therapy when compared to assessment for Interferon/Ribavirin combination therapy (5%) in the last year. A total of 361 patients had no esophageal or gastric varices. Small sized varices (grade I) were present in 301 patients while medium sized varices (grade II) were reported in 188 patients and 291 patients encountered in large sized varices (grade III). Thirty patients (2.6%) had gastric varices, of them 17 were GOV type 1, 9 were GOV type 2 and 4 were IGV type 1 (only 2 patients had isolated gastric varices without associated esophageal varices). Endotherapy (band ligation and/or gastric variceal injection) was performed in 320 patients. Follow-up for these patients was arranged according to the established guidelines.

Conclusion: According to the results of this study screening endoscopy for early cirrhotic patients awaiting oral anti-HCV therapy seems to be valid. Endoscopic work burden is expected to rise with increased demand on newer sofosbuvir-based regimens. More cases eligible for endotherapy are detected earlier with shifting of workload from advanced to earlier stages of CLD.

Introduction: The diagnosis of AIH needs to be considered in any patients with elevated aminotransferases. NAFLD is an exclusion diagnosis and there are no specific serum markers for these two diseases. Most patients may be asymptomatic or have nonspecific symptoms in both diseases. In our study we want to evaluate the role of AIH score (after Hennes) in NAFLD patients.

Aims & Methods: We included 152 patients with high levels of aminotransferases or bright liver on ultrasonography , 40 males (26.31%) and 112 females with age from 23 to 79 years.35 patients (23.02%) were overweight, 9 patients had normal weight and 24 (15.79%) had severe obesity. Blood samples were collected to determinate aminotransferases, alkaline phosphatase, IgG level, gamma-globulin, anti-nuclear antibody (ANA), albumin, bilirubin, platelet count. We excluded the patients with other known cause of liver disease : viral, alcohol, genetic or drug-induced and others autoimmune diseases. The abdominal ultrasonography was performed by the same physician and steatosis was graded using a semi-quantitative scale of 1 (mild) to 3 (severe). 54 patients accepted liver biopsy. Histological samples were evaluated by one pathologist who was not blinded to the patient's history. We considered AIH probable if the score was > 6 and definite if the score was > 7.

Results: 28 patients (18.42 %) were positive for ANA with median titer > 1:40 (20 patients) or > 1:80 (8 patients). IgG levels were upper normal limit in 19 patients and > 1.1 normal limit in 6 patients. Only 12 patients were both positive for ANA and had IgG levels upper normal limit. All these patients ANA positive or abnormal IgG levels accepted liver biopsy. Before the liver biopsy 4 patients had AIH score equal to 6, after the liver biopsy only 1 patient had portal tract plasma cell infiltration, a characteristic feature for AIH but not specific. We could not find any independent factor predictive(gender, age, weight, gamma globulin, aminotransferases, bilirubin or alkaline phosphatase level) for ANA presence.

Conclusion: AIH score is not very strong for predicting the disease, especially for borderline diagnosis.

Introduction: In a chronic orphan disease such as primary sclerosing cholangitis (PSC) it is important to identify biomarkers for disease progression. Biomarkers can be used to measure treatment effect in clinical trials and improve patient management and counselling. Several recent publications have assessed the prognostic value of alkaline phosphatase (ALP), using various thresholds over various periods of follow up (FU).

Aims & Methods: With this study we aimed to assess the prognostic value of alkaline phosphatase at diagnosis (T0) and 1 year FU (T1) at different follow-up times in a large-population based PSC cohort. Furthermore we aimed to determine the most optimal threshold value of ALP.

Patient charts of PSC patients that were included in the population based Epi PSC PBC cohort were reviewed for ALP values at T0 and T1 (range +/- 3 months). ALP values were expressed in times upper limit of normal (xULN). A combined clinical endpoint was defined as development of cholangiocarcinoma, liver transplantation (LTx), or PSC-related death. The association between ALP level (measured as xULN at T0 and T1 as well as relative change ((T1-T0)/T0*100%)) and the hazard of reaching a clinical endpoint was assessed using cubic spline functions. The Uno's C-statistics were calculated for each month of FU to assess the discriminatory power of ALP at T0 and T1 and relative change at T1. The Harrell's C-statistics were calculated for each threshold ranging from 0.5xULN to 3.0xULN with a step of 0.1 at T0 and T1 and relative change ranging from -100% to 100% with a step of 5%, from which the optimal threshold was determined. Kaplan Meier survival curve was used to

present the survival probability of the two groups classified by the optimal threshold.

Results: A total of 367 patients were included, with a median FU of 100 months (IQR 67-150). The mean age at diagnosis was 40 (±14), 66% was male. ALP values at T1 were missing for 21 patients, 8 patients were excluded for T1 analyses as they reached an endpoint within 1 year FU. Median ALP at T0 was 1.99xULN (IQR 1.38-3.37) vs 1.22xULN (IQR 0.80-1.89) at T1. A total of 72 patients (20%) reached an endpoint; 15 (4%) PSC-related death, 41 (11%) LTx, 16 (4%) cholangiocarcinoma. A positive association was observed between the hazard of reaching an endpoint and ALP level in the range of 0-3xULN at T0 and T1, as well as reduction in relative change at T1. ALP measured at T1 had better predictive value than at T0 or the relative change in most of the FU time. With the optimal threshold of 1.3xULN at T1 (C-statistic 0.61 (95%CI 0.55-0.68)), the difference in endpoint-free survival between the two groups was statistically significant (log-rank test $p < 0.001$). Patients with ALP above 1.3xULN at T1 had a 1.47 times higher probability of reaching an endpoint compared with patients with ALP below 1.3xULN at T1.

Conclusion: The use of ALP to predict endpoint-free survival in PSC patients holds best prognostic value at T1, with an optimal threshold of 1.3xULN. These results confirm the usefulness of ALP as surrogate endpoint in clinical intervention studies in PSC. Furthermore, ALP at T1 may be an important factor to include in prognostic modeling for PSC.

Introduction: Primary biliary cirrhosis (PBC) is a chronic autoimmune cholestatic liver disease which can lead to cirrhosis, liver transplant or death. Hepatobiliary injury is reflected by increased plasma alkaline phosphatase (ALP) and bilirubin that correlate with disease progression. Obeticholic acid (OCA), a modified bile acid and farnesoid x receptor (FXR) agonist, has been evaluated in three international double-blind placebo-controlled PBC studies.

Aims & Methods: Two Phase 2 studies evaluating OCA as monotherapy (Study 201; N = 59) or in conjunction with UDCA (Study 202; N ± 165) recruited subjects with ALP ≥1.5 xULN, randomized to receive OCA 10 mg, OCA 25 mg (Study 202 only), OCA 50 mg or placebo. The Phase 3 POISE study enrolled subjects (N ± 216) with an inadequate response to UDCA who were randomized to receive placebo, OCA 10 mg, or OCA 5 mg uptitrated to 10 mg based on clinical response. This analysis evaluated the three studies for the Phase 2 primary endpoint (mean % change in ALP) and the Phase 3 primary composite endpoint (ALP < 1.67xULN with a minimum 15% reduction and normal bilirubin, shown to correlate with survival (Lammers 2014)).

Results: Baseline characteristics were generally similar between treatment groups. All 3 studies met their pre-specified primary endpoints. Statistically significant reduction in ALP compared to placebo was seen in all 3 studies and at all doses (Table 1). At three months of treatment, significantly more OCA-treated subjects also achieved the composite POISE endpoint in all three studies (Table 1). OCA treatment was also associated with statistically significant decreases in other liver enzymes including GGT, ALT and AST. While the subjects in the monotherapy group had higher ALP at baseline than the OCA plus UDCA group, the two groups reached similar ALP levels by end of the double-blind period. Pruritus was the most common adverse event with a dose-related increase in incidence with OCA.

Conclusion: A significantly larger percentage of subjects treated with OCA, with or without UDCA, achieved both lower ALP and a composite endpoint shown to correlate with long-term, transplant-free survival compared to placebo-treated subjects. The efficacy of OCA compared to placebo was consistent across the 3 studies, spanning doses from 5 to 50 mg over 3-12 months of treatment. Safety & tolerability profile of OCA showed consistent results across studies.

Introduction: Relapse after the withdrawal of corticosteroids occurs in 50–87% of patients with autoimmune hepatitis (AH). The ultimate goal of complete remission after treatment withdrawal can be achieved in a small proportion of patients. We aimed to investigate the predictive factors for relapse after treatment withdrawal in patients with AH

Aims & Methods: We retrospectively evaluated the patients who had diagnosed AH with clinical and laboratory and histological findings in our outpatient clinic. Inclusion criteria were >1 year follow-up, reliable demographic and laboratory data at baseline and 3 months interval. Exclusion criteria were HIV infection, suspected other liver diseases (eg. steatohepatitis), and missed follow-up more than 6 months. Treatment stopped in patients with >1 year biochemical remission, if they have no cirrhosis, no evidence of advanced liver disease. When suspected, liver biopsy was performed. Demographic data, baseline laboratory values, baseline biopsy findings, changes of the blood tests at 6 months of treatment, the time of biochemical remission, drug dosages and types were investigated as the predictors of relapse after drug discontinuation.

Results: Eighty-one of a total of 158 patients with AH were enrolled into the study. Treatment was discontinued in 39 (48%) patients (M/F:4/35, age 54 + 14.). In these 39 patients treatment duration after ALT normalization was 41.4 ± 23.6 month. Control liver biopsies were performed in 25 (64%) patients. Relapse occurred in 17 patients (43%) at a median time of 20 months (4-48). Age and gender were not related to relapse. Among several parameters basal globuline and platelet count were found to be related to relapse. Basal globuline was 4.21 ± 0.9 and 3.43 ± 0.76, platelet count $287 \pm 101 \times 10^3/\mu l$ and $207 \pm 61 \times 10^3/\mu l$ in relapsers and non-relapsers, respectively. Focal necrosis (FN) and bile duct injuries (BDI) were more prevalant in relapsers comparing to those remained in remission (FN 100% vs. 57%; BDI 50% vs. 4%). The parameteres in control biopsies were not found to be related to relapses. ALT normalization time under the treatment was longer in relapsers (median 4 months vs. 2 months).

Conclusion: Relapse rate in our population (43%) was low, probably due to the strict selection of the patients to discontinue the treatment and longer duration of treatment after ALT normalization. Basal biopsy findings and ALT normalization time under the treatment should be taken into consideration before cessation of treatment. Control biopsies may not be performed before drug discontinuation.

Introduction: Primary sclerosing cholangitis (PSC) is a chronic nonsuppurative inflammation of extra- and intrahepatic bile ducts leading to ductal fibrosis and strictures and eventually to cirrhosis. Furthermore, PSC is associated with a markedly increased risk of cholangiocarcinoma (CCA). At present good surrogate markers for bile duct inflammation for estimating disease activity and risk for progression and CCA are not available. IL-6 is a inflammatory cytokine and plays a major role in the response of bile duct epithelia to inflammation. It has been implicated as an autocrine promoter of growth for several cancers such as CCA (1). A significant increase in serum IL-6 levels has been shown in association with CCA (2). Calprotectin, a heterodimer of S100A8 and S100A9, is a calcium binding protein released from neutrophils and monocytes, is widely used as a fecal marker of inflammation in IBD (3). We have previously shown a

close correlation between neutrophilic inflammation in brush cytology (BC) and the risk of biliary dysplasia and CCA.

Aims & Methods

Aims: To evaluate the diagnostic value of several inflammatory markers (IL-6, calprotectin, CRP, α1-acid glycoprotein) in bile and serum as surrogate markers of inflammation compared to neutrophils in bile duct BC in PSC.

Patients and Methods: In total, 53 patients (18 females/35 males) with confirmed PSC referred for ERC for disease surveillance were included. After cannulation of the common bile duct with papillotomy knife with guide wire a bile sample was aspirated using balloon catheter and immersed immediately in liquid nitrogen and then stored in -20°C. Serum and bile concentrations of IL-6, calprotectin, CRP, MMP-9, α1-acid glycoprotein were quantitated using commercially available ELISA kits. BC was collected both from extra- and intrahepatic bile ducts for Papanicolau staining for grading dysplasia and inflammation. Neutrophilic inflammation in BC was evaluated semiquantitatively (0 = neutrophils/epithelial cells <0.05, 1 = neutrophils /epithelial cells 0.05-0.4, 2 = neutrophils/epithelial cells >0.4).

Results: Serum levels of CRP, IL-6, calprotectin and α1-acid glycoprotein did not correlate with disease activity assessed by neutrophilic inflammation in BC. However, in bile both IL-6 (AUC = 0.829) and calprotectin (AUC = 0.987) levels were significantly associated with neutrophilic count in BC (neutrophils 0 or 1 vs 2).
